About the Author

Dr. Bandaru Venkata Ramana obtained his Ph.D from the Indian Institute of Technology (IIT), Bombay in the year 1974. He has been a Post-Doctoral fellow of CSIR for one year. He has more than 30 years of experience in teaching the subject of Engineering Mathematics at IIT, Bombay (1970–1974), Regional Engineering College, Warangal (1975–1981), Jawaharlal Nehru Technological University (1981 onwards, more than 20 years), and Federal University of Technology, Nigeria (1983–1985 on overseas assignment). He has taught to all branches of B. Tech, M. Tech, and also to M. Sc. (Tech) Maths, M. Sc. (Tech) Physics, and MCA students.

Since 1987, he is working as the Professor and Head of the Department of Mathematics, JNTU, College of Engineering, Kakinada. Presently, he is Professor of Mathematics, Eritrea Institute of Technology, Eritrea.

He is the Chairman, Board of Studies in Mathematics for J.N. Technological University, Hyderabad.

He is a life member of the Indian Mathematical Society, Indian Society for Technical Education, and Indian Society for Technical and Applied Mechanics. He has to his credit several research publications in international journals.

Dr. Ramana can be contacted at ramanabv46@yahoo.com.

*To
my beloved parents
Sri Bandaru Subba Rao
and
Smt Bandaru Nagaratnam
who made me what I am today*

Foreword

George Boole, an English mathematician, in 1854 has written a monumental work entitled “An investigation of the Laws of Thought”. In 1938, Claude E. Shannon (MIT, USA), in his classical paper entitled “A symbolic analysis of relay and switching circuits” in the Transactions of AIEE, has developed the algebra of switching functions and showed how its structure is related to the ideas established by Boole. This is a classical example of how an abstract mathematics in the 19th century became an applied mathematical discipline in the 20th century. Such is the power of mathematics, the queen of sciences. In my view the aim of Engineering Mathematics is to make the student think **mathematically** and develop “*mathematical maturity*”.

The need for a good text book on “Engineering Mathematics” for students of engineering and technology in India can be easily understood. Although several books are available, almost none of them have the right combination, simplicity, rigour, pedagogy and syllabus compatibility, dealing with all aspects of the course. I am confident that this present book will be able to fill this void. It gives me great pleasure to introduce “**HIGHER ENGINEERING MATHEMATICS**” by **B.V.RAMANA** the publication of which heralds the completion of a book that caters completely and effectively from a modern point of view of the students of Engineering mathematics and physics and computer science.

This book has been organized and executed with lot of care, dedication and passion for lucidity. The author has been an outstanding teacher and has vast and varied experience in India and abroad in the field of mathematics. A conscious attempt has been made to simplify the concepts to facilitate better understanding of the subject.

This book is self-contained, presentation is detailed, examples are simple, notations are modern and standard and finally the chapters are largely independent. The contents of the book are exhaustive containing Differential & integral calculus, Ordinary differential equations, Linear algebra, vector calculus, Fourier analysis, partial differential equations, complex function theory, probability & statistics, Numerical analysis and finally special topics Linear programming and calculus of variations.

Dr. Ramana, a senior most professor of Jawaharlal Nehru Technological University, Hyderabad deserves our praise and thanks for accomplishing this trying task. Tata McGraw-Hill, a prestigious publishing house, also deserves a pat for doing an excellent job.

I wish Dr. Ramana all success in his future endeavors.

Dr. K. RAJAGOPAL

Preface

Mathematics is a necessary avenue to scientific knowledge which opens new vistas of mental activity. A sound knowledge of Engineering Mathematics is a 'sine qua non' for the modern engineer to attain new heights in all aspects of engineering practice.

This book is a self-contained, comprehensive volume covering the entire gamut of the course of Engineering Mathematics for 4 years' B.Tech program of I.I.Ts, N.I.Ts, and all other universities in India.

The contents of this book are divided into 8 parts as follows:

Part I: Preliminaries:

Ch. 1: Vector Algebra, Theory of Equations, and Complex Numbers, Matrices and Determinants, Sequences and Series, Analytical Solid Geometry, Calculus of Variations, Linear Programming, on website.

Part II: Differential and Integral Calculus

Ch. 2: Differential Calculus

Ch. 3: Partial Differentiation

Ch. 4: Maxima and Minima

Ch. 5: Curve Tracing

Ch. 6: Integral Calculus

Ch. 7: Multiple Integrals

Part III: Ordinary Differential Equations

Ch. 8: Ordinary Differential Equations: First Order and First Degree

Ch. 9: Linear Differential Equations of Second Order and Higher Order

Ch. 10: Series Solutions

Ch. 11: Special Functions—Gamma, Beta, Bessel and Legendre

Ch. 12: Laplace Transform

Part IV: Linear Algebra and Vector Calculus

Ch. 13: Matrices

Ch. 14: Eigen Values and Eigen Vectors

Ch. 15: Vector Differential Calculus: Gradient, Divergence and Curl

Ch. 16: Vector Integral Calculus

Part V: Fourier Analysis and Partial Differential Equations

Ch. 17: Fourier Series

Ch. 18: Partial Differential Equations

Ch. 19: Applications of Partial Differential Equations

Ch. 20: Fourier Integral, Fourier Transforms and Integral Transforms

Ch. 21: Linear Difference Equations and Z-Transforms

Part VI: Complex Analysis

Ch. 22: Complex Function Theory

Ch. 23: Complex Integration

Ch. 24: Theory of Residues

Ch. 25: Conformal Mapping.

Part VII: Probability and Statistics

Ch. 26: Probability

Ch. 27: Probability Distributions

Ch. 28: Sampling Distribution

Ch. 29: Estimation and Tests of Hypothesis

Ch. 30: Curve Fitting, Regression and Correlation Analysis

Ch. 31: Joint Probability Distribution and Markov Chains

Part VIII: Numerical Analysis

Ch. 32: Numerical Analysis

Ch. 33. Numerical Solutions of ODE and PDE

Web Supplement Besides the above, the following additional chapters are available at <http://www.mhhe.com/ramanahem>

1. Matrices and Determinants
2. Sequence and Series
3. Analytical Solid Geometry
4. Calculus of Variations
5. Linear Programming

The site also contains chapter-wise summary of all the chapters in the book.

This book is written in a lucid, easy to understand language. Each topic has been thoroughly covered in scope, content and also from the examination point of view. For each topic, several worked out examples, carefully selected to cover all aspects of the topic, are presented. This is followed by practice exercise with answers to all the problems and hints to the difficult ones. There are more than 1500 worked examples and 3500 exercise problems.

This textbook is the outcome of my more than 30 years of teaching experience of engineering mathematics at Indian Institute of Technology, Bombay (1970-74), National Institute of Technology,

Warangal (1975-81), J.N. Technological University, Hyderabad (since 1981), Federal University of Technology, Nigeria (1983-85), Eritrea Institute of Technology, Eritrea (since 2005).

I am hopeful that this ‘new’ exhaustive book will be useful to both students as well as teachers. If you have any queries, please feel free to write to me at: ramanabv48@rediffmail.com.

In spite of our best efforts, some errors might have crept in to the book. Report of any such error and all suggestions for improving the future editions of the book are welcome and will be gratefully acknowledged.

B V RAMANA

Acknowledgements

Thanks giving is a sacred Indian culture. Although I owe a lot to many, due to space constraint, I am explicitly expressing my thanks to only few.

I express my thanks to

1. Professor K. Rajagopal, Vice-Chancellor, J.N. Technological University, Hyderabad
2. Professor B.C. Jinaga, Rector, JNTU
3. Professor K. Lalkishore, Registrar, JNTU
4. Professor K. Satya Prasad, Principal, JNTU College of Engineering, Kakinada
5. Professor M.P. Ranga Rao, IIT Bombay
6. Professor Gebrebrhan Ogbazgh, Vice-president (academic), Eritrea Institute of Technology
7. Dr C. Siva Ram, Ph.D. AT&T, USA
8. Professor S. Satya Sri, Rangaraya Medical College, Kakinada
9. Ms. Vibha Mahajan, Ms. Shukti Mukherjee, Ms. Mini Narayanan, and Mr. Sohan Gaur of Tata McGraw-Hill Publishing Co. Ltd., New Delhi.

My wife Smt B. Mahalakshmi deserves special thanks for her continued patience, care, support and encouragement all through this project.

Finally my sincere thanks to my senior brother Sri Bandaru Ramachandra Rao of Mandapeta for his moral support.

B V RAMANA

Tata McGraw-Hill Publishing Co. Ltd would like to join the author in acknowledging the useful comments and suggestions of the following reviewers during the preparation of the book:

1. Prof. K.P. Patil, Head, Department of Mathematics, Veermata Jijabai Technology Institute (VJTI), Mumbai.
2. Dr. Meena Sankaranarayanan, Senior Research Fellow, Institute for Infocomm Research, Singapore.
3. Dr. V. K. Singh, Professor, Department of Mathematics, Indraprastha Engineering College, Ghaziabad.
4. Prof. A. Vincent Antony Kumar, Department of Mathematics, PSNA College of Engineering and Technology, Dindigul, Tamil Nadu
5. Dr. P.S. Wain, Head, Department of Applied Sciences, Sinhgad Institute of Technology, Lonavala, Pune.

xviii *Acknowledgements*

6. Dr. M.N. Mehta, Department of Mathematics, SVNIT, Surat.
7. Dr. P.C. Agarwal, Head, Department of Mathematics, ISS Academy of Technical Education, Noida, UP.
8. Dr. S.P. Mohanty, Professor and Head, Department of Mathematics, College of Engineering and Technology, Biju Patnaik University of Technology, Bhubaneswar.
9. Dr. D.V. Singh, Professor & Chairman, Department of Mathematics, NIT, Kurukshetra.
10. Prof. G. Prema, Department of Mathematics, Amrita Vishwa Vidyapeetham, Coimbatore.
11. Dr. B.B. Mishra, Associate Professor and Head, Department of Mathematics, KIIT (DU), Bhubaneswar.

Contents

<i>Foreword</i>	<i>xiii</i>
<i>Preface</i>	<i>xiv</i>
<i>Acknowledgements</i>	<i>xvii</i>

PART—I PRELIMINARIES

1. Vector Algebra, Theory of Equations, and Complex Numbers	1.1
1.1 Vector Algebra	1.1
1.2 Theory of Equations	1.13
1.3 Cardano's Method	1.14
1.4 Ferrari's Method	1.17
1.5 Complex Numbers	1.19
1.6 Roots of Complex Numbers	1.22

PART—II DIFFERENTIAL AND INTEGRAL CALCULUS

2. Differential Calculus	2.1
2.1 Derivation of n^{th} Derivative of Some Elementary Functions	2.1
2.2 Leibnitz's Theorem (Rule or Formula)	2.7
2.3 Angle Between the Radius Vector and the Tangent	2.10
2.4 Rolle's Theorem	2.14
2.5 Lagrange's Mean Value Theorem	2.17
2.6 Cauchy's Mean Value Theorem	2.21
2.7 Generalized Mean Value Theorem	2.23
2.8 Taylor's Series and Maclaurin's Series Expansions	2.26
2.9 Indeterminate Forms	2.33
2.10 Derivatives of Arcs	2.40
2.11 Curvature	2.44
2.12 Evolute	2.61
2.13 Envelopes	2.65
3. Partial Differentiation	3.1
3.1 Functions of Several Variables: Limit and Continuity	3.1
3.2 Partial Differentiation	3.5

3.3 Variable Treated as Constant	3.9
3.4 Total Derivative	3.11
3.5 Partial Differentiation of Composite Functions: Change of Variables	3.13
3.6 Differentiation of an Implicit Function	3.16
3.7 Euler's Theorem	3.18
3.8 Jacobian	3.22
3.9 Functional Dependence	3.27
3.10 Errors and Approximations	3.29
3.11 Differentiation Under Integral Sign: Leibnitz's Rule	3.31

4. Maxima and Minima	4.1
4.1 Taylor's Theorem for Function of Two Variables	4.1
4.2 Maxima and Minima of Functions of Two Variables: With and Without Constraints	4.5
4.3 Lagrange's Method of Undetermined Multipliers	4.10

5. Curve Tracing	5.1
5.1 Curve Tracing: Curves in Cartesian Form	5.1
5.2 Curve Tracing: Standard Curves in Cartesian Form	5.8
5.3 Curve Tracing: Polar Curves	5.15
5.4 Curve Tracing: Standard Polar Curves	5.20
5.5 Curve Tracing: Parametric Curves	5.24
5.6 Curve Tracing: Standard Parametric Curves	5.26

6. Integral Calculus	6.1
6.1 Reduction Formulae	6.1
6.2 Area of a Plane Region: Quadrature	6.2
6.3 Length of Plane Curve: Rectification	6.20
6.4 Volume of Solid of Revolution	6.26
6.5 Area of the Surface of a Solid of Revolution	6.38
6.6 Improper Integrals	6.45

7. Multiple Integrals	7.1
7.1 Double Integral	7.1
7.2 Application of Double Integral	7.4
7.3 Change of Order of Integration: Double Integral	7.12
7.4 General Change of Variables in Double Integral	7.14
7.5 Triple Integrals	7.21
7.6 General Change of Variables in a Triple Integral	7.24
7.7 Dirichlet's Integral	7.31

PART—III ORDINARY DIFFERENTIAL EQUATIONS

8. Ordinary Differential Equations: First Order and First Degree	8.1
8.1 Introduction to Mathematical Modeling	8.1
8.2 Basic Definitions	8.2
8.3 First Order First Degree Differential Equations	8.4
8.4 Variables Separable or Separable Equation	8.4
8.5 Homogeneous Equation—Reduction to Separable Form	8.6
8.6 Non-homogeneous Equations Reducible to Homogeneous Form	8.8
8.7 Exact Differential Equations	8.10
8.8 Reduction of Non-exact Differential Equations: Using Integrating Factors	8.12
8.9 Linear Differential Equation: First Order	8.19
8.10 Bernoulli Equation	8.22
8.11 First Order Nonlinear Differential Equations	8.25
8.12 Clairaut's Equation	8.29
8.13 Lagrange's Equation	8.32
8.14 Formation of Ordinary Differential Equations by Elimination of Arbitrary Constants	8.33
8.15 Geometrical Applications	8.36
8.16 Orthogonal Trajectories of Curves	8.39
8.17 Law of Natural Growth	8.44

8.18 Law of Natural Decay	8.45
8.19 Newton's Law of Cooling	8.46
8.20 Velocity of Escape from Earth	8.48
8.21 Simple Electric Circuits	8.50

9. Linear Differential Equations of Second Order and Higher Order **9.1**

9.1 Linear Independence and Dependence	9.1
9.2 Linear Differential Equations of Second Order with Variable Coefficients	9.2
9.3 Second Order Differential Equations with Constant Coefficients; Homogeneous	9.2
9.4 Higher Order Linear Homogeneous Differential Equations	9.5
9.5 Non-homogeneous Equations	9.9
9.6 Differential Equations with Variable Coefficients: Reducible to Equations with Constant Coefficients	9.25
9.7 Method of Variation of Parameters	9.29
9.8 The Method of Undetermined Coefficients	9.32
9.9 System of Simultaneous Linear D.E. with Constant Coefficients	9.38
9.10 Method of Reduction of Order	9.41
9.11 Higher Order Linear Equations with Variable Coefficients	9.43
9.12 Simple Harmonic Motion	9.48
9.13 Mass-spring Mechanical System	9.50
9.14 RLC-Circuit	9.59
9.15 Simple Pendulum	9.63

10. Series Solutions **10.1**

10.1 Classification of Singularities	10.1
10.2 Power Series Solution	10.2
10.3 Frobenius Method	10.7
10.4 Orthogonality of Functions	10.17
10.5 Sturm-Liouville Problems	10.21
10.6 Gram-Schmidt Orthogonalization Process	10.28

11. Special Functions—Gamma, Beta, Bessel and Legendre **11.1**

11.1 Gamma Function	11.1
11.2 Beta Function	11.2
11.3 Bessel's Functions	11.9
11.4 Differential Equations Reducible to Bessel's Equation	11.19

11.5	Legendre Functions	11.21	
11.6	Fourier-Legendre and Fourier-Bessel Series	11.30	
11.7	Chebyshev Polynomials	11.35	
12.	Laplace Transform	12.1	
12.1	Laplace Transform	12.1	
12.2	Applications, Advantages and Sufficient Conditions for Existence of Laplace Transform	12.3	
12.3	General Properties of Laplace Transform	12.3	
12.4	Laplace Transform of Periodic Function	12.18	
12.5	Inverse Laplace Transform	12.20	
12.6	General Properties of Inverse Laplace Transform	12.21	
12.7	Use of Partial Fractions to Find Inverse L.T.	12.30	
12.8	Convolution	12.33	
12.9	Application of Laplace Transform to Differential Equations with Constant Coefficients	12.35	
12.10	Application of Laplace Transform to System of Simultaneous Differential Equations	12.38	
12.11	Table of General Properties of Laplace Transform	12.41	
12.12	Table of Some Laplace Transforms	12.41	
 PART—IV LINEAR ALGEBRA AND VECTOR CALCULUS			
13.	Matrices	13.1	
13.1	Inverse of a Matrix	13.2	
13.2	Rank of a Matrix	13.3	
13.3	Normal Form	13.8	
13.4	System of Linear Non-homogeneous Equations	13.10	
13.5	System of Homogeneous Equations	13.15	
13.6	Gaussian Elimination Method	13.17	
13.7	LU-decompositions	13.20	
13.8	LU-decomposition from Gaussian Elimination	13.21	
13.9	Solution to Tridiagonal Systems	13.25	
13.10	Crout Reduction for Tridiagonal Linear Systems	13.25	
14.	Eigen Values and Eigen Vectors	14.1	
14.1	Linear Transformation	14.1	
14.2	Eigen Values and Eigen Vectors	14.1	
14.3	Properties of Eigen Values and Eigen Vectors	14.2	
14.4	Cayley-Hamilton Theorem	14.9	
14.5	Diagonalization Powers of a Matrix	14.13	
14.6	Real Matrices: Symmetric, Skew-symmetric, Orthogonal Quadratic Form	14.18	
14.7	Canonical Form: Or Sum of the Squares Form	14.21	
14.8	Transformation (Reduction) of Quadratic Form to Canonical Form	14.23	
14.9	Complex Matrices: Hermitian, Skew-Hermitian, Unitary Matrices	14.27	
14.10	Sylvester's Law of Inertia	14.32	
15.	Vector Differential Calculus: Gradient, Divergence and Curl	25.1	
15.1	Vector Differentiation	15.1	
15.2	Directional Derivative, Gradient of a Scalar Function and Conservative Field	15.5	
15.3	Divergence	15.10	
15.4	Curl	15.11	
15.5	Related Properties of Gradient, Divergence and Curl of Sums	15.14	
15.6	Second-order Differential Operator	15.16	
15.7	Curvilinear Coordinates: Cylindrical and Spherical Coordinates	15.20	
16.	Vector Integral Calculus	16.1	
16.1	Vector Integration: Integration of a Vector Function of a Scalar Argument	16.1	
16.2	Line Integrals: Work Done, Potential, Conservative Field and Area	16.4	
16.3	Surface Integrals: Surface Area and Flux	16.11	
16.4	Volume Integrals	16.16	
16.5	Green's Theorem in Plane: Transformation Between Line Integral and Double Integral Area in Cartesian and Polar Coordinates	16.19	

- 16.6 Stokes' Theorem 16.24
- 16.7 Gauss Divergence Theorem 16.29

PART—V

FOURIER ANALYSIS AND PARTIAL DIFFERENTIAL EQUATIONS

- 17. Fourier Series 17.1**
 - 17.1 Euler's (Fourier–Euler) Formulae 17.2
 - 17.2 Fourier Series for Even and Odd Functions 17.7
 - 17.3 Fourier Series for Functions Having Period $2L$ 17.10
 - 17.4 Half Range Expansions: Fourier Cosine and Sine Series 17.14
 - 17.5 Practical Harmonic Analysis 17.20
- 18. Partial Differential Equations 18.1**
 - 18.1 Partial Differential Equations 18.1
 - 18.2 Partial Differential Equations of First Order 18.7
 - 18.3 Linear Partial Differential Equations of First Order 18.7
 - 18.4 Non-linear Partial Differential Equations of First Order 18.11
 - 18.5 Charpit's Method 18.16
 - 18.6 Homogeneous Linear Partial Differential Equations with Constant Coefficients 18.18
 - 18.7 Non-homogeneous Linear Partial Differential Equations with Constant Coefficients 18.22
 - 18.8 Cauchy Type Differential Equation 18.29
 - 18.9 Non-linear Partial Differential Equations of Second Order: Monge's Method 18.30
 - 18.10 Solution of Second Order P.D.E.: Miscellaneous 18.36
- 19. Applications of Partial Differential Equations 19.1**
 - 19.1 Method of Separation of Variables 19.1
 - 19.2 Classification of Partial Differential Equations of Second Order 19.2
 - 19.3 Derivation of One-dimensional Heat Equation 19.3

- 19.4 Solution of One-dimensional Heat Equation 19.3
- 19.5 Derivation of One-dimensional Wave Equation 19.12
- 19.6 Solution of One-dimensional Wave Equation by Separation of Variables 19.13
- 19.7 Laplace's Equation or Potential Equation or Two-dimensional Steady-state Heat Flow 19.17
- 19.8 Laplace Equation in Polar Coordinates 19.25
- 19.9 Derivation and Solution of Two-dimensional Heat Equation 19.30
- 19.10 Derivation and Solution of Two-dimensional Wave Equation 19.37
- 19.11 Vibrations of Circular Membrane 19.42
- 19.12 Transmission Line Equations 19.45

20. Fourier Integral, Fourier Transforms and Integral Transforms 20.1

- 20.1 Fourier Integral Theorem 20.1
- 20.2 Fourier Transform 20.3
- 20.3 Convolution 20.4
- 20.4 Finite Fourier Sine and Cosine Transforms 20.12
- 20.5 Parseval's Identity for Fourier Transforms 20.17

21. Linear Difference Equations and Z-Transforms 21.1

- 21.1 Linear Difference Equations 21.1
- 21.2 Z-transforms 21.12
- 21.3 Standard Z-transforms 21.20

PART—VI

COMPLEX ANALYSIS

22. Complex Function Theory 22.1

- 22.1 Complex Function 22.1
- 22.2 Continuity 22.2
- 22.3 Differentiability 22.2
- 22.4 Analyticity 22.3
- 22.5 Cauchy-Riemann (C-R) Equations: In Cartesian Coordinates 22.3
- 22.6 Harmonic and Conjugate Harmonic Functions 22.4
- 22.7 Cauchy-Riemann Equations: In Polar Coordinates 22.5

22.8	Elementary Functions	22.14		
23.	Complex Integration	23.1		
23.1	Line Integral in Complex Plane	23.1		
23.2	Cauchy's Integral Theorem	23.6		
23.3	Cauchy's Integral Formula	23.12		
23.4	Derivative of Analytic Functions	23.14		
23.5	Complex Sequence, Series and Power Series	23.16		
23.6	Taylor's Series (Theorem)	23.17		
23.7	Laurent Series	23.21		
23.8	Zeros and Poles	23.27		
24.	Theory of Residues	24.1		
24.1	Residue	24.1		
24.2	Residue Theorem	24.2		
24.3	Evaluation of Real Integrals	24.7		
24.4	Argument Principle	24.17		
24.5	Rouche's Theorem	24.19		
24.6	Fundamental Theorem of Algebra	24.21		
24.7	Liouville Theorem	24.21		
25.	Conformal Mapping	25.1		
25.1	Mapping (or Transformation or Operator)	25.1		
25.2	Conformal Mapping	25.1		
25.3	Conformal Mapping by Elementary Functions	25.2		
25.4	Transformation: $w = z^n$	25.5		
25.5	Mapping $w = z^2$	25.6		
25.6	Transformation $w = e^z$	25.9		
25.7	Transformation $w = \sin z$	25.11		
25.8	Joukowski's (Zhukovsky's) Transformation	25.15		
25.9	Bilinear Transformation	25.15		
25.10	Schwarz-Christoffel Transformation	25.20		
PART—VII				
PROBABILITY AND STATISTICS				
26.	Probability	26.1		
26.1	Review of Set Theory	26.1		
26.2	Review of Counting	26.4		
26.3	Introduction to Probability	26.6		
26.4	Theorem of Total Probability (or the Rule of Elimination)	26.18		
26.5	Bayes' Theorem (or Bayes' Rule)	26.20		
27.	Probability Distributions	27.1		
27.1	Probability Distributions	27.1		
27.2	Chebyshev's Theorem	27.3		
27.3	Discrete Uniform Distribution	27.9		
27.4	Binomial Distribution	27.11		
27.5	Hypergeometric Distribution	27.15		
27.6	Poisson Distribution	27.19		
27.7	Poisson Process	27.24		
27.8	Continuous Uniform Distribution	27.26		
27.9	Normal Distribution	27.28		
27.10	Normal Approximation to Binomial Distribution	27.39		
27.11	Error Function	27.41		
27.12	The Exponential Distribution	27.44		
27.13	The Gamma Distribution	27.48		
27.14	The Weibull Distribution	27.50		
28.	Sampling Distribution	28.1		
28.1	Population and Sample	28.1		
28.2	Sampling Distribution	28.2		
28.3	Sampling Distribution of Means: (σ Known)	28.3		
28.4	Sampling Distribution of Proportions	28.9		
28.5	Sampling Distribution of Differences and Sums	28.9		
28.6	Sampling Distribution of Mean (σ Unknown): t -distribution	28.12		
28.7	Chi-squared Distribution	28.15		
28.8	Sampling Distribution of Variance s^2	28.16		
28.9	F -Distribution	28.16		
29.	Estimation and Test of Hypothesis	29.1		
29.1	Point Estimation	29.1		
29.2	Interval Estimation	29.3		
29.3	Bayesian Estimation	29.5		
29.4	Test of Hypothesis	29.7		
29.5	Test of Hypothesis Concerning Single Population Mean μ : (With Known Variance σ^2 : Large Sample)	29.9		
29.6	Test of Hypothesis Concerning Two Means	29.13		
29.7	Test for One Mean (Small Sample: T -distribution)	29.16		
29.8	Small-sample Test Concerning Difference between Two Means	29.18		
29.9	Paired-sample t -test	29.21		

29.10	Test of Hypothesis: One Proportion: Small Samples	29.23	32.4	Newton-Gregory Forward Interpolation Formula	32.13

INTRODUCTION

Chapter Introduction provide a quick look into the concepts that will be discussed in the chapter

Examples

3.20 — HIGHER ENGINEERING MATHEMATICS—II

WORKED OUT EXAMPLES

Example 1: Find the degree of the following homogeneous functions:

a. $x^2 - 2xy + y^2$ d. $x^{\frac{1}{2}}y^{-\frac{4}{3}}\tan^{-1}(y/x)$
b. $\log y - \log x$ e. $3x^2yz + 5xy^2z + 4x^4$
c. $(\sqrt{x^2 + y^2})^3$ f. $[z^2/(x^4 + y^4)]^{\frac{1}{2}}$

Ans:
a. 2
b. $\log y - \log x = \ln\left(\frac{y}{x}\right) = x^0 \ln\left(\frac{y}{x}\right)$ degree zero
c. $(\sqrt{x^2 + y^2})^3 = x^3\sqrt{1 + \left(\frac{y}{x}\right)^2}$ degree 3
d. $x^{\frac{1}{2}}y^{-\frac{4}{3}}\tan^{-1}(y/x) = x^{-1} \cdot x^{-\frac{4}{3}}y^{-\frac{4}{3}}\tan^{-1}\frac{y}{x} = x^{-1}\left(\frac{y}{x}\right)^{\frac{4}{3}}\tan^{-1}\frac{y}{x}$, degree: -1
e. degree 4
f. $\left[\frac{z^2}{x^4 + y^4}\right]^{\frac{1}{2}} = \left[\frac{z^2}{x^4}\frac{1}{1 + \left(\frac{y}{x}\right)^4}\right]^{\frac{1}{2}} = z^{-\frac{1}{2}}\left[\frac{1}{\left(\frac{y}{x}\right)^4 + \left(\frac{y}{x}\right)^0}\right]^{\frac{1}{2}}$ degree $= -2/3$.

Example 2: Verify Euler's theorem for the following functions by computing both sides of Euler's Equation (1) directly:

i. $(ax + by)^{\frac{1}{3}}$ ii. $x^{\frac{1}{2}}y^{-\frac{4}{3}}\tan^{-1}(y/x)$

Solution: i. $f = (ax + by)^{\frac{1}{3}}$ is homogeneous function of degree $\frac{1}{3}$
Differentiating f partially w.r.t. x and y , we get
 $f_x = \frac{\partial f}{\partial x} = \frac{1}{3}(ax + by)^{-\frac{2}{3}} \cdot a$
 $f_y = \frac{\partial f}{\partial y} = \frac{1}{3}(ax + by)^{-\frac{2}{3}} \cdot b$
Multiplying by x and y and adding, we get the L.H.S. of (1)
$$x f_x + y f_y = \frac{1}{3}(ax + by)^{-\frac{2}{3}}ax + \frac{1}{3}(ax + by)^{-\frac{2}{3}}by$$
$$= \frac{1}{3}(ax + by)^{-\frac{2}{3}}(ax + by)$$
$$= \frac{1}{3}(ax + by)^{\frac{1}{3}} = \frac{1}{3}f.$$

Since f is homogeneous function of degree $\frac{1}{3}$ the R.H.S. of (1) is $nf = \frac{1}{3}f$.
Thus
$$x f_x + y f_y = \text{L.H.S.} = \frac{1}{3}f = \text{R.H.S.}$$

ii. $f = x^{\frac{1}{2}}y^{-\frac{4}{3}}\tan^{-1}(y/x)$ is homogeneous function of degree -1
$$f_x = \frac{1}{2}x^{-\frac{1}{2}}y^{-\frac{4}{3}}\tan^{-1}\left(\frac{y}{x}\right) + x^{\frac{1}{2}}y^{-\frac{4}{3}} \cdot \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \left(-\frac{y}{x^2}\right)$$
$$f_y = x^{\frac{1}{2}}\left(-\frac{4}{3}\right)y^{-\frac{7}{3}}\tan^{-1}\left(\frac{y}{x}\right) + x^{\frac{1}{2}}y^{-\frac{4}{3}} \cdot \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{1}{x}$$

so
$$x f_x + y f_y = \frac{1}{2}x^{\frac{1}{2}}y^{-\frac{4}{3}}\tan^{-1}(y/x) + x^{\frac{1}{2}}y^{-\frac{4}{3}}\left(\frac{-y}{x^2 + y^2}\right)$$
$$= \frac{4}{3}x^{\frac{1}{2}}y^{-\frac{4}{3}}\tan^{-1}(y/x) + x^{\frac{1}{2}}y^{-\frac{4}{3}} \cdot \frac{1}{x^2 + y^2}$$
$$= -x^{\frac{1}{2}}y^{-\frac{4}{3}}\tan^{-1}(y/x) = -f.$$

Example 3: If $u = \log \frac{x^2 + y^2}{x + y}$, prove that $x u_x + y u_y = 1$

Solution: Let
$$f = e^u = \frac{x^2 + y^2}{x + y} = \frac{x^2\left(1 + \left(\frac{y}{x}\right)^2\right)}{x\left(1 + \frac{y}{x}\right)} = x\phi\left(\frac{y}{x}\right)$$

 f is a homogeneous function of degree 1.
Applying Euler's theorem for the function f , we get
$$x f_x + y f_y = n \cdot f = f.$$

Since $f = e^u$, $f_x = e^u \cdot u_x$, $f_y = e^u u_y$
so $x \cdot e^u u_x + y e^u u_y = f = e^u$
since $e^u \neq 0$, $x u_x + y u_y = 1$.

Example 4: Show that $x u_x + y u_y + z u_z = -2 \cot u$ when
$$u = \cos^{-1}\left(\frac{x^3 + y^3 + z^3}{ax + by + cz}\right)$$

Solution: Let
$$f = \cos u = \frac{x^3 + y^3 + z^3}{ax + by + cz}$$

Here f is a homogeneous function of degree 2 in the three variables x, y, z . By Euler's theorem

Chapter 11

Special Functions—Gamma, Beta, Bessel and Legendre

INTRODUCTION

We consider Fourier-Legendre series and Fourier-Bessel series, Chebyshev-polynomials which are useful in approximation theory are also presented.

Algebraic function $f(x)$ is obtained by the algebraic operations of addition, subtraction, multiplication, division and square rooting of x polynomial and rational functions are such functions. Transcendental functions include trigonometric functions (sine, cosine, tan) exponential, logarithmic and hyperbolic functions.

Algebraic and transcendental functions together constitute the elementary functions. Special functions (or higher functions) are functions other than the elementary functions such as Gamma, Beta functions (expressed as integrals) Bessel's functions, Legendre polynomials (as solutions of ordinary differential equations). Special functions also include Laguerre, Hermite, Chebyshev polynomials, error function, sine integral, exponential integral, Fresnel integrals, etc.

Many integrals which can not be expressed in terms of elementary functions can be evaluated in terms of beta and gamma functions.

Heat equation, wave equation and Laplace's equation with cylindrical symmetry can be solved in terms of Bessel's functions, with spherical symmetry by Legendre polynomials.

11.1 GAMMA FUNCTION

Gamma function denoted by $\Gamma(p)$ is defined by the improper integral which is dependent on the

parameter p ,

$$\Gamma(p) = \int_0^{\infty} e^{-t} t^{p-1} dt, \quad (p > 0) \quad (1)$$

Gamma function is also known as Euler's integral of the second kind.

Integrating by parts

$$\begin{aligned} \Gamma(p+1) &= \int_0^{\infty} e^{-t} t^p dt \\ &= -e^{-t} t^p \Big|_0^{\infty} + p \int_0^{\infty} e^{-t} t^{p-1} dt \\ &= 0 + p\Gamma(p) \end{aligned}$$

$$\text{Thus } \Gamma(p+1) = p\Gamma(p) \quad (2)$$

(2) is known as the functional relation or reduction or recurrence formula for gamma function.

Result:

$$\Gamma(n+a) = (n+a-1)(n+a-2)\cdots(n+a-3)\cdots a \cdot \Gamma(a), n \text{ is integer.}$$

By definition

$$\Gamma(1) = \int_0^{\infty} e^{-t} dt = \left[-e^{-t} \right]_0^{\infty} = 1 \quad (3)$$

By the reduction formula (2),

$$\Gamma(2) = 1 \cdot \Gamma(1) = 1$$

$$\text{and } \Gamma(3) = 2 \cdot \Gamma(2) = 2 \cdot 1 = 2!$$

and in general when p is a positive integer n

$$\begin{aligned} \Gamma(n+1) &= n\Gamma(n) = n(n-1)\Gamma(n-1) \\ &= n(n-1)(n-2)\Gamma(n-2) \\ &= n \cdot (n-1)(n-2)\cdots 3 \cdot 2 \cdot 1 = n! \end{aligned}$$

Every chapter contains worked out example problems which will guide the student while understanding the concepts and working out the exercise problems

Exercises

In all the chapters there are exercise problems within the text for the students to solve. This will hone their problem-solving skills like nothing else can. The answers to these exercises are provided alongside for the students to verify

Figures

Figures are used exhaustively in the text to illustrate the concepts and methods described.

Web supplement

The book is accompanied by a dedicated website at <http://www.mhhe.com/ramanahem> containing additional chapters on the following topics for the students

- Matrices & Determinants
- Sequence and Series
- Analytical Solid Geometry
- Calculus of Variations
- Linear Programming

It also has chapter-wise summaries.

9.16 — HIGHER ENGINEERING MATHEMATICS—III

EXERCISE

Solve the following:

1. $(D^2 + 10D^2 + 9) = \cos(2x + 3)$
Ans. $y = c_1 \cos x + c_2 \sin x + c_3 \cos 3x + c_4 \sin 3x - \frac{1}{10} \cos(2x + 3)$

2. $(D^2 + 2D + 5)y = 6 \sin 2x + 7 \cos 2x$
Ans. $y = e^{-x}(c_1 \sin 2x + c_2 \cos 2x) + 2 \sin 2x - \cos 2x$

3. $(D^2 + D^2 + D + 1)y = \sin 2x + \cos 3x$
Ans. $y = c_1 e^{-x} + c_2 \cos x + c_3 \sin x + \frac{1}{10}(2 \cos 2x - \sin 2x) - \frac{1}{10}(3 \sin 3x + \cos 3x)$

4. $(D^2 + 4)y = \sin x + \sin 2x$
Ans. $y = c_1 \sin 2x + c_2 \cos 2x + \frac{1}{10} \sin x - \frac{1}{10} \cos x$

5. $(D^2 - 8D + 9)y = 8 \sin 5x$
Ans. $y = c_1 e^{4x} e^{-5x} + c_2 e^{4x} e^{-5x} + \frac{1}{10}(5 \cos 5x - 2 \sin 5x)$

6. $(D^2 + 16)y = e^{-3x} + \cos 4x$
Ans. $y = c_1 \cos 4x + c_2 \sin 4x + \frac{1}{10} e^{-3x} + \frac{1}{10} \sin 4x$

7. $(D^2 - 2D + 2)y = e^x + \cos x$
Ans. $y = e^x(c_1 \cos x + c_2 \sin x) + \frac{1}{10} \cos x + \frac{1}{10} \sin x$

8. $(D^2 + 9)y = \cos^2 x$
Ans. $y = c_1 \cos 3x + c_2 \sin 3x + \frac{1}{10} + \frac{1}{10} \cos 2x$

9. $(D^2 + 2D + 1)y = \cos^2 x - \cos^2 x$
Ans. $y = (c_1 + c_2)e^{-x} + \frac{1}{10} + \frac{1}{10}(2 \sin 2x + \cos 2x)$

10. $(D^2 + 1)y = \cos x$
Ans. $y = c_1 \cos x + c_2 \sin x + \sin x \ln \sin x - x \cos x$

11. $(D^2 - 4D + 13)y = 8 \sin 3x$,
 $y(0) = 1, y'(0) = 2$
Ans. $y = \frac{1}{10} e^{2x}(\sin 3x + 2 \cos 3x) + \sin 3x + \frac{1}{10} \cos 3x$

12. $(D^2 + 2D^2 + 5^2)y = \cos mx$
Ans. $y = (c_1 \cos mx + c_2 \sin mx)(c_2 + c_4 x) + \frac{1}{10} \cos mx$, with $m \neq 5$

13. $(D^2 + 4)y = \cos x \cos 3x$
Ans. $y = (c_1 \cos 2x + c_2 \sin 2x) - \frac{1}{10} \cos 4x + \frac{1}{10} \sin 4x$

14. $(2D^2 - 2D + 1)y = \sin 3x - \cos 2x$
Ans. $y = e^{\frac{x}{2}}(c_1 \cos \frac{x}{2} + c_2 \sin \frac{x}{2}) + \frac{1}{10} \sin 3x - \frac{1}{10} \cos 2x$

15. $(D^2 + 4D)y = \sin 2x$
Ans. $y = c_1 + c_2 \cos 2x + c_3 \sin 2x - \frac{1}{10} \sin 2x$

P.I. When $F(x) = x^m$, m being a Positive Integer

Case (i): Consider $f(D)y = x^m$ so that $P.I. = y_p = \frac{1}{f(D)} x^m$

Expanding $\frac{1}{f(D)}$ in ascending power of D , we get $y_p = [a_0 + a_1 D + a_2 D^2 + \dots + a_n D^n] x^m$ since all the terms beyond D^0 are omitted as $D^k x^m = 0$ when $k > m$. This result can be extended when $F(x) = P_n(x)$ a polynomial in x of degree n so that $y_p = [a_0 + a_1 D + a_2 D^2 + \dots + a_n D^n] P_n(x)$

In particular $(D + a)y = P_n(x)$ we get $P.I. = y_p = \frac{1}{D + a} [P_n(x)] = \frac{1}{a} \left[\frac{1}{1 + \frac{D}{a}} \right] P_n(x) = \frac{1}{a} \left[1 - \frac{D}{a} + \frac{D^2}{a^2} - \dots + (-1)^n \frac{D^n}{a^n} \right] P_n(x)$ wherein terms of order higher than m are omitted.

PRELIMINARIES

- *Chapter 1 Vector Algebra, Theory of Equations, and Complex Numbers*

Chapter 1

Preliminaries

Vector Algebra, Theory of Equations, and Complex Numbers

INTRODUCTION

The preliminary Chapter 1 contains an elementary treatment of Vector Algebra, Theory of Equations, and Complex Numbers. Vector Algebra and Analytical Solid Geometry are prerequisites for Vector Differential Calculus of Chapter 15 and 16. The theory of equations deals with the analytical solutions of cubic and quartic equations while several numerical methods for solutions of algebraic and transcendental equations are considered in the Chapter 32 on Numerical Analysis. Complex numbers is the introductory part for the complex function theory dealt in Chapters 22, 23, 24 and 25.

1.1 VECTOR ALGEBRA

Vectors are very useful in engineering mathematics since many rules of vector calculation are as simple

as that of real numbers and is a shorthand simplifying several calculations.

Vector analysis was introduced by Gibbs.*

Scalars are physical quantities which possess only magnitude and are completely defined by a single real number.

Examples: Mass, temperature, volume, kinetic energy, salinity, length, voltage, time, work, electric charge.

Vectors are physical quantities which possess both magnitude and direction. Thus geometrically vectors are *directed line segment* (or an *arrow*) which are determined completely by their magnitude (length) and direction.

Examples: Force, velocity, acceleration, momentum, displacement, weight.

Vectors are denoted by lower case bold face type letters a or by an arrow overhead the letter as $\vec{a}$ or $\overline{a}$.

* Josiah Willard Gibbs (1839-1903), American mathematician.

Fig. 1.1

A vector $\vec{a}$ depicted as an arrow (directed line segment) has a tail A known as the *initial point* (or origin) and a tip B known as the *terminal point* (or terminus).

The magnitude (or absolute value) of a vector $\vec{a}$ (length of the directed line segment) is denoted by $|\vec{a}|$ or a (non bold face). It is also known as *norm* (or Euclidean norm) of $\vec{a}$.

Unit vector is a vector of unit magnitude (i.e., of length 1). If $\vec{a}$ is any vector of non zero magnitude ($a \neq 0$), then $\frac{\vec{a}}{a}$ is a unit vector in the direction of $\vec{a}$ i.e., a unit vector is obtained by dividing it by its magnitude.

Zero (or null) vector is a vector of zero magnitude and has no specified direction.

Equality: Two vectors $\vec{a}$ and $\vec{b}$ are said to be equal, denoted as $\vec{a} = \vec{b}$, if both $\vec{a}$ and $\vec{b}$ have the same magnitude and same direction without regard to their initial points (also known as *free** vectors). Thus a vector can be moved parallel to itself without any change.

Negative of a vector $\vec{a}$, denoted by $-\vec{a}$, is a vector having the same magnitude as $\vec{a}$ but having opposite direction.

Note: Length of $-\vec{a}$ is *not* negative.

Fig. 1.2

Scalar multiplication $\alpha\vec{a}$ is a vector of magnitude $|\alpha|a$ and having the same direction of $\vec{a}$, if $\alpha > 0$ and of opposite direction if $\alpha < 0$.

* In contrast, *bound* vectors are fixed vectors and are restricted to their initial points (such as application of force at a point).

Here $|\alpha|$ is the absolute value of the scalar α .

Unequal: $\vec{a}$, $\vec{b}$, are said to be unequal, written as $\vec{a} \neq \vec{b}$ when magnitudes of $\vec{a}$ and $\vec{b}$ are different or direction of $\vec{a}$ and $\vec{b}$ or both magnitudes and direction of $\vec{a}$ and $\vec{b}$ are different.

In vector algebra, addition, subtraction and multiplication of vectors are introduced.

Addition

To obtain the sum or resultant of two vectors $\vec{a}$ and $\vec{b}$, move $\vec{b}$ so that initial point of $\vec{b}$ coincides with the terminal point of $\vec{a}$. Then the sum of $\vec{a}$ and $\vec{b}$, written as $\vec{a} + \vec{b}$, is defined by the vector (arrow) from the initial point of $\vec{a}$ to the terminal point $\vec{b}$. Similarly placing the tail of $\vec{a}$ with the tip of $\vec{b}$, the resultant $\vec{b} + \vec{a}$ is obtained. Thus the vector addition follows the parallelogram law of addition, i.e., the resultant of a parallelogram with $\vec{a}$ and $\vec{b}$ as adjacent sides is given by the diagonal of the parallelogram. Vector addition is commutative $\vec{a} + \vec{b} = \vec{b} + \vec{a}$ and is associative $\vec{a} + (\vec{b} + \vec{c}) = (\vec{a} + \vec{b}) + \vec{c}$.

Fig. 1.3

Difference

$$\vec{a} - \vec{b} = \vec{a} + (-\vec{b})$$

Rectangular unit vectors:

Fig. 1.4

Consider a right handed rectangular coordinate system. Let $\vec{i}$, $\vec{j}$, $\vec{k}$ be unit vectors along the positive X , Y and Z axes. Let $p(x, y, z)$ be any point and $O(0, 0, 0)$ be the origin.

Fig. 1.5

Positive vector

$\vec{r}$ of a point $P(x, y, z)$ is $\overrightarrow{OP}$ with origin O as the initial point and P as the terminal point. Now $\vec{r}$ can be expressed as a linear combination of the unit vectors $\vec{i}, \vec{j}, \vec{k}$. Here $\overrightarrow{OA} = x\vec{i}$, $\overrightarrow{AB} = y\vec{j}$ and $\overrightarrow{BP} = z\vec{k}$ since x, y, z are the lengths of OA, AB and BP respectively and $\vec{i}, \vec{j}, \vec{k}$ are unit vectors in the positive X, Y, Z axes. By vector addition

$$\vec{r} = \overrightarrow{OP} = \overrightarrow{OA} + \overrightarrow{AB} + \overrightarrow{BP} = x\vec{i} + y\vec{j} + z\vec{k}$$

Fig. 1.6

Generalizing this, if $P(x_1, y_1, z_1)$ and $Q(x_2, y_2, z_2)$ be any two points, then the vector $\overrightarrow{PQ}$ can be represented as

$$\overrightarrow{PQ} = (x_2 - x_1)\vec{i} + (y_2 - y_1)\vec{j} + (z_2 - z_1)\vec{k}$$

Here $x_2 - x_1, y_2 - y_1, z_2 - z_1$ are known as *components* of $\overrightarrow{PQ}$ in the X, Y, Z directions. Now

$$|\overrightarrow{PQ}| = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

which is the distance between the points P and Q (and thus the length or modulus of the vector $\overrightarrow{PQ}$). With this the earlier definitions can be expressed in terms of the components. Suppose $\vec{a} = a_1\vec{i} + a_2\vec{j} + a_3\vec{k}$ and $\vec{b} = b_1\vec{i} + b_2\vec{j} + b_3\vec{k}$. Then

1. $\vec{a} = \vec{b}$ if $a_i = b_i$ for $i = 1, 2, 3$ i.e., their corresponding (respective) components are equal
2. $\vec{a} = 0$ if $a_1 = a_2 = a_3 = 0$

3. $\vec{a} \pm \vec{b} = (a_1 \pm b_1)\vec{i} + (a_2 \pm b_2)\vec{j} + (a_3 \pm b_3)\vec{k}$ i.e., addition (subtraction) by adding (subtracting) the corresponding components.
4. $\alpha\vec{a} = \alpha a_1\vec{i} + \alpha a_2\vec{j} + \alpha a_3\vec{k}$ i.e., scalar multiplication amounts to multiplication of each component.

Multiplication

(a) **Inner product or scalar product or dot product** of two vectors $\vec{a}$ and $\vec{b}$, is denoted by $\vec{a} \cdot \vec{b}$, read as $\vec{a}$ dot $\vec{b}$, is defined as

$$\vec{a} \cdot \vec{b} = |\vec{a}||\vec{b}|\cos\theta$$

where θ is the angle between $\vec{a}$ and $\vec{b}$ and lies in the interval $0 \leq \theta \leq \pi$. Note that dot product is a scalar quantity. It is positive, zero or negative depending on whether θ is acute angle, right angle or obtuse angle. Thus for non-zero vectors.

$$\vec{a} \cdot \vec{b} = 0 \text{ implies that } \theta = \frac{\pi}{2}$$

i.e., $\vec{a}$ and $\vec{b}$ are perpendicular or orthogonal to each other. Now

$$\vec{a} \cdot \vec{a} = |\vec{a}||\vec{a}|\cos 0 = |\vec{a}|^2$$

$$\text{or } |\vec{a}| = \sqrt{\vec{a} \cdot \vec{a}} = \sqrt{a_1^2 + a_2^2 + a_3^2}$$

For the unit vectors we have

$$\vec{i} \cdot \vec{j} = \vec{j} \cdot \vec{k} = \vec{k} \cdot \vec{i} = 0 \quad \text{and}$$

$$\vec{i} \cdot \vec{i} = \vec{j} \cdot \vec{j} = \vec{k} \cdot \vec{k} = 1.$$

The dot product in the component form is $\vec{a} \cdot \vec{b} = (a_1\vec{i} + a_2\vec{j} + a_3\vec{k}) \cdot (b_1\vec{i} + b_2\vec{j} + b_3\vec{k})$

$$\vec{a} \cdot \vec{b} = a_1b_1 + a_2b_2 + a_3b_3$$

i.e., sum of the products of the corresponding components.

Properties

1. $\vec{a} \cdot \vec{b} = \vec{b} \cdot \vec{a}$ (Commutative)
2. $\vec{a} \cdot (\vec{b} + \vec{c}) = (\vec{a} \cdot \vec{b}) + (\vec{a} \cdot \vec{c})$ (Distributive)
3. $\vec{a} \cdot (\alpha\vec{b} + \beta\vec{c}) = \alpha\vec{a} \cdot \vec{b} + \beta\vec{a} \cdot \vec{c}$ (Linearity)
4. $\vec{a} \cdot \vec{a} \geq 0$
 $\vec{a} \cdot \vec{a} = 0$ iff $\vec{a} = \vec{0}$ (Positive definiteness)

1.4 — HIGHER ENGINEERING MATHEMATICS—I

1. Angle The angle θ between two vectors $\vec{a}$ and $\vec{b}$ is defined as

$$\cos \theta = \frac{\vec{a} \cdot \vec{b}}{|\vec{a}||\vec{b}|} = \frac{\vec{a} \cdot \vec{b}}{\sqrt{\vec{a} \cdot \vec{a}} \sqrt{\vec{b} \cdot \vec{b}}}$$

Note:

Direction cosines of a vector $\vec{a}$ are the cosine of the angles which $\vec{a}$ makes with x, y, z axes and are given by $\vec{a} \cdot \frac{\vec{i}}{|\vec{a}|}, \vec{a} \cdot \frac{\vec{j}}{|\vec{a}|}, \vec{a} \cdot \frac{\vec{k}}{|\vec{a}|}$, respectively.

2. Projection Since $|\vec{b}| \cos \theta$ is the projection of $\vec{b}$ on $\vec{a}$, $\vec{a} \cdot \vec{b} = (|\vec{a}|)(|\vec{b}| \cos \theta)$ is the product of $|\vec{a}|$ and $|\vec{b}| \cos \theta$, i.e. product of length of $\vec{a}$ and projection of $\vec{b}$ on $\vec{a}$. Similarly $\vec{a} \cdot \vec{b}$ can be interpreted as the product of length of $\vec{b}$ with the projection of $\vec{a}$ on $\vec{b}$, i.e. dot product is length of either multiplied by projection of the other upon it. Thus the scalar projection of $\vec{a}$ in the direction of $\vec{b}$ is

$$a \cos \theta = \vec{a} \cdot \frac{\vec{b}}{|\vec{b}|}$$

and vector projection of $\vec{a}$ in the direction of $\vec{b}$ is

$$(a \cos \theta) \frac{\vec{b}}{|\vec{b}|} = \left(\vec{a} \cdot \frac{\vec{b}}{|\vec{b}|} \right) \frac{\vec{b}}{|\vec{b}|} = \left(\frac{\vec{a} \cdot \vec{b}}{b^2} \right) \vec{b}$$

Fig. 1.7

3. Work done by a force The work done by a constant force $\vec{F}$ in moving an object through a distance d = (magnitude of force in the direction of motion) (distance moved)

$$= (F \cos \theta)(d) = \vec{F} \cdot \vec{d}$$

Fig. 1.8

(b) Vector product (or cross product)

Vector product of two vectors $\vec{a}$ and $\vec{b}$, denoted by $\vec{a} \times \vec{b}$, read as $\vec{a}$ cross $\vec{b}$, is defined as

$$\vec{c} = \vec{a} \times \vec{b} = |\vec{a}||\vec{b}| \sin \theta \vec{u}, \quad 0 \leq \theta \leq \pi$$

The vector $\vec{c}$ is perpendicular to both $\vec{a}$ and $\vec{b}$ such that $\vec{a}, \vec{b}, \vec{c}$ in this order form a *right handed system of vectors*. Here $\vec{u}$ is a unit vector in the direction of $\vec{a} \times \vec{b}$ as shown in Fig. 1.9.

Thus the modulus of $\vec{a} \times \vec{b}$ is the area of a parallelogram with $\vec{a}$ and $\vec{b}$ as adjacent sides as shown in Fig. 1.9(b).

Fig. 1.9

Parallel If $\vec{a} \times \vec{b} = 0$, then either $\vec{a} = 0$ or $\vec{b} = 0$ or both or $\theta = 0$ or π . Thus when $\vec{a} \times \vec{b} = 0$, then either at least one of the vectors $\vec{a}, \vec{b}$ is zero or else $\vec{a}$ and $\vec{b}$ are parallel non zero vectors.

Corollary $\vec{a} \times \vec{a} = 0$ for any vector $\vec{a}$. Since the direction of $\vec{b} \times \vec{a}$ is opposite to that of $\vec{a} \times \vec{b}$, the cross product is anticommutative (i.e., *not* commutative) so

$$\vec{a} \times \vec{b} = -\vec{b} \times \vec{a}$$

However it is distributive

$$\vec{a} \times (\vec{b} + \vec{c}) = \vec{a} \times \vec{b} + \vec{a} \times \vec{c}$$

Now for the unit vectors $\vec{i}, \vec{j}, \vec{k}$ we have

$$\vec{i} \times \vec{i} = \vec{j} \times \vec{j} = \vec{k} \times \vec{k} = 0 \quad (\text{parallel})$$

$$\vec{i} \times \vec{j} = \vec{k}, \quad \vec{j} \times \vec{k} = \vec{i}, \quad \vec{k} \times \vec{i} = \vec{j} \quad (\text{right handed})$$

while

$$\vec{j} \times \vec{i} = -\vec{k}, \quad \vec{k} \times \vec{j} = -\vec{i}, \quad \vec{i} \times \vec{k} = -\vec{j} \quad (\text{left handed})$$

Fig. 1.10

In the component form

$$\begin{aligned}\bar{a} \times \bar{b} &= (a_1\bar{i} + a_2\bar{j} + a_3\bar{k}) \times (b_1\bar{i} + b_2\bar{j} + b_3\bar{k}) \\ &= (a_2b_3 - a_3b_2)\bar{i} + (a_3b_1 - a_1b_3)\bar{j} + (a_1b_2 - a_2b_1)\bar{k} \\ &= \begin{vmatrix} i & j & k \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}\end{aligned}$$

Moment of a force $\bar{F}$ about a point P

The magnitude of the moment M (known as *torque*) of a force $\bar{F}$ about a point P is the product of F and the perpendicular distance of P from the line of action of force $\bar{F}$. Thus $M = (F)(PQ) = (F)(r \sin \theta)$ since $PQ = r \sin \theta$. Here $\bar{PR} = \bar{r}$ is the vector from P to the initial point R of $\bar{F}$. The direction of the moment is perpendicular to both $\bar{r}$ and $\bar{F}$. Thus the moment vector $\bar{M}$ is given by

$$\bar{M} = \bar{r} \times \bar{F}$$

where $|\bar{M}| = M = rF \sin \theta$

Fig. 1.11

Moment of a force $\bar{F}$ about a line L

Let P be any point on the line L which is in the direction of a unit vector $\hat{a}$. Then the moment of the force $\bar{F}$ about the line L is the resolved part along L of the moment of $\bar{F}$ about any point on L . Thus moment $\bar{M}$ of $\bar{F}$ about the line $L = (\bar{PQ} \times \bar{F}) \cdot \hat{a}$.

Fig. 1.12

Velocity of a rotating body

Suppose a rigid body rotates about an axis L through the point with angular speed ω . Let $\bar{r}$ be the position vector of any point P on the rigid body. Let θ be the angle between $\bar{r}$ and the axis of revolution L . Then the distance d of the point P from the axis is given by $r \sin \theta$

$$\text{i.e.,} \quad d = |\bar{r}| \sin \theta$$

since P travels in a circle of radius d . The magnitude of linear velocity $\bar{v}$ is

$$|\bar{v}| = \omega d = \omega |\bar{r}| \sin \theta = |\bar{\omega}| |\bar{r}| \sin \theta$$

Also $\bar{v}$ must be perpendicular to both $\bar{\omega}$ and $\bar{r}$ such that $\bar{r}$, $\bar{\omega}$, $\bar{v}$ form a right handed system. Therefore the linear velocity $\bar{v}$ of the body is

$$\bar{v} = \bar{\omega} \times \bar{r}$$

Here $\bar{\omega}$ is known as the *angular velocity*.

Fig. 1.13

(c) Scalar triple product or box product or mixed triple product of three vectors $\bar{a}$, $\bar{b}$, $\bar{c}$ is defined by

$$\bar{a} \cdot (\bar{b} \times \bar{c}) = \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = [\bar{a}, \bar{b}, \bar{c}] = [\bar{a} \bar{b} \bar{c}]$$

Geometrically, the absolute value of the scalar triple product is the volume of a parallelepiped with $\bar{a}$, $\bar{b}$, $\bar{c}$ as the coterminal (or concurrent) edges. If $\bar{n}$ is a unit normal to the base parallelogram then area of the base parallelogram is $|\bar{b} \times \bar{c}|$ and height h of the terminal point of $\bar{a}$ above the parallelogram is $\bar{a} \cdot \bar{n}$. Then

1.6 — HIGHER ENGINEERING MATHEMATICS—I

volume of parallelepiped = (height h) (area of base parallelogram)

$$= (\vec{a} \cdot \vec{n})(|\vec{b} \times \vec{c}|) = \vec{a} \cdot (|\vec{b} \times \vec{c}| \vec{n}) = \vec{a} \cdot (\vec{b} \times \vec{c})$$

Fig. 1.14

Corollary 1: If $\vec{a}, \vec{b}, \vec{c}$ are coplanar (i.e., they lie in the same plane) then the volume of the parallelepiped is zero. Thus for coplanar vectors the scalar triple product is zero.

i.e., $\vec{a}, \vec{b}, \vec{c}$ are coplanar if $\vec{a} \cdot (\vec{b} \times \vec{c}) = 0$. Then $\vec{a}, \vec{b}, \vec{c}$ are said to be linearly dependent.

Corollary 2: Volume of a tetrahedron with $\vec{a}, \vec{b}, \vec{c}$ as the coterminus edges = $\frac{1}{6}$ of the volume of the parallelepiped with $\vec{a}, \vec{b}, \vec{c}$ as edges.

Corollary 3: Since the value of the determinant is unaltered by the interchange of two rows, we have

$$\vec{a} \cdot (\vec{b} \times \vec{c}) = \vec{b} \cdot (\vec{c} \times \vec{a}) = \vec{c} \cdot (\vec{a} \times \vec{b}) = (\vec{a} \times \vec{b}) \cdot \vec{c}$$

i.e., dot and cross in a triple scalar product can be interchanged without affecting its value.

(d) **Vector triple product** of $\vec{a}, \vec{b}, \vec{c}$ is defined as

$$\vec{a} \times (\vec{b} \times \vec{c}) = (\vec{a} \cdot \vec{c})\vec{b} - (\vec{a} \cdot \vec{b})\vec{c}$$

In general

$$\vec{a} \times (\vec{b} \times \vec{c}) \neq (\vec{a} \times \vec{b}) \times \vec{c}$$

i.e., not associative.

Also

$$(\vec{a} \times \vec{b}) \times \vec{c} = (\vec{a} \cdot \vec{c})\vec{b} - (\vec{b} \cdot \vec{c})\vec{a}$$

Results

$$1. (\vec{a} \times \vec{b}) \cdot (\vec{c} \times \vec{d}) = (\vec{a} \cdot \vec{c})(\vec{b} \cdot \vec{d}) - (\vec{a} \cdot \vec{d})(\vec{b} \cdot \vec{c})$$

Proof: Put $\vec{a} \times \vec{b} = \vec{x}$ then

$$(\vec{a} \times \vec{b}) \cdot (\vec{c} \times \vec{d}) = \vec{x} \cdot (\vec{c} \times \vec{d}) = (\vec{x} \times \vec{c}) \cdot \vec{d}$$

$$\begin{aligned} &= (\vec{a} \times \vec{b}) \times \vec{c} \cdot \vec{d} \\ &= [(\vec{a} \cdot \vec{c})\vec{b} - (\vec{b} \cdot \vec{c})\vec{a}] \cdot \vec{d} \\ &= (\vec{a} \cdot \vec{c})(\vec{b} \cdot \vec{d}) - (\vec{b} \cdot \vec{c})(\vec{a} \cdot \vec{d}) \end{aligned}$$

$$2. (\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d}) = \vec{b}(\vec{a} \cdot \vec{c} \times \vec{d}) - \vec{a}(\vec{b} \cdot \vec{c} \times \vec{d})$$

$$\begin{aligned} &= [\vec{a} \cdot \vec{c}]\vec{b} - [\vec{b} \cdot \vec{c}]\vec{a} \\ &= \vec{c}(\vec{a} \cdot \vec{b} \times \vec{d}) - \vec{d}(\vec{a} \cdot \vec{b} \times \vec{c}) \\ &= [\vec{a} \cdot \vec{b} \times \vec{d}]\vec{c} - [\vec{a} \cdot \vec{b} \times \vec{c}]\vec{d} \end{aligned}$$

Proof: Put $\vec{a} \times \vec{b} = \vec{x}$. Then

$$\begin{aligned} (\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d}) &= \vec{x} \times (\vec{c} \times \vec{d}) = (\vec{x} \cdot \vec{d})\vec{c} - (\vec{x} \cdot \vec{c})\vec{d} \\ &= (\vec{a} \times \vec{b} \cdot \vec{d})\vec{c} - (\vec{a} \times \vec{b} \cdot \vec{c})\vec{d} \\ &= [\vec{a} \cdot \vec{b} \times \vec{d}]\vec{c} - [\vec{a} \cdot \vec{b} \times \vec{c}]\vec{d} \end{aligned}$$

Linear independence: Set of vectors $\vec{a}, \vec{b}, \vec{c}$ are said to be linearly independent if $\alpha\vec{a} + \beta\vec{b} + \gamma\vec{c} = 0$ implies that $\alpha = \beta = \gamma = 0$. Otherwise they are said to be linearly dependent when not all α, β, γ are zero.

Vector Algebra

WORKED OUT EXAMPLES

Example 1: Prove that the line joining the mid-points of two sides of a triangle is parallel to the third side and half of it.

Solution: Let A, B, C be the vertices of the triangle with position vectors $\vec{a}, \vec{b}, \vec{c}$ wrt an origin O . Let D and E be the middle points of AC and BC respectively. Then

$$\begin{aligned} \vec{DE} &= \vec{DA} + \vec{AB} + \vec{BE} = \frac{1}{2}\vec{CA} + \vec{AB} + \frac{1}{2}\vec{BC} \\ &= \frac{1}{2}(\vec{a} - \vec{c}) + (\vec{b} - \vec{a}) + \frac{1}{2}(\vec{c} - \vec{b}) = \frac{\vec{b} - \vec{a}}{2} = \frac{1}{2}\vec{AB} \end{aligned}$$

Thus DE is parallel to the third side AB and half of it.

Fig. 1.15

Example 2: Prove that the vectors $\vec{a} = 3\vec{i} + \vec{j} - 2\vec{k}$, $\vec{b} = -\vec{i} + 3\vec{j} + 4\vec{k}$, $\vec{c} = 4\vec{i} - 2\vec{j} - 6\vec{k}$ can form the sides of a triangle. Find the lengths of the medians of the triangle.

Solution: Consider $\alpha\vec{a} + \beta\vec{b} + \gamma\vec{c} = 0$ or

Fig. 1.16

$$\alpha(3\vec{i} + \vec{j} - 2\vec{k}) + \beta(-\vec{i} + 3\vec{j} + 4\vec{k}) + \gamma(4\vec{i} - 2\vec{j} - 6\vec{k}) = 0$$

Equating each of the components of $\vec{i}$, $\vec{j}$, $\vec{k}$ to zero, we get

$$\begin{aligned} 3\alpha - \beta + 4\gamma &= 0 \\ \alpha + 3\beta - 2\gamma &= 0 \\ -2\alpha + 4\beta - 6\gamma &= 0 \end{aligned}$$

Solving $\beta = \gamma = -\alpha$. Choose $\alpha = 1$. Thus $-\vec{a} + \vec{b} + \vec{c} = 0$ i.e., three vectors are linearly dependent i.e., non-collinear. Therefore they form a plane triangle. Let S be the mid point of PQ . So that RS is a median. Now

$$\begin{aligned} \vec{RS} &= \vec{RP} + \vec{PS} = -\vec{a} + \frac{1}{2}\vec{b} \\ &= -(3\vec{i} + \vec{j} - 2\vec{k}) + \frac{1}{2}(-\vec{i} + 3\vec{j} + 4\vec{k}) \\ &= -\frac{7}{2}\vec{i} + \frac{1}{2}\vec{j} + 4\vec{k} \end{aligned}$$

$\therefore |\vec{RS}| = \text{length of the median}$

$$= \sqrt{\frac{49}{4} + \frac{1}{4} + 16} = \sqrt{\frac{114}{4}} = \frac{1}{2}\sqrt{114}$$

Similarly PT be another median. Then

$$\begin{aligned} \vec{PT} &= \vec{PQ} + \frac{1}{2}\vec{QT} = \vec{b} + \frac{1}{2}\vec{c} \\ &= (\vec{i} + 3\vec{j} + 4\vec{k}) + \frac{1}{2}(4\vec{i} - 2\vec{j} - 6\vec{k}) \\ &= \vec{i} + 2\vec{j} + \vec{k} \end{aligned}$$

So $|\vec{PT}| = \text{length of median} = \sqrt{1^2 + 2^2 + 1^2} = \sqrt{6}$
Finally $\vec{QU} = \vec{QR} + \frac{1}{2}\vec{RU} = \vec{c} + \frac{1}{2}(-\vec{a})$

$$\begin{aligned} &= (4\vec{i} - 2\vec{j} - 6\vec{k}) - \frac{1}{2}(3\vec{i} + \vec{j} - 2\vec{k}) \\ &= \frac{5}{2}\vec{i} - \frac{5}{2}\vec{j} - 5\vec{k} \end{aligned}$$

$$|\vec{QU}| = \sqrt{\frac{25}{4} + \frac{25}{4} + 25} = \sqrt{\frac{150}{4}}$$

Example 3: If $\vec{a} = \vec{i} + \vec{j} + \vec{k}$, $\vec{b} = 2\vec{i} - \vec{j} + 4\vec{k}$, $\vec{c} = 3\vec{i} + 2\vec{j} - \vec{k}$ then find a unit vector parallel to $2\vec{a} - 3\vec{b} + 4\vec{c}$.

Solution: $2\vec{a} - 3\vec{b} + 4\vec{c} = 2(\vec{i} + \vec{j} + \vec{k}) - 3(2\vec{i} - \vec{j} + 4\vec{k}) + 4(3\vec{i} + 2\vec{j} - \vec{k})$. So

$$\begin{aligned} 2\vec{a} - 3\vec{b} + 4\vec{c} &= 8\vec{i} + 13\vec{j} - 14\vec{k} \\ |2\vec{a} - 3\vec{b} + 4\vec{c}| &= \sqrt{8^2 + 13^2 + 14^2} \\ &= \sqrt{64 + 169 + 196} = \sqrt{429} \end{aligned}$$

Unit vector parallel to $2\vec{a} - 3\vec{b} + 4\vec{c}$ is $\frac{2\vec{a} - 3\vec{b} + 4\vec{c}}{|2\vec{a} - 3\vec{b} + 4\vec{c}|}$
$$= \frac{1}{\sqrt{429}}[8\vec{i} + 13\vec{j} - 14\vec{k}]$$

Example 4: Prove that $\vec{a} = \vec{i} - 3\vec{j} + 2\vec{k}$, $\vec{b} = 2\vec{i} - 4\vec{j} - \vec{k}$ and $\vec{c} = 3\vec{i} + 2\vec{j} - \vec{k}$ are linearly independent.

Solution: Consider $\alpha\vec{a} + \beta\vec{b} + \gamma\vec{c} = 0$. Then

$$\begin{aligned} \alpha(\vec{i} - 3\vec{j} + 2\vec{k}) + \beta(2\vec{i} - 4\vec{j} - \vec{k}) \\ + \gamma(3\vec{i} + 2\vec{j} - \vec{k}) &= 0 \end{aligned}$$

Equating each component to zero, we have $\alpha + 2\beta + 3\gamma = 0$, $-3\alpha - 4\beta + 2\gamma = 0$, $2\alpha - \beta - \gamma = 0$. Solving $\alpha = \beta = \gamma = 0$. $\therefore \vec{a}, \vec{b}, \vec{c}$ are linearly independent.

1.8 — HIGHER ENGINEERING MATHEMATICS—I

Example 5: Find the unit vector perpendicular to each of the vectors $2i + j + k$ and $i - 2j + k$.

Solution: Let $\bar{a} = a_1i + a_2j + a_3k$ be the required unit vector so that $|\bar{a}| = \sqrt{a_1^2 + a_2^2 + a_3^2} = 1$. Since $\bar{a}$ is perpendicular to $2i + j + k$, we have $(a_1i + a_2j + a_3k) \cdot (2i + j + k) = 0$

$$\text{or } 2a_1 + a_2 + a_3 = 0$$

Similarly since $\bar{a}$ is perpendicular to $i - 2j + k$,

$$a_1 - 2a_2 + a_3 = 0.$$

$$\text{Solving } 5a_2 - a_3 = 0 \therefore a_3 = 5a_2$$

$$\text{So } a_1 = 2a_2 - a_3 = 2a_2 - 5a_2 = -3a_2$$

Since $a_1^2 + a_2^2 + a_3^2 = 1$, we have

$$9a_2^2 + a_2^2 + 25a_2^2 = 1$$

$$a_2^2 = \frac{1}{35} \text{ or } a_2 = \pm \frac{1}{\sqrt{35}}$$

Thus the unit vector are

$$\pm \frac{1}{\sqrt{35}}[-3i + j + 5k]$$

Example 6: Determine the projection of $\bar{a}$ on $\bar{b}$ and $\bar{b}$ on $\bar{a}$ given $\bar{a} = i + j + k$ and $\bar{b} = 2i - j + 5k$.

Solution: Projection of $\bar{a}$ on $\bar{b}$ is $\bar{a} \cdot \frac{\bar{b}}{|\bar{b}|}$

$$= (\bar{i} + \bar{j} + \bar{k}) \cdot \frac{(2\bar{i} - \bar{j} + 5\bar{k})}{\sqrt{4 + 1 + 25}} = \frac{2 - 1 + 5}{\sqrt{30}} = \frac{6}{\sqrt{30}}$$

projection of $\bar{b}$ on $\bar{a}$ is $\bar{b} \cdot \frac{\bar{a}}{|\bar{a}|}$

$$= (2\bar{i} - \bar{j} + 5\bar{k}) \cdot \frac{(\bar{i} + \bar{j} + \bar{k})}{\sqrt{3}} = \frac{6}{\sqrt{3}}$$

Example 7: Determine the three sides and angles of a triangle with vertices $(1, -1, 1)$, $(2, 3, -1)$, $(3, 0, 2)$.

Fig. 1.17

Solution: Let $P(1, -1, 1)$, $Q(2, 3, -1)$ and $R(3, 0, 2)$ be the three vertices of the triangle. Then the side

$$\overline{PQ} = (2 - 1)i + (3 - (-1))j + (-1 - 1)k$$

i.e., $\overline{PQ} = i + 4j - 2k$, similarly $\overline{QR} = +i - 3j + 3k$ and $\overline{RP} = -2i - j - k$. Let α, β, γ be the angles.

$$\text{Then } \cos \alpha = \frac{\overline{PQ} \cdot \overline{PR}}{|\overline{PQ}| |\overline{PR}|} = \frac{(i + 4j - 2k) \cdot (2i + j + k)}{\sqrt{1 + 16 + 4} \sqrt{4 + 1 + 1}}$$

$$\cos \alpha = \frac{2 + 4 - 2}{\sqrt{21} \sqrt{6}} = \frac{4}{\sqrt{21} \sqrt{6}} \text{ so } \alpha = \cos^{-1} \frac{4}{\sqrt{126}}$$

$$\text{Similarly } \cos \beta = \frac{\overline{QP} \cdot \overline{QR}}{|\overline{QP}| |\overline{QR}|} = \frac{(-i - 4j + 2k) \cdot (-i - 3j + 3k)}{\sqrt{21} \sqrt{19}}$$

$$= \frac{-1 + 12 + 6}{\sqrt{21} \sqrt{19}} = \frac{+17}{\sqrt{399}}$$

$$\text{Finally } \cos \gamma = \frac{\overline{RP} \cdot \overline{RQ}}{|\overline{RP}| |\overline{RQ}|} = \frac{(-2i - j - k) \cdot (-i + 3j - 3k)}{\sqrt{6} \sqrt{19}}$$

$$= \frac{+2 - 3 + 3}{\sqrt{6} \sqrt{19}} = \frac{2}{\sqrt{6} \sqrt{19}}$$

Example 8: Forces $\bar{F}_1 = 3i + 5j + 6k$, $\bar{F}_2 = +i + 2j + k$ and $\bar{F}_3 = 3i + 8j$ act on a particle P whose position vector is $3i - 4j + 2k$. Determine the work done by the forces in a displacement of the particle to the point $Q(5, 2, 1)$.

Also find the vector moment of the resultant of the three forces acting at P about the point Q .

Solution: The resultant force $\bar{F} = \bar{F}_1 + \bar{F}_2 + \bar{F}_3$ so $\bar{F} = (3i + 5j + 6k) + (i + 2j + k) + (3i + 8j)$

$$\bar{F} = 7i + 15j + 7k$$

displacement vector

$$= \bar{r} = \overline{PQ} = 2i + 6j - k$$

since point P is $(3, -4, 2)$.

Fig. 1.18

Work done = $\vec{F} \cdot \vec{r}$

$$= (7\vec{i} + 15\vec{j} + 7\vec{k}) \cdot (2\vec{i} + 6\vec{j} - \vec{k})$$

$$= 14 + 90 - 7 = 97$$

Vector moment of the resultant force $\vec{F} = 7\vec{i} + 15\vec{j} + 7\vec{k}$ acting at $P(3, -4, 2)$ about the point $Q(5, 2, 1)$ is $\vec{QP} \times \vec{F}$

$$= (-2\vec{i} - 6\vec{j} + \vec{k}) \times (7\vec{i} + 15\vec{j} + 7\vec{k})$$

$$= \begin{vmatrix} \vec{i} & \vec{j} & \vec{k} \\ -2 & -6 & 1 \\ 7 & 15 & 7 \end{vmatrix} = \vec{i}(-42 - 15) - \vec{j}(-14 - 7) + \vec{k}(-30 + 42)$$

$$= -57\vec{i} + 21\vec{j} + 12\vec{k}$$

Example 9: A rigid body is rotating at 5 radians per second about an axis OM where M is the point $3\vec{i} - 4\vec{j} + 2\vec{k}$ relative to O . Find the magnitude of the linear velocity of the particle of the body at the point $5\vec{i} + 2\vec{j} + 3\vec{k}$.

Solution:

Unit vector in the direction of the axis is $\frac{3\vec{i} - 4\vec{j} + 2\vec{k}}{\sqrt{9 + 16 + 4}} = \frac{3\vec{i} - 4\vec{j} + 2\vec{k}}{\sqrt{29}}$

$$\therefore \text{Angular velocity } \vec{\omega} = 5 \left(\frac{3\vec{i} - 4\vec{j} + 2\vec{k}}{\sqrt{29}} \right)$$

The point on the axis is M given by $3\vec{i} - 4\vec{j} + 2\vec{k}$. The point P on the right body is $5\vec{i} + 2\vec{j} + 3\vec{k}$. So $\vec{MP} = (5\vec{i} + 2\vec{j} + 3\vec{k}) - (3\vec{i} - 4\vec{j} + 2\vec{k})$

$$= 2\vec{i} + 6\vec{j} - \vec{k}$$

The linear velocity $\vec{v}$ at P is $\vec{\omega} \times \vec{MP}$

$$= \frac{5}{\sqrt{29}} (3\vec{i} - 4\vec{j} + 2\vec{k}) \times (2\vec{i} + 6\vec{j} - \vec{k})$$

$$= \frac{5}{\sqrt{29}} \begin{vmatrix} \vec{i} & \vec{j} & \vec{k} \\ 3 & -4 & 2 \\ 2 & 6 & -1 \end{vmatrix} = \frac{5}{\sqrt{29}} (-8\vec{i} + 7\vec{j} + 26\vec{k})$$

$$\text{Magnitude of velocity} = \sqrt{\frac{25}{29} (64 + 49 + 676)}$$

$$= \sqrt{\frac{25 \times 789}{29}} = \sqrt{\frac{19725}{29}} = 26.08$$

Example 10: Find the area of triangle with vertices at the points $A(3, -1, 2)$, $B(1, -1, -3)$ and $C(4, -3, 1)$.

Solution: We know that the area of a triangle is $\frac{1}{2}$ of the parallelogram. Thus area of triangle with $\vec{AB}$ and $\vec{AC}$ as the sides = $\frac{1}{2}$ area of the parallelogram with $\vec{AB}$ and $\vec{AC}$ as the adjacent sides = $\frac{1}{2} |\vec{AB} \times \vec{AC}|$.

Fig. 1.19

Now $\vec{AB} = -2\vec{i} + 0\vec{j} - 5\vec{k}$ and $\vec{AC} = \vec{i} - 2\vec{j} - \vec{k}$

$$\text{Area of } \Delta = \frac{1}{2} \left| \begin{vmatrix} \vec{i} & \vec{j} & \vec{k} \\ -2 & 0 & -5 \\ 1 & -2 & -1 \end{vmatrix} \right| = \frac{1}{2} |-10\vec{i} - 7\vec{j} + 4\vec{k}|$$

$$= \frac{1}{2} \sqrt{100 + 49 + 16} = \frac{1}{2} \sqrt{165}$$

Example 11: Find the area of a parallelogram with $\vec{A}$ and $\vec{B}$ as diagonals where $\vec{A} = 3\vec{i} + \vec{j} - 2\vec{k}$ and $\vec{B} = \vec{i} - 3\vec{j} + 4\vec{k}$.

Solution: Let $\vec{a}$ and $\vec{b}$ be the two adjacent sides of the parallelogram. Then

$$\vec{A} = \vec{a} + \vec{b} = 3\vec{i} + \vec{j} - 2\vec{k}$$

and

$$\vec{B} = \vec{a} - \vec{b} = \vec{i} - 3\vec{j} + 4\vec{k}$$

Solving $\vec{a} = 2\vec{i} - \vec{j} + \vec{k}$ and $\vec{b} = \vec{i} + 2\vec{j} - 3\vec{k}$

Fig. 1.20

1.10 — HIGHER ENGINEERING MATHEMATICS—I

Area of the required parallelogram

$$= |\vec{a} \times \vec{b}| = \begin{vmatrix} i & j & k \\ 2 & -1 & 1 \\ 1 & 2 & -3 \end{vmatrix} = |i + 7j + 5k| = \sqrt{75}$$

Example 12: Prove by vector methods that

- (i) $\cos(A - B) = \cos A \cos B + \sin A \sin B$ and
 (ii) $\sin(A - B) = \sin A \cdot \cos B - \sin B \cdot \cos A$

Solution: Let P and Q be any two points such that the position vector OP of length p makes an angle A with x -axis and position vector of length q makes an angle $B < A$. Then

$$\begin{aligned} \overrightarrow{OP} &= p \cos A \vec{i} + p \sin A \vec{j} \text{ and} \\ \overrightarrow{OQ} &= q \cos B \vec{i} + q \sin B \vec{j}. \text{ Now} \end{aligned}$$

Fig. 1.21

- a) $\overrightarrow{OP} \cdot \overrightarrow{OQ} = |\overrightarrow{OP}| |\overrightarrow{OQ}| \cos \theta = pq \cos(A - B)$
 $= (p \cos A \vec{i} + p \sin A \vec{j}) \cdot (q \cos B \vec{i} + q \sin B \vec{j})$
 $= pq(\cos A \cos B + \sin A \sin B)$
 $\therefore \cos(A - B) = \cos A \cos B + \sin A \sin B$
 b) Since $\overrightarrow{OQ}$, $\overrightarrow{OP}$ and $\overrightarrow{OQ} \times \overrightarrow{OP}$ form a right handed system, consider

$$\begin{aligned} \overrightarrow{OQ} \times \overrightarrow{OP} &= |\overrightarrow{OQ}| |\overrightarrow{OP}| \sin \theta \cdot \vec{k} = pq \sin(A - B) \vec{k} \\ &= (q \cos B \vec{i} + q \sin B \vec{j}) \times (p \cos A \vec{i} + p \sin A \vec{j}) \\ &= pq(\sin A \cos B - \sin B \cos A) \vec{k} \end{aligned}$$

since $\vec{i} \times \vec{j} = \vec{k}$ while $\vec{j} \times \vec{i} = -\vec{k}$. Hence the result.

Example 13: If $\vec{a} + \vec{b} + \vec{c} = 0$ show that $\vec{a} \times \vec{b} = \vec{b} \times \vec{c} = \vec{c} \times \vec{a}$.

Solution: $\vec{a} + \vec{b} + \vec{c} = 0$ or $\vec{c} = -(\vec{a} + \vec{b})$.

$$\begin{aligned} \text{Now } \vec{b} \times \vec{c} &= \vec{b} \times (-\vec{a} - \vec{b}) = -\vec{b} \times \vec{a} - \vec{b} \times \vec{b} \\ &= -\vec{b} \times \vec{a} = \vec{a} \times \vec{b} \end{aligned}$$

$$\begin{aligned} \text{Similarly } \vec{c} \times \vec{a} &= -(\vec{a} + \vec{b}) \times \vec{a} = -\vec{a} \times \vec{a} - \vec{b} \times \vec{a} \\ &= \vec{a} \times \vec{b} \end{aligned}$$

Example 14: Find the equation of a straight line L passing through the points A and B having position vectors $\vec{a}$ and $\vec{b}$ wrt an origin O .

Solution: Let $\vec{r}$ be the position vector of any point P on the straight line L , passing through A and B .

Fig. 1.22

$$\text{Then } \overrightarrow{OP} = \vec{r} = \overrightarrow{OA} + \overrightarrow{AP} \therefore \overrightarrow{AP} = \vec{r} - \vec{a}.$$

$$\text{Similarly } \overrightarrow{OB} = \vec{b} = \overrightarrow{OA} + \overrightarrow{AB} \therefore \overrightarrow{AB} = \vec{b} - \vec{a}$$

Since $\overrightarrow{AP}$ and $\overrightarrow{AB}$ are collinear vectors, there exists a scalar t such that $\overrightarrow{AP} = t \overrightarrow{AB}$ or

$$\vec{r} - \vec{a} = t(\vec{b} - \vec{a})$$

or

$$\boxed{\vec{r} = \vec{a} + t(\vec{b} - \vec{a})}$$

Example 15: (a) Find the volume of a parallelepiped whose edges are $\vec{a} = 2\vec{i} - 3\vec{j} + 4\vec{k}$, $\vec{b} = \vec{i} + 2\vec{j} - \vec{k}$, $\vec{c} = 3\vec{i} - \vec{j} + 2\vec{k}$

(b) Find the volume of the tetrahedron having the following vertices $(2, 1, 8)$, $(3, 2, 9)$, $(2, 1, 4)$, $(3, 3, 10)$.

Solution: (a) Volume of parallelepiped

$$= \vec{a} \cdot (\vec{b} \times \vec{c}) = \begin{vmatrix} 2 & -3 & 4 \\ 1 & 2 & -1 \\ 3 & -1 & 2 \end{vmatrix} = |-7| = 7$$

(b) Let the four points be $A(2, 1, 8)$, $B(3, 2, 9)$, $C(2, 1, 4)$, $D(3, 3, 10)$. Then the three edges of the parallelepiped are $\overrightarrow{AB} = \vec{i} + \vec{j} + \vec{k}$, $\overrightarrow{BC} = -\vec{i} - \vec{j} - 5\vec{k}$, $\overrightarrow{CD} = \vec{i} + 2\vec{j} + 6\vec{k}$. Then volume of tetrahedron = $\frac{1}{6}$ of volume of parallelepiped with $\overrightarrow{AB}$, $\overrightarrow{BC}$, $\overrightarrow{CD}$ as the edges

$$= \frac{1}{6} \begin{vmatrix} 1 & 1 & 1 \\ -1 & -1 & -5 \\ 1 & 2 & 6 \end{vmatrix} = \frac{4}{6} = \frac{2}{3}.$$

Example 16: Find the constant b such that the three vectors $\vec{a} = 2\vec{i} - \vec{j} + \vec{k}$, $\vec{b} = \vec{i} + 2\vec{j} - 3\vec{k}$ and $\vec{c} = 3\vec{i} + b\vec{j} + 5\vec{k}$ are coplanar.

Solution: If the three vectors are coplanar (i.e., lie in the same plane) then the volume of the parallelepiped

is zero i.e., $\vec{a} \cdot (\vec{b} \times \vec{c}) = 0$. So $\begin{vmatrix} 2 & -1 & 1 \\ 1 & 2 & -3 \\ 3 & b & 5 \end{vmatrix} = 0$ or

$$7b = -28 \quad \text{or} \quad b = -4$$

Example 17: (a) Show that $(\vec{a} \times \vec{c}) \times \vec{b} = 0$ if

$$\vec{a} \times (\vec{b} \times \vec{c}) = (\vec{a} \times \vec{b}) \times \vec{c}$$

(b) Show that $(\vec{b} \times \vec{c}) \times (\vec{a} \times \vec{d}) + (\vec{c} \times \vec{a}) \times (\vec{b} \times \vec{d}) + (\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d}) = -2[abc]\vec{d}$

Solution: (a) $\vec{a} \times (\vec{b} \times \vec{c}) = (\vec{a} \cdot \vec{c})\vec{b} - (\vec{a} \cdot \vec{b})\vec{c} = (\vec{a} \times \vec{b}) \times \vec{c}$

$$= (\vec{a} \cdot \vec{c})\vec{b} - (\vec{b} \cdot \vec{c})\vec{a}$$

$$\therefore (\vec{a} \cdot \vec{b})\vec{c} = (\vec{b} \cdot \vec{c})\vec{a}$$

Now $(\vec{a} \times \vec{c}) \times \vec{b} = (\vec{a} \cdot \vec{b}) \cdot \vec{c} - (\vec{c} \cdot \vec{b})\vec{a} = 0$ from the above result.

Note that $(\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d}) = \vec{b}[\vec{a}\vec{c}\vec{d}] - \vec{a}[\vec{b}\vec{c}\vec{d}]$ or $= c[abd] - d[\vec{a}\vec{b}\vec{c}]$.

Using the first formula for the first and third terms and using the second formula for the second term

$$(b) (\vec{b} \times \vec{c}) \times (\vec{a} \times \vec{d}) + (\vec{c} \times \vec{a}) \times (\vec{b} \times \vec{d}) +$$

$$(\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d})$$

$$= [\vec{b}\vec{c}\vec{d}]\vec{a} - [\vec{b}\vec{c}\vec{a}]\vec{d} + [\vec{c}\vec{b}\vec{d}]\vec{a} - [\vec{a}\vec{b}\vec{d}]\vec{c}$$

$$+ [\vec{a}\vec{b}\vec{d}]\vec{c} - [\vec{a}\vec{b}\vec{c}]\vec{d} = -2[\vec{a}\vec{b}\vec{c}]\vec{d}.$$

Example 18: If $\vec{a}, \vec{b}, \vec{c}$ are any vectors prove that

$$(a) \vec{a} \times (\vec{b} \times \vec{c}) + \vec{b} \times (\vec{c} \times \vec{a}) + \vec{c} \times (\vec{a} \times \vec{b}) = 0$$

$$(b) (\vec{a} \times \vec{b}) \cdot (\vec{c} \times \vec{d}) + (\vec{b} \times \vec{c}) \cdot (\vec{a} \times \vec{d}) + (\vec{c} \times \vec{a}) \cdot (\vec{b} \times \vec{d}) = 0$$

Solution: (a) LHS $= (\vec{a} \cdot \vec{c})\vec{b} - (\vec{a} \cdot \vec{b})\vec{c} + (\vec{b} \cdot \vec{a})\vec{c} - (\vec{b} \cdot \vec{c})\vec{a} + (\vec{c} \cdot \vec{b})\vec{a} - (\vec{c} \cdot \vec{a})\vec{b} = 0$ since dot product is commutative so $\vec{a} \cdot \vec{c} = \vec{c} \cdot \vec{a}$, $\vec{a} \cdot \vec{b} = \vec{b} \cdot \vec{a}$, $\vec{b} \cdot \vec{c} = \vec{c} \cdot \vec{b}$

$$(b) \text{ Since } (\vec{a} \times \vec{b}) \cdot (\vec{c} \times \vec{d}) = (\vec{a} \cdot \vec{c})(\vec{b} \cdot \vec{d}) - (\vec{a} \cdot \vec{d})(\vec{b} \cdot \vec{c})$$

$$\text{LHS} = (\vec{a} \cdot \vec{c})(\vec{b} \cdot \vec{d}) - (\vec{a} \cdot \vec{d})(\vec{b} \cdot \vec{c}) + (\vec{b} \cdot \vec{a})(\vec{c} \cdot \vec{d}) - (\vec{b} \cdot \vec{d})(\vec{c} \cdot \vec{a}) + (\vec{c} \cdot \vec{b})(\vec{a} \cdot \vec{d}) - (\vec{c} \cdot \vec{d})(\vec{a} \cdot \vec{b}) = 0, \text{ since dot product is commutative.}$$

Example 19: Compute $(\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d})$ (a) directly (b) by using formula when $\vec{a} = 2i - 2j + k$, $\vec{b} = i + 8j - 4k$, $\vec{c} = 12i - 4j - 3k$, $\vec{d} = i + 2j - k$

Solution: Direct $\vec{a} \times \vec{b} = \begin{vmatrix} i & j & k \\ 2 & -2 & 1 \\ 1 & 8 & -4 \end{vmatrix} = 9j + 18k$

$$\vec{c} \times \vec{d} = \begin{vmatrix} i & j & k \\ 12 & -4 & -3 \\ 1 & 2 & -1 \end{vmatrix} = 10i + 9j + 28k$$

$$(\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d}) = \begin{vmatrix} i & j & k \\ 0 & 9 & 18 \\ 10 & 9 & 28 \end{vmatrix} = 90(i + 2j - k)$$

(b) Using formula $(\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d}) = [\vec{a}\vec{b}\vec{d}]\vec{c} - [\vec{a}\vec{b}\vec{c}]\vec{d}$

$$\text{Now } [\vec{a}\vec{b}\vec{d}] = \begin{vmatrix} 2 & -2 & 1 \\ 1 & 8 & -4 \\ 1 & 2 & -1 \end{vmatrix} = 2(0) + 6 - 6 = 0$$

$$[\vec{a}\vec{b}\vec{c}] = \begin{vmatrix} 2 & -2 & 1 \\ 1 & 8 & -4 \\ 12 & -4 & -3 \end{vmatrix} = -80 + 90 - 100 = -90$$

$$(\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d}) = 0 \cdot \vec{c} - (-90)(i + 2j - k) = 90(i + 2j - k)$$

EXERCISE

1. Show that the diagonals of a parallelogram bisect each other.

Hint: P is point of intersection of diagonals of the parallelogram $ABCD$; with $\vec{AB} = \vec{a}$, $\vec{AD} = \vec{b}$. Then $\vec{AP} = \vec{BP}$, $\vec{a} = y(\vec{a} + \vec{b}) - x(\vec{b} - \vec{a})$, $\vec{a}, \vec{b}$, non collinear $x = y = \frac{1}{2}$.

2. If the mid-points of the consecutive sides of any quadrilateral are connected by straight lines show that the resulting quadrilateral is a parallelogram.

Hint: $ABCD$ is a quadrilateral with $\vec{AB} = \vec{a}$, $\vec{BC} = \vec{b}$, $\vec{CD} = \vec{c}$, $\vec{DA} = \vec{d}$; P, Q, R, S are mid-points of AB, BC, CD, DA ; $\vec{a} + \vec{b} + \vec{c} + \vec{d} = 0$,

$$\vec{PQ} = \frac{1}{2}(\vec{a} + \vec{b}) = -\frac{1}{2}(\vec{c} + \vec{d}) = \vec{SR},$$

$$\vec{QR} = \frac{1}{2}(\vec{b} + \vec{c}) = -\frac{1}{2}(\vec{d} + \vec{a}) = \vec{PS}$$

3. Find $|2\vec{a} - 3\vec{b} - 5\vec{c}|$ if $\vec{a} = 3i - 2j + k$, $\vec{b} = 2i - 4j - 3k$, $\vec{c} = -i + 2j + 2k$

$$\text{Ans. } 2\vec{a} - 3\vec{b} - 5\vec{c} = 5i - 2j + k; \quad |2\vec{a} - 3\vec{b} - 5\vec{c}| = \sqrt{30}$$

1.12 — HIGHER ENGINEERING MATHEMATICS—I

4. Determine a unit vector parallel to the resultant of the vectors $\vec{a} = 3\vec{i} + 4\vec{j} + 5\vec{k}$, $\vec{b} = 2\vec{i} + 3\vec{j} + 3\vec{k}$.

Ans. $(5\vec{i} + 7\vec{j} + 8\vec{k})/\sqrt{138}$

5. If $ABCDEF$ is a regular hexagon, determine, $\vec{CD}$, $\vec{DE}$, $\vec{EF}$, $\vec{FA}$ given that $\vec{AB} = \vec{a}$, $\vec{BC} = \vec{b}$.

Ans. $\vec{CD} = \vec{b} - \vec{a}$, $\vec{DE} = -\vec{a}$, $\vec{EF} = -\vec{b}$, $\vec{FA} = \vec{a} - \vec{b}$

Hint: $\vec{AC} = \vec{a} + \vec{b}$, $\vec{AD} = \vec{b} - \vec{a}$, $\vec{DE} = -\vec{a}$, $\vec{EF} = -\vec{b}$

6. Prove that the points $A(0, 4, 1)$, $B(2, 3, -1)$, $C(4, 5, 0)$, $D(2, 6, 2)$ form a square.

Hint: $\vec{AB} = \vec{DC} = 2\vec{i} - \vec{j} - 2\vec{k}$, $\vec{BC} = \vec{AD} = 2\vec{i} + 2\vec{j} + \vec{k}$

7. Let E be the mid point of the side $\vec{CD}$ of a parallelogram $ABCD$. Prove that the diagonal $\vec{BD}$ and $\vec{AE}$ trisect each other.

Hint: $\vec{AB} = \vec{a}$, $\vec{AD} = \vec{b}$, $\vec{AE} = \vec{b} + \frac{\vec{a}}{2}$, $\vec{AF} = \alpha \vec{AE} = \alpha \left(\vec{b} + \frac{\vec{a}}{2} \right)$.

Also $\vec{AF} = \vec{AB} + \vec{BF} = \vec{a} + \beta(\vec{b} - \vec{a}) - \alpha \left(\vec{b} + \frac{\vec{a}}{2} \right)$. Since $\vec{a}$, $\vec{b}$ are non collinear, $\alpha - \beta = 0$, $\frac{\alpha}{2} - 1 + \beta = 0 \therefore \beta = \frac{2}{3}$.

8. Show that $\vec{a} = \frac{2\vec{i}-2\vec{j}+\vec{k}}{3}$, $\vec{b} = \frac{\vec{i}+2\vec{j}+2\vec{k}}{3}$, $\vec{c} = \frac{2\vec{i}+\vec{j}-2\vec{k}}{3}$ are mutually orthogonal unit vectors.

Hint: $\vec{a} \cdot \vec{b} = \vec{b} \cdot \vec{c} = \vec{c} \cdot \vec{a} = 0$

9. Determine the projection of $\vec{a} = 2\vec{i} - 3\vec{j} + 6\vec{k}$ on $\vec{b} = \vec{i} + 2\vec{j} + 2\vec{k}$. Also find the projection of $\vec{b}$ on $\vec{a}$.

Ans. $\frac{8}{3}, \frac{8}{7}$

Hint: $\vec{a} \cdot \frac{\vec{b}}{|\vec{b}|}$, $\vec{b} \cdot \frac{\vec{a}}{|\vec{a}|}$

10. Find the angle between $\vec{a} = 3\vec{i} + 4\vec{j} + 2\vec{k}$ and $\vec{b} = 2\vec{i} - 2\vec{j} + 3\vec{k}$

Ans. $\cos \theta = \frac{4}{\sqrt{29}\sqrt{17}}$

11. Determine the unit vector perpendicular to both $\vec{a} = \vec{i} - \vec{j} + \vec{k}$ and $\vec{b} = \vec{i} + 2\vec{j} - \vec{k}$

Ans. $\pm \frac{1}{\sqrt{14}}[\vec{i} - 2\vec{j} - 3\vec{k}]$

12. Determine unit vectors which make an angle 60° with $\vec{a} = \vec{i} - \vec{j}$ and angle 60° with $\vec{b} = \vec{i} + \vec{k}$

Ans. $\frac{-\vec{j} + \vec{k}}{\sqrt{2}}$, $\frac{\sqrt{2}}{6}(4\vec{i} - \vec{j} + \vec{k})$.

Hint: $a_1\vec{i} + a_2\vec{j} + a_3\vec{k}$ be the unit vector, $a_1^2 + a_2^2 + a_3^2 = 1$, $\cos 60 = \frac{1}{2} = \frac{a_1 - a_2}{\sqrt{2}}$,

$\cos 60 = \frac{1}{2} = \frac{a_1 + a_3}{\sqrt{2}}$.

13. Prove that the points $A(5, -1, 1)$, $B(7, -4, 7)$, $C(1, -6, 10)$, $D(-1, -3, 4)$ form the vertices of a rhombus.

Hint: $\vec{AD} = \vec{BC}$, $\vec{AB} = \vec{DC}$, $|\vec{AD}| = |\vec{AB}| = 7$, $|\vec{AC}| \cdot \vec{BD} = 0$ i.e., diagonals at right angles. Also $\vec{AB} \cdot \vec{AD} \neq 0$, $\vec{AB} \cdot \vec{BC} \neq 0$ corner angles not right angles.

14. Determine the sides and angles of triangle with vertices $\vec{i} - 2\vec{j} + 2\vec{k}$, $2\vec{i} - \vec{j} - \vec{k}$, $3\vec{i} - \vec{j} + 2\vec{k}$

Ans. Sides are $\vec{i} - 2\vec{j} + 3\vec{k}$, $-2\vec{i} - \vec{j}$, $\vec{i} + 3\vec{j} - 3\vec{k}$.
Angles are $\cos^{-1} \sqrt{\frac{5}{19}}$, $\cos^{-1} \sqrt{\frac{14}{19}}$, 90°

15. Show that $\vec{a} = 2\vec{i} + \vec{j} - 3\vec{k}$, $\vec{b} = \vec{i} - 4\vec{k}$, $\vec{c} = 4\vec{i} + 3\vec{j} - \vec{k}$ are linearly dependent.

16. Show that $\vec{a} = (\vec{a} \cdot \vec{i})\vec{i} + (\vec{a} \cdot \vec{j})\vec{j} + (\vec{a} \cdot \vec{k})\vec{k}$ for any vector $\vec{a} = a_1\vec{i} + a_2\vec{j} + a_3\vec{k}$

17. Find the work done in moving an object along a vector $2\vec{i} - 5\vec{j} + 6\vec{k}$ when the applied force $\vec{F}$ is $3\vec{i} - \vec{j} + \vec{k}$

Ans. 17

18. Find the direction cosines of $\vec{a} = 2\vec{i} - 3\vec{j} + 4\vec{k}$ or find the angles which $\vec{a}$ makes with the coordinate axes.

Ans. $\cos \alpha = \frac{2}{\sqrt{29}}$, $\cos \beta = -\frac{3}{\sqrt{29}}$, $\cos \gamma = \frac{4}{\sqrt{29}}$

19. If $\vec{a} = 4\vec{i} + 3\vec{j} + \vec{k}$, $\vec{b} = 2\vec{i} - \vec{j} + 2\vec{k}$, find a unit vector in the direction of $\vec{a} \times \vec{b}$. Determine the angle between $\vec{a}$ and $\vec{b}$.

Ans. $\frac{7\vec{i}-6\vec{j}-10\vec{k}}{\sqrt{185}}$, $\theta = \sin^{-1} \frac{\sqrt{185}}{3\sqrt{26}} = 62^\circ \cdot 40'$

20. Find the work done in displacing a particle

from P to Q having position vectors $4i - 3j - 2k$, and $6i + j - 3k$ when constant forces $\vec{F}_1 = 2i - 5j + 6k$, $\vec{F}_2 = -i + 2j - k$, $\vec{F}_3 = i + j + k$ act on the particle.

Ans. -10

Hint: resultant force $\vec{F} = 2i - 2j + 6k$, displacement vector $\vec{d} = 2i + 4j - k$, $\vec{F} \cdot \vec{d} =$ work done.

21. Determine the torque about the point P , $2i + j - k$ of a force $\vec{F} = 4i + k$ acting through the point A with position vector $i - j + 2k$.

Ans. 15.4

Hint: $|\vec{PA} \times \vec{F}| = |(-i - 2j + 3k) \times (4i + k)| = |-2i + 13j + 8k|$ where $\vec{PA} = (i - j + 2k) - (2i + j - k)$

22. Find the moment about a line L through the origin having direction of $2i + 2j + k$ due to a 30 kg force acting at a point $A(-4, 2, 5)$ in the direction of $12i - 4j - 3k$.

Ans. 89.23

Hint: $\vec{F} = 30(12i - 4j - 3k)/13$, moment of $\vec{F}$ about $O = \vec{OA} \times \vec{F} = (-4i + 2j + 5k) \times \vec{F} = \frac{60}{13}(7i + 24j - 4k)$.

Moment of $\vec{F}$ about the line $L = \frac{60}{13}(7i + 24j - 4k) \cdot \frac{2i+2j+k}{3}$

23. A rigid body is spinning with angular velocity 27 radians/second about an axis parallel to $2i + j - 2k$ passing through the point $A, i + 3j - k$. Find the (linear) velocity of the point P on the body with position vector $4i + 8j + k$.

Ans. $9\sqrt{293}$

Hint: $\vec{v} = \vec{\omega} \times \vec{AP} = 27 \left(\frac{2i+j-2k}{3} \right) \times (3i + 5j + 2k) = 9(12i - 10j + 7k)$

where $\vec{AP} = (4i + 8j + k) - (i + 3j - k)$

24. Find the volume of a parallelepiped whose coterminus edges are $\vec{a} = 3i - 2j + 5k$, $\vec{b} = i + j + k$, $\vec{c} = 2i + 4j - k$

Ans. $|-11| = 11$

25. Determine the volume of the tetrahedron having vertices at $(0, 1, 1)$, $(1, 0, 0)$, $(2, 2, 3)$, $(-1, 0, 4)$

Ans. $\frac{1}{6}(14) = \frac{7}{3}$

26. Determine the constant b such that the vectors $4i + 2j - k$, $bi + j + k$, $3i - j - 5k$ are coplanar

Ans. $b = -1$

27. If $\vec{a} = 3i - j + 2k$, $\vec{b} = 2i + j - k$, $\vec{c} = i - 2j + 2k$ find $\vec{a} \times (\vec{b} \times \vec{c})$ (a) directly (b) using dot formula

Ans. $15i + 15j - 15k$

Hint: (a) $\vec{b} \times \vec{c} = -5j - 5k$ (b) $\vec{a} \cdot \vec{c} = 9$, $\vec{a} \cdot \vec{b} = 3$ so $\vec{a} \times (\vec{b} \times \vec{c}) = (\vec{a} \cdot \vec{c})\vec{b} - (\vec{a} \cdot \vec{b})\vec{c} = 9(2i + j - k) - 3(i - 2j + 2k)$

28. Compute $(\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d})$ (a) directly (b) using the formula when $\vec{a} = 10i + 10j + 5k$, $\vec{b} = 5i - 2j - 14k$, $\vec{c} = 4i + 7j - 4k$, $\vec{d} = 2i - j + k$

Ans. $-3810i - 2250j + 1065k$

29. If $\vec{a} \cdot (\vec{b} \times \vec{c}) = 0$ prove that either (a) $\vec{a}$, $\vec{b}$, $\vec{c}$ are coplanar but no two of them are collinear or (b) two of vectors $\vec{a}$, $\vec{b}$, $\vec{c}$ are collinear or (c) all of the vectors $\vec{a}$, $\vec{b}$, $\vec{c}$ are collinear.

30. Show that if four vectors $\vec{a}$, $\vec{b}$, $\vec{c}$, $\vec{d}$ are coplanar then $(\vec{a} \times \vec{b}) \times (\vec{c} \times \vec{d}) = 0$

1.2 THEORY OF EQUATIONS

Theory of equations includes solution of equations which are needed in the study of characteristic equations, zeros of Bessel functions, integration etc.

A polynomial or a rational integral algebraic function is a function

$$y = a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_n$$

where $a_0, a_1, a_2, \dots, a_n$ are constants called *coefficients* and n is a non negative integer called the *degree* of the polynomial.

For $n = 1, 2, 3, 4$, the functions are known as linear, quadratic, cubic and quartic functions. A constant may be regarded as a polynomial of degree zero.

1.14 — HIGHER ENGINEERING MATHEMATICS—I

An *algebraic function* is any function $y = f(x)$ which satisfies an equation of the form

$$P_0(x)y^n + P_1(x)y^{n-1} + \dots + P_n(x) = 0$$

where $P_0(x), P_1(x), \dots, P_n(x)$ are polynomials in x . A *transcendental function* is one which is not an algebraic equation.

Trigonometric functions $\cos, \sin, \tan$, logarithmic, exponential, hyperbolic functions are examples of transcendental functions.

An equation

$$f(x) = 0$$

is said to be an algebraic equation or transcendent equation depending on whether $f(x)$ is an algebraic or transcendental function.

Any value of x^* , for which the equation (1) is satisfied, is known as the *solution* of the equation i.e., $f(x^*) = 0$. In case of algebraic equations, solutions are also known as *roots* (or *zeros*) of the equation. Geometrically the curve (graph of) $y = f(x)$ crosses (meets) the x -axis at the point x^* . Theory of equations consists of methods of obtaining solutions of equations. For the linear equation $ax + b = 0$, the solution is $x = -\frac{b}{a}$, $a \neq 0$. For the quadratic equation $ax^2 + bx + c = 0$, the solutions (or roots) are given by $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$, $a \neq 0$. The roots of the cubic equation can be obtained by Cardano's method, while the roots of quartic are obtained by Ferrari's method. However no literal equations (formulae) exist for algebraic equations of degree $n \geq 5$ or for any transcendental equations. In these cases, one has to resort to numerical methods to find an approximate solution (or root).

For an algebraic equation

$$f(x) = a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_n = 0$$

- There are exactly n real or complex roots (where n is degree of the equation). Roots need not be distinct.
- has at least one real root whose sign is opposite to that of the last term a_n , if n is odd
- $f(a)$ is the remainder when $f(x)$ is divided by $(x - a)$
- Complex roots occur in conjugate pairs, when the coefficients $a_0, a_1, \dots, a_n$ are real.

(e) The following relations hold good between the roots and coefficients of equation

- $\frac{-a_1}{a_0}$ = sum of the roots
 - $\frac{-a_2}{a_0}$ = sum of the product of the roots taken two at a time
 - $\frac{-a_3}{a_0}$ = sum of the product of the roots taken three at a time.
 - $(-1)^n \frac{a_n}{a_0}$ = product of the roots.
- (f) At least one root lies between a and b if $f(a)$ and $f(b)$ are of different (opposite) signs.

1.3 CARDANO'S* METHOD

Cardano's method obtains algebraic solution of a cubic equation. Cardano published this result in 1545 in *Ars Magna* (also credited to Tartaglia and Ferraro and Vieta (1591)).

Consider the general type of cubic equation

$$a^*x^3 + b^*x^2 + c^*x + d^* = 0 \quad (1)$$

Dividing by a^* , we get the equation

$$x^3 + bx^2 + cx + d = 0 \quad (2)$$

This equation can be reduced to a simpler form by removing the x^2 term by the substitution

$$x = u - \frac{b}{3} \quad (3)$$

so

$$\begin{aligned} \left(u - \frac{b}{3}\right)^3 + b\left(u - \frac{b}{3}\right)^2 + c\left(u - \frac{b}{3}\right) + d &= 0 \\ \left(u^3 - \frac{3b}{3}u^2 + 3u\frac{b^2}{9} - \frac{b^3}{27}\right) + b\left(u^2 - \frac{2b}{3}u + \frac{b^2}{9}\right) \\ &+ cu - \frac{cb}{3} + d = 0 \end{aligned}$$

$$\text{or} \quad u^3 + pu + q = 0 \quad (4)$$

$$\text{where } p = c - \frac{b^2}{3}, q = d - \frac{bc}{3} + \frac{2b^3}{27} \quad (5)$$

To solve the standard cubic equation put

$$u = y + z \quad (6)$$

* Girolamo Cardano (1501-1576), Italian mathematician.

$$\begin{aligned} \text{so } u^3 &= (y+z)^3 = y^3 + z^3 + 3yz(y+z) \\ &= y^3 + z^3 + 3yzu \end{aligned}$$

$$\text{or } u^3 - 3yzu - (y^3 + z^3) = 0 \quad (7)$$

comparing (4) and (7), we get $p = -3yz$ and $q = -(y^3 + z^3)$

$$\text{or } yz = -\frac{p}{3} \text{ i.e., } y^3 z^3 = -\frac{p^3}{27}$$

$$\text{or } yz = \frac{-p}{3} \text{ i.e., } y^3 z^3 = \frac{-p^3}{27}$$

$$\text{and } y^3 + z^3 = -q$$

Then y^3 and z^3 are the solutions (roots) of the quadratic equation

$$t^2 + qt - \frac{p^3}{27} = 0 \quad (8)$$

Since sum of the roots of (8) is $y^3 + z^3 = -q$ and product of the roots of (8) is $y^3 z^3 = -\frac{p^3}{27}$. Solving the quadratic equation (8), we get

$$y^3 = \frac{-q + \sqrt{q^2 + 4\frac{p^3}{27}}}{2} = \frac{-q}{2} + \sqrt{\frac{q^2}{4} + \frac{p^3}{27}} \quad (9)$$

and

$$z^3 = \frac{-q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}} \quad (10)$$

Let the discriminant of (8) be

$$R = \frac{q^2}{4} + \frac{p^3}{27} \quad (11)$$

Case (i) Suppose $R > 0$, then y^3 and z^3 are both real and the roots cubic equation (4) are $y + z$, $\omega y + \omega^2 z$, $\omega^2 y + \omega z$. (12)

Here $\omega = \frac{-1+\sqrt{3}i}{2}$, $\omega^2 = \frac{-1-\sqrt{3}i}{2}$ and $\omega \cdot \omega^2 = \omega^3 = 1$. ($1, \omega, \omega^2$ are cube roots of unity such that $1 + \omega + \omega^2 = 0$).

Hence the required roots of the given cubic equation (2) are

$$\left. \begin{aligned} x_1 &= u_1 - \frac{b}{3} = y + z - \frac{b}{3}, \\ x_2 &= u_2 - \frac{b}{3} = \omega y + \omega^2 z - \frac{b}{3}, \\ x_3 &= u_3 - \frac{b}{3} = \omega^2 y + \omega z - \frac{b}{3} \end{aligned} \right\} \quad (13)$$

Case (ii) If $R = 0$, then equal roots $y = z$. Then the roots of (4) are $y + z$, $y(\omega + \omega^2)$, $y(\omega + \omega^2)$

$$\text{or } 2y, -y, -y \quad (14)$$

(since $\omega + \omega^2 = -1$ and $y = z$)

Hence roots of (2) are

$$2y - \frac{b}{3}, -y - \frac{b}{3}, -y - \frac{b}{3} \quad (15)$$

Case (iii) If $R < 0$ then y^3 and z^3 are complex. Suppose $y^3 = a + ib$ and $z^3 = a - ib$.

If the cube roots of these quantities are $m + in$ and $m - in$, then the roots of the cubic equation (4) are

$$\left. \begin{aligned} y + z &= (m + in) + (m - in) = 2m \\ \omega y + \omega^2 z &= \omega(m + in) + \omega^2(m - in) = -m - n\sqrt{3} \\ \omega^2 y + \omega z &= \omega^2(m + in) + \omega(m - in) = -m + n\sqrt{3} \end{aligned} \right\} \quad (16)$$

Using De Moivre's result, this irreducible case Cardano's solution can be expressed in terms of trigonometric functions as follows:

Let the solution of (4) be

$$u = y + z = (a + ib)^{1/3} + (a - ib)^{1/3} \quad (17)$$

Put $a = r \cos \theta$, $b = r \sin \theta$, so $r^2 = a^2 + b^2$, $\tan \theta = \frac{b}{a}$. Then

$$(a + ib)^{1/3} = \{r(\cos \theta + i \sin \theta)\}^{1/3}$$

$$= r^{1/3} \left(\cos \frac{\theta + 2k\pi}{3} + i \sin \frac{\theta + 2k\pi}{3} \right), \quad k = 0, 1, 2 \text{ (using De Moivre's Theorem)} \quad (18)$$

$$\text{In a similar way } (a - ib)^{1/3} = r^{1/3} \left(\cos \frac{\theta + 2k\pi}{3} - i \sin \frac{\theta + 2k\pi}{3} \right), \quad k = 0, 1, 2 \quad (19)$$

Here $r^{1/3}$ is the arithmetical cube root of r . Thus substituting (18), (19) in (17) we get $u = 2r^{1/3} \cos \frac{\theta}{3}$, $2r^{1/3} \cos \frac{\theta + 2\pi}{3}$, $2r^{1/3} \cos \frac{\theta + 4\pi}{3}$. Hence the required roots of the given cubic equation (2) are

$$\left\{ 2r^{1/3} \cos \left(\frac{\theta}{3} \right) - \frac{b}{3}, 2r^{1/3} \cos \left(\frac{\theta + 2\pi}{3} \right) - \frac{b}{3}, 2r^{1/3} \cos \left(\frac{\theta + 4\pi}{3} \right) - \frac{b}{3} \right\} \quad (20)$$

The numbers (13) (in case (i)), (15) (in case (ii)) and (20) (in case (iii)) are known as *Cardano's formulas* for the roots of a reduced cubic equation (4).

WORKED OUT EXAMPLES

Example 1: Solve $28x^3 - 9x^2 + 1 = 0$.

Solution: Rewriting $x^3 - \frac{9}{28}x^2 + \frac{1}{28} = 0$. To remove the x^2 term, put

$$x = u - \frac{b}{3} = u - \frac{1}{3} \left(-\frac{9}{28} \right) = u + \frac{3}{28}$$

1.16 — HIGHER ENGINEERING MATHEMATICS—I

Substituting

$$\left(u + \frac{3}{28}\right)^3 - \frac{9}{28}\left(u + \frac{3}{28}\right)^2 + \frac{1}{28} = 0$$

or

$$u^3 - \frac{27}{(28)^2}u + \frac{730}{(28)^3} = 0$$

so $p = -27/(28)^2$ and $q = 730/(28)^3$.

Let $u = y + z$. Then $y^3 + z^3 = -q = -730/(28)^3$ and $y^3 z^3 = \frac{-p^3}{27} = \frac{-(27)^3}{(28)^6} \cdot \frac{1}{27}$. Now y^3 and z^3 are the roots of the quadratic equation in t

$$t^2 + \frac{730}{(28)^3}t - \frac{(27)^2}{(28)^6} = 0$$

Here the discriminant

$$R = \left[\frac{730}{(28)^3}\right]^2 + 4\frac{(27)^2}{(28)^6} > 0$$

so the values of both y and z are real. Solving for t ,

$$\begin{aligned} & \left(\frac{-730}{(28)^3} \pm \sqrt{\left(\frac{730}{(28)^3}\right)^2 - 4\frac{(27)^2}{(28)^6}}\right) / 2 \\ &= \frac{-730 \pm 728}{2(28)^3} \end{aligned}$$

so $y^3 = -\frac{2}{2(28)^3}$ or $y = -\frac{1}{28}$

and $z^3 = \frac{-728}{(28)^3} = -\left(\frac{9}{28}\right)^3$ or $z = -\frac{9}{28}$

Thus $u = y + z = -\frac{1}{28} - \frac{9}{28} = \frac{-10}{28}$

Hence $x = u + \frac{3}{28} = \frac{-10}{28} + \frac{3}{28} = \frac{-7}{28} = \frac{-1}{4}$ is a root of the given cubic equation. Similarly the other two roots are:

$$\begin{aligned} \omega y + \omega^2 z &= \left(\frac{-1 + \sqrt{3}i}{2}\right)\left(-\frac{1}{28}\right) \\ &+ \left(\frac{-1 - \sqrt{3}i}{2}\right)\left(\frac{-9}{28}\right) \\ &= -\frac{1}{2.28}[-10 - 8\sqrt{3}i] = \frac{5 + 4\sqrt{3}i}{28} \end{aligned}$$

so $x = u + \frac{3}{28} = \frac{5 + 4\sqrt{3}i}{28} + \frac{3}{28} = \frac{8 + 4\sqrt{3}i}{28} = \frac{2 + \sqrt{3}i}{7}$

Also

$$\begin{aligned} \omega^2 y + \omega z &= \left(\frac{-1 - \sqrt{3}i}{2}\right)\left(-\frac{1}{28}\right) + \left(\frac{-1 + \sqrt{3}i}{2}\right)\left(\frac{-9}{28}\right) \\ &= \frac{5 - 4\sqrt{3}i}{28} \end{aligned}$$

so

$$\begin{aligned} x &= u + \frac{3}{28} = \frac{5 - 4\sqrt{3}i}{28} + \frac{3}{28} \\ &= \frac{8 - 4\sqrt{3}i}{28} = \frac{2 - \sqrt{3}i}{7} \end{aligned}$$

Thus the three roots of the given cubic equation are $-\frac{1}{4}, \frac{2 + \sqrt{3}i}{7}, \frac{2 - \sqrt{3}i}{7}$

Example 2: Solve $x^3 - 27x + 54 = 0$.

Solution: Here $p = -27$, $q = 54$. Since x^2 term is absent, no translation is needed.

So put $x = y + z$. Then $y^3 + z^3 = -q = -54$ and $y^3 z^3 = -\frac{p^3}{27} = -\frac{(-27)^3}{27} = (27)^2$. Thus y^3, z^3 are the roots of the quadratic in t :

$$t^2 + 54t + (27)^2 = 0$$

Its discriminant $R = (54)^2 - 4(27)^2 = 2916 - 2916 = 0$. Therefore t has equal roots i.e., $y^3 = z^3$ or $y = z$.

So $y^3 = \frac{-54}{2} \pm 0 = -27$ or $y = -3 = z$.

The required three roots of the given cubic equation are: $2y, -y, -y$ i.e., $-6, 3, 3$.

Example 3: Solve $x^3 - 3x^2 - 12x + 16 = 0$

Solution: To get rid of the x^2 term, put $x = u - \frac{b}{3} = u - \frac{(-3)}{3} = u + 1$. Then $(u + 1)^3 - 3(u + 1)^2 - 12(u + 1) + 16 = 0$.

$$\begin{aligned} u^3 + 3u^2 + 3u + 1 - 3(u^2 + 2u + 1) - 12u - 12 + 16 &= 0 \text{ or} \\ u^3 - 15u + 2 &= 0 \end{aligned}$$

or

Here $p = -15$, $q = 2$. Now put $u = y + z$. Then $y^3 + z^3 = -q = -2$ and

$$y^3 z^3 = \frac{-p^3}{27} = -\frac{(-15)^3}{27} = \frac{(15)^3}{27} = 5^3$$

Thus y^3 and z^3 are the roots of the quadratic in t given by

$$t^2 + 2t + 5^3 = 0$$

It discriminant is

$$R = 4 - 4(125) = -496 < 0$$

So the roots y^3 and z^3 are complex conjugate.

$$y^3 = \frac{-2 \pm \sqrt{4 - 4(125)}}{2} = -1 + \sqrt{124}i$$

put $x = -1$, $y = \sqrt{124}$, $r = \sqrt{x^2 + y^2} = \sqrt{1 + 124} = \sqrt{125}$, $\tan \theta = \frac{y}{x} = \frac{\sqrt{124}}{-1} = -\sqrt{124}$

and $r^{1/3} = (125)^{1/6} = \sqrt{5}$

So $y = (-1 + \sqrt{124}i)^{1/3} = r^{1/3} \text{cis} \left(\frac{\theta + 2k\pi}{2} \right)$, $k = 0, 1, 2$

$y = \sqrt{5} \text{cis} \left(\frac{\theta + 2k\pi}{2} \right)$, $k = 0, 1, 2$

Here $\text{cis} = \cos + i \sin$

In a similar way

$z^3 = -1 - \sqrt{124}i$ or $z = (-1 - \sqrt{124} \cdot i)^{1/3}$

$z = \sqrt{5} \left(\cos \frac{\theta + 2k\pi}{2} - i \sin \frac{\theta + 2k\pi}{2} \right)$, $k = 0, 1, 2$

Since $u = y + z$, and $x = u + 1$, the required three roots of the given cubic equation are

$1 + 2\sqrt{5} \cos \frac{\theta}{3}$, $1 + 2\sqrt{5} \cos \frac{\theta + 2\pi}{3}$,

$1 + 2\sqrt{5} \cos \frac{\theta + 4\pi}{3}$ where $\theta = \tan^{-1}(-\sqrt{124})$

EXERCISE

Solve the following cubic equations by Cardano's method.

1. $x^3 - 15x + 126 = 0$

Hint: $t^2 - 126t + 125 = 0$, $y^3 = 125$, $y = 5$, $z^3 = 1$, $z = 1$

Ans. $y + z = 5 + 1 = 6$, $\omega y + \omega^2 z = -3 + 2\sqrt{3}i$, $\omega^2 y + \omega z = -3 - 2\sqrt{3}i$

2. $x^3 - 15x^2 - 33x + 847 = 0$

Hint: Put $x = u + 5$, $u = y + z$, $u^3 - 108y + 432 = 0$, $t^2 + 432t + 46656 = 0$. $R = \text{discriminant} = 0$, Equal roots $y^3 = z^3 = -216$, or $y = z = -6$

Ans. 11, 11, -7

3. $x^3 + 72x - 1720 = 0$

Hint: $y^3 = 1728$, $y = 12$, $z^3 = -8$, $z = -2$

Ans. $y + z = 12 - 2 = 10$, $-5 \pm 7\sqrt{3}i$

4. $x^3 + 3x^2 - 144x + 540 = 0$

Hint: Put $x = u - 1$, $u^3 - 147y + 686 = 0$, $t^2 + 686t + (343)^2 = 0$. Equal roots, $y^3 = z^3 = -343$ or $y = z = -7$

Ans. -15, 6, 6

5. $2x^3 + 3x^2 + 3x + 1 = 0$

Ans. $-\frac{1}{2}$, $\frac{-1 \pm \sqrt{3}i}{2}$

6. $x^3 - 18x - 35 = 0$

Ans. 5, $\frac{-5 \pm \sqrt{3}i}{2}$

Hint: $x = y + z$, $t^2 - 35t + 216 = 0$, $y^3 = 27$, $y = 3$, $v^3 = 8$, $v = 2$, $x = 3 + 2 = 5$, $3\omega + 2\omega^2 = \frac{-5 + \sqrt{3}i}{2}$ and $3\omega^2 + 2\omega = \frac{-5 - \sqrt{3}i}{2}$

7. $x^3 - 3x^2 + 3 = 0$

Hint: Put $x = u + 1$, $u^3 - 3u + 1 = 0$, put $u = y + z$, $t^2 + t + 1 = 0$, $u^3 = \frac{-1 + \sqrt{3}i}{2}$, $v^3 = \frac{-1 - \sqrt{3}i}{2}$, $u = y + z = 2 \cos \frac{2\pi}{9}$, $2 \cos \frac{8\pi}{9}$, $2 \cos \frac{14\pi}{9}$

Ans. $1 + 2 \cos \frac{2\pi}{9}$, $1 + 2 \cos \frac{8\pi}{9}$, $1 + 2 \cos \frac{14\pi}{9}$.

8. $x^3 + 6x + 2 = 0$

Ans. $A - B$, $\omega A - \omega^2 B$, $\omega^2 A - \omega B$ where $A = 2^{1/3}$, $B = 4^{1/3}$.

9. $x^3 - 9x^2 - 9x - 15 = 0$

Hint: Put $x = u + 3$

Ans. $3 + A + B$, $3 + \omega A + \omega^2 B$, $3 + \omega^2 A + \omega B$ where $A = (24)^{1/3}$, $B = (72)^{1/3}$

10. $x^3 + 21x + 342 = 0$

Ans. -6 , $3 \pm 4\sqrt{3}i$

11. $x^3 - 6x^2 + 6x - 5 = 0$

Hint: Put $x = u + 2$, $u^3 - 6u - 9 = 0$, $u = y + z$, $t^2 - 9t + 8 = 0$, $y^3 = 8$, $y = 2$, $z^3 = 1$, $z = 1$

Ans. $x = (y + z) + 2 = (2 + 1) + 2 = 5$; $\frac{-3 \pm \sqrt{3}i}{2}$

1.4 FERRARI'S* METHOD

Ferrari's method obtains the general solution of a bi-quadratic (or quartic) equation (Fourth degree polynomial).

* Scipio Ferrari, Italian mathematician, pupil of Cardano.

1.18 — HIGHER ENGINEERING MATHEMATICS—I

Consider

$$x^4 + 2px^3 + qx^2 + 2rx + s = 0 \quad (1)$$

Add $(ax + b)^2$ on both sides of (1). Then

$$\begin{aligned} x^4 + 2px^3 + (q + a^2)x^2 + 2(r + ab)x \\ + (s + b^2) = (ax + b)^2 \end{aligned} \quad (2)$$

Here the two unknowns a and b are determined such that the LHS of (2) is a perfect square say $(x^2 + px + k)^2$.

Comparing the coefficients on both sides

$$p^2 + 2k = q + a^2, \quad pk = r + ab, \quad k^2 = s + b^2 \quad (3)$$

Eliminating a and b from these equations we get

$$(pk - r)^2 = a^2b^2 = (p^2 + 2k - q)(k^2 - s)$$

or

$$2k^3 - qk^2 + 2k(pr - s) + (qs - p^2s - r^2) = 0 \quad (4)$$

Choose any root k of this resolvent cubic equation (4) which has always a real root (since odd degree, sign is that of its last term). Substituting k in (3), we obtain values of a and b . Now

$$(x^2 + px + k)^2 = (ax + b)^2$$

$$\text{or } (x^2 + px + k) \pm (ax + b) = 0$$

Thus the four roots of the biquadratic equation (1) are obtained from the two quadratic equations

$$x^2 + (p - a)x + (k - b) = 0 \quad (5)$$

$$\text{and } x^2 + (p + a)x + (k + b) = 0 \quad (6)$$

Note: Abel has demonstrated the impossibility of obtaining algebraical solution of equations of degree higher than four. In such cases Horner's method of approximation is used to find numerical solution to any required degree of accuracy.

WORKED OUT EXAMPLES

Example 1: Solve $x^4 + 2x^3 - 7x^2 - 8x + 12 = 0$

Solution: Let the quartic equation be

$$x^4 + 2px^3 + qx^2 + 2rx + s = 0$$

so here $2p = 2, q = -7, 2r = -8, s = 12$ or $p = 1, q = -7, r = -4, s = 12$. The equation for cubic k is

$$\begin{aligned} 2k^3 - qk^2 + 2k(pr - s) + (qs - p^2s - r^2) &= 0 \\ 2k^3 + 7k^2 + 2k(-4 - 12) + (-84 - 12 - 16) &= 0 \\ 2k^3 + 7k^2 - 32k - 112 &= 0 \end{aligned}$$

By trial, $k = 4$ is a root of this cubic

$$\begin{aligned} (2 \cdot 4^3 + 7 \cdot 4^2 - 32 \cdot 4 - 112) &= 128 + 112 \\ &- 128 - 112 = 0 \end{aligned}$$

Substituting $k = 4$ in

$$p^2 + 2k = q + a^2, \quad pk = r + ab, \quad k^2 = s + b^2$$

we have

$$1 + 8 = -7 + a^2 \quad \therefore a = 4$$

$$1 \cdot 4 = -4 + ab \quad \therefore 8 = ab = 4b \quad \therefore b = 2$$

$$4^2 = 12 + b^2 = 12 + 4$$

Thus the four roots of the given quartic equation are obtained from the solutions of the two quadratic equations

$$x^2 + (p \mp a)x + (k \mp b) = 0$$

$$\text{i.e., } x^2 + (1 - 4)x + (4 - 2) = x^2 - 3x + 2 = 0$$

$$x^2 + (1 + 4)x + (4 + 2) = x^2 + 5x + 6 = 0$$

Solving the two quadratics

$$x^2 - 3x + 2 = (x - 1)(x - 2) = 0$$

$$\text{and } x^2 + 5x + 6 = (x + 2)(x + 3) = 0$$

The four roots of the biquadratic equation are 1, 2, -2, -3.

Aliter: The above problem can be done as follows:
 $x^4 + 2x^3 - 7x^2 - 8x + 12 = 0$.

Introducing an unknown λ , combine the terms x^4 and $2x^3$ to form a perfect square

$$\begin{aligned} (x^2 + x + \lambda)^2 + \{-x^2 - \lambda^2 - 2\lambda x - 2\lambda x^2\} - 7x^2 \\ - 8x + 12 = 0 \end{aligned}$$

$$\begin{aligned} (x^2 + x + \lambda)^2 - \{(8 + 2\lambda)x^2 + (8 + 2\lambda)x \\ + (\lambda^2 - 12)\} = 0 \end{aligned}$$

The second expression in $\{ \}$ brackets will be a perfect square if $b^2 = 4ac$ i.e.,

$$(8 + 2\lambda)^2 = 4(8 + 2\lambda)(\lambda^2 - 12)$$

$$\text{or } 2\lambda^2 - \lambda - 28 = 0$$

Solving $\lambda = 4, -\frac{7}{2}$. With $\lambda = 4$, we have

$$(x^2 + x + 4)^2 - \{16x^2 + 16x + 4\} = 0$$

$$(x^2 + x + 4)^2 - \{2(2x + 1)\}^2 = 0$$

Thus the four roots are given by the roots of the two quadratic equations

$$(x^2 + x + 4) + 2(2x + 1) = 0 \text{ i.e., } x^2 + 5x + 6 = 0$$

and

$$(x^2 + x + 4) - 2(2x + 1) = 0 \text{ i.e., } x^2 - 3x + 2 = 0$$

The four roots are $-2, -3, 1, 2$

Example 2: Solve $x^4 - 8x^2 + 24x + 7 = 0$

Solution: Here $2p = 0$, i.e., $p = 0$, $q = -8$, $2r = 24$ i.e., $r = 12$ and $s = 7$. The cubic for k is

$$2k^3 + 8k^2 + 2k(0 - 7) + (0 - 56 - 144) = 0$$

$$k^3 + 4k^2 - 7k - 100 = 0$$

which has $k = 4$ as a root ($64 + 64 - 28 - 100 = 0$) solving for a, b

$$0 + 8 = -8 + a^2 \quad \therefore a = 4,$$

$$0 = 12 + 4b \quad \therefore b = -3$$

$$16 = 7 + b^2 = 7 + 9$$

Thus the four roots are given by the roots of two quadratic equations $x^2 + (0 - 4)x + (4 - (-3)) = x^2 - 4x + 7 = 0$ and $x^2 + (0 - 4)x + (4 - 3) = x^2 + 4x + 1 = 0$

The roots are $2 \pm \sqrt{3}i$ and $-2 \pm \sqrt{3}$.

EXERCISE

Solve the following biquadratic equations by Ferrari's method.

$$1. x^4 - 2x^3 - 5x^2 + 10x - 3 = 0$$

Hint: $2k^3 + 5k^2 - 4k - 7 = 0$, $k = -1$, $a = 2$, $b = 2$, $x^2 - 3x + 1 = 0$, $x^2 + x - 3 = 0$

$$\text{Ans. } \frac{3 \pm \sqrt{5}}{2}, \frac{-1 \pm \sqrt{13}}{2}$$

$$2. x^4 - 2x^2 + 8x - 3 = 0$$

Hint: $x^2 + 2x - 1 = 0$, $x^2 - 2x + 3 = 0$

$$\text{Ans. } -1 \pm \sqrt{2}, 1 \pm \sqrt{2}i$$

$$3. x^4 - 12x^3 + 41x^2 - 18x - 72 = 0$$

Hint: $x^2 - 5x - 6 = 0$, $x^2 - 7x + 12 = 0$

$$\text{Ans. } -1, 3, 4, 6$$

$$4. x^4 - 10x^3 + 35x^2 - 50x + 24 = 0$$

Hint: $2k^3 - 35k^2 + 202k - 385 = 0$, $k = 5$, $a = 0$, $b = 1$, $x^2 - 5x + 4 = 0$, $x^2 - 5x + 6 = 0$

$$\text{Ans. } 1, 4, 2, 3$$

$$5. x^4 + 8x^3 + 9x^2 - 8x - 10 = 0$$

Hint: $2k^3 - 9k^2 - 12k + 54 = 0$, $k = \frac{9}{2}$, $a = 4$, $b = \frac{11}{2}$, $x^2 - 1 = 0$, $x^2 + 8x + 10 = 0$

$$\text{Ans. } \pm 1, -4 \pm \sqrt{6}$$

$$6. x^4 - 3x^2 - 42x - 40 = 0$$

$$\text{Ans. } 4, -1, -\frac{1}{2}(3 \pm \sqrt{31}i)$$

$$7. x^4 - 2x^3 - 12x^2 + 10x + 3 = 0$$

$$\text{Ans. } 1, -3, 2 \pm \sqrt{5}$$

$$8. 4x^4 - 20x^3 + 33x^2 - 20x + 4 = 0$$

$$\text{Ans. } 2, 2, \frac{1}{2}, \frac{1}{2}$$

$$9. x^4 - 3x^2 - 6x - 2 = 0$$

$$\text{Ans. } 1 \pm \sqrt{2}, -1 \pm i$$

$$10. x^4 - 10x^2 - 20x - 16 = 0$$

$$\text{Ans. } 4, -2, -1 \pm i$$

1.5 COMPLEX NUMBERS

Gauss first introduced the term “complex number” Cardano* first used complex numbers in solving cubic equations. Complex numbers find applications in electric circuits, mechanical vibrating systems. Argand wrote a short book on the geometric representation of complex numbers in 1806. Kuhn of Denzig was the first mathematician who proposed geometric representation of imaginary number i .

*Girolamo Cardano (1501-1576) Italian mathematician.

1.20 — HIGHER ENGINEERING MATHEMATICS—I

There are *no* real solutions to equations such as $x^2 + 2 = 0$ or $x^2 + 3x + 4 = 0$. This led to the introduction of complex numbers. A *complex number* denoted by z is defined as

$$z = x + iy$$

where x and y are real, while $i = \sqrt{-1}$ is known as the *imaginary unit*. Here x is known as the real part of z and y as the imaginary part of z and are denoted as

$$x = \text{Real part of } z = \text{Re}(z)$$

$$y = \text{Imaginary part of } z = \text{Im}(z).$$

For $y = 0$, real numbers form a subset of the complex numbers. When $x = 0$, the complex number is known purely imaginary complex number z . It can be represented as an ordered pair (x, y) and thus as a point in a plane known as *complex plane* or *Argand* diagram*. Here the x -axis is called as real axis, while the y -axis as imaginary axis.

Equality:

Two complex numbers $z_1 = x_1 + iy_1$ and $z_2 = x_2 + iy_2$ are said to be equal if $x_1 = x_2$ and $y_1 = y_2$. Thus $z_1 = z_2$ when their corresponding real parts are equal and corresponding imaginary parts are also equal. Otherwise they are said to be *not* equal i.e., $z_1 \neq z_2$.

Note: However inequalities between complex numbers such as $z_1 > z_2$ or $z_1 \leq z_2$ has no meaning since the field of complex numbers can *not* be ordered. Thus $2 + 3i > 3 + 7i$ or $-6 - 2i < 0$ have no meaning.

Zero

A complex number z is zero if both the real and imaginary parts x and y are zero.

Conjugate complex numbers or complex conjugate number of z denoted by $\bar{z}$ is defined as

$$\bar{z} = x - iy$$

i.e., z and $\bar{z}$ differ only in the sign of the imaginary part.

Trigonometric form of a Complex Number

Since every complex number is represented as a point in the complex plane and vice versa, the complex

number $z = x + iy$ is geometrically represented by the position vector $\overline{OP}$ where O is the origin and P is the point (x, y) . Let (r, θ) denote the polar coordinates of P ; with origin treated as the pole and positive x -axis as the polar axis. Then

$$x = r \cos \theta, y = r \sin \theta$$

$$\text{So } z = x + iy = r \cos \theta + i \sin \theta$$

$$z = r(\cos \theta + i \sin \theta) = r \text{ cis } \theta$$

This expression is known as the *trigonometric form* or *polar form*. Here r is termed as *modulus* or absolute value of the complex number and is denoted by $|z|$.

Fig. 1.23

Thus $r = |z| = \sqrt{x^2 + y^2}$ represents the distance of z from origin. Here θ is the *argument* (or amplitude or phase) of z , denoted as

$\theta = \arg z = \tan^{-1} \frac{y}{x}$. The polar form is also known as modulus-amplitude form.

Thus absolute value of z is

$$|z| = \sqrt{x^2 + y^2}.$$

Amplitude, θ , the directed angle from positive x -axis is positive in the counterclockwise direction and is reckoned negative in the clockwise (opposite direction). θ is measured in radians. It is not unique, but multivalued and is determined up to $2\pi k$, for any integer k .

Principal value

Principal value of argument z is denoted by $\text{Arg } z$ is the value of θ which lies in the interval $-\pi < \theta \leq \pi$.

Note: Although z and $\bar{z}$ have the same moduli. Their arguments are equal in magnitude but differ in sign.

That is

$$\arg z = -\arg \bar{z}$$

* Jean Robert Argand (1768-1822), French mathematician.

while $|z| = \sqrt{x^2 + y^2} = |\bar{z}|$

For any z ,

1. $|z| \geq |Re(z)| \geq Re(z)$
2. $|z| \geq |Im(z)| \geq Im(z)$.

Complex Algebra

Addition

Sum of two complex numbers

$$\begin{aligned} z_1 + z_2 &= (x_1 + iy_1) + (x_2 + iy_2) = \\ &= (x_1 + x_2) + i(y_1 + y_2) \end{aligned}$$

obtained by adding the corresponding real and imaginary parts.

Fig. 1.24

So sum of two complex numbers $z_1 + z_2$ is given by the diagonal of the parallelogram with z_1 and z_2 as adjacent sides (Fig. 1.24).

Difference

Subtraction $z_1 - z_2$ is defined

$$z_1 - z_2 = (x_1 - x_2) + i(y_1 - y_2)$$

So $|z_1 - z_2| = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$

Thus the modulus of the difference between two numbers z_1 and z_2 equals to the distance between z_1 and z_2 [in the complex plane (see Fig. 1.25)].

Fig. 1.25

Multiplication

$$\begin{aligned} z_1 \cdot z_2 &= (x_1 + iy_1)(x_2 + iy_2) = (x_1x_2 - y_1y_2) \\ &\quad + i(x_1y_2 + x_2y_1) \end{aligned}$$

Since $i^2 = -1$, ($i^3 = -i$, $i^4 = 1$ etc. and in general $i^{4k} = 1$, $i^{4k+1} = i$, $i^{4k+2} = -1$, $i^{4k+3} = -i$).

In the polar form

Suppose $z_1 = r_1 \operatorname{cis} \theta_1$, $z_2 = r_2 \operatorname{cis} \theta_2$ then

$$z_1 z_2 = (r_1 \operatorname{cis} \theta_1)(r_2 \operatorname{cis} \theta_2)$$

$$\begin{aligned} &= r_1 r_2 [\cos \theta_1 + i \sin \theta_1][\cos \theta_2 + i \sin \theta_2] \\ &= r_1 r_2 [(\cos \theta_1 \cos \theta_2 - \sin \theta_1 \sin \theta_2) + \\ &\quad + i(\sin \theta_1 \cos \theta_2 + \cos \theta_1 \sin \theta_2)] \end{aligned}$$

Thus $z = r e^{i\theta} = z_1 z_2$

$$z_1 z_2 = r_1 r_2 [\cos(\theta_1 + \theta_2) + i \sin(\theta_1 + \theta_2)]$$

Thus the modulus of the product is the product of the moduli i.e., $r = |z| = r_1 r_2 = |z_1| |z_2|$ and the argument of the product is the sum of the arguments, i.e., $\theta = \theta_1 + \theta_2$, or $\arg(z_1 z_2) = \arg z_1 + \arg z_2$.

Division

$\frac{z_1}{z_2}$ is defined as the inverse operation of multiplication. Thus the quotient $z = \frac{z_1}{z_2}$ is defined as $z \cdot z_2 = z_1$.

In practice $\frac{z_1}{z_2}$ is obtained by multiplying the numerator or denominator by $\bar{z}_2$, the conjugate of z_2 .

$$\begin{aligned} \text{Thus } z = x + iy &= \frac{z_1}{z_2} = \frac{z_1 \cdot \bar{z}_2}{z_2 \cdot \bar{z}_2} \\ &= \frac{(x_1 + iy_1)(x_2 - iy_2)}{(x_2 + iy_2)(x_2 - iy_2)} \end{aligned}$$

$$\frac{z_1}{z_2} = \frac{(x_1x_2 + y_1y_2) + i(y_1x_2 - x_1y_2)}{x_2^2 + y_2^2}$$

$$\text{Thus } Re(z) = Re\left(\frac{z_1}{z_2}\right) = \frac{x_1x_2 + y_1y_2}{x_2^2 + y_2^2} \text{ and}$$

$$Im(z) = Im\left(\frac{z_1}{z_2}\right) = \frac{y_1x_2 - x_1y_2}{x_2^2 + y_2^2}$$

Note that $z\bar{z} = x^2 + y^2 = |z|^2 = |\bar{z}|^2$.

Thus for any $z = x + iy$, ($\bar{z} = x - iy$),

1. $Re z = x = \frac{1}{2}(z + \bar{z})$
2. $Im z = y = \frac{1}{2i}(z - \bar{z})$
3. $z = \bar{z}$ then z must be real.
4. $\overline{z_1 \pm z_2} = \bar{z}_1 \pm \bar{z}_2$
5. $\overline{(z_1 z_2)} = \bar{z}_1 \bar{z}_2$

1.22 — HIGHER ENGINEERING MATHEMATICS—I

$$6. \left(\frac{\bar{z}_1}{z_2} \right) = \frac{\bar{z}_1}{z_2}$$

In polar form

$$\begin{aligned} \frac{z_1}{z_2} &= \frac{r_1(\cos \theta_1 + i \sin \theta_1)}{r_2(\cos \theta_2 + i \sin \theta_2)} \\ &= \frac{r_1}{r_2} [\cos(\theta_1 - \theta_2) + i \sin(\theta_1 - \theta_2)] \end{aligned}$$

Thus the modulus of the quotient is quotient of the moduli i.e., $r = \left| \frac{z_1}{z_2} \right| = \frac{r_1}{r_2} = \frac{|z_1|}{|z_2|}$ and the argument of the quotient is the difference between the arguments i.e., $\theta = \theta_1 - \theta_2$ or $\arg \left(\frac{z_1}{z_2} \right) = \arg z_1 - \arg z_2$.

Triangle inequality

Book work: Prove that

$$|z_1 + z_2| \leq |z_1| + |z_2|$$

Proof Let $z_1 = x_1 + iy_1$, $z_2 = x_2 + iy_2$. Then consider $|z_1 + z_2| \leq |z_1| + |z_2|$

$$\sqrt{(x_1 + x_2)^2 + (y_1 + y_2)^2} \leq \sqrt{x_1^2 + y_1^2} + \sqrt{x_2^2 + y_2^2}$$

Squaring on both sides

$$\begin{aligned} (x_1 + x_2)^2 + (y_1 + y_2)^2 &\leq (x_1^2 + y_1^2) + (x_2^2 + y_2^2) + \\ &+ 2\sqrt{x_1^2 + y_1^2} \cdot \sqrt{x_2^2 + y_2^2} \end{aligned}$$

or

$$2(x_1 + x_2)(y_1 + y_2) \leq 2\sqrt{x_1^2 + y_1^2} \cdot \sqrt{x_2^2 + y_2^2}$$

Squaring again on both sides

$$(x_1 + x_2)^2(y_1 + y_2)^2 \leq (x_1^2 + y_1^2)(x_2^2 + y_2^2)$$

$$\text{or } 2x_1x_2y_1y_2 \leq x_1^2y_2^2 + x_2^2y_1^2$$

i.e., $(x_1y_2 - x_2y_1)^2 \geq 0$ which is always true.

Thus $|z_1 + z_2| \leq |z_1| + |z_2|$

Note: Geometrically the triangle inequality states that the sum of the two sides of a triangle $|z_1| + |z_2|$ is greater than the third side of the triangle $|z_1 + z_2|$. The equality sign holds good i.e., $|z_1 + z_2| = |z_1| + |z_2|$ when the triangle degenerates into a straight line.

Result 1: Generalization

$$|z_1 + z_2 + z_3| \leq |z_1| + |z_2| + |z_3|$$

or in general

$$\left| \sum_{i=1}^n z_i \right| \leq \sum_{i=1}^n |z_i|$$

Result 2. $|z_1 - z_2| \geq ||z_1| - |z_2||$

Since $|z_1| = |z_1 - z_2 + z_2| \leq |z_1 - z_2| + |z_2|$

Similarly

Result 3. $|z_1 + z_2| \geq ||z_1| - |z_2||$

Result 4. $|z_1 - z_2| \geq |z_1| - |z_2|$

Result 5. $|z_1 + z_2|^2 + |z_1 - z_2|^2 = 2(|z_1|^2 + |z_2|^2)$

(known as parallelogram equality)

(Hint: Use $|z_1 + z_2|^2 = r_1^2 + r_2^2 + 2r_1r_2 \cos(\theta_2 - \theta_1)$ and $|z_1 - z_2|^2 = r_1^2 + r_2^2 - 2r_1r_2 \cos(\theta_1 - \theta_2)$)

De Moivre's Theorem: Power of complex numbers:

Let $z_1 = r_1 \text{cis } \theta_1$, $z_2 = r_2 \text{cis } \theta_2$; $\dots$, $z_n = r_n \text{cis } \theta_n$. Then by the product rule in polar form, we get

$$\begin{aligned} z_1 \cdot z_2 \cdot \dots \cdot z_n &= (r_1 \text{cis } \theta_1)(r_2 \text{cis } \theta_2) \dots (r_n \text{cis } \theta_n) \\ &= (r_1 r_2 \dots r_n)(\text{cis } \theta_1)(\text{cis } \theta_2) \dots (\text{cis } \theta_n) \\ &= (r_1 r_2 \dots r_n) \text{cis } (\theta_1 + \theta_2 + \dots + \theta_n) \end{aligned}$$

Thus

$$\text{cis } \theta_1 \cdot \text{cis } \theta_2 \dots \text{cis } \theta_n = \text{cis } (\theta_1 + \theta_2 + \dots + \theta_n)$$

If we choose $z_1 = z_2 = \dots = z_n = z = r \text{cis } \theta$ then $z^n = r^n \text{cis } n\theta$ or for choice of $r = 1$, we get

$$(\cos \theta + i \sin \theta)^n = \cos n\theta + i \sin n\theta$$

which is known as De Moivre's theorem. In a similar way

$$\frac{1}{z} = \frac{1}{r \text{cis } \theta} = \frac{1}{r}(\text{cis } \theta)^{-1} = \frac{1}{r}(\cos \theta - i \sin \theta)$$

$$\frac{1}{z^n} = \frac{1}{r^n}(\text{cis } \theta)^{-n} = \frac{1}{r^n}(\cos n\theta - i \sin n\theta)$$

Thus

$$(\cos \theta + i \sin \theta)^{-n} = \cos n\theta - i \sin n\theta$$

De Moivre's theorem is valid for all rational values of n (including positive, negative integral values and zero).

$$(\text{cis } m\theta)^n = \text{cis } mn\theta = (\text{cis } n\theta)^m$$

1.6 ROOTS OF COMPLEX NUMBERS

Let $z = \omega^n$ where n is an integer $1, 2, 3, \dots$. This is a single-valued function which associates a unique value z for each ω . Now consider the inverse function

$$\omega = z^{\frac{1}{n}} = \sqrt[n]{z}$$

which is multivalued, namely n valued. For any given $z \neq 0$ and the given integer n , there corresponds precisely n distinct values of ω which are known as the n roots of z . Thus the n^{th} root of a complex number is another complex number whose n^{th} power is equal to the radicand. To determine these n roots, let $\omega = R(\cos \phi + i \sin \phi)$ and $z = r(\cos \theta + i \sin \theta)$. Then

$$\begin{aligned}\omega^n &= [R(\cos \phi + i \sin \phi)]^n \\ &= R^n(\cos n\phi + i \sin n\phi) \\ &= z = r(\cos \theta + i \sin \theta)\end{aligned}$$

by using De Moivre's theorem. Since the moduli of equal complex numbers must be equal, while their amplitudes may circle with centre at origin and of radius $r^{1/n}$. They constitute the n vertices of a regular polygon of n sides inscribed in the circle, spaced at equal angular intervals of $\frac{2\pi}{n}$, beginning with the radius whose angle is $\frac{\theta}{n}$.

Principal value of $\omega = z^{1/n}$ is obtained for $k = 0$ and by taking principal value of argument of z .

In particular, the n^{th} roots of a real non-zero number A also has n values since the real number A can be expressed in trigonometric form as

$$A = |A|(\cos \theta + i \sin \theta) = |A|\text{cis } 0 \text{ for } A > 0$$

and

$$A = |A|(\cos \pi + i \sin \pi) = |A|\text{cis } \pi \text{ for } A < 0$$

Solution of Binomial Equation

The n roots of the binomial equation

$$x^n = A$$

differ by a multiple of 2π , we have

$$R^n = r \text{ and } n\phi = \theta + 2k\pi$$

or $R = \sqrt[n]{r}$ where the root is real positive and

$$\phi = \frac{\theta + 2k\pi}{n}$$

where k is an integer. For $k = 0, 1, 2, \dots, (n-1)$ we get n different roots since for these values of k , ϕ defines n distinct angles which identify n different complex numbers. But as k takes $n, n+1, \dots$ or $-1, -2, \dots$, the same angles ϕ are repeated again and again, thus giving the root values that coincide with those (already) obtained. Thus the n^{th} root of a complex number has n distinct values given by

$$\omega = z^{\frac{1}{n}} = \sqrt[n]{z} = r^{\frac{1}{n}} \left[\cos \left(\frac{\theta + 2k\pi}{n} \right) + i \sin \left(\frac{\theta + 2k\pi}{n} \right) \right] \quad (1)$$

$$\text{where } k = 0, 1, 2, \dots, n-1$$

Geometrically, these n values are given by

$$x = \sqrt[n]{A} \left(\cos \frac{2k\pi}{n} + i \sin \frac{2k\pi}{n} \right) \quad (2)$$

for $k = 0, 1, 2, \dots, n-1$ when A is a real positive number. In particular the n^{th} roots of unity (for $A = 1$) are given by

$$1^{1/n} = \left(\cos \frac{2k\pi}{n} + i \sin \frac{2k\pi}{n} \right), k = 0, 1, \dots, n-1$$

similarly when A is a real negative number, then

$$x = \sqrt[n]{A} \left[\cos \left(\frac{\pi + 2k\pi}{n} \right) + i \sin \left(\frac{\pi + 2k\pi}{n} \right) \right] \quad (3)$$

for $k = 0, 1, 2, \dots, (n-1)$. In particular the n^{th} roots of -1 (for $A = -1$) are given by

$$(-1)^{\frac{1}{n}} = \cos \left(\frac{\pi + 2k\pi}{n} \right) + i \sin \left(\frac{\pi + 2k\pi}{n} \right)$$

for $k = 0, 1, 2, \dots, (n-1)$.

When A is a complex number, these n values of x are obtained from (1). Now the *general rational power* of a complex number is defined as

$$\begin{aligned}z^{p/q} &= (x^{1/q})^p = \left[r^{1/q} \text{cis } \frac{\theta + 2k\pi}{q} \right]^p \\ &= r^{p/q} \text{cis } \left(\frac{p}{q}(\theta + 2k\pi) \right)\end{aligned}$$

for $k = 0, 1, 2, \dots, q-1$.

WORKED OUT EXAMPLES

Example 1: Express in the form $a + ib$ and find its modulus.

$$(a) \frac{3+i}{5+5i} \quad (b) \frac{(1+i)(2+3i)}{4-i}$$

$$\text{Solution: } (a) \frac{3+i}{5+5i} = \frac{(3+i)(5-5i)}{(5+5i)(5-5i)} = \frac{15+5-10i}{25+25}$$

$$= \frac{2-i}{5} = \frac{2}{5} - \frac{i}{5}$$

$$\text{modulus of } \frac{3+i}{5+5i} = \left| \frac{2-i}{5} \right| = \sqrt{\left(\frac{2}{5}\right)^2 + \left(\frac{1}{5}\right)^2}$$

$$= \sqrt{\frac{4}{25} + \frac{1}{25}} = \sqrt{\frac{5}{25}} = \frac{1}{5}$$

$$(b) \frac{(1+i)(2+3i)}{(4-i)} = \frac{(2-3+5i)(4+i)}{(4-i)(4+i)}$$

$$= \frac{-4-5+19i}{17} = \frac{-9+19i}{17} = \frac{-9}{17} + \frac{19 \cdot i}{17}$$

$$\text{modulus} = \left| \frac{-9+19i}{17} \right| = \sqrt{\left(\frac{9}{17}\right)^2 + \left(\frac{19}{17}\right)^2} = \sqrt{\frac{442}{289}}$$

Example 2: Express $\sqrt{3} + i$ in the modulus amplitude form and find the principal argument of $-\sqrt{3} + i$.

$$\text{Solution: } x + iy = -\sqrt{3} + i, \text{ so } x = -\sqrt{3}, y = 1, \text{ then } r = \sqrt{x^2 + y^2} = \sqrt{3 + 1} = \sqrt{4} = 2, x = -\sqrt{3} = r \cos \theta = 2 \cos \theta. \text{ So } \cos \theta = \frac{-\sqrt{3}}{2} \text{ and } y = 1 = r \sin \theta = 2 \sin \theta, \text{ so } \sin \theta = \frac{1}{2} \cdot \cos \text{ is negative and sine positive. } \theta \text{ in the 2nd quadrant}$$

$$\theta = \pi - \frac{\pi}{6} \pm 2n\pi = \frac{5\pi}{6} \pm 2n\pi, n = 0, 1, 2, \dots$$

modulus amplitude form of $-\sqrt{3} + i$ is $2e^{i(\frac{5\pi}{6} \pm 2n\pi)}$ where 2 is the modulus and $\theta = \frac{5\pi}{6} \pm 2n\pi$ is the amplitude (or argument). The principal argument lies $-\pi \leq \theta < \pi$. Thus $\frac{5\pi}{6}$ is the principal argument.

Example 3: Solve the equation $\frac{iy}{ix+1} - \frac{3y+4i}{3x+y} = 0$ given that x and y are real.

Solution:

$$\frac{iy}{ix+1} - \frac{3y+4i}{3x+y} = \frac{iy(-ix+1)}{(ix+1)(-ix+1)} - \frac{(3y+4i)}{(3x+y)}$$

$$= \frac{xy + iy}{1 + x^2} - \frac{(3y+4i)}{(3x+y)} = 0$$

$$(xy + iy)(3x + y) - (1 + x^2)(3y + 4i) = 0$$

or

$$y(xy - 3) + i(3xy + y^2 - 4x^2 - 4) = 0$$

$$\Rightarrow y(xy - 3) = 0 \text{ and } 3xy + y^2 - 4x^2 - 4 = 0.$$

If $y = 0$, then $x^2 + 1 = 0$. Since x is real, $x^2 + 1 = 0$ is not possible. Thus $y \neq 0$.

Assume $y \neq 0$ then $xy = 3$ or $y = \frac{3}{x}$. Eliminating y , $3x \cdot \frac{3}{x} + \frac{9}{x^2} - 4x^2 - 4 = 0$

$$\text{or } 4x^4 - 5x^2 - 9 = 0 \text{ or } (4x^2 - 9)(x^2 + 1) = 0.$$

Since x is real, $x^2 + 1 \neq 0$. Then $4x^2 - 9 = 0$ or $x = \pm \frac{3}{2}$

Thus $x = 1.5$, $y = \pm 2$ are the solutions.

Example 4: Determine the curve represented by $z\bar{z} + (1+i)z + (1-i)\bar{z} = 0$.

Solution: $(x^2 + y^2) + (1+i)(x + iy) + (1-i)(x - iy) = 0$ or $x^2 + 2x + y^2 - 2y = 0$
Rewriting $(x+1)^2 + (y-1)^2 = (\sqrt{2})^2$; which is the equation of a circle with centre at $(-1, 1)$ and of radius $\sqrt{2}$.

Example 5: Locate the points $z_1 = 9 + i$, $z_2 = 4 + 13i$, $z_3 = -8 + 8i$ and $z_4 = -3 - 4i$ in the Argand diagram and show that these four points form a square.

Solution: Distance between z_1 and z_2 = length of the side AB

$$= |z_1 - z_2| = |9 - i - (4 - 13i)| = |5 + 12i|$$

$$= \sqrt{25 + 144} = \sqrt{169} = 13$$

Similarly

$$|z_1 - z_3| = |17 - 7i| = \sqrt{338}$$

$$|z_1 - z_4| = |12 - 5i| = \sqrt{144 + 25} = 13$$

$$|z_2 - z_3| = |12 - 5i| = 13$$

$$|z_2 - z_4| = |7 + 17i| = \sqrt{338}$$

$$|z_3 - z_4| = |-5 + 12i| = 13$$

Since $AB = AD = BC = CD$ (these four sides are equal) the four points z_1, z_2, z_3, z_4 form a square in the Argand diagram (complex plane).

Fig. 1.26

Example 6: Show that multiplication of a complex number by 'i' corresponds to a counterclockwise rotation of the corresponding vector through the angle $\frac{\pi}{2}$.

Solution: Let the complex number be $z = x + iy = r(\cos \theta + i \sin \theta) = re^{i\theta}$. Then

$$iz = ire^{i\theta} = e^{i\frac{\pi}{2}} \cdot r \cdot e^{i\theta} = re^{i(\theta+\pi/2)}$$

Thus the argument of iz is $\theta + \frac{\pi}{2}$ which is $\frac{\pi}{2}$ more than the argument of z . Hence OZ is rotated through an angle $\frac{\pi}{2}$ in the counterclockwise direction.

Fig. 1.27

Example 7: Determine the domain in the z -plane represented by (a) $3 < |z - 4| \leq 5$ (b) $Im(z) < 6$ (c) $\frac{\pi}{4} < \arg(z) < \frac{\pi}{2}$.

Solution: (a) $3 < |z - 4| \leq 5$

$$\begin{aligned} |z - 4| &= |x + iy - 4| = |(x - 4) + iy| \\ &= \sqrt{(x - 4)^2 + y^2} \end{aligned}$$

From $3 < \sqrt{(x - 4)^2 + y^2}$

we get $9 < (x - 4)^2 + y^2$

From $\sqrt{(x - 4)^2 + y^2} \leq 5$, we get

$$(x - 4)^2 + y^2 \leq 25.$$

Thus the inequality represents the annulus region between two concentric circles with both centered at (4, 0) and of radii 3 and 5. The boundary of the outer circle with radius 5 is also included in the region.

Fig. 1.28

(b) $Im(z) = y < 6$

The open half region below the line $y = 6$.

Fig. 1.29(a)

(c) The wedge region in the first quadrant bounded by the lines $\theta = \frac{\pi}{4}$, and $\theta = \frac{\pi}{2}$.

Fig. 1.29(b)

Example 8: If $z = 1 + i$, plot z^2 , z^3 , $\frac{1}{z}$ in the complex plane.

Fig. 1.30

Solution: $z = x + iy = 1 + i$, so $x = 1$, $y = 1$, then $r = \sqrt{x^2 + y^2} = \sqrt{2}$, $1 = x = \sqrt{2} \cos \theta$. Then $\cos \theta = \sin \theta = \frac{1}{\sqrt{2}}$. Thus $\theta = \frac{\pi}{4}$. Hence

1.26 — HIGHER ENGINEERING MATHEMATICS—I

$z = 1 + i = \sqrt{2} e^{i\frac{\pi}{4}}$. Then $z^2 = 2e^{i\frac{\pi}{2}} = 2i$

$$z^3 = 2^{3/2} e^{i3\pi/4} = 2(-1 + i)$$

$$\frac{1}{z} = \frac{1}{\sqrt{2}} e^{-i\pi/4} = \frac{1}{2}(1 - i)$$

Example 9: Find the locus of z when $\frac{z-i}{z-2}$ is purely imaginary.

Solution:
$$\frac{z-i}{z-2} = \frac{(x+iy)-i}{(x+iy)-2} = \frac{x+i(y-1)}{(x-2)+iy}$$
$$= \frac{[x+i(y-1)][(x-2)-iy]}{[(x-2)+iy][(x-2)-iy]}$$
$$= \frac{x(x-2) + y(y-1) + i[(x)(-y) + (y-1)(x-2)]}{(x-2)^2 + y^2}$$

Since $\frac{z-i}{z-2}$ is purely imaginary, its real part $\frac{x(x-2)+y(y-1)}{(x-2)^2+y^2}$ must be zero. Then $x(x-2) + y(y-1) = 0$ or $x^2 - 2x + y^2 - y = 0$.

Rewriting $(x^2 - 2x + 1) + (y^2 - y + \frac{1}{4}) = \frac{5}{4}$ or $(x-1)^2 + (y-\frac{1}{2})^2 = (\sqrt{\frac{5}{4}})^2$. Thus the locus of z is a circle with center at $(1, \frac{1}{2})$ and radius $\sqrt{\frac{5}{4}}$.

Fig. 1.31

De Moivre's Theorem

Example 10: Simplify $\frac{(\cos 5\theta - i \sin 5\theta)^2 (\cos 7\theta + i \sin 7\theta)^{-3}}{(\cos 4\theta - i \sin 4\theta)^9 (\cos \theta + i \sin \theta)^5}$

Solution: Using De Moivre's theorem

$$(\cos 5\theta - i \sin 5\theta)^2 = \cos 10\theta - i \sin 10\theta$$
$$= (\cos \theta + i \sin \theta)^{-10}$$

$$(\cos 7\theta + i \sin 7\theta)^{-3} = \cos 21\theta - i \sin 21\theta$$
$$= (\cos \theta + i \sin \theta)^{-21}$$

$$(\cos 4\theta + i \sin 4\theta)^9 = \cos 36\theta - i \sin 36\theta$$
$$= (\cos \theta + i \sin \theta)^{-36}$$

Substituting these values in given expression, we get

$$\frac{(\cos \theta + i \sin \theta)^{-10} (\cos \theta + i \sin \theta)^{-21}}{(\cos \theta + i \sin \theta)^{-36} (\cos \theta + i \sin \theta)^5}$$
$$= \frac{(\cos \theta + i \sin \theta)^{-31}}{(\cos \theta + i \sin \theta)^{-31}} = 1$$

Example 11: Show that $[(\cos \alpha - \cos \beta) + i(\sin \alpha - \sin \beta)]^n + [(\cos \alpha - \cos \beta) - i(\sin \alpha - \sin \beta)]^n$

$$= 2^{n+1} \sin n \left(\alpha - \frac{\beta}{2} \right) \cdot \cos n \left(\frac{\pi + \alpha + \beta}{2} \right)$$

Solution: Put $\cos \alpha - \cos \beta = r \cos \theta$,

$$\sin \alpha - \sin \beta = r \sin \theta$$

$$\text{Then } r^2 = (\cos \alpha - \cos \beta)^2 + (\sin \alpha - \sin \beta)^2 \quad (1)$$

$$= \cos^2 \alpha + \cos^2 \beta - 2 \cos \alpha \cdot \cos \beta + \sin^2 \alpha + \sin^2 \beta$$
$$- 2 \sin \alpha \sin \beta$$

$$= 2 - 2 \cos \alpha \cos \beta - 2 \sin \alpha \sin \beta$$

$$= 2 - [\cos(\alpha + \beta) + \cos(\alpha - \beta)] - [\cos(\alpha - \beta) - \cos(\alpha + \beta)]$$

$$= 2 - 2 \cos(\alpha - \beta) = 2(1 - \cos(\alpha - \beta))$$

$$r^2 = 2 \cdot 2 \cdot \sin^2 \left(\frac{\alpha - \beta}{2} \right)$$

$$\text{So } r = 2 \sin \left(\frac{\alpha - \beta}{2} \right) \text{ or } r^n = 2^n \sin^n \left(\frac{\alpha - \beta}{2} \right) \quad (2)$$

Now using (1) eliminating α, β in terms of r and θ , $[(\cos \alpha - \cos \beta) + i(\sin \alpha - \sin \beta)]^n + [(\cos \alpha - \cos \beta) - i(\sin \alpha - \sin \beta)]^n$

$$= (r \cos \theta + i r \sin \theta)^n + (r \cos \theta - i r \sin \theta)^n$$

$$= r^n [\cos n\theta + i \sin n\theta + \cos n\theta - i \sin n\theta]$$

$$= r^n \cdot 2 \cdot \cos n\theta \quad (3)$$

Fig. 1.32

Now from (1) $\tan \theta = \frac{r \sin \theta}{r \cos \theta} = \frac{\sin \alpha - \sin \beta}{\cos \alpha - \cos \beta}$, so

$$\cos \theta = \frac{\cos \alpha - \cos \beta}{r} = \frac{\cos \alpha - \cos \beta}{2 \sin \left(\frac{\alpha - \beta}{2} \right)}$$

$$= \frac{-2 \sin \frac{(\alpha+\beta)}{2} \cdot \sin \frac{(\alpha-\beta)}{2}}{2 \sin \frac{(\alpha-\beta)}{2}} = -\sin \frac{(\alpha+\beta)}{2}$$

$$\cos \theta = \cos \left(\frac{\pi}{2} + \frac{\alpha+\beta}{2} \right)$$

$$\text{Thus } \theta = \frac{\pi}{2} + \frac{\alpha+\beta}{2}$$

$$\text{Then } \cos n\theta = \cos n \left(\frac{\pi}{2} + \frac{\alpha+\beta}{2} \right) \quad (4)$$

Substituting (3) and (4) in (2), we get the required result as

$$= 2^n \cdot \sin n \left(\frac{\alpha-\beta}{2} \right) \cdot 2 \cdot \cos n \left(\frac{\pi}{2} + \frac{\alpha+\beta}{2} \right)$$

Example 12: If $z = \text{cis } \theta$ and $\omega = \text{cis } \phi$ show that

$$z^m \omega^n + z^{-m} \omega^{-n} = 2 \cos(m\theta + n\phi).$$

$$\begin{aligned} \text{Solution:} \quad & \text{Consider } z^m \omega^n + z^{-m} \omega^{-n} \\ &= (\text{cis } \theta)^m (\text{cis } \phi)^n + (\text{cis } \theta)^{-m} (\text{cis } \phi)^{-n} \\ & \quad \text{(using De Moivre's theorem)} \\ &= (\cos m\theta + i \sin m\theta)(\cos n\phi + i \sin n\phi) \\ & \quad + (\cos m\theta - i \sin m\theta)(\cos n\phi - i \sin n\phi) \\ &= (\cos m\theta \cdot \cos n\phi - \sin m\theta \cdot \sin n\phi) \\ &= \cos(m\theta + n\phi) \end{aligned}$$

Example 13: If $\sin \alpha + 2 \sin \beta + 3 \sin \gamma = 0$ and $\cos \alpha + 2 \cos \beta + 3 \cos \gamma = 0$ then prove that $\sin 3\alpha + 8 \sin 3\beta + 27 \sin 3\gamma = 18 \sin(\alpha + \beta + \gamma)$ and $\cos 3\alpha + 8 \cos 3\beta + 27 \cos 3\gamma = 18 \cos(\alpha + \beta + \gamma)$

Solution: Put $a = \text{cis } \alpha, b = \text{cis } \beta, c = \text{cis } \gamma$. Then $a + 2b + 3c = \text{cis } \alpha + 2\text{cis } \beta + 3\text{cis } \gamma$
 $= (\cos \alpha + i \sin \alpha) + 2(\cos \beta + i \sin \beta) + 3(\cos \gamma + i \sin \gamma)$
 $= (\cos \alpha + 2 \cos \beta + 3 \cos \gamma) + i(\sin \alpha + 2 \sin \beta + 3 \sin \gamma)$
 $= 0 + i \cdot 0 = 0$ using the given hypothesis.
 Thus $(a + 2b) = -3c$
 Cubing on both sides

$$(a + 2b)^3 = -27c^3$$

$$a^3 + 8b^3 + 3a^2 \cdot 2b + 3a \cdot 4b^2 = -27c^3$$

$$a^3 + 8b^3 + 6ab(a + 2b) = -27c^3$$

$$a^3 + 8b^3 + 6ab(-3c) = -27c^3$$

Then

$$a^3 + 8b^3 + 27c^3 = 18abc$$

$$(\text{cis } \alpha)^3 + 8(\text{cis } \beta)^3 + 27(\text{cis } \gamma)^3 = 18 \cdot \text{cis } \alpha \text{ cis } \beta \text{ cis } \gamma$$

$$(\cos 3\alpha + i \sin 3\alpha) + 8(\cos 3\beta + i \sin 3\beta)$$

$$+ 27(\cos 3\gamma + i \sin 3\gamma) = 18 \text{ cis }(\alpha + \beta + \gamma)$$

or

$$(\cos 3\alpha + 8 \cos 3\beta + 27 \cos 3\gamma)$$

$$+ i(\sin 3\alpha + 8 \sin 3\beta + 27 \sin 3\gamma)$$

$$= 18[\cos(\alpha + \beta + \gamma) + i \sin(\alpha + \beta + \gamma)]$$

On comparing the real and imaginary parts on both sides, the two required results are obtained.

WORKED OUT EXAMPLES

Extraction of Roots

Example 1: Solve $z^4 + 1 = 0$ and locate the roots in the argand diagram.

Solution: $z^4 = -1$ so $z = (-1)^{\frac{1}{4}}$.

Consider $-1 = x + iy$ so $x = -1, y = 0$; then

$$r = \sqrt{x^2 + y^2} = \sqrt{1} = 1$$

$$-1 = x = r \cos \theta = \cos \theta, 0 = y = r \sin \theta$$

$$\therefore \theta = \pi.$$

$$\text{Thus } -1 = r e^{i\theta} = 1 \cdot e^{i\pi}$$

$$\text{Now } z = (-1)^{\frac{1}{4}} = r^{\frac{1}{n}} \text{cis} \left(\frac{\theta + 2k\pi}{n} \right) =$$

$$1^{\frac{1}{4}} \text{cis} \left(\frac{(\pi + 2k\pi)}{4} \right)$$

$$\text{i.e., } z = \cos \left(\frac{(\pi + 2k\pi)}{4} \right) + i \sin \left(\frac{(\pi + 2k\pi)}{4} \right);$$

with $k = 0, 1, 2, 3$

Fig. 1.33

1.28 — HIGHER ENGINEERING MATHEMATICS—I

$$\begin{aligned}\text{For } k = 0, z_1 &= \cos \frac{\pi}{4} + i \sin \frac{\pi}{4} = \frac{1}{\sqrt{2}} + \frac{i}{\sqrt{2}} \\ &= \frac{1}{\sqrt{2}}(1 + i)\end{aligned}$$

$$\begin{aligned}\text{For } k = 1, z_2 &= \cos \frac{3\pi}{4} + i \sin \frac{3\pi}{4} = -\frac{1}{\sqrt{2}} + \frac{i}{\sqrt{2}} \\ &= \frac{1}{\sqrt{2}}(-1 + i)\end{aligned}$$

$$\begin{aligned}\text{For } k = 2, z_3 &= \cos \frac{5\pi}{4} + i \sin \frac{5\pi}{4} = -\frac{1}{\sqrt{2}} - \frac{i}{\sqrt{2}} \\ &= \frac{1}{\sqrt{2}}(-1 - i)\end{aligned}$$

$$\begin{aligned}\text{For } k = 3, z_4 &= \cos \frac{7\pi}{4} + i \sin \frac{7\pi}{4} = \frac{1}{\sqrt{2}} - \frac{i}{\sqrt{2}} \\ &= \frac{1}{\sqrt{2}}(1 - i)\end{aligned}$$

Thus the four roots of $(-1)^{\frac{1}{4}}$ are $\frac{1}{\sqrt{2}}(\pm 1 \pm i)$, i.e., z_1, z_2, z_3, z_4 are the solutions of the given equation. The four roots lie on a circle of radius 'one' making angles $\frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}$ and $\frac{7\pi}{4}$ respectively with the positive x -axis.

Example 2: Find all solutions of the equation $z^4 - (1 + 4i)z^2 + 4i = 0$

$$\begin{aligned}\text{Solution: } z^4 - z^2 - 4iz^2 + 4i &= \\ &= z^2(z^2 - 1) - 4i(z^2 - 1) = 0\end{aligned}$$

$$(z^2 - 1)(z^2 - 4i) = 0$$

Then $z^2 - 1 = 0$ and $z^2 = 4i$ or $z = \pm 1$ and $z = \pm 2\sqrt{i}$

But $\sqrt{i} = (e^{i\pi/2})^{1/2} = e^{i\pi/4}$ so $z = \pm 1$, $z = \pm 2e^{i\pi/4} = \pm 2\left(\frac{1}{\sqrt{2}} + i\frac{1}{\sqrt{2}}\right)$. The solutions are $\pm 1, \pm 2\sqrt{2}(1 + i)$.

Example 3: Find all values of $(-1 + i\sqrt{3})^{3/2}$

Solution: Let $-1 + i\sqrt{3} = x + iy$, so $x = -1$, $y = \sqrt{3}$. Then $r = \sqrt{x^2 + y^2} = \sqrt{1 + 3} = \sqrt{4} = 2$
 $-1 = x = r \cos \theta = 2 \cos \theta$, so $\cos \theta = -\frac{1}{2}$
 $\sqrt{3} = y = r \sin \theta = 2 \sin \theta$, so $\sin \theta = \frac{\sqrt{3}}{2}$
 $\therefore \theta = \pi - \frac{\pi}{3} = \frac{2\pi}{3}$. Thus

$$-1 + i\sqrt{3} = re^{i\theta} = 2e^{i\frac{2\pi}{3}}$$

Now

$$\begin{aligned}(-1 + i\sqrt{3})^{3/2} &= \left(2e^{i\frac{2\pi}{3}}\right)^{3/2} = (8e^{i2\pi})^{1/2} \\ &= \sqrt{8}e^{i\left(\frac{2\pi+2k\pi}{2}\right)} \text{ with } k = 0, 1\end{aligned}$$

$$= \sqrt{8}e^{i\pi} = -\sqrt{8} = -2\sqrt{2} \text{ for } k = 0$$

$$= \sqrt{8}e^{i2\pi} = +\sqrt{8} = 2\sqrt{2} \text{ for } k = 1$$

Thus the solutions are $\pm 2\sqrt{2}$.

Example 4: Find the n^{th} roots of unity or solve $z^n - 1 = 0$.

Solution: $z^n = 1$, or $z = 1^{1/n} = (1 \cdot e^{i0})^{\frac{1}{n}}$ since $1 = x + iy$, $x = 1$, $y = 0$, $r = 1$, $\theta = 0$ so $1 = 1 \cdot e^{i0}$. Then $z = 1^{1/n}e^{i\left(\frac{\theta+2k\pi}{n}\right)} = e^{\frac{i2k\pi}{n}}$ with $k = 0, 1, \dots, (n-1)$

For $k = 0, z = 1$

$$\text{For } k = 1, \omega_1 = e^{i2\pi/n} = \cos \frac{2\pi}{n} + i \sin \frac{2\pi}{n}$$

$$\begin{aligned}\text{For } k = 2, \omega_2 &= e^{i4\pi/n} = \left(\cos \frac{4\pi}{n} + i \sin \frac{4\pi}{n}\right) \\ &= \left(\cos \frac{2\pi}{n} + i \sin \frac{2\pi}{n}\right)^2 = \omega_1^2\end{aligned}$$

$$\text{For } k = 3, \omega_3 = e^{i6\pi/n} = \text{cis} \frac{6\pi}{n} = \left(\text{cis} \frac{2\pi}{n}\right)^3 = \omega_1^3$$

Thus for $k = (n-1)$, $\omega_{n-1} = e^{i2(n-1)\frac{\pi}{n}} = \left(\text{cis} \frac{2\pi}{n}\right)^{n-1} = \omega_1^{n-1}$

Therefore, the n distinct roots of unity are $1, \omega, \omega^2, \omega^3, \dots, \omega^{n-1}$. Here

$$\omega = e^{\frac{i2\pi}{n}} = \cos \frac{2\pi}{n} + i \sin \frac{2\pi}{n}$$

obtained for $k = 1$ is known as the primitive n^{th} root of 1 (i.e., root with the smallest non-zero angle). In the Argand diagram, these n roots of unity are represented by n distinct vertices of a regular polygon of n sides inscribed in a unit circle spaced at angular intervals of $\frac{2\pi}{n}$, beginning with one vertex at the point 1.

Cube roots: $\sqrt[3]{1}$ 4th roots: $\sqrt[4]{1}$ 5th roots: $\sqrt[5]{1}$

$$1, -\frac{1}{2} \pm \frac{\sqrt{3}}{2}i \quad \pm 1, \pm i \quad \theta = 0, \frac{2\pi}{5}, \frac{4\pi}{5}, \frac{6\pi}{5}, \frac{8\pi}{5}$$

Fig. 1.34

Fig. 1.35

Fig. 1.36

Example 5: If ω is a complex 4th root of unity, prove that $1 + \omega + \omega^2 + \omega^3 = 0$

Solution: $1 = 1 \cdot e^{i2k\pi/4} = e^{ik\pi/2}$ with $k = 0, 1, 2, 3, 4$. Then ω corresponds root with $k = 1$. Thus for $k = 1$, $\omega = e^{i\pi/2} = i$. Now $1 + \omega + \omega^2 + \omega^3 = 1 + i + i^2 + i^3 = 1 + i - 1 - i = 0$

Example 6: Solve the equation $z^7 + z^4 + z^3 + 1 = 0$.

Solution: Observe that $z = -1$ is a solution of the given equation since $(-1)^7 + (-1)^4 + (-1)^3 + 1 = 0$.

By synthetic division,

$$\begin{array}{r|rrrrrrrr} 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 \\ & & -1 & 1 & -1 & 0 & -1 & 1 & -1 \\ \hline & 1 & -1 & 1 & 0 & 1 & -1 & 1 & 0 \end{array}$$

$$\begin{aligned} z^7 + z^4 + z^3 + 1 &= \\ (z + 1)(z^6 - z^5 + z^4 + z^2 - z + 1) &= 0 \end{aligned}$$

Now consider

$$z^6 - z^5 + z^4 + z^2 - z + 1 = 0$$

Dividing by z^3 ,

$$z^3 - z^2 + z + \frac{1}{z} - \frac{1}{z^2} + \frac{1}{z^3} = 0$$

or

$$\left(z^3 + \frac{1}{z^3}\right) - \left(z^2 + \frac{1}{z^2}\right) + \left(z + \frac{1}{z}\right) = 0$$

Rewriting

$$\begin{aligned} \left[\left(z + \frac{1}{z}\right)^3 - 3\left(z + \frac{1}{z}\right)\right] - \left[\left(z + \frac{1}{z}\right)^2 - 2\right] \\ + \left[z + \frac{1}{z}\right] = 0 \end{aligned}$$

or

$$\left(z + \frac{1}{z}\right)^3 - \left(z + \frac{1}{z}\right)^2 - 2\left(z + \frac{1}{z}\right) + 2 = 0$$

Put $\omega = z + \frac{1}{z}$, then

$$\omega^3 - \omega^2 - 2\omega + 2 = 0$$

for which $\omega = 1$ is a root (solution). By synthetic division.

$$\begin{array}{r|rrrr} 1 & 1 & -1 & -2 & +2 \\ & & 1 & 0 & -2 \\ \hline & 1 & 0 & -2 & 0 \end{array}$$

$$\omega^3 - \omega^2 - 2\omega + 2 = (\omega - 1)(\omega^2 - 2) = 0$$

Thus $\omega = 1$ and

$$\omega^2 = 2 \text{ or } z + \frac{1}{z} = 1 \text{ and } \omega = z + \frac{1}{z} = \pm\sqrt{2}.$$

Solving $z^2 - z + 1 = 0$ and $z^2 \pm \sqrt{2}z - 1 = 0$, we get $z = \frac{1 \pm \sqrt{1-4}}{2} = \frac{1 \pm \sqrt{3}i}{2}$ and

$$z = \frac{\pm\sqrt{2} \pm \sqrt{2-4}}{2} = \frac{\pm 1 \pm i}{\sqrt{2}}$$

Hence the seven solutions of the equation are

$$z = -1, \frac{1 \pm \sqrt{3}i}{2}, \frac{\pm 1 \pm i}{\sqrt{2}}.$$

Example 7: Determine the roots common to the equations $z^4 + 1 = 0$ and $z^6 - i = 0$.

Solution: The roots of $z^4 + 1 = 0$ are $z = (-1)^{1/4} = 1 \cdot \text{cis}\left(\frac{2k\pi + \pi}{4}\right)$ with $k = 0, 1, 2, 3$

i.e., $\text{cis}\frac{\pi}{4}, \text{cis}\frac{3\pi}{4}, \text{cis}\frac{5\pi}{4}, \text{cis}\frac{7\pi}{4}$.

Similarly the roots of $z^6 - i = 0$ are $z = i^{1/6} = 1 \cdot \text{cis}\left(\frac{2k\pi + \frac{\pi}{2}}{6}\right)$ for $k = 0, 1, 2, 3, 4, 5$

i.e., $\text{cis}\frac{\pi}{12}, \text{cis}\frac{5\pi}{12}, \text{cis}\frac{9\pi}{12}, \text{cis}\frac{13\pi}{12}, \text{cis}\frac{17\pi}{12}, \text{cis}\frac{21\pi}{12}$.

Note that

$$\text{cis}\frac{3\pi}{4} = -\frac{1}{\sqrt{2}} + \frac{i}{\sqrt{2}} = \text{cis}\frac{9\pi}{12} = \text{cis}\frac{3\pi}{4}$$

and $\text{cis}\frac{7\pi}{4} = \frac{1}{\sqrt{2}} - \frac{i}{\sqrt{2}} = \text{cis}\frac{21\pi}{12}$ are the two common roots. Thus the $\frac{(-1+i)}{\sqrt{2}}$ and $\frac{1-i}{\sqrt{2}}$ are the common solutions.

Example 8: Find the equation whose roots are $2 \cos \frac{2\pi}{7}, 2 \cos \frac{4\pi}{7}, 2 \cos \frac{6\pi}{7}$.

Solution: Let $z = \cos \theta + i \sin \theta = \text{cis}\theta$. Then

$$z^7 = (\text{cis}\theta)^7 = \cos 7\theta + i \sin 7\theta$$

For $\theta = 0, \frac{2\pi}{7}, \frac{4\pi}{7}, \frac{6\pi}{7}, \frac{8\pi}{7}, \frac{10\pi}{7}, \frac{12\pi}{7}$
 $z^7 = \text{cis}7\theta = 1$ or $z^7 - 1 = 0$. Note that $\theta = 0$ corresponds to $z = 1$. Now by synthetic division

1.30 — HIGHER ENGINEERING MATHEMATICS—I

$$\begin{array}{r|rrrrrrrr} 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ & & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ \hline & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 \end{array}$$

Fig. 1.37

Rewrite

$$z^7 - 1 = (z - 1)(z^6 + z^5 + z^4 + z^3 + z^2 + z + 1) = 0$$

Thus $\theta = \frac{2\pi}{7}, \frac{4\pi}{7}, \frac{6\pi}{7}, \frac{8\pi}{7}, \frac{10\pi}{7}, \frac{12\pi}{7}$ corresponds to the equation

$$z^6 + z^5 + z^4 + z^3 + z^2 + z + 1 = 0.$$

Dividing throughout by z^3 ,

$$z^3 + z^2 + z + 1 + \frac{1}{z} + \frac{1}{z^2} + \frac{1}{z^3} = 0$$

$$\text{or } \left(z^3 + \frac{1}{z^3}\right) + \left(z^2 + \frac{1}{z^2}\right) + \left(z + \frac{1}{z}\right) + 1 = 0$$

$$\begin{aligned} \text{or } \left(z + \frac{1}{z}\right)^3 - 3\left(z + \frac{1}{z}\right) + \left(z + \frac{1}{z}\right)^2 - \\ - 2 + \left(z + \frac{1}{z}\right) + 1 = 0 \end{aligned}$$

$$\begin{aligned} \text{i.e., } \left(z + \frac{1}{z}\right)^3 + \left(z + \frac{1}{z}\right)^2 - 2 \cdot \left(z + \frac{1}{z}\right) + 1 = 0. \\ \text{put } z + \frac{1}{z} = (\cos \theta + i \sin \theta) + (\cos \theta - i \sin \theta) \end{aligned}$$

$$= 2 \cos \theta = \omega$$

Then the above solution reduces to

$$\omega^3 + \omega^2 - 2\omega + 1 = 0$$

observe that

$$\cos \frac{8\pi}{7} = \cos \left(2\pi - \frac{6\pi}{7}\right) = \cos \frac{6\pi}{7},$$

$$\cos \left(\frac{10\pi}{7}\right) = \cos \left(2\pi - \frac{4\pi}{7}\right) = \cos \frac{4\pi}{7} \text{ and}$$

$$\cos \left(\frac{12\pi}{7}\right) = \cos \left(2\pi - \frac{2\pi}{7}\right) = \cos \frac{2\pi}{7}$$

Hence $2 \cos \frac{2\pi}{7}, 2 \cos \frac{4\pi}{7}, 2 \cos \frac{6\pi}{7}$ are the roots of the equation $\omega^3 + \omega^2 - 2\omega + 1 = 0$.

Example 9: Express $\sin^7 \theta$ in sines of multiples of θ .

Solution: Let $z = \text{cis } \theta$, then $z - \frac{1}{z} = 2i \sin \theta$, $z^p = \text{cis } p\theta$, $\frac{1}{z^p} = \cos p\theta - i \sin p\theta$, so $z^p - \frac{1}{z^p} = 2i \sin p\theta$

$$\begin{aligned} \text{Consider } (2i \sin \theta)^7 &= 2^7 \cdot i^7 \cdot \sin^7 \theta = \left(z - \frac{1}{z}\right)^7 \\ &= z^7 - 7 \cdot z^6 \cdot \frac{1}{z} + 21 \cdot z^5 \cdot \frac{1}{z^2} - 35z^4 \cdot \frac{1}{z^3} + \\ &+ 35 \cdot z^3 \cdot \frac{1}{z^4} - 21 \cdot z^2 \cdot \frac{1}{z^5} + 7 \cdot z \cdot \frac{1}{z^6} - \frac{1}{z^7} \\ &= \left(z^7 - \frac{1}{z^7}\right) - 7\left(z^5 - \frac{1}{z^5}\right) + 21\left(z^3 + \frac{1}{z^3}\right) - \\ &35\left(z - \frac{1}{z}\right) \\ &= 2i \sin 7\theta - 7 \cdot 2i \sin 5\theta + 21 \cdot 2i \cdot \sin 3\theta - \\ &- 35 \cdot 2i \sin \theta \end{aligned}$$

Simplifying

$$2^6 \sin^7 \theta = 35 \sin \theta - 21 \sin 3\theta + 7 \sin 5\theta - \sin 7\theta$$

Here the RHS is expressed in sines of multiples of θ .

Example 10: Show that

$$32 \sin^4 \theta \cdot \cos^2 \theta = \cos 6\theta - 2 \cos 4\theta - \cos 2\theta + 2$$

Solution: When $z = \text{cis } \theta$, then $z + \frac{1}{z} = 2 \cos \theta$ and $z - \frac{1}{z} = 2i \sin \theta$; consider $z^p + \frac{1}{z^p} = 2 \cos p\theta$.

$$\begin{aligned} \text{Consider } (2i \sin \theta)^4 (2 \cos \theta)^2 &= \left(z - \frac{1}{z}\right)^4 \left(z + \frac{1}{z}\right)^2 \\ &= \left(z^4 - 4z^3 \cdot \frac{1}{z} + 6z^2 \cdot \frac{1}{z^2} - 4z \cdot \frac{1}{z^3} + \frac{1}{z^4}\right) \times \\ &\quad \times \left(z^2 + 2 + \frac{1}{z^2}\right) \end{aligned}$$

$$\begin{aligned} &= \left(z^4 - 4z^2 + 6 - 4\frac{1}{z^2} + \frac{1}{z^4}\right) \left(z^2 + 2 + \frac{1}{z^2}\right) \\ &= \left(z^6 + \frac{1}{z^6}\right) - 2\left(z^4 + \frac{1}{z^4}\right) - \left(z^2 + \frac{1}{z^2}\right) + 4. \end{aligned}$$

Then

$$= 2 \cos 6\theta - 2 \cdot 2 \cos 4\theta - 2 \cdot \cos 2\theta + 4$$

$$2^4 \cdot i^4 \sin^4 \theta \cdot 2^2 \cdot \cos^2 \theta = 2[\cos 6\theta - 2 \cos 4\theta - \cos 2\theta + 4]$$

$$32 \cdot \sin^4 \theta \cdot \cos^2 \theta = \cos 6\theta - 2 \cos 4\theta - \cos 2\theta + 4$$

EXERCISE

1. Express in $a + ib$ form and find modulus of

$$(a) \frac{2+6i}{1-i} \quad (b) \frac{1+4i}{4+i} \quad (c) \frac{2-\sqrt{3}i}{1+i} \quad (d) \frac{(2+3i)}{(3-4i)}$$

Ans. (a) $-2 + 4i$, $\sqrt{20}$ (b) $\frac{8+15i}{17}$, 1
 (c) $\frac{1}{2}[2 - \sqrt{3} - i(2 + \sqrt{3})]$, $\frac{7}{2}$ (d) $\frac{-6+17i}{2i}$, $\frac{\sqrt{13}}{5}$

2. Find the modulus and amplitude of
 (a) $\frac{(3-\sqrt{2}i)^2}{1+2i}$ (b) $1 + \sin \alpha + i \cos \alpha$
 (c) $1 - \cos \alpha + i \sin \alpha$ (d) $2 + 2\sqrt{3}i$

Ans. (a) $\frac{11\sqrt{5}}{5}$, $\frac{6\sqrt{2}+14}{12\sqrt{2}-7}$ (b) $\sqrt{2}\sqrt{1 + \sin \alpha}$, $\frac{\pi}{4} - \frac{\alpha}{2}$
 (c) $2 \sin \frac{\alpha}{2}$, $\frac{\pi-\alpha}{2}$ (d) 4 , $\frac{\pi}{3}$

3. Show that $1 + 4i$, $2 + 7i$ and $3 + 10i$ are collinear

Hint: $2 + 7i - (1 + 4i) = 1 + 3i$, $3 + 10i - (1 + 4i) = 2 + 6i$ so $1 + 3i = 2(1 + 3i) = 2 + 6i$

4. Determine the region in complex plane represented by (a) $1 < |z + 2i| \leq 3$ (b) $\operatorname{Re}(z) > 3$
 (c) $\frac{\pi}{6} \leq \operatorname{amp}(z) \leq \frac{\pi}{3}$

Ans. (a) Annulus region between the concentric circles with centre at $(0, 2)$ and radii 1 and 3.
 (b) right open plane to the right of the line $x = 3$.

(c) wedge region in the first quadrant bounded by the rays $\theta = \frac{\pi}{6}$ and $\theta = \frac{\pi}{3}$.

5. Determine the locus given by

$$|z - 1| + |z + 1| = 3$$

Ans. Ellipse with foci at $z = \pm 1$ and major axis 3

6. If $z_1 = 2 + 4i$ and $z_2 = 3 - 5i$. Verify that
 (a) $(z_1 \pm z_2) = \overline{z_1} \pm \overline{z_2}$ (b) $(z_1 z_2) = \overline{z_1} \overline{z_2}$
 (c) $\left(\frac{z_1}{z_2}\right) = \frac{\overline{z_1}}{\overline{z_2}}$

7. If $z_1 = 4 + 3i$ and $z_2 = 2 - 5i$, find
 (a) $z_1 z_2$ (b) $\frac{1}{z_1}$ (c) $\operatorname{Re}(z_1^3)$ (d) $(\operatorname{Re} z_1)^3$
 (e) $z_1 \overline{z_2}$ (f) $\overline{z_1} z_2$ (h) $\overline{z_1} / \overline{z_2}$

Ans. (a) $23 - 14i$ (b) $0.16 - 0.12i$ (c) -44
 (d) 64 (e) $-7 + 26i$ (f) $-7 - 26i$
 (h) $(-7 - 26i)/29$

8. If $z_1 = -2 + 2i$ and $z_2 = 3i$ then find
 (a) $|z_1 z_2|$ (b) $\left|\frac{z_1}{z_2}\right|$
 (c) $\arg z_1 z_2$ (d) $\arg \frac{z_1}{z_2}$

Ans. (a) $6\sqrt{2}$ (b) $\frac{2\sqrt{2}}{3}$ (c) $\frac{-3\pi}{4}$ (d) $\frac{\pi}{4}$

Hint: $z_1 z_2 = -6 - 6i$, $\frac{z_1}{z_2} = \frac{2}{3}(1 + i)$,

$$\arg z_1 = \frac{3\pi}{4}, \arg z_2 = \frac{\pi}{2}$$

9. Verify the triangle inequality for
 (a) $z_1 = 2 + 3i$, $z_2 = 4 - i$ (b) $z_1 = 1 + i$, $z_2 = 7i$

Hint: (a) $|z_1 + z_2| = |6 + 2i| = \sqrt{40} = 6.32$,
 $|z_1| + |z_2| = \sqrt{13} + \sqrt{17} = 7.73$

(b) $|z_1 + z_2| = |1 + 8i| = \sqrt{65} = 8.063$,
 $|z_1| = \sqrt{2}$, $|z_2| = 7$,

$$|z_1| + |z_2| = \sqrt{2} + 7 = 1.414 + 7 = 8.414$$

De Moivre's Theorem

10. Show that $(\cos 4\theta - i \sin 4\theta)^5 \times (\cos 4\theta + i \sin 4\theta)^{-3} \times (\cos 3\theta + i \sin 3\theta)^4 \times (\cos 5\theta + i \sin 5\theta)^4 = 1$

11. Simplify $(1 + \cos \theta + i \sin \theta)^n (1 + \cos \theta - i \sin \theta)^n$

Ans. $2^{n+1} \cdot \cos^n \frac{\theta}{2} \cdot \cos \frac{n\theta}{2}$

Hint: Put $1 + \cos \theta = r \cos \alpha$, $\sin \theta = \sin \alpha$,
 $r = 2 \cos \frac{\theta}{2}$, $\alpha = \frac{\theta}{2}$.

12. If $z = \operatorname{cis} \theta$, show that (a) $z^p + \frac{1}{z^p} = 2 \cos p\theta$
 (b) $z^p - \frac{1}{z^p} = 2i \sin p\theta$ (c) $\frac{z^{2n+1}}{z^{2n-1} + z} = \frac{\cos n\theta}{\cos(n-1)\theta}$.

13. Show that $\cos 3\alpha + \cos 3\beta + \cos 3\gamma = 3 \cos(\alpha + \beta + \gamma)$ and $\sin 3\alpha + \sin 3\beta + \sin 3\gamma = 3 \sin(\alpha + \beta + \gamma)$ if $\sin \alpha + \sin \beta + \sin \gamma = 0$ and $\cos \alpha + \cos \beta + \cos \gamma = 0$

Hint: Put $a = \operatorname{cis} \alpha$, $b = \operatorname{cis} \beta$, $c = \operatorname{cis} \gamma$, $a^3 + b^3 + c^3 = 3abc$

14. Prove that

$$(a) 1 + \cos \theta + \cos 2\theta + \cdots + \cos n\theta = \frac{1}{2} + \frac{\sin(n+\frac{1}{2})\theta}{2 \sin \frac{\theta}{2}}$$

$$(b) \sin \theta + \sin 2\theta + \cdots + \sin n\theta = \frac{1}{2} \cot \frac{\theta}{2} - \frac{\cos(n+\frac{1}{2})\theta}{2 \sin \frac{\theta}{2}}$$

Hint: Use $1 + z + z^2 + \cdots + z^n = \frac{1-z^{n+1}}{1-z}$ when $z \neq 1$.

15. Show that

$$(a) \cos 4\theta = \cos^4 \theta - 6 \cos^2 \theta \cdot \sin^2 \theta + \sin^4 \theta$$

$$(b) \sin 4\theta = 4(\cos^3 \theta \cdot \sin \theta - \cos \theta \cdot \sin^3 \theta)$$

1.32 — HIGHER ENGINEERING MATHEMATICS—I

Hint: Expand $(\text{cis}\theta)^4$ by De Moivre's theorem and binomial expansion.

16. Expand

(a) $128 \cdot \cos^8 \theta$ in a series of cosines of multiples of θ

(b) $512 \cdot \sin^7 \theta \cdot \cos^3 \theta$ in a series of sines of multiples of θ .

Ans. (a) $\cos 8\theta + 8 \cos 6\theta + 28 \cos 4\theta + 56 \cos 2\theta + 35$

(b) $14 \sin 2\theta - 8 \sin 4\theta - 3 \sin 6\theta + 4 \sin 8\theta - \sin 10\theta$

Roots

17. If ω is a complex cube root of unity, show that $1 + \omega + \omega^2 = 0$

Hint: $\omega = -\frac{1}{2} + i\frac{\sqrt{3}}{2}$, $\omega^2 = -\frac{1}{2} - i\frac{\sqrt{3}}{2}$

18. Solve the binomial equation $z^4 = 1$

Ans. $\pm 1, \pm i$

Hint: $1^{1/4} = \text{cis} \frac{0+2k\pi}{4}$, $k = 0, 1, 2, 3$

19. Find all the (a) square (b) cube roots of i

Ans. (a) $\pm \frac{1}{\sqrt{2}}(1 + i)$ (b) $-i, \frac{\pm\sqrt{3}+i}{2}$

Hint: (a) $i^{1/2} = \text{cis} \left(\left(\frac{\pi}{2} + 2k\pi \right) / 2 \right)$, $k = 0, 1$

(b) $i^{1/3} = \text{cis} \left(\left(\frac{\pi}{2} + 2k\pi \right) / 3 \right)$, $k = 0, 1, 2$

20. Solve the binomial equation $z^5 = -32$

Ans. $2\text{cis}((\pi + 2k\pi)/5)$ for $k = 0, 1, 2, 3, 4$.

Hint: -32 in polar form is $32 \cdot \text{cis}\pi$, so $r = 32$, $\theta = \pi$

21. Find all roots of (a) $(-i)^{1/3}$ (b) $8^{1/6}$

Ans. (a) $i, \pm \frac{\sqrt{3}}{2} - \frac{i}{2}$ (b) $\pm\sqrt{2}, (\pm 1 \pm i\sqrt{3})/\sqrt{2}$

Hint: (a) $-i = e^{-i\pi/2}$, $r = 1$, $\theta = -\frac{\pi}{2}$,

$(-i)^{1/3} = \text{cis} \left(\left(-\frac{\pi}{2} + 2k\pi \right) / 3 \right)$, $k = 0, 1, 2, 3$

(b) $8 = 8e^{i0}$, $r = 8$, $\theta = 0$, $8^{1/6} = \text{cis} \left(\frac{0+2k\pi}{6} \right)$, $k = 0, 1, 2, 3, 4, 5$

22. Find the fourth roots of $-8i$

Ans. $8^{1/4} \text{cis} \left(\left(\frac{3\pi}{2} + 2k\pi \right) / 4 \right)$ for $k = 0, 1, 2, 3$

Hint: $-8i = 8\text{cis} \frac{3\pi}{2}$.

23. Find all distinct values of (a) $(-1 - i)^{4/5}$

(b) $((1 + \sqrt{3}i)/2)^{3/4}$

Ans. (a) $2^{2/5} \text{cis} \left(\frac{5\pi+2k\pi}{5} \right)$, $k = 0, 1, 2, 3, 4$

Hint: (a) $-1 - i = \sqrt{2}e^{i5\pi/4}$, $(-1 - i)^4 = 4^{1/5} \text{cis} 5\pi$

(b) $\text{cis}(2k + 1)\frac{\pi}{4}$ for $k = 0, 1, 2, 3$

Hint: (b) $\left(\frac{1}{2} + \frac{\sqrt{3}i}{2} \right)^3 = (\text{cis} \frac{\pi}{3})^3 = \text{cis}\pi$

24. Solve $z^4 - z^3 + z^2 - z + 1 = 0$

Ans. $\text{cis} \frac{\pi}{5}, \text{cis} \frac{3\pi}{5}, \text{cis} \left(\frac{7\pi}{5} \right), \text{cis} \left(\frac{9\pi}{5} \right)$

Hint: $(z + 1)(z^4 - z^3 + z^2 - z + 1) = z^5 + 1 = 0$ whose roots are $\text{cis} \left(\frac{(2k+1)\pi}{5} \right)$ for $k = 0, 1, 2, 3, 4$. Out of these for $k = 2$, $\text{cis}\pi = -1$ is deleted.

25. Find the equation whose roots are $2 \cos \frac{\pi}{7}$, $2 \cos \frac{3\pi}{7}$, $2 \cos \frac{5\pi}{7}$.

Ans. $\omega^3 - \omega^2 - 2\omega + 1 = 0$

Hint: $z = \text{cis}\theta$, $z^7 + 1 = (z + 1)(z^6 - z^5 + z^4 - z^3 + z^2 - z + 1) = 0$

$(-1)^{1/7} = \text{cis} \left(\frac{\pi+2k\pi}{7} \right)$ with $k = 0, 1, 2, 3, 4, 5, 6$, deleting $z = -1$ corresponding to $k = 3$, the six roots of $z^6 - z^5 + z^4 - z^3 + z^2 - z + 1 = 0$ are $z = \text{cis}\theta$, with $\theta = \frac{\pi}{7}, \frac{3\pi}{7}, \frac{5\pi}{7}, \frac{9\pi}{7}, \frac{11\pi}{7}, \frac{13\pi}{7}$. Dividing by z^3 , introducing $\omega = z + \frac{1}{z}$, we have $[\omega^3 - 3\omega] - [\omega^2 - 2] + \omega = 0$.

Chapter 2

Differential Calculus

INTRODUCTION

Calculus is one of the most beautiful intellectual achievements of human being. The mathematical study of change, motion, growth or decay is calculus. One of the most important ideas of differential calculus is derivative which measures the rate of change of a given function. Concept of derivative is very useful in engineering, science, economics, medicine and computer science. In this chapter we study the 300-year old Mitchel Rolle's theorem, Lagrange's mean value theorem which connects the average rate of change of a function over an interval with the instantaneous rate of change of the function at a point within that interval, generalized mean value theorem (Taylor's theorem) which enables to express any differentiable function in power series, namely Taylor's and Maclaurin's series. We also consider the problem of finding curvature, evolutes and envelope of a curve.

Suppose a function $y = f(x) = x^4 + e^{2x} + 3 \sin 4x$ is differentiated w.r.t. x , then we get the first order derivative of y denoted by $y' = f' = 4x^3 + 2e^{2x} + 12 \cos 4x$ which is itself a function of x . Differentiating y' again w.r.t. x , we get the second order derivative, denoted as $y'' = f'' = 12x^2 + 4e^{2x} - 48 \sin 4x$, which is again a function of x . So by differentiating a second order derivative, we get the third order derivative and so on. Thus by differentiating a function $y = f(x)$, n times successively, we get the n th order derivative of y or simply n th derivative of

y denoted by $y^{(n)}(x)$, $f^{(n)}(x)$, $D^n y$, $\frac{d^n y}{dx^n}$ or $y_n(x)$.

Note: The order of the derivative is taken in parentheses so as to avoid confusion with the exponent of a power. The order of the derivative is also denoted sometimes by Roman numerals for example 4th, 5th, 6th order derivatives are denoted by y^{iv} , y^{v} , y^{vi} etc.

2.1 DERIVATION OF n TH DERIVATIVE OF SOME ELEMENTARY FUNCTIONS

Power Function

Consider $y = (ax + b)^m$, where m is any real number. Differentiating y w.r.t. x , successively, we get

$$y_1 = m(ax + b)^{m-1} \cdot a$$

$$y_2 = m(m-1)(ax + b)^{m-2} \cdot a^2$$

$$y_3 = m(m-1)(m-2)(ax + b)^{m-3} \cdot a^3$$

After n differentiations,

$$y_n = m(m-1)(m-2) \cdots (m-(n-1))a^n(ax + b)^{m-n}.$$

Case a: When m is a positive integer, then

$$y_n = \frac{m(m-1)(m-2) \cdots (m-(n-1))(m-n) \cdots 3 \cdot 2 \cdot 1}{(m-n) \cdots 3 \cdot 2 \cdot 1} \times a^n(ax + b)^{m-n}$$

$$y_n = \frac{d^n}{dx^n} \left\{ (ax + b)^m \right\} = \frac{m!}{(m-n)!} a^n(ax + b)^{m-n}.$$

Case b: When $m = n$ is a positive integer

$$y_n = \frac{d^n}{dx^n} \left\{ (ax + b)^n \right\} = \frac{n!}{0!} a^n(ax + b)^0$$

2.2 — HIGHER ENGINEERING MATHEMATICS—II

$$= n!a^n = \text{a constant.}$$

Case c: When $n > m$, then

$$y_n = 0$$

i.e., all the derivatives of order $m + 1, m + 2, m + 3$ etc. are zero.

Case d: When $m = -1$, then

$$y = (ax + b)^{-1} = \frac{1}{ax + b}$$

$$\text{and } y_n = (-1)(-2)(-3) \cdots (-n)a^n \cdot (ax + b)^{-1-n}$$

$$y_n = \frac{d^n}{dx^n} \left\{ \frac{1}{ax + b} \right\} = \frac{(-1)^n \cdot n!a^n}{(ax + b)^{n+1}}$$

Case e: If $y = \ln(ax + b)$, then

$$y_1 = \frac{a}{ax + b}$$

using result of Case (d) and differentiating $(n - 1)$ times

$$y_n = \frac{(-1)^{n-1}(n-1)!a^n}{(ax + b)^n}$$

$$\text{Thus } \frac{d^n}{dx^n} \left\{ \ln(ax + b) \right\} = \frac{(-1)^{n-1}(n-1)!a^n}{(ax + b)^n}.$$

Exponential Function

Consider $y = a^{mx}$.

Differentiating y w.r.t. x , successively, we get

$$y_1 = ma^{mx} \cdot \log_e a$$

$$y_2 = m^2 a^{mx} \cdot (\log_e a)^2$$

$$\text{In general, } y_n = m^n a^{mx} (\log_e a)^n.$$

In particular, when $a = e$

$$y_n = \frac{d^n}{dx^n} \{e^{mx}\} = m^n e^{mx} (\log_e e)^n = m^n e^{mx}.$$

Trigonometric Functions

Case a: Suppose $y = \cos(ax + b)$. Then

$$y_1 = -a \cdot \sin(ax + b) = a \cos \left(ax + b + \frac{\pi}{2} \right)$$

$$y_2 = -a^2 \cdot \cos(ax + b) = a^2 \cos \left(ax + b + 2 \frac{\pi}{2} \right)$$

$$y_3 = +a^3 \cdot \sin(ax + b) = a^3 \cos \left(ax + b + 3 \frac{\pi}{2} \right).$$

Generalizing,

$$y_n = \frac{d^n}{dx^n} \left\{ \cos(ax + b) \right\} = a^n \cos \left(ax + b + n \frac{\pi}{2} \right).$$

In a similar way, we can get

Case b:

$$y_n = \frac{d^n}{dx^n} \left\{ \sin(ax + b) \right\} = a^n \sin \left(ax + b + n \frac{\pi}{2} \right).$$

Product Functions

Case a: Consider $y = e^{ax} \cdot \cos(bx + c)$.

Differentiating,

$$y_1 = ae^{ax} \cos(bx + c) - e^{ax} \cdot b \cdot \sin(bx + c)$$

$$y_1 = e^{ax} \left[a \cdot \cos(bx + c) - b \sin(bx + c) \right].$$

To rewrite this in the form of cos, put

$$a = r \cos \phi, \quad b = r \sin \phi.$$

Then

$$y_1 = e^{ax} \left[r \cos \phi \cdot \cos(bx + c) - r \sin \phi \cdot \sin(bx + c) \right]$$

$$y_1 = re^{ax} \left[\cos(bx + c + \phi) \right].$$

Here $r = \sqrt{a^2 + b^2}$ and $\phi = \tan^{-1} \left(\frac{b}{a} \right)$.

Differentiating y , again w.r.t. x , we get

$$y_2 = rae^{ax} \cos(bx + c + \phi) - re^{ax} \cdot b \cdot \sin(bx + c + \phi).$$

Substituting for a and b ,

$$y_2 = re^{ax} r \cos \phi \cdot \cos(bx + c + \phi) - r \cdot e^{ax} \cdot r \sin \phi \cdot \sin(bx + c + \phi)$$

$$= r^2 e^{ax} \left[\cos \phi \cdot \cos(bx + c + \phi) - \sin \phi \cdot \sin(bx + c + \phi) \right]$$

$$\therefore y_2 = r^2 e^{ax} \left[\cos(bx + c + 2\phi) \right].$$

Observe that differentiation increases, the power of r and angle ϕ . Thus

$$y_3 = r^3 e^{ax} \left[\cos(bx + c + 3\phi) \right].$$

In general,

$$y_n = \frac{d^n}{dx^n} \left\{ e^{ax} \cos(bx + c) \right\} = r^n e^{ax} \cdot \cos(bx + c + n\phi).$$

Case b: In a similar way, we obtain

$$y_n = \frac{d^n}{dx^n} \left\{ e^{ax} \sin(bx + c) \right\} = r^n e^{ax} \cdot \sin(bx + c + n\phi).$$

Case c: When the function $f(x)$ is the product of the powers of sine and cosine functions, then express $f(x)$ as the sum of the sine and cosines of multiples of the independent variable (angles) and use results in *Trigonometric Functions* (mentioned above).

Example:

$$\begin{aligned} \sin^2 x \cdot \cos 3x &= \left(\frac{1 - \cos 2x}{2} \right) \cos 3x \\ &= \frac{1}{2} \cos 3x - \frac{1}{2} \cos 2x \cdot \cos 3x \\ &= \frac{1}{2} \cos 3x - \frac{1}{2} \cdot \frac{1}{2} [\cos 5x + \cos x] \end{aligned}$$

Case d: When the function $f(x)$ is an algebraic rational function then using partial fractions $f(x)$ can be decomposed into real linear factors and apply result *Power Function*. In case, $f(x)$ gets decomposed into complex linear factors, apply *Case (d)* and use DeMoivre's theorem $(\cos x \pm i \sin x)^n = \cos nx \pm i \sin nx$.

Example: $\frac{1}{x^2-5x+6} = \frac{1}{(x-2)(x-3)} = \frac{1}{x-3} - \frac{1}{x-2}.$

Example: $\frac{x}{x^2+a^2} = \frac{1}{2} \left[\frac{1}{x-ai} + \frac{1}{x+ai} \right].$

Higher Derivatives of Sum

We have the obvious formulas

$$\begin{aligned} \frac{d^n}{dx^n} \{u(x) + v(x)\} &= (u + v)^{(n)} = \frac{d^n u}{dx^n} + \frac{d^n v}{dx^n} \\ &= u^{(n)} + v^{(n)} \\ \text{and } \frac{d^n}{dx^n} \{cu(x)\} &= (cu)^{(n)} = c \frac{d^n u}{dx^n} = cu^{(n)} \end{aligned}$$

where c is any arbitrary constant.

WORKED OUT EXAMPLES

Example 1: Find the fifth derivative of $x^3 \ln x$.

Solution: Let $y = x^3 \ln x$ so $y_1 = 3x^2 \ln x + x^3 \cdot \frac{1}{x}$;
 $y_2 = 6x \ln x + 3x^2 \cdot \frac{1}{x} + 2x$; $y_3 = 6 \ln x + 6 \cdot x \cdot \frac{1}{x} + 3 + 2$;
 $y_4 = \frac{6}{x} + 0$; $y_5 = -\frac{6}{x^2}.$

Example 2: If $y = \frac{ax+b}{cx+d}$ prove that $2y_1 y_3 = 3y_2^2$.

Solution:

$$\begin{aligned} y_1 &= \frac{(cx+d)a - (ax+b)c}{(cx+d)^2} = \frac{ad-bc}{(cx+d)^2} \\ y_2 &= \frac{-2c(ad-bc)}{(cx+d)^3} \\ y_3 &= \frac{6c^2(ad-bc)}{(cx+d)^4}. \end{aligned}$$

Now

$$\begin{aligned} 2y_1 y_3 &= 2 \cdot \frac{(ad-bc)}{(cx+d)^2} \cdot \frac{6c^2(ad-bc)}{(cx+d)^4} \\ &= \frac{12c^2(ad-bc)^2}{(cx+d)^6} = 3 \cdot \left[\frac{-2c(ad-bc)}{(cx+d)^3} \right]^2 = 3y_2^2. \end{aligned}$$

Example 3: If $y = \sinh \left[m \log \left\{ x + \sqrt{x^2 + 1} \right\} \right]$, prove that $(x^2 + 1)y_2 + xy_1 = m^3 y$.

Solution:

$$\begin{aligned} y_1 &= \cosh \left[m \ln \left\{ x + \sqrt{x^2 + 1} \right\} \right] \cdot m \times \\ &\quad \times \frac{1}{\left(x + \sqrt{x^2 + 1} \right)} \left[1 + \frac{1}{2} \frac{2x}{\sqrt{x^2 + 1}} \right] \\ y_1 &= \frac{m}{\sqrt{x^2 + 1}} \cdot \cosh \left[m \ln \left\{ x + \sqrt{x^2 + 1} \right\} \right]. \end{aligned}$$

Squaring on both sides

$$(1 + x^2)y_1^2 = m^2 \cosh^2 \left[m \ln \left\{ x + \sqrt{x^2 + 1} \right\} \right].$$

Differentiating

$$(1 + x^2)2y_1 y_2 + 2xy_1^2 = m^2 \cdot 2 \cdot \cosh \left[m \ln \left\{ x + \sqrt{x^2 + 1} \right\} \right] \times$$

2.4 — HIGHER ENGINEERING MATHEMATICS—II

$$\begin{aligned} & \times \sinh \left[m \ln \left\{ x + \sqrt{x^2 + 1} \right\} \right] \cdot m \times \\ & \times \frac{1}{x + \sqrt{x^2 + 1}} \cdot \left[1 + \frac{1}{2} \frac{2x}{\sqrt{x^2 + 1}} \right] \end{aligned}$$

$$\therefore (1 + x^2)2y_1y_2 + 2xy_1^2 = 2m^3y_1 \cdot y$$

$$\text{or } (1 + x^2)y_2 + xy_1 = m^3y.$$

Example 4: If $x = a \left\{ \cos t + \frac{1}{2} \ln \tan^2 \left(\frac{t}{2} \right) \right\}$ and $y = a \sin t$, then find $\frac{d^2y}{dx^2}$.

Solution: $\frac{dy}{dt} = a \cos t$

$$\frac{dx}{dt} = -a \sin t + \frac{1}{2} a \frac{1}{\tan^2 \frac{t}{2}} \cdot 2 \tan \left(\frac{t}{2} \right) \cdot \frac{1}{2} \sec^2 \left(\frac{t}{2} \right)$$

$$= a \left[-\sin t + \frac{1}{2 \sin \left(\frac{t}{2} \right) \cdot \cos \left(\frac{t}{2} \right)} \right]$$

$$= a \left[-\sin t + \frac{1}{\sin t} \right]$$

$$\frac{dx}{dt} = \frac{a(1 - \sin^2 t)}{\sin t} = \frac{a \cos^2 t}{\sin t}.$$

$$\text{So } \frac{dy}{dx} = \frac{\left(\frac{dy}{dt} \right)}{\left(\frac{dx}{dt} \right)} = a \cos t \cdot \frac{\sin t}{a \cos^2 t} = \tan t$$

$$\frac{d^2y}{dx^2} = \frac{d}{dx} \left(\frac{dy}{dx} \right) = \frac{d}{dx} (\tan t) = \frac{d}{dt} (\tan t) \frac{dt}{dx}$$

$$\frac{d^2y}{dx^2} = \sec^2 t \cdot \frac{\sin t}{a \cos^2 t} = \frac{\sin t}{a \cos^4 t}.$$

Example 5: Find $\frac{d^2y}{dx^2}$ if $x^3 + y^3 = 3axy$.

Solution: Differentiating the implicit equation

$$3x^2 + 3y^2y_1 = 3ay + 3axy_1$$

$$(y^2 - ax)y_1 = (ay - x^2).$$

Differentiating

$$(2yy_1 - a)y_1 + (y^2 - ax)y_2 = ay_1 - 2x.$$

Substituting y_1

$$2y \left(\frac{ay - x^2}{y^2 - ax} \right)^2 - 2a \left(\frac{ay - x^2}{y^2 - ax} \right) + (y^2 - ax)y_2 = -2x$$

$$y(ay - x^2)^2 - a(ay - x^2)(y^2 - ax) + \frac{y^2}{2}(y^2 - ax)^3$$

$$\begin{aligned} & = -x(y^2 - ax)^2 \\ & (a^2y^3 + x^4y - 2ax^2y^2) - a(ay^3 - a^2xy - x^2y^2 + ax^3) \\ & + \frac{y^2}{2}(y^2 - ax)^3 = -xy^4 - a^2x^3 + 2ax^2y^2 \end{aligned}$$

or

$$-3a x^2y^2 + xy(x^3 + y^3) + a^3xy + \frac{y^2}{2}(y^2 - ax)^3 = 0.$$

Since $x^3 + y^3 = 3axy$, we have

$$y_2 = \frac{-2a^3xy}{(y^2 - ax)^3}$$

Example 6: Show that $D^{2n}(x^2 - 1)^n = (2n)!$

Solution: In the binomial series expansion of $(x^2 - 1)^n$, the highest power of x is x^{2n} . All the remaining terms will be degree less than $2n$. So when $(x^2 - 1)^n$ is differentiated $2n$ times, derivatives of all the terms except x^{2n} , become zero. Now

$$\begin{aligned} \frac{d^{2n}}{dx^{2n}} \{x^{2n}\} &= 2n \cdot (2n - 1)(2n - 2) \cdots (2n - (2n - 1)) \\ &= 2n(2n - 1)(2n - 2) \cdots 3 \cdot 2 \cdot 1 = (2n)! \end{aligned}$$

Example 7: If $y = \sin^3 x$, find y_n .

Solution:

$$y = \sin^3 x = \sin x \cdot \sin^2 x$$

$$= \sin x \left(\frac{1 - \cos 2x}{2} \right)$$

$$= \frac{1}{2} \sin x - \frac{1}{2} \cdot \sin x \cdot \cos 2x$$

$$= \frac{1}{2} \sin x - \frac{1}{4} \sin 3x + \frac{1}{4} \sin x$$

$$y = \frac{3}{4} \sin x - \frac{1}{4} \sin 3x$$

$$y_n = \frac{3}{4} \sin \left(x + n \frac{\pi}{2} \right) - \frac{1}{4} \cdot 3^n \cdot \sin \left(3x + \frac{n\pi}{2} \right).$$

Example 8: Find the n th derivative of

$$y = e^{2x} \cdot \cos x \cdot \sin^2 2x.$$

Solution: Rewriting

$$\cos x \cdot \sin^2 2x = \cos x \cdot \left(\frac{1 - \cos 4x}{2} \right)$$

$$\begin{aligned}
 &= \frac{1}{2} \cos x - \frac{1}{2} \cos x \cdot \cos 4x \\
 &= \frac{1}{2} \cos x - \frac{1}{4} \cos 5x - \frac{1}{4} \cos 3x.
 \end{aligned}$$

So $y = e^{2x} \left[\frac{1}{2} \cos x - \frac{1}{4} \cos 5x - \frac{1}{4} \cos 3x \right]$

$$\begin{aligned}
 \therefore y_n &= \frac{1}{2} \frac{d^n}{dx^n} e^{2x} \cos x - \frac{1}{4} \frac{d^n}{dx^n} e^{2x} \cos x - \\
 &\quad - \frac{1}{4} \frac{d^n}{dx^n} e^{2x} \cos 3x
 \end{aligned}$$

when $y = e^{ax} \cos(bx + c)$, then

$$y_n = r^n e^{ax} \cos(bx + c + n\phi)$$

where $r = \sqrt{a^2 + b^2}$, $\phi = \tan^{-1} \left(\frac{b}{a} \right)$.

So $y_n = \frac{1}{2} (\sqrt{5})^n e^{2x} \cdot \cos \left(x + n \tan^{-1} \frac{1}{2} \right)$

$$\begin{aligned}
 &\quad - \frac{1}{4} (\sqrt{29})^n e^{2x} \cdot \cos \left(5x + n \tan^{-1} \frac{5}{2} \right) \\
 &\quad - \frac{1}{4} (\sqrt{13})^3 e^{2x} \cdot \cos \left(3x + n \tan^{-1} \frac{3}{2} \right).
 \end{aligned}$$

Example 9: If $y = \frac{x+1}{x^2-4}$, find y_n .

Solution:

$$\begin{aligned}
 y &= \frac{x+1}{x^2-4} = \frac{x+1}{(x-2)(x+2)} = \frac{3}{4} \cdot \frac{1}{x-2} + \frac{1}{4} \cdot \frac{1}{x+2} \\
 y_n &= \frac{3}{4} \cdot \frac{(-1)^n n!}{(x-2)^{n+1}} + \frac{1}{4} \cdot \frac{(-1)^n n!}{(x+2)^{n+1}}
 \end{aligned}$$

Example 10: Determine $y_n(0)$ if $y = \frac{x^3}{x^2-1}$.

Solution:

$$\begin{aligned}
 y &= \frac{x^3}{x^2-1} = \frac{x^3-1+1}{x^2-1} = \frac{(x-1)(x^2+x+1)}{x^2-1} + \frac{1}{x^2-1} \\
 &= \frac{x^2+x+1}{x+1} + \frac{1}{(x-1)(x+1)} \\
 &= \frac{x^2-1+1}{x+1} + 1 + \frac{1}{(x-1)(x+1)} \\
 y &= x + \frac{1}{x+1} + \frac{1}{2} \left[\frac{1}{x-1} - \frac{1}{x+1} \right]
 \end{aligned}$$

$$y_n = \frac{d^n}{dx^n} \left\{ \frac{x^3}{x^2-1} \right\} = 0 + \frac{1}{2} \cdot \frac{(-1)^n n!}{(x+1)^{n+1}} + \frac{1}{2} \cdot \frac{(-1)^n \cdot n!}{(x-1)^{n+1}}.$$

At $x = 0$, $y_n(0) = \frac{(-1)^n \cdot n!}{2} \left[\frac{1}{1^{n+1}} + \frac{1}{(-1)^{n+1}} \right]$

when n is even, $y_n(0) = \frac{(-1)^n n!}{2} [1 - 1] = 0$

when n is odd, $y_n(0) = \frac{(-1)^n n!}{2} \cdot 2 = -n!$.

Example 11: If $y = \tan^{-1} \frac{2x}{1-x^2}$, find y_n . (UPTU 2002)

Solution: Differentiating y w.r.t. x ,

$$y_1 = \frac{d}{dx} \tan^{-1} \frac{2x}{1-x^2} = \frac{1}{1 + \left(\frac{2x}{1-x^2} \right)^2} \cdot \frac{d}{dx} \left(\frac{2x}{1-x^2} \right)$$

$$\begin{aligned}
 y_1 &= \frac{(1-x^2)^2}{(1+x^4-2x^2+4x^2)} \cdot \frac{(1-x^2)2 - 2x(-2x)}{(1-x^2)^2} \\
 &= \frac{2(1+x^2)}{(1+x^2)^2} = \frac{2}{(1+x^2)}.
 \end{aligned}$$

We know that

$$y_n = \frac{d^n}{dx^n} \left\{ \frac{1}{x^2+a^2} \right\} = \frac{(-1)^n n!}{a^{n+2}} \sin(n+1)\theta \cdot \sin^{n+1} \theta$$

where $\theta = \cot^{-1} \left(\frac{x}{a} \right) = \tan^{-1} \left(\frac{a}{x} \right)$.

Now differentiating y_1 , $(n-1)$ times

$$\begin{aligned}
 y_n &= \frac{d^{n-1}}{dx^{n-1}} y_1 = \frac{d^{n-1}}{dx^{n-1}} \left\{ \frac{2}{1+x^2} \right\} \\
 &= 2(-1)^{n-1} (n-1)! \sin n\theta \cdot \sin^n \theta
 \end{aligned}$$

where $\theta = \tan^{-1} \frac{1}{x} = \cot^{-1} x$.

Example 12: Find the n th derivative of

$$y = \frac{x}{x^2+x+1}.$$

Solution: The roots of $x^2+x+1=0$ are $z_{1,2} = \frac{-1 \pm \sqrt{1-4}}{2}$

i.e., $z_1 = \frac{-1 + \sqrt{3}i}{2}$, $z_2 = \frac{-1 - \sqrt{3}i}{2}$.

In terms of linear complex factors,

$$y = \frac{x}{(x-z_1)(x-z_2)} = \frac{A}{x-z_1} + \frac{B}{x-z_2}$$

2.6 — HIGHER ENGINEERING MATHEMATICS—II

$$x = A(x - z_2) + B(x - z_1)$$

$$\text{when } x = z_1, \quad z_1 = A(z_1 - z_2) \quad \text{or} \quad A = \frac{z_1}{z_1 - z_2}$$

$$\text{when } x = z_2, \quad z_2 = B(z_2 - z_1) \quad \text{or} \quad B = \frac{z_2}{z_2 - z_1}.$$

Here $z_1 - z_2 = \sqrt{3}i = ai$ where $a = \sqrt{3}$. So

$$y = \frac{1}{z_1 - z_2} \left[\frac{z_1}{x - z_1} - \frac{z_2}{x - z_2} \right].$$

To find y_n , apply *Power Function Case (d)*, then

$$y_n = \frac{z_1}{z_1 - z_2} \cdot \frac{(-1)^n \cdot n! \cdot 1^n}{(x - z_1)^{n+1}} - \frac{z_2}{z_1 - z_2} \cdot \frac{(-1)^n n! 1^n}{(x - z_2)^{n+1}} \quad (1)$$

$$\text{Now } x - z_1 = x - \left(\frac{-1 + \sqrt{3}i}{2} \right) = \frac{2x + 1 - ai}{2}.$$

$$\text{Put } \frac{2x+1}{2} = r \cos \theta, \quad \frac{a}{2} = r \sin \theta, \text{ then}$$

$$r^2 = \left(\frac{2x+1}{2} \right)^2 + \frac{a^2}{4} = \frac{4x^2 + 1 + 4x}{4} + \frac{3}{4} = x^2 + x + 1.$$

$$\text{So } r = \sqrt{x^2 + x + 1} \quad \text{and} \quad \theta = \tan^{-1} \left(\frac{\sqrt{3}}{2x+1} \right)$$

By De Moivre's theorem

$$\begin{aligned} (x - z_1)^{n+1} &= (r \cos \theta - i r \sin \theta)^{n+1} \\ &= (r e^{-i\theta})^{n+1} = r^{n+1} e^{-i(n+1)\theta} \end{aligned} \quad (2)$$

Similarly,

$$\begin{aligned} (x + z_2)^{n+1} &= (r \cos \theta + i r \sin \theta)^{n+1} \\ &= (r e^{i\theta})^{n+1} = r^{n+1} e^{i(n+1)\theta} \end{aligned} \quad (3)$$

Also

$$\frac{z_1}{z_1 - z_2} = \frac{-1 + \sqrt{3}i}{2} \cdot \frac{1}{\sqrt{3}i} = \frac{3 + \sqrt{3}i}{6} \quad (4)$$

and

$$\frac{z_2}{z_1 - z_2} = \frac{-1 - \sqrt{3}i}{2} \cdot \frac{1}{\sqrt{3}i} = \frac{-3 + \sqrt{3}i}{6} \quad (5)$$

Substituting (2), (3), (4), (5) in (1), we get

$$\begin{aligned} y_n &= \frac{(-1)^n \cdot n!}{r^{n+1}} \cdot \frac{1}{6} \left[(3 + \sqrt{3}i) e^{+i(n+1)\theta} - (-3 + \sqrt{3}i) e^{-i(n+1)\theta} \right] \\ &= \frac{(-1)^n \cdot n!}{r^{n+1}} \cdot \frac{1}{6} \left[(3 + \sqrt{3}i) \{ \cos(n+1)\theta + i \sin(n+1)\theta \} \right. \\ &\quad \left. + (3 - \sqrt{3}i) \{ \cos(n+1)\theta - i \sin(n+1)\theta \} \right] \\ &= \frac{(-1)^n n!}{r^{n+1}} \cdot \frac{1}{6} \left[6 \cos(n+1)\theta - 2\sqrt{3} \sin(n+1)\theta \right] \end{aligned}$$

$$y_n = \frac{(-1)^n \cdot n!}{r^{n+1}} \cdot \left[\cos(n+1)\theta - \frac{1}{\sqrt{3}} \sin(n+1)\theta \right].$$

$$\text{where } r = \sqrt{x^2 + x + 1} \quad \text{and} \quad \theta = \tan^{-1} \left(\frac{\sqrt{3}}{2x+1} \right).$$

EXERCISE

Find the derivatives of y of indicated order (1 to 5).

$$1. \quad y = \left(\frac{1}{x} \right)^x, \quad y_{2(1)}. \quad \text{Ans. } 0$$

$$2. \quad y = 3x^8, \quad y^{(8)}. \quad \text{Ans. } y^{(8)} = 3 \cdot 8!$$

$$3. \quad y = 2\sqrt{x}, \quad y^{(4)}. \quad \text{Ans. } y^{(4)} = -\frac{15}{8\sqrt{x}^7}$$

$$4. \quad y = ax^5 + bx^4 + cx^3 + dx^2 + ex + f, \quad y^{(6)}.$$

$$\text{Ans. } y^{(6)} = 0$$

$$5. \quad y = \tan x, \quad y''.$$

$$\text{Ans. } y''' = 6 \sec^4 x - 4 \sec^2 x$$

$$6. \quad \text{If } y = e^x \sin x, \text{ prove that } y'' - 2y' + 2y = 0.$$

$$7. \quad \text{If } p^2 = a^2 \cos^2 \theta + b^2 \sin^2 \theta, \text{ prove that}$$

$$p + \frac{d^2 p}{d\theta^2} = \frac{a^2 b^2}{p^3}.$$

$$8. \quad \text{Show that } y'' + \tan y \cdot (y')^2 = 0 \text{ when } y = \tan^{-1}(\sinh x).$$

$$9. \quad \text{If } b^2 x^2 + a^2 y^2 = a^2 b^2, \text{ then find } y_2 \text{ and } y_3.$$

$$\text{Ans. } y_2 = -\frac{b^4}{a^2 y^3}, \quad y_3 = -\frac{3b^6 x}{a^4 y^5}$$

$$10. \quad \text{If } \rho = \tan(\phi + \rho), \text{ find } \frac{d^3 \rho}{d\phi^3}.$$

$$\text{Ans. } -\frac{2(5+8\rho^2+3\rho^4)}{\rho^8}$$

$$11. \quad \text{Find } y_2 \text{ when } x = a(t - \sin t), y = a(1 - \cos t).$$

$$\text{Ans. } \frac{d^2 y}{dx^2} = -\frac{1}{4a \sin^4 \left(\frac{t}{2} \right)}$$

$$12. \quad \text{If } x = a \cos t, y = a \sin t, \text{ find } \frac{d^3 y}{dx^3}.$$

$$\text{Ans. } -\frac{3 \cos t}{a^2 \sin^5 t}$$

$$13. \quad \text{Find } y_{2n} \text{ and } y_{2n+1} \text{ where } y = \sinh x.$$

$$\text{Ans. } \frac{d^{2n}}{dx^{2n}}(\sinh x) = \sinh x, \quad \frac{d^{2n+1}}{dx^{2n+1}}(\sinh x) = \cosh x$$

$$14. \quad \text{Find } y_n \text{ where (a) } y = \frac{1-x}{1+x}; \text{ (b) } y = e^x x; \text{ (c) } y = x \sin x.$$

Ans. (a) $2(-1)^n \cdot \frac{n!}{(1+x)^{n+1}}$; (b) $e^x(x+n)$;
 (c) $x \sin\left(x + n\frac{\pi}{2}\right) - n \cos\left(x + n\frac{\pi}{2}\right)$.

15. If $y = \cos^4 x$, find y_n .

Hint: $y = \cos^4 x = \left(\frac{1+\cos 2x}{2}\right)^2 = \frac{3}{8} + \frac{1}{2} \cos 2x + \frac{1}{8} \cos 4x$.

Ans. $\frac{1}{2} 2^n \cos\left(2x + n\frac{\pi}{2}\right) + \frac{1}{8} 4^n \cos\left(4x + n\frac{\pi}{2}\right)$

16. Find n th derivative of $y = e^{ax} \cos^2 x \cdot \sin x$.

Hint: $\cos^2 x \cdot \sin x = \frac{1+\cos 2x}{2} \sin x = \frac{1}{4} \sin x + \frac{1}{4} \sin 3x$.

Ans. $\frac{1}{4}(a^2 + 1)^{\frac{n}{2}} e^{ax} \cdot \sin\left(x + n \tan^{-1} \frac{1}{a}\right) + \frac{1}{4}(a^2 + 9)^{\frac{n}{2}} e^{ax} \cdot \sin\left(3x + n \tan^{-1} \frac{3}{a}\right)$

17. If $y = \cos x \cdot \cos 2x \cdot \cos 3x$ find y_n .

Hint: $\cos x \cdot \cos 2x \cdot \cos 3x = \frac{1}{4} [\cos 6x + \cos 4x + \cos 2x + 1]$.

Ans. $\frac{1}{4} [6^n \cos\left(6x + n\frac{\pi}{2}\right) + 4^n \cos\left(4x + n\frac{\pi}{2}\right) + 2^n \cos\left(2x + n\frac{\pi}{2}\right)]$.

18. Determine y_n if $y = \frac{x^2}{(x-1)^2(x+2)}$.

Hint: $\frac{x^2}{(x-1)^2(x+2)} = \frac{5}{9} \frac{1}{x-1} + \frac{1}{3} \frac{1}{(x-1)^2} + \frac{4}{9} \frac{1}{x+2}$.

Ans. $\frac{(-1)^n n!}{9} \left\{ \frac{5}{(x-1)^{n+1}} + \frac{3}{(x-1)^{n+2}} + \frac{4}{(x+2)^{n+1}} \right\}$

19. Calculate y_n where $y = \frac{x}{x^2+a^2}$.

Hint: $\frac{x}{x^2+a^2} = \frac{1}{2} \left[\frac{1}{(x-ai)} + \frac{1}{x+ai} \right]$, use De Moivre's theorem.

Ans. $\frac{(-1)^n \cdot n!}{r^{n+1}} \cos(n+1)\theta$, $r = \sqrt{x^2+a^2}$,
 $\theta = \tan^{-1}\left(\frac{a}{x}\right)$.

20. If $y = \frac{1}{x^2+x+1}$, then find y_n .

Ans. $\frac{2(-1)^n \cdot n!}{\sqrt{3} r^{n+1}} \sin(n+1)\theta$ where $r = \sqrt{x^2+x+1}$,
 and $\theta = \cot^{-1}\left(\frac{2x+1}{\sqrt{3}}\right)$.

21. Find the n th derivative of (a) $y = \tan^{-1}\left(\frac{1+x}{1-x}\right)$;
 (b) $y = \sin^{-1}\left(\frac{2x}{1+x^2}\right)$.

Ans. (a) $(-1)^{n-1} \cdot (n-1)! \sin^n \theta \cdot \sin n\theta$ where $\theta = \cot^{-1} x$; (b) same as (a).

2.2 LEIBNITZ'S THEOREM (RULE or FORMULA)

Let $u(x)$ and $v(x)$ be two functions of x having derivatives of n th order. Then the n th derivative of the product of these two functions is

$$\frac{d^n}{dx^n} \{u(x)v(x)\} = (uv)_n = u_n v_0 + n c_1 u_{n-1} v_1 + n c_2 u_{n-2} v_2 + \cdots + n c_r u_{n-r} v_r + \cdots + n c_n u_0 v_n.$$

Proof by mathematical induction:

By direct differentiation, we have

$$\frac{d}{dx}(uv) = (uv)_1 = \frac{du}{dx}v + u\frac{dv}{dx} = u_1 v_0 + u_0 v_1$$

$$\frac{d^2}{dx^2}(uv) = (uv)_2 = u_2 v_0 + u_1 v_1 + u_1 v_1 + u_0 v_2 = u_2 v_0 + 2u_1 v_1 + u_0 v_2.$$

Here the subscripts indicate the orders of derivative and zero indices in the end terms indicate the functions themselves (i.e., derivatives of zero order). Thus

$$(uv)_3 = u_3 v_0 + u_2 v_1 + 2u_2 v_1 + 2u_1 v_2 + u_1 v_2 + u_0 v_3 = u_3 v_0 + 3u_2 v_1 + 3u_1 v_2 + u_0 v_3.$$

Similarly,

$$(uv)_4 = u_4 v_0 + 4u_3 v_1 + 6u_2 v_2 + 4u_1 v_3 + u_0 v_4.$$

Assume that the Leibnitz's theorem is valid for k . Then

$$(uv)_k = u_k v_0 + k c_1 u_{k-1} v_1 + k c_2 u_{k-2} v_2 + \cdots + k c_{r-1} u_{k-r+1} v_{r-1} + k c_r u_{k-r} v_r + \cdots + k c_k u_0 v_k.$$

Differentiating the above both sides

$$(uv)_{k+1} = u_{k+1} v_0 + (u_k v_1 + k c_1 u_{k-1} v_2) + (k c_1 u_{k-1} v_2 + k c_2 u_{k-2} v_3) + \cdots + k c_{r-1} u_{k-r+1} v_r + (k c_r u_{k-r} v_{r+1} + k c_{r+1} u_{k-r+1} v_{r+1}) + \cdots + k c_k u_0 v_{k+1}.$$

We know that

$$k c_{r-1} + k c_r = (k+1) c_r, \\ k c_k = (k+1) c_{(k+1)} = 1 \\ 1 + k c_1 = 1 + k = (k+1) c_1.$$

2.8 — HIGHER ENGINEERING MATHEMATICS—II

Therefore

$$\begin{aligned}(uv)_{k+1} &= u_{k+1}v_0 + (k+1)c_1u_kv_1 + (k+1)c_2u_{k-1}v_2 \\ &\quad + \cdots + (k+1)c_ru_{k-r+1}v_r \\ &\quad + \cdots + (k+1)c(k+1)u_0v_{k+1}\end{aligned}$$

i.e., theorem is valid for $k+1$ also.

Hence by mathematical induction the result is valid for any n .

Note: The Leibnitz's rule (or formula) is obtained by expanding $(u+v)^n$ by the binomial theorem and in the expansion obtained the exponents of the powers of u and v are replaced by (subscripts) indices that are the orders of the derivatives.

WORKED OUT EXAMPLES

Example 1: Find the n th derivative of $y = x^2 \sin x$ at $x = 0$.

Solution: $y = x^2 \sin x = \sin x \cdot x^2 = u(x)v(x)$.
Applying Leibnitz's rule with $u = \sin x$, $v = x^2$

$$\begin{aligned}y_n &= \frac{d^n}{dx^n} \sin x \cdot x^2 + n c_1 \frac{d^{n-1}}{dx^{n-1}} (\sin x) \cdot 2x \\ &\quad + n c_2 \cdot \frac{d^{n-2}}{dx^{n-2}} (\sin x) \cdot 2 + 0.\end{aligned}$$

We know that

$$\begin{aligned}\frac{d^n}{dx^n} \{\sin(ax+b)\} &= a^n \sin \left(ax+b + \frac{n\pi}{2} \right) \\ y_n &= x^2 \cdot \sin \left(x + \frac{n\pi}{2} \right) + 2nx \cdot \sin \left(x + \frac{n\pi}{2} - \frac{\pi}{2} \right) \\ &\quad + n(n-1) \sin \left(x + \frac{n\pi}{2} - \pi \right) \\ y_n &= (x^2 - n^2 + n) \sin \left(x + \frac{n\pi}{2} \right) - 2nx \cdot \cos \left(x + \frac{n\pi}{2} \right) \\ y_n(\text{at } x=0) &= (n - n^2) \sin \left(\frac{n\pi}{2} \right).\end{aligned}$$

Example 2: Determine the n th derivative of $y = e^x \ln x$.

Solution: Applying Leibnitz's rule

$$\begin{aligned}y_n(e^x)_n \cdot \ln x + n c_1 (e^x)_{n-1} (\ln x)_1 \\ + n c_2 (e^x)_{n-2} (\ln x)_2 + \cdots + n c_n (e^x) (\ln x)_n.\end{aligned}$$

$$\text{Since } \frac{d^n}{dx^n} \ln(ax+b) = \frac{(-1)^{n-1} (n-1)! a^n}{(ax+b)^n}$$

$$\text{and } \frac{d^n}{dx^n} e^{mx} = m^n e^{mx}$$

$$\begin{aligned}y_n &= e^x \left[\ln x + n c_1 \frac{1}{x} - n c_2 x^{-2} + 2! n c_3 x^{-3} + \cdots \right. \\ &\quad \left. + (-1)^{n-1} (n-1)! n c_n x^{-n} \right].\end{aligned}$$

Example 3: If $y = a \cos(\ln x) + b \sin(\ln x)$, prove that $x^2 y_{n+2} + (2n+1)x y_{n+1} + (n^2+1)y_n = 0$.

Solution: Differentiating y w.r.t. x ,

$$y_1 = -a \cdot \sin(\ln x) \cdot \left(\frac{1}{x} \right) + b \cdot \cos(\ln x) \cdot \frac{1}{x}$$

$$x y_1 = -a \sin(\ln x) + b \cos(\ln x).$$

Differentiating

$$x y_2 + y_1 = -a \cdot \cos(\ln x) \cdot \frac{1}{x} - b \sin(\ln x) \cdot \frac{1}{x}$$

$$x^2 y_2 + x y_1 = -[a \cos(\ln x) + b \sin(\ln x)] = -y$$

$$\text{or } x^2 y_2 + x y_1 + y = 0.$$

Differentiating n times using Leibnitz's rule, we get

$$\begin{aligned}&[x^2 y_{n+2} + n c_1 \cdot 2x \cdot y_{n+1} + n c_2 \cdot 2 \cdot y_n] + \\ &+ [x y_{n+1} + n c_1 \cdot 1 \cdot y_n] + y_n = 0.\end{aligned}$$

Rewriting

$$x^2 y_{n+2} + [2nx + x] y_{n+1} + [n(n-1) + n + 1] y_n = 0.$$

Example 4: Find the n th derivative of $y = x^{n-1} \cdot \ln x$ at $x = \frac{1}{2}$.

Solution: Differentiating

$$y_1 = (n-1)x^{n-2} \cdot \ln x + x^{n-1} \cdot \frac{1}{x}$$

$$x y_1 = (n-1)x^{n-1} \ln x + x^{n-1}$$

$$x y_1 = (n-1)y + x^{n-1}.$$

Differentiating $(n-1)$ times using Leibnitz's rule

$$[x y_n + (n-1)c_1 \cdot 1 \cdot y_{n-1}] = (n-1)y_{n-1} + (n-1)!$$

$$\text{since } \frac{d^n(ax+b)^m}{dx^n} = \frac{m!}{(m-n)!} a^n (ax+b)^{m-n}$$

or $xy_n = (n-1)!$ i.e., $y_n = \frac{(n-1)!}{x}$
 at $x = \frac{1}{2}$, $y_n\left(\frac{1}{2}\right) = 2(n-1)!$.

Example 5: Determine $y_n(0)$ where $y = e^{m \cdot \cos^{-1} x}$.

Solution: Differentiating y w.r.t. x ,

$$y_1 = e^{m \cdot \cos^{-1} x} \cdot m \cdot \left(\frac{-1}{\sqrt{1-x^2}} \right) = -\frac{m}{\sqrt{1-x^2}} \cdot y.$$

Squaring on both sides

$$(1-x^2)y_1^2 = m^2 y^2.$$

Differentiating again

$$(1-x^2)2y_1y_2 - 2xy_1^2 = m^2 \cdot 2yy_1$$

$$\text{or } (1-x^2)y_2 - xy_1 = m^2 y.$$

Using Leibnitz's rule, differentiate both sides n times

$$\begin{aligned} & \left[(1-x^2)y_{n+2} + n_{c_1}(-2x)y_{n+1} + n_{c_2}(-2)y_n \right] - \\ & - [xy_{n+1} + n_{c_1} \cdot 1 \cdot y_n] = m^2 y_n \end{aligned}$$

or

$$(1-x^2)y_{n+2} - (2n+1)xy_{n+1} - (n^2 + m^2)y_n = 0.$$

Put $x = 0$, then

$$y_{n+2}(0) = (n^2 + m^2)y_n(0).$$

$$\text{At } x = 0, \quad y(0) = e^{\frac{m\pi}{2}}$$

$$y_1(0) = -me^{\frac{m\pi}{2}}$$

$$\text{For } n = 0, \quad y_2(0) = (0^2 + m^2)y_0(0) = m^2 e^{\frac{m\pi}{2}}$$

$$\begin{aligned} \text{For } n = 1, \quad y_3(0) &= (1^2 + m^2)y_1(0) \\ &= (1^2 + m^2)(-me^{\frac{m\pi}{2}}) \end{aligned}$$

$$\begin{aligned} \text{For } n = 2, \quad y_4(0) &= (2^2 + m^2)y_2(0) \\ &= m^2(2^2 + m^2)e^{\frac{m\pi}{2}} \end{aligned}$$

$$\begin{aligned} \text{For } n = 3, \quad y_5(0) &= (3^2 + m^2)y_3(0) \\ &= -m(1^2 + m^2)(3^2 + m^2)e^{\frac{m\pi}{2}} \end{aligned}$$

$$\begin{aligned} \text{In general, } y_{2n}(0) &= m^2(2^2 + m^2)(4^2 + m^2) \cdots \times \\ &\times \left((2n-2)^2 + m^2 \right) \cdot e^{\frac{m\pi}{2}} \\ y_{2n+1}(0) &= -m(1^2 + m^2)(3^2 + m^2) \cdots \times \\ &\times \left((2n-1)^2 + m^2 \right) e^{\frac{m\pi}{2}}. \end{aligned}$$

Example 6: If $y = \sin(m \sin^{-1} x)$, prove that

$$(1-x^2)y_{n+2} - (2n+1)xy_{n+1} - (n^2 - m^2)y_n = 0.$$

(UPTU 2002)

Solution: Differentiating y w.r.t. x ,

$$y_1 = \cos(m \sin^{-1} x) \cdot m \cdot \frac{1}{\sqrt{1-x^2}}$$

$$\text{or } \sqrt{1-x^2}y_1 = m \cdot \cos(m \sin^{-1} x).$$

Differentiating again w.r.t. x ,

$$\begin{aligned} \sqrt{1-x^2}y_2 + \frac{1}{2} \frac{1}{\sqrt{1-x^2}} \cdot (-2x) \cdot y_1 \\ = -m \sin(m \sin^{-1} x) \cdot m \cdot \frac{1}{\sqrt{1-x^2}} \end{aligned}$$

$$\text{or } (1-x^2)y_2 - xy_1 + m^2 y = 0.$$

Differentiating n times by Leibnitz's rule

$$\begin{aligned} & \left[(1-x^2)y_{n+2} + n \cdot (-2x)y_{n+1} + \frac{n(n-1)}{2}(-2)y_n \right] - \\ & - [xy_{n+1} + n \cdot 1 \cdot y_n] + m^2 y_n = 0. \end{aligned}$$

Collecting the terms

$$(1-x^2)y_{n+2} - (2n+1)xy_{n+1} - (n^2 - m^2)y_n = 0.$$

EXERCISE

- Find the n th derivative of (a) $y = e^{ax}x^2$; (b) $y = \ln(1+x)$; (c) $y = \frac{1-x}{1+x}$; (d) $x \sin x$; (e) $e^x(2x+3)^3$; (f) $x^2 e^x \cos x$.

$$\text{Ans. a. } y^{(n)} = e^{ax} \left[a^n x^2 + 2na^{n-1}x + n(n-1)a^{n-2} \right]$$

$$\text{b. } (-1)^{n-1}(n-1)!/(1+x)^n$$

$$\text{c. } 2(-1)^n n!/(1+x)^{n+1}$$

$$\text{d. } x \sin \left(x + n \frac{\pi}{2} \right) - n \cos \left(x + n \frac{\pi}{2} \right)$$

$$\text{e. } e^x \left\{ (2x+3)^2 + 6n(2x+3)^2 + 12(n-1)(2x+3) + 8n(n-1)(n-2) \right\}$$

$$\begin{aligned} \text{f. } 2^{\frac{(n-2)}{2}} e^x \left[2x^2 \cos \left(x + n \frac{\pi}{4} \right) \right. \\ \left. + 2^{\frac{3}{2}} nx \cdot \cos \left(x + n - \frac{1}{4} \frac{\pi}{4} \right) \right. \\ \left. + n(n-1) \cos \left(x + n - 2 \frac{\pi}{4} \right) \right]. \end{aligned}$$

2.10 — HIGHER ENGINEERING MATHEMATICS—II

2. If $y = \tan^{-1} \left(\frac{1+x}{1-x} \right)$, show that the n th derivative $y_n = (-1)^{n-1} (n-1)! \sin^n \theta \cdot \sin n\theta$ where $\theta = \cot^{-1} x$.

Hint: $y_n = \frac{1}{2i} \left[\frac{1}{x-i} - \frac{1}{x+i} \right]_{n-1} = \frac{(-1)^{n-1} (n-1)!}{2i} \times \left[\frac{1}{(x-i)^n} - \frac{1}{(x+i)^n} \right]$, put $x = r \cos \theta$, $1 = r \sin \theta$, $x = \cot \theta$.

3. If $y = e^x \sin x$, prove that $y'' - 2y' + 2y = 0$.
 4. Using Leibnitz's rule, differentiate n times, the Chebyshev D.E.

$$(1-x^2)y'' - xy' + a^2y = 0.$$

Ans. $(1-x^2)y_{n+2} - (2n+1)xy_{n+1} + (a^2-n^2)y_n = 0$

5. If $\cos^{-1} \left(\frac{y}{b} \right) = \log \left(\frac{x}{a} \right)^n$, prove that

$$x^2 y_{n+2} + (2n+1)xy_{n+1} + 2n^2 y_n = 0$$

6. Find $y_n(0)$ if $y = (\sin^{-1} x)^2$.

Hint: Put $x = 0$ in $(1-x^2)y_{n+2} - (2n+1)xy_{n+1} - n^2 y_n = 0$.

Ans. $y_n(0) = 0$ when n is odd and $y_n(0) = 2 \cdot 2^2 \cdot 4^2 \cdot 6^2 \cdots (n-2)^2$ when n is even and $n \neq 2$.

7. Determine $y_n(0)$ if $y = e^{m \sin^{-1} x}$.

Hint: Put $x = 0$ in

$$(1-x^2)y_{n+2} - (2n+1)xy_{n+1} - (n^2+m^2)y_n = 0.$$

Ans.

$$y_n(0) = \begin{cases} m^2(2^2+m^2)(4^2+m^2) \cdots ((n-2)^2+m^2), & n \text{ even} \\ m(1^2+m^2)(3^2+m^2) \cdots ((n-2)^2+m^2), & n \text{ odd} \end{cases}$$

8. If $y^{\frac{1}{m}} + y^{-\frac{1}{m}} = 2x$, prove that

$$(x^2-1)y_{n+2} + (2n+1)xy_{n+1} + (n^2-m^2)y_n = 0.$$

9. Find $y_n(0)$ when $y = \cos(m \sin^{-1} x)$.

Hint: Put $x = 0$ in

$$(1-x^2)y_{n+2} - (2n+1)xy_{n+1} + (m^2-n^2)y_n = 0.$$

Ans. $y_n(0) = 0$ if n is odd

$$y_n(0) = m^2(2^2-m^2)(4^2-m^2) \cdots ((n-2)^2-m^2) \text{ if } n \text{ is even.}$$

10. If $\sin^{-1} y = 2 \log(x+1)$, show that

$$(x+1)^2 y_{n+2} + (2n+1)(x+1)y_{n+1} + (n^2+4)y_n = 0.$$

2.3 ANGLE BETWEEN THE RADIUS VECTOR AND THE TANGENT

Let $r = f(\theta)$ be the equation of the curve in polar coordinates (r, θ) . The formulas for changing from polar coordinates to the rectangular cartesian coordinates are

Fig. 2.1

$$x = r \cos \theta = f(\theta) \cos \theta \quad (1)$$

$$y = r \sin \theta = f(\theta) \sin \theta \quad (2)$$

These are the parametric equations of the given curve in terms of the parameter θ which is the polar angle. Let PT be the tangent to the curve at a point $P(r, \theta)$. Let ψ be the angle between the tangent PT and the positive x -axis. Let ϕ be the angle between the radius vector OP and the tangent PT i.e., $\angle TPO = \phi$. We know that

$$\text{slope of the tangent } PT = \tan \psi = \frac{dy}{dx} = \frac{\frac{dy}{d\theta}}{\frac{dx}{d\theta}} \quad (3)$$

Differentiating (1) and (2) w.r.t. the parameter θ

$$\frac{dx}{d\theta} = \frac{df}{d\theta} \cdot \cos \theta - f \sin \theta = f' \cos \theta - f \sin \theta \quad (4)$$

$$\frac{dy}{d\theta} = \frac{df}{d\theta} \cdot \sin \theta + f \cos \theta = f' \sin \theta + f \cos \theta \quad (5)$$

where ' dash denotes differentiation w.r.t. θ .

Substituting (4) and (5) in (3), we have

$$\tan \psi = \frac{f' \sin \theta + f \cos \theta}{f' \cos \theta - f \sin \theta} \quad (6)$$

From the triangle OPT ,

$$\theta + \phi + \angle OTP = \pi$$

$$\theta + \phi + (\pi - \psi) = \pi$$

$$\therefore \phi = \psi - \theta \quad (7)$$

From (6)

$$\tan \phi = \tan(\psi - \theta) = \frac{\tan \psi - \tan \theta}{1 + \tan \psi \cdot \tan \theta} \quad (8)$$

Substitute values of $\tan \psi$ from (6) into (8)

$$\begin{aligned} \tan \phi &= \frac{\frac{f' \sin \theta + f \cos \theta}{f' \cos \theta - f \sin \theta} - \tan \theta}{1 + \frac{f' \sin \theta + f \cos \theta}{f' \cos \theta - f \sin \theta} \cdot \tan \theta} \\ \tan \phi &= \frac{(f' \sin \theta + f \cos \theta) \cos \theta - (f' \cos \theta - f \sin \theta) \sin \theta}{(f' \cos \theta - f \sin \theta) \cos \theta + (f' \sin \theta + f \cos \theta) \sin \theta} \\ &= \frac{f(\cos^2 \theta + \sin^2 \theta)}{f'(\cos^2 \theta + \sin^2 \theta)} = \frac{f}{f'} = \frac{r}{\frac{dr}{d\theta}} \end{aligned}$$

$$\therefore \boxed{\tan \phi = r \frac{d\theta}{dr}} \quad (9)$$

or $\frac{dr}{d\theta} = r \cot \phi$.

Geometric meaning: Thus the derivative of the radius vector r w.r.t. the polar angle θ is equal to the length of the radius vector multiplied by the cotangent of the angle between the radius vector OP and the tangent PT to the curve at the point $P(r, \theta)$.

Corollary 1: Slope of the tangent PT :

For a given curve $r = f(\theta)$, calculate $\frac{dr}{d\theta} = f'(\theta)$ and substituting $r, \theta, f'(\theta)$ in (6), we get the slope of the tangent $\tan \psi$.

Corollary 2: Angle of intersection of two curves c_1 and c_2 . Let PT_1 and PT_2 be the tangents to the two curves c_1 and c_2 respectively at the common point of intersection. Let ϕ_1 and ϕ_2 be the angles between the radius vector OP and tangents PT_1 and PT_2 respectively.

Angle of intersection of two curves $= \angle T_1PT_2 = \alpha$

$$\alpha = \angle OPT_2 - \angle OPT_1 = \phi_2 - \phi_1 \quad (10)$$

Corollary 3: The curves are said to intersect at right angle or intersect orthogonally if the angle between them $\alpha = 90^\circ$.

Fig. 2.2

Polar Subtangent and Tangent and Polar Subnormal and Normal

Let NOT be a straight line through the pole O and perpendicular to the radius vector OP . The tangent at P and the normal at P meets this line in T and N respectively. Then OT and ON are known as the polar subtangent and polar subnormal respectively,

$$\text{polar subtangent} = OT = r \cdot \tan \phi = r \cdot \frac{rd\theta}{dr} = r^2 \frac{d\theta}{dr} \quad (11)$$

Fig. 2.3

where (9) is used to replace $\tan \phi$.

$$\text{Polar subnormal} = ON = r \cdot \cot \phi = r \cdot \frac{1}{r} \frac{dr}{d\theta} = \frac{dr}{d\theta} \quad (12)$$

2.12 — HIGHER ENGINEERING MATHEMATICS—II

$$\text{Polar tangent} = PT = r \sqrt{1 + \tan^2 \phi} = r \sqrt{1 + r^2 \left(\frac{d\theta}{dr} \right)^2}$$

$$\text{Polar normal} = PN = r \sqrt{1 + \cot^2 \phi} = \sqrt{r^2 + \left(\frac{dr}{d\theta} \right)^2}$$

Length of the Perpendicular from Pole on the Tangent

Let p be the length of the perpendicular OM drawn from the pole on to the tangent PT . Then from the right angle triangle OPM

$$p = r \sin \phi.$$

Rewriting

$$\frac{1}{p^2} = \frac{1}{r^2 \sin^2 \phi} = \frac{1}{r^2} \operatorname{cosec}^2 \phi = \frac{1}{r^2} (1 + \cot^2 \phi)$$

$$\frac{1}{p^2} = \frac{1}{r^2} \left[1 + \frac{1}{r^2} \left(\frac{dr}{d\theta} \right)^2 \right] = \frac{1}{r^2} + \frac{1}{r^4} \left(\frac{dr}{d\theta} \right)^2$$

where (9) is used to replace $\cot \phi$.

WORKED OUT EXAMPLES

Example 1: For the parabola $\frac{2a}{r} = 1 - \cos \theta$, show that (i) $\phi = \pi - \frac{\theta}{2}$; (ii) $p = a \operatorname{cosec} \frac{\theta}{2}$; (iii) polar subtangent = $2a \operatorname{cosec} \theta$; (iv) Find polar subnormal.

Solution: Differentiating the equation of parabola

$$\frac{2a}{r} = 1 - \cos \theta$$

w.r.t. θ , we get

$$-\frac{2a}{r^2} = \sin \theta \frac{d\theta}{dr}$$

or

$$\frac{d\theta}{dr} = -\frac{2a}{r^2 \sin \theta}$$

$$\text{i. Now } \tan \phi = r \frac{d\theta}{dr} = r \left(-\frac{2a}{r^2 \sin \theta} \right) = -\frac{2a}{r} \cdot \frac{1}{\sin \theta}$$

$$= -\frac{(1 - \cos \theta)}{\sin \theta} = -\frac{2 \sin^2 \frac{\theta}{2}}{2 \sin \frac{\theta}{2} \cdot \cos \frac{\theta}{2}} = -\tan \frac{\theta}{2}$$

$$\tan \phi = \tan \left(\pi - \frac{\theta}{2} \right)$$

$$\therefore \phi = \pi - \frac{\theta}{2}$$

$$\begin{aligned} \text{ii. } p &= r \sin \phi = \frac{2a}{1 - \cos \theta} \cdot \sin \left(\pi - \frac{\theta}{2} \right) = \frac{2a \sin \frac{\theta}{2}}{1 - \cos \theta} \\ &= \frac{2a \sin \frac{\theta}{2}}{2 \sin^2 \frac{\theta}{2}} = a \operatorname{cosec} \frac{\theta}{2} \end{aligned}$$

$$\begin{aligned} \text{iii. Polar subtangent} &= r^2 \frac{d\theta}{dr} = -\frac{2a}{\sin \theta} = \\ &= -2a \operatorname{cosec} \theta \end{aligned}$$

$$\begin{aligned} \text{iv. Polar subnormal} &= \frac{dr}{d\theta} = \frac{r^2 \sin \theta}{-2a} = \\ &= \frac{4a^2}{(1 - \cos \theta)^2} \cdot \frac{\sin \theta}{-2a} = -\frac{2a \cdot 2 \sin \frac{\theta}{2} \cdot \cos \frac{\theta}{2}}{4 \sin^2 \frac{\theta}{2}} = -a \cot \frac{\theta}{2}. \end{aligned}$$

Example 2: Show that the curves $r = ae^\theta$ and $re^\theta = b$ intersect at right angles.

Solution: Point of intersection of the two curves

$$ae^\theta = r = be^{-\theta} \quad \text{or} \quad e^{2\theta} = \frac{b}{a}.$$

$$\text{So} \quad \theta = \frac{1}{2} \ln \left(\frac{b}{a} \right).$$

$$\text{For the curve } r = ae^\theta, \quad \frac{dr}{d\theta} = ae^\theta \quad \text{so}$$

$$\tan \phi_1 = r \frac{d\theta}{dr} = (ae^\theta) \cdot a^{-1} e^{-\theta} = 1 \quad \therefore \phi_1 = \frac{\pi}{4}.$$

$$\text{For the curve } re^\theta = b, \quad \frac{dr}{d\theta} = -be^{-\theta} \quad \text{so}$$

$$\tan \phi_2 = r \frac{d\theta}{dr} = be^{-\theta} \cdot \frac{1}{-b} e^\theta = -1 \quad \therefore \phi_2 = \pi - \frac{\pi}{4}.$$

Angle of intersection of the two curves is

$$\phi_2 - \phi_1 = \left(\pi - \frac{\pi}{4} \right) - \left(\frac{\pi}{4} \right) = \pi - \frac{\pi}{2} = \frac{\pi}{2}$$

i.e., they cut orthogonally.

Example 3: Find the angle of intersection of the curves $r = a$ and $r = 2a \cos \theta$.

Solution: For the curve $r = a$, $\frac{dr}{d\theta} = 0$ so

$$\tan \phi_1 = r \frac{d\theta}{dr} = \infty \quad \therefore \phi_1 = \frac{\pi}{2}$$

for the curve $r = 2a \cos \theta$, $\frac{dr}{d\theta} = -2a \sin \theta$ so

$$\tan \phi_2 = r \frac{d\theta}{dr} = r \cdot \frac{1}{-2a \sin \theta} = \frac{2a \cos \theta}{-2a \sin \theta} = -\cot \theta$$

Points of intersection of the two curves are

$$a = r = 2a \cos \theta \quad \therefore \quad \cos \theta = \frac{1}{2}.$$

$$\text{So,} \quad \theta = \frac{\pi}{3}, \quad \frac{5\pi}{3}.$$

Hence the points of intersection are $(a, \frac{\pi}{3})$ and $(a, \frac{5\pi}{3})$.

$$\text{At } \theta = \frac{\pi}{3}, \quad \tan \phi_1 = \infty, \quad \text{so } \phi_1 = \frac{\pi}{2}$$

$$\tan \phi_2 = -\cot \frac{\pi}{3} = -\frac{1}{\sqrt{3}}$$

$$\text{Then} \quad \phi_2 = \frac{\pi}{2} + \theta = \frac{\pi}{2} + \frac{\pi}{3}$$

$$\text{Angle of intersection is } \frac{\pi}{2} + \frac{\pi}{3} - \frac{\pi}{2} = \frac{\pi}{3}.$$

Example 4: Prove that (i) for the curve $r = a\theta$, the polar subnormal is constant; (ii) for the curve $r\theta = a$ the polar subtangent is constant.

Solution:

i. For $r = a\theta$, $\frac{dr}{d\theta} = a = \text{constant}$

$$\text{Polar subnormal} = \frac{dr}{d\theta} = a = \text{constant}.$$

ii. For $r\theta = a$, $\frac{dr}{d\theta} = -\frac{a}{\theta^2}$

$$\text{Polar subtangent} = r^2 \frac{d\theta}{dr} = \frac{r^2 \theta^2}{-a} = \frac{a^2}{-a} = -a = \text{constant}.$$

Example 5: For the curve $r^3 = a^3 \cos 3\theta$, show that the normal at any point (r, θ) to the curve makes an angle 4θ with the initial line.

Solution: Differentiating w.r.t. r ,

$$3r^2 = -3a^3 \sin 3\theta \cdot \frac{d\theta}{dr}$$

$$\frac{d\theta}{dr} = \frac{-r^2}{a^3 \sin 3\theta}.$$

$$\text{Now} \quad \tan \phi = r \frac{d\theta}{dr} = r \left(-\frac{r^2}{a^3 \sin 3\theta} \right) = -\frac{a^3 \cos 3\theta}{a^3 \sin 3\theta}$$

$$\tan \phi = -\cot 3\theta = \tan \left(\frac{\pi}{2} + 3\theta \right)$$

$$\therefore \quad \phi = \frac{\pi}{2} + 3\theta.$$

Slope of the tangent $\psi = \phi + \theta = \frac{\pi}{2} + 3\theta + \theta$
 $\therefore$ Slope of the normal at any point (r, θ) is 4θ .

Example 6: Find the polar tangent and polar normal to the curve $\theta = \cos^{-1} \frac{r}{k} - \sqrt{\frac{k^2 - r^2}{r^2}}$.

Solution: Differentiating w.r.t. r , we get

$$\begin{aligned} \frac{d\theta}{dr} &= -\frac{1}{\sqrt{1 - \left(\frac{r}{k}\right)^2}} \cdot \frac{1}{k} - \frac{1}{2} \sqrt{\frac{r^2}{k^2 - r^2}} \cdot \frac{r^2(-2r) - (k^2 - r^2)2r}{r^4} \\ &= \frac{\sqrt{k^2 - r^2}}{r^2}. \end{aligned}$$

$$\text{Polar tangent} = r \sqrt{1 + r^2 \left(\frac{d\theta}{dr} \right)^2}$$

$$= r \sqrt{1 + r^2 \frac{(k^2 - r^2)}{r^4}} = r \frac{k}{r} = k$$

$$\text{Polar normal} = \sqrt{r^2 + \left(\frac{dr}{d\theta} \right)^2} = \sqrt{r^2 + \frac{r^4}{k^2 - r^2}}$$

$$= \sqrt{\frac{k^2 r^2}{k^2 - r^2}} = \frac{kr}{\sqrt{k^2 - r^2}}.$$

EXERCISE

1. Show that, for the cardioid $r = a(1 - \cos \theta)$,
 (i) $\phi = \frac{\theta}{2}$; (ii) $p = 2a \sin^3 \frac{\theta}{2}$; (iii) polar subtangent $= 2a \sin^2 \frac{\theta}{2} \cdot \tan \frac{\theta}{2}$; (iv) polar subnormal $= a \sin \theta$.

2. Prove that the curves $r^m = a^m \cos m\theta$ and $r^m = a^m \sin m\theta$ intersects orthogonally.

Hint: $r \frac{d\theta}{dr} = -\cot m\theta$, $\phi_1 = \frac{\pi}{2} + m\theta$, $r \frac{d\theta}{dr} = \tan m\theta$, $\phi_2 = m\theta$, $\phi_1 - \phi_2 = \frac{\pi}{2}$

3. Determine the angle of intersection of the curves $r = 3 \cos \theta$, and $r = 1 + \cos \theta$.

Hint: Points of intersection $(r = \frac{3}{2}, \theta = \frac{\pi}{3})$,
 $(\frac{3}{2}, \frac{5\pi}{3})$, $\tan \phi_1 = -\cot \frac{\pi}{3} = -\frac{1}{\sqrt{3}}$, $\tan \phi_2 = -\cot \frac{\theta}{2} = -\cot \frac{\pi}{6} = -\sqrt{3}$, $\tan(\phi_1 - \phi_2) = \frac{1}{\sqrt{3}}$,
 $\therefore \phi_1 - \phi_2 = \frac{\pi}{6}$

Ans. $\frac{\pi}{6}$

2.14 — HIGHER ENGINEERING MATHEMATICS—II

4. Show that the angle of intersection of the curves $r = \sin \theta + \cos \theta$, $r = 2 \sin \theta$ is $\frac{\pi}{4}$.

Hint: $\theta = \frac{\pi}{4}$ is point of intersection, $\tan \phi_1 = \infty \therefore \phi_1 = \frac{\pi}{2}$, $\tan \phi_2 = 1$, $\therefore \phi_2 = \frac{\pi}{4}$, $\phi_1 - \phi_2 = \frac{\pi}{2} - \frac{\pi}{4} = \frac{\pi}{4}$.

5. Prove that the tangent to the logarithmic spiral $r = e^{a\theta}$ intersects the radius vector at a constant angle.

Hint: $\frac{dr}{d\theta} = ae^{a\theta}$, $\cot \phi = \frac{1}{r} \frac{dr}{d\theta} = a \therefore \phi = \cot^{-1} a = \text{const.}$

6. Prove that for the curve $r = ae^{m\theta^2}$, the ratio of polar subnormal to polar subtangent is proportional to θ^2 .

7. Find ϕ for the following curves

- (a) $\frac{1}{r} = 1 + e \cos \theta$; (b) $r = a(1 + \cos \theta)$;
(c) $\frac{2a}{r} = 1 + \cos \theta$

Ans. (a) $\cot^{-1} \left(\frac{e \sin \theta}{1 + e \cos \theta} \right)$; (b) $\frac{\pi}{2} + \frac{\theta}{2}$; (c) $\frac{\pi}{2} - \frac{\theta}{2}$.

8. Show that the following pair of curves cut orthogonally:

- (a) $\frac{2a}{r} = 1 + \cos \theta$, $\frac{2b}{r} = 1 - \cos \theta$; (b) $r = a \cos \theta$, $r = a \sin \theta$; (c) $r^2 \sin 2\theta = a^2$, $r^2 \cos 2\theta = b^2$; (d) $r = a(1 + \cos \theta)$, $r = b(1 - \cos \theta)$.

2.4 ROLLE'S THEOREM

If $f(x)$ is (i) continuous in $[a, b]$ (ii) derivable in (a, b) and (iii) $f(a) = f(b)$, then there exists at least one value $c \in (a, b)$ such that $f'(c) = 0$.

Proof:

- I. If $f(x) = 0$ for all x , then $f'(x) = 0$ for all x .
II. Since f is continuous in $[a, b]$, it is bounded and attains its maximum M and minimum m say at two numbers c and d lying in between a and b such that

$$f(c) = M \text{ and } f(d) = m.$$

Case a: If $M = m$, then f is a constant function so that f' is zero for all x in (a, b) .

Case b: If $M \neq m$, then $M = f(c) \geq f(c+h)$ for values of h both positive and negative. Then

$$\frac{f(c+h) - f(c)}{h} \leq 0 \quad \text{for } h > 0 \quad (13)$$

and

$$\frac{f(c+h) - f(c)}{h} \geq 0 \quad \text{for } h < 0 \quad (14)$$

Since f is differentiable in (a, b) from (1) and (2) as $h \rightarrow 0$, we have

$$f'(c) \leq 0 \quad \text{and} \quad f'(c) \geq 0$$

Hence $f'(c) = 0$ for some value c in (a, b) . Similarly if $m = f(d) \leq f(d+h)$ for values of h both positive and negative it follows that

$$\frac{f(d+h) - f(d)}{h} \geq 0 \quad \text{for } h > 0$$

and

$$\frac{f(d+h) - f(d)}{h} \leq 0 \quad \text{for } h < 0$$

As $h \rightarrow 0$, $f'(d) \geq 0$ and $f'(d) \leq 0$. Hence $f'(d) = 0$.

Note 1: Geometrically, Rolle's theorem states that the tangents at c_1, c_2, c_3 are parallel to x -axis (see Fig. 2.4).

Fig. 2.4

Note 2: The function $y = f(x) = 1 - x^{\frac{2}{3}}$ in $[-1, 1]$ is not differentiable at origin O, it does not satisfy the condition of Rolle's theorem, so $f'(c) \neq 0$ for any $c \in (-1, 1)$ (refer Fig. 2.5).

Fig. 2.5

Note 3: Alternate form: Let $b = a + h$ then $c = a + \theta h$ lies between a and b provided $0 < \theta < 1$. Thus the result of Rolle's theorem may be stated as

$$f'(c) = f'(a + \theta h) = 0 \text{ with } 0 < \theta < 1.$$

Note 4: For $f(a) = f(b) = 0$, it follows from Rolle's theorem that there exists at least on $c \in (a, b)$ where $f'(c) = 0$. Thus the real root c of the equation $f'(x) = 0$ lies between a and b which are two adjacent real roots of the equation $f(x) = 0$, i.e., the real roots of equation $f'(x) = 0$ separate the real roots of the equation $f(x) = 0$.

WORKED OUT EXAMPLES

Verify Rolle's theorem for the following functions:

Example 1: $f(x) = x(x-2)e^{\frac{3x}{4}}$ in $(0, 2)$

Solution: $f(0) = 0, f(2) = 0, f$ is continuous and differentiable, so by Rolle's theorem, $0 = f'(c)$. Here

$$\begin{aligned} f'(x) &= [(x-2) + x + \frac{3}{4}(x)(x-2)]e^{\frac{3x}{4}} \\ &= 0 \quad \text{or} \quad 3x^2 + 2x - 8 = 0 \end{aligned}$$

$\therefore c = -2$ or $\frac{8}{3}$ but $c = -2$ does not lie in $(0, 2)$ thus $c = \frac{8}{3} \in (0, 2)$.

Example 2: $f(x) = x^{2m-1}(a-x)^{2n}$ in $(0, a)$

Solution: $f(0) = f(a) = 0$. f is continuous and differentiable in $[0, a]$. By Rolle's theorem, $f'(c) = 0$ for some c in $(0, a)$.

$$\begin{aligned} f'(x) &= (2m-1)x^{2m-2}(a-x)^{2n} \\ &\quad + x^{2m-1} \cdot 2n(a-x)^{2n-1} \cdot (-1) \\ &= x^{2m-1} \cdot (a-x)^{2n} \left[(2m-1) \cdot \frac{1}{x} - \frac{2n}{a-x} \right] \end{aligned}$$

$$\therefore f'(c) = 0 \quad \text{if} \quad (2m-1) \frac{1}{c} - \frac{2n}{a-c} = 0$$

$$\text{or} \quad c = \frac{a(2m-1)}{(2m+2n-1)}.$$

Example 3: Find a root (solution) of the equation $x \ln x - 2 + x = 0$ lying in $(1, 2)$.

Solution: Choose $f(x) = (x-2) \ln x$ which is continuous, differentiable in $(1, 2)$ and further $f(1) = f(2) = 0$. Thus f satisfies all the 3 conditions of Rolle's theorem. So there exists a ' c ' $\in (1, 2)$ such that $f'(c) = 0$. Here

$$f'(x) = \ln x + (x-2) \cdot \frac{1}{x}$$

$$f'(x) = \frac{x \ln x + x - 2}{x}$$

Thus $f'(c) = \frac{c \ln c + c - 2}{c} = 0$
or c is the root (solution) of the equation

$$x \ln x - 2 + x = 0.$$

Example 4: Show that the equation $f''(x) = 0$ has at least one real root between a and b if f, f', f'' are continuous in $a \leq x \leq b$ and the curve $y = f(x)$ crosses the x -axis at least at 3 distinct points between a and b inclusive.

Solution: Let c, d, e be the three points where $y = f(x)$ crosses the x -axis. Then $f(c) = f(d) = f(e) = 0$. Assume $a < c < d < e < b$. The function f satisfies Rolle's theorem in the two intervals (c, d) and (d, e) , since f and f' are continuous and $f(c) = f(d) = f(e) = 0$. Therefore there exists at least one point in each interval (c, d) and (d, e) such that derivative is zero.

Let $c_1 \in (c, d)$ such that $f'(c_1) = 0$ and $c_2 \in (d, e)$ such that $f'(c_2) = 0$. Now the function f' satisfies Rolle's theorem because f', f'' are continuous and $f'(c_1) = f'(c_2) = 0$. Therefore by Rolle's theorem there exists a number c_3 in between c_1 and c_2 such that $f''(c_3) = 0$. Thus at least one root c_3 of the equation $f''(x) = 0$ lies in the interval (a, b) .

Example 5: Without solving, show that the equation $x^4 + 2x^3 - 2 = 0$ has one and only one real root between 0 and 1.

Solution: Let $f(x) = x^4 + 2x^3 - 2$ which is continuous and differentiable in $(0, 1)$. $f'(x) = 4x^3 + 6x^2 = x^2(4x + 6) = 0$ only when $x = 0$ or $x = -\frac{6}{4}$ both of which do not lie in between 0 and 1. Thus $f'(x) \neq 0$ for any $x \in (0, 1)$. By Rolle's theorem, there do not exist a and b such that $f(a) = 0$ and $f(b) = 0$ i.e., the equation $f(x) = 0$ can not have two real roots. Further $f(0) = -2$ and $f(1) = 1$ are of opposite signs and $f'(x) > 0$ for every x in $(0, 1)$. Therefore $f(x)$ crosses the x -axis exactly once. In other words, $f(x) = 0$ has one and only one root in between 0 and 1.

2.16 — HIGHER ENGINEERING MATHEMATICS—II

EXERCISE

Verify Rolle's theorem for the following functions $f(x)$ in the indicated interval:

1. $\sin x/e^x$ in $[0, \pi]$

Ans. $c = \pi/4$

2. $x^3 - 12x$ in $[0, 2\sqrt{3}]$

Ans. $c = 2$

3. $\sin x$ in $[0, 2\pi]$

Ans. $\frac{\pi}{2}$ and $\frac{3\pi}{2}$

4. $|x|$ in $[-1, 1]$

Hint: Function is not differentiable at 0.

Ans. Rolle's theorem is not valid

5. $f(x) = \begin{cases} 1, & \text{when } x = 0 \\ x, & \text{when } 0 < x \leq 1 \end{cases}$

Hint: Function is discontinuous at 0.

Ans. Rolle's theorem not applicable.

6. x^2 in $[1, 2]$

Hint: $f(1) = 1 \neq f(2) = 4$.

Ans. Rolle's theorem not applicable

7. $\ln[(x^2 + ab)/((a + b)x)]$ in $[a, b]$.

Ans. $c = \sqrt{ab}$

8. $2 + (x - 1)^{\frac{2}{3}}$ in $[0, 2]$

Hint: Not differentiable at $x = 1 \in (0, 2)$.

Ans. Rolle's theorem not applicable

9. $e^x(\sin x - \cos x)$ in $[\frac{\pi}{4}, \frac{5\pi}{4}]$

Ans. $c = \pi$

10. $2x^3 + x^2 - 4x - 2$ in $[-\sqrt{2}, \sqrt{2}]$

Ans. $\frac{2}{3}$ and -1

11. $(x - a)^m(x - b)^n$ in $[a, b]$ with $b > a$, $n > 1, m > 1$

Ans. $c = \frac{mb+na}{m+n}$

12. $x^3 - 4x$ in $[-2, 2]$

Ans. $\pm\sqrt{2}/3$

13. $x^3 - 3x^2 - x + 3$ in $[1, 3]$

Ans. $1 + 2/\sqrt{3}$

14. $\ln\{(x^2 + 6)/5x\}$ in $[2, 3]$

Ans. $c = \sqrt{6}$

15. $x(x + 3)e^{-x/2}$ in $[-3, 0]$

Ans. -2

16. $(x + 2)^3(x - 3)^4$ in $[-2, 3]$

Ans. $1/7$

17. $\tan x$ in $[0, \pi]$

Hint: $\tan x$ is discontinuous at $x = \pi/2$.

Ans. Rolle's theorem not applicable

18. $1 - (x - 3)^{\frac{2}{3}}$

Hint: $f(2) = f(4) = 0$, but f' does not exist at $x = 3 \in (2, 4)$.

Ans. Rolle's theorem not applicable

19. $\frac{x^2 - 4x}{x + 2}$

Hint: The point of discontinuity $x = -2$ does not belong to $(0, 4)$ where $f(0) = f(4) = 0$.

Ans. $c = 2(\sqrt{3} - 1)$

20. Show that between any two roots of $e^x \cos x - 1 = 0$, there exists at least one root of $e^x \sin x - 1 = 0$.

Hint: Take $f(x) = e^x \cos x - 1$ in $[a, b]$ so $f' = e^x \cos x - e^x \sin x$. Since $e^x \cos x = 1$ so $f' = 1 - e^x \sin x$. Let a, b be two roots of $f(x)$. Then by Rolle's theorem $c \in (a, b) \ni f'(c) = 0$ i.e., c is a root of $1 - e^x \sin x = 0$.

21. Show that polynomial equation

$$a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_n = 0$$

has at least one real root in $(0, 1)$ if

$$\frac{a_0}{n+1} + \frac{a_1}{n} + \dots + \frac{a_{n-1}}{2} + a_n = 0$$

and $a_0, a_1, \dots, a_n$, are real numbers.

Hint: Take $f(x) = \frac{a_0}{n+1} x^{n+1} + \frac{a_1}{n} x^n + \dots + \frac{a_{n-1}}{2} x^2 + a_n x$ in $[0, 1]$. Apply Rolle's theorem.

22. Prove that if a rational integral function $f(x)$ has n zeros between a and b then $f'(x)$ has

$(n - 1)$ zeros in (a, b) .

Hint: Suppose $x_1, x_2, \dots, x_n$ are the n zeros of f in (a, b) so $f(x_i) = 0$, for $i = 1, 2, \dots, n$. Then by Rolle's theorem applied to the $(n - 1)$ intervals $(x_1, x_2), (x_2, x_3), \dots, (x_{n-1}, x_n) \exists c_i \ni f'(c_i) = 0$, for $i = 1, 2, \dots, n - 1$.

Without solving exactly, show that the following equations have one and only one real root in the given interval.

23. $x^4 + 3x + 1 = 0$ in $(-2, -1)$.
24. $2x^3 - 3x^2 - 12x - 6 = 0$ in $(-1, 0)$.
25. If f and F are continuous in $[a, b]$ and derivable in (a, b) with $F'(x) \neq 0$ for every x in (a, b) then prove that there exists $c \in (a, b)$ such that

$$\frac{f'(c)}{F'(c)} = \frac{f(b) - f(a)}{F(b) - F(a)}.$$

Hint: Choose $\phi(x) = f(x)[F(b) - F(a)] - [f(b) - f(a)][F(x) - F(a)]$.

$\phi(b) = f(b)[F(b) - F(a)] = \phi(a)$,

ϕ satisfies Rolle's theorem. But

$\phi'(x) = f'(x)[F(b) - F(a)] - f'(x)[F(x) - F(a)] - F'(x)[f(b) - f(a)]$, $\phi'(c) = 0$.

2.5 LAGRANGE'S MEAN VALUE THEOREM

Let f be (i) continuous in $[a, b]$ and (ii) derivable in (a, b) . Then there exists at least one value $c \in (a, b)$ such that

$$\frac{f(b) - f(a)}{b - a} = f'(c).$$

Proof: Choose $\phi(x) = f(x) + x \cdot A$, $x \in [a, b]$. Since f and x are continuous in $[a, b]$ and derivable in (a, b) , therefore ϕ is continuous in $[a, b]$ and derivable in (a, b) . Now choose the unknown constant A such that $f(b) + b \cdot A = \phi(b) = \phi(a) = f(a) + a \cdot A$ so that

$$A = \frac{f(b) - f(a)}{a - b}$$

Thus ϕ satisfies all the three conditions of the Rolle's theorem. Therefore by Rolle's theorem there exists a number $c \in (a, b)$ such that

$$0 = \phi'(c) = f'(c) + A$$

$$\text{Thus } f'(c) = -A = \frac{f(b) - f(a)}{b - a}.$$

Alternate Form of Lagrange's Mean Value Theorem

If $b = a + h$ then

$$\frac{f(a + h) - f(a)}{a + h - a} = f'(a + \theta h)$$

$c = a + \theta h$ lies between a and $b = (a + h)$ when $0 < \theta < 1$.

Thus $f(a + h) = f(a) + hf'(a + \theta h)$, $0 < \theta < 1$.

Note 1: Lagrange's Mean Value (LMV) theorem is generalization of Rolle's theorem. In the special case when $f(b) = f(a)$ then LMV theorem reduces to Rolle's theorem.

Note 2: Geometrically LMV theorem states that the tangent to the curve at D is parallel to the chord AB (see Fig. 2.6).

Fig. 2.6

Note 3: The average rate of change of f over the interval (a, b) given by $\frac{f(b) - f(a)}{b - a}$ is equal to $f'(c)$ which is the actual rate of change of f at some point of the interval (a, b) .

Note 4: Using LMV theorem, approximate solution of equation $f(x) = 0$ can be obtained by Newton's method as follows:

Suppose $a + h$ is exact (actual) root so that

$$0 = f(a + h) = f(a) + hf'(a + \theta h), 0 < \theta < 1$$

Therefore $h \simeq -\frac{f(a)}{f'(a)}$.

2.18 — HIGHER ENGINEERING MATHEMATICS—II

Thus starting at a guess value 'a', h (correction) can be calculated approximately. By iteration a better root can be obtained.

Note 5: If M^* and m^* are the maximum and minimum of $f'(x)$ in $a < x < b$ then

$$m^*(b-a) < f(b) - f(a) < (b-a)M^*.$$

Note 6: Application of LMV theorem for sign of derivative.

Let $f(x)$ satisfy conditions of LMV theorem in $[a, b]$ and x_1, x_2 be any two points of $[a, b]$ such that $x_1 < x_2$. Applying LMV theorem in $[x_1, x_2]$, there exists a number $c \in (x_1, x_2)$ such that

$$f(x_2) - f(x_1) = (x_2 - x_1)f'(c) \quad (1)$$

I. If $f'(x) = 0$ for every $x \in (x_1, x_2)$ then

$$f(x_2) - f(x_1) = 0$$

or $f(x_2) = f(x_1) = \text{constant}$

So f is a constant function in $[x, x_2]$.

II. If $f'(x) > 0$ then it follows from (1) that

$$f(x_2) - f(x_1) > 0 \text{ or } f(x_2) > f(x_1)$$

since $(x_2 - x_1) > 0$. So f is strictly increasing function.

III. If $f'(x) < 0$ then it follows from (1) that

$$f(x_2) - f(x_1) < 0 \text{ or } f(x_2) < f(x_1)$$

i.e., f is strictly decreasing function.

WORKED OUT EXAMPLES

Verify the Lagrange's Mean Value theorem:

Example 1: $f(x) = x^2$ in $(1, 5)$

Solution: f is continuous and differentiable in $(2, 3)$ so by LMV theorem,

$$\frac{f(b) - f(a)}{b - a} = f'(c)$$

for some c in (a, b) .

Here $f(5) = 25$, $f(1) = 1$, $f'(x) = 2x$. Therefore

$$\frac{25 - 1}{5 - 1} = 2c \quad \therefore c = 3 \in (1, 5).$$

Example 2: $f(x) = x^{\frac{2}{3}}$, $(-1, 1)$

Solution: LMV theorem is not applicable because f is not differentiable at $x = 0 \in (-1, 1)$.

Example 3: $f(x) = \cot \pi x$, $(-\frac{1}{2}, \frac{1}{2})$

Solution: LMV theorem is not valid because f is discontinuous at $0 \in (-\frac{1}{2}, \frac{1}{2})$.

Example 4: Deduce Lagrange's Mean Value theorem from Rolle's theorem.

Solution: Choose $g(x) = f(x) - f(a) - A(x - a)$ where A is a constant and f is continuous in $[a, b]$ and derivable in (a, b) . Then $g(x)$ is also continuous in $[a, b]$ and derivable in (a, b) . Further $g(a) = 0$ and determine A such that

$$g(b) = f(b) - f(a) - A(b - a) = 0$$

$$\text{Solving } A = \frac{f(b) - f(a)}{b - a}$$

Thus g satisfies all the conditions of Rolle's theorem. Therefore there exists a number $c \in (a, b)$ such that

$$g'(c) = 0$$

$$\text{But } g'(x) = f'(x) - A$$

$$\text{so } 0 = g'(c) = f'(c) - A$$

$$\therefore f'(c) = A = \frac{f(b) - f(a)}{(b - a)}$$

which is the result of Lagrange's Mean Value theorem.

Example 5: Show that $\frac{h}{1+h^2} < \tan^{-1} h < h$ when $h \neq 0$ and $h > 0$.

Solution: Take $f(x) = \tan^{-1} x$ in $0 \leq x \leq h$. By LMV theorem

$$\frac{\tan^{-1} h - \tan^{-1} 0}{h - 0} = \frac{1}{1 + c^2}$$

where $0 < c < h$.

$$\text{or } \tan^{-1} h = \frac{h}{1+c^2}.$$

Since $0 < c < h \Rightarrow 0^2 < c^2 < h^2$

$$1 < 1 + c^2 < 1 + h^2$$

or
$$h > \frac{h}{1 + c^2} > \frac{h}{1 + h^2}$$

or
$$h > \frac{h}{1 + c^2} = \tan^{-1} h > \frac{h}{1 + h^2}.$$

Example 6: Separate the intervals in which the polynomial $f(x) = (4 - x^2)^2$ is increasing or decreasing.

Solution: $f'(x) = 2(4 - x^2)(-2x) = 4x(x^2 - 4)$.
Since $f(2) = 0$ and $f(-2) = 0$, so $y = f(x)$ crosses x -axis at -2 and 2 .

Note that

$f' > 0$ when $x > 0$ and $x > 2$ so f is increasing in $(2, \infty)$

$f' < 0$ when $x > 0$ and $x < 2$ so f is decreasing in $(0, 2)$

$f' > 0$ when $x < 0$ and $x > -2$ so f is increasing in $(-2, 0)$

$f' < 0$ when $x < 0$ and $x < -2$ so f is decreasing in $(-\infty, -2)$.

Example 7: Show that, for any $x \geq 0$

$$1 + x < e^x < 1 + xe^x.$$

Solution: Take $f(x) = e^x - (1 + x)$. Then $f'(x) = e^x - 1 \geq 0$ for any $x \geq 0$, so f is an increasing function and $f(0) = 0$. Therefore $f > 0$ for any $x \geq 0$

i.e.,
$$e^x - (1 + x) > 0 \text{ or } 1 + x < e^x \quad (1)$$

Similarly choose $g(x) = 1 + xe^x - e^x$.
 $g(0) = 0$, and $g'(x) = e^x + xe^x - e^x = xe^x \geq 0$ for any $x \geq 0$. Thus g is an increasing function and therefore $g > 0$

i.e.,
$$1 + xe^x - e^x > 0$$

or
$$e^x < 1 + xe^x \quad (2)$$

Results (1) and (2) form the required inequality.

Example 8: Show that for $x \in (0, 1)$

$$x < -\ln(1 - x) < x/(1 - x)$$

Solution: Rewrite the inequality as

$$-x > \ln(1 - x) > \frac{x}{x - 1} \quad (1)$$

or
$$-1 > \frac{\ln(1 - x)}{x} > \frac{1}{x - 1}$$

Now choose $f(x) = \ln(1 - x)$ which is continuous and differentiable in $(0, 1)$. So applying LMV theorem in $(0, x)$ for any x between 0 and 1.

$$\begin{aligned} \frac{\ln(1 - x) - \ln(1 - 0)}{x - 0} &= f'(c) = -\frac{1}{1 - c} \\ &= \frac{1}{x\theta - 1} \end{aligned} \quad (2)$$

because c lies between 0 and x .

Here $0 < \theta < 1$.

Since $\theta x < x \Rightarrow \theta x - 1 < x - 1$

$$\text{or } \frac{1}{x\theta - 1} > \frac{1}{x - 1} \quad (3)$$

Also for $\theta > 0$, $x > 0$, $x\theta > 0$ or $-x\theta < 0$

$$1 - x\theta < 1$$

so
$$\frac{1}{1 - x\theta} > 1$$

or
$$\frac{1}{x\theta - 1} < -1 \quad (4)$$

From (2), (3) and (4), we get the inequality (1)

i.e.,
$$-1 > \frac{1}{x\theta - 1} = \frac{\ln(1 - x)}{x} > \frac{1}{x - 1}.$$

Example 9: Calculate approximately the root of the equation $x^4 - 12x + 7 = 0$ near 2.

Solution: Choose $f(x) = x^4 - 12x + 7$ so $f'(x) = 4x^3 - 12$

By LMV theorem, $f(a + h) = f(a) + hf'(a + \theta h)$

so
$$h \simeq -\frac{f(a)}{f'(a)}$$

$$f(2) = 16 - 24 + 7 = -1, f'(2) = 32 - 12 = 20$$

$$h \simeq -\frac{(-1)}{20} = +0.05$$

An approximate root $x = a + h = 2 + 0.05 = 2.05$
Applying LMV theorem again

$$\begin{aligned} h &\simeq -\frac{f(2.05)}{f'(2.05)} = -\frac{0.061}{22.46} \\ &= -0.0027 \end{aligned}$$

A better approximated root

$$\begin{aligned} &= a + h = 2.05 - 0.0027 \\ &= 2.0473. \end{aligned}$$

2.20 — HIGHER ENGINEERING MATHEMATICS—II

Example 10: Calculate approximately $\sqrt[5]{245}$ by using LMV theorem.

Solution: Choose $f(x) = x^{\frac{1}{5}}$, $a = 243$, $b = 245$ then $f'(x) = \frac{1}{5} \cdot x^{-\frac{4}{5}}$. By LMV theorem,

$$f(a+h) = f(a) + h \cdot f'(c)$$

Take $c = 243$ approximately

$$f(245) = f(243) + (245 - 243) \cdot f'(243)$$

$$\begin{aligned}(245)^{\frac{1}{5}} &= (243)^{\frac{1}{5}} + 2 \cdot \frac{1}{5} (243)^{-\frac{4}{5}} \\ &= 3 + \frac{2}{5} \cdot \frac{1}{34} = 3.0049.\end{aligned}$$

EXERCISE

Verify Lagrange's Mean Value theorem for the following functions $f(x)$ in the indicated interval:

1. $x(x-1)(x-2)$ in $(0, \frac{1}{2})$

Ans. $c = 0.236$

2. $\ln x$ in (e^2, e^3)

Ans. $c = (e-1)e^2$

3. $x^{\frac{1}{3}}$ in $(-1, 1)$

Hint: Derivative at $x = 0$ does not exist.

Ans. LMV theorem not applicable

4. $1 - 3x$ in $(1, 4)$

Hint: $\frac{f(4)-f(1)}{4-1} = -3 = f'(c) = -3$, true for any c .

Ans. any number in $(1, 4)$

5. e^{-x} in $(-1, 1)$

Ans. $c = \ln\left(\frac{2e}{e^2-1}\right) = -0.161$

6. $\sin^{-1} x$ in $(0, 1)$

Ans. $c = \frac{\sqrt{\pi^2-4}}{\pi} = 0.7712$

7. $\cos x$ in $(0, \frac{\pi}{2})$

Ans. $c = \sin^{-1}(2/\pi)$

8. If $f(x)$ is a quadratic expression, then the value of c of the Lagrange's Mean Value theorem in any interval $[a, a+h]$ is the mid-point of that interval.

Hint: Let $f(x) = Ax^2 + Bx + D$, then $c = a + \frac{h}{2} = a + \theta h$ so $\theta = \frac{1}{2}$. Use LMV theorem of the form

$$f(a+h) = f(a) + hf'(a+\theta h).$$

Separate the intervals in which the following function $f(x)$ is increasing or decreasing.

9. $2x^3 - 15x^2 + 36x + 1$

Ans. increasing in $(-\infty, 2)$ and $(3, \infty)$ decreasing in $(2, 3)$

10. $x^3 + 8x^2 + 5x - 2$

Ans. increasing in $(-\infty, -5)$ and $(-\frac{1}{3}, \infty)$ decreasing in $(-5, -\frac{1}{3})$

11. Show that $x - \frac{x^2}{2} < \ln(1+x) < x - \frac{x^2}{2(1+x)}$, for any $x > 0$.

Hint: Choose $f(x) = \ln(1+x) - (x - \frac{x^2}{2})$ and

$$g(x) = x - \frac{x^2}{2(1+x)} - \ln(1+x)$$

prove that f and g are increasing (i.e., $f' > 0$, $g' > 0$).

Note: $f(0) = g(0) = 0$, so $f > 0$ and $g > 0$.

12. Show that $\frac{\tan x}{x} > \frac{x}{\sin x}$ for $0 < x < \frac{\pi}{2}$.

Hint: Take $f(x) = \tan x \cdot \sin x - x^2$

$$f'' > 0, f'(0) = 0, \text{ so } f' > 0$$

Also $f(0) = 0$, so $f > 0$.

13. Use LMV theorem to prove that if $0 < u < v < 1$

$$\frac{v-u}{1+v^2} < \tan^{-1} v - \tan^{-1} u < \frac{v-u}{1+u^2}$$

Deduce that $\frac{\pi}{4} + \frac{3}{25} < \tan^{-1} \frac{4}{3} < \frac{\pi}{4} + \frac{1}{6}$.

Hint: Take $f(x) = \tan^{-1} x$, $u < x < v$.

14. Show that for any x

$$x - \frac{x^3}{6} < \sin x < x - \frac{x^3}{6} + \frac{x^5}{120}.$$

15. For any x show that

$$1 - x < e^{-x} < 1 - x + \frac{x^2}{2}.$$

16. Using LMV theorem prove that

$$\frac{\pi}{3} - \frac{1}{5\sqrt{3}} > \cos^{-1} \frac{3}{5} > \frac{\pi}{3} - \frac{1}{8}.$$

17. Determine the root of the equation $x^3 + 5x - 10 = 0$ which lies in $(1, 2)$ correct to two decimal places.

Ans. 1.43

18. Using Mean Value theorem calculate approximately $\sqrt[3]{65}$.

Hint: Take $f(x) = x^{\frac{1}{3}}$ in $(64, 65)$.

Use $f(a+h) = f(a) + hf'(a)$.

Ans. 2.0052

19. A circular hole 4 inches in diameter and 1 foot deep in a metal block is drilled out to increase the diameter to 4.12 inches. Estimate the amount of metal removed.

Hint: $V = f(x) = \pi(12)x^2$ inches.

By LMV theorem

$$\begin{aligned} f(2.06) - f(2) &= \text{by MVT} = 0.06 f'(x_1) \\ &= 0.06(24\pi x_1) \end{aligned}$$

where $2 < x_1 < 2.06$.

Ans. $2.88\pi \text{ in}^3$

20. Find an approximate value of the root of the equation $x^3 - 2x - 5 = 0$ in $(2, 3)$.

Hint:

$$h = -\frac{f(2)}{f'(2)} = +0.1, \text{ root} = 2 + 0.1$$

$$h = -\frac{f(2.1)}{f'(2.1)} = -0.00543$$

$$\text{root} = 2.1 - 0.00543 = 2.0946.$$

Ans. 2.0946

2.6 CAUCHY'S MEAN VALUE THEOREM

Let $f(x)$ and $g(x)$ be two functions which are both derivable in $[a, b]$ and $g'(x) \neq 0$ for any value of x in $[a, b]$. Then there exists at least one value c in between a and b such that

$$\frac{f(b) - f(a)}{g(b) - g(a)} = \frac{f'(c)}{g'(c)}$$

Proof: Define $\phi(x) = f(x) + Ag(x)$ where A is an unknown constant. ϕ is derivable in $[a, b]$ because f and g are derivable in $[a, b]$ by hypothesis. Choose A such that $\phi(b) = \phi(a)$ i.e.,

$$f(b) + Ag(b) = \phi(b) = \phi(a) = f(a) + Ag(a)$$

$$\text{or} \quad A = \frac{f(b) - f(a)}{g(a) - g(b)}$$

with $g(a) - g(b) \neq 0$. If $g(a) - g(b) = 0$ then $g(a) = g(b)$ and g satisfies conditions of Rolle's theorem and then $g'(c) = 0$ for some c . This contradicts the hypothesis that $g'(x) \neq 0$ for any x . Thus $g(a) - g(b) \neq 0$. Now the new function ϕ satisfies the conditions of Rolle's theorem. Therefore there exists at least one $c \in (a, b)$ such that

$$0 = \phi'(c) = f'(c) + Ag'(c)$$

Thus

$$\frac{f'(c)}{g'(c)} = -A = \frac{f(b) - f(a)}{g(b) - g(a)}$$

with $g(b) - g(a) \neq 0$ as $g'(c) \neq 0$ for any c .

Alternate Form of Cauchy's Mean Value Theorem

Replacing b by $a + h$,

$$\frac{f'(a + \theta h)}{g'(a + \theta h)} = \frac{f(a + h) - f(a)}{g(a + h) - g(a)}, 0 < \theta < 1$$

Note: Cauchy's mean value theorem is a generalization of Lagrange's mean value theorem. When $g(x) = x$, CMV theorem reduces to LMV theorem.

WORKED OUT EXAMPLES

Example 1: Verify Cauchy's mean value (CMV) theorem for the functions

- $f(x) = x^4, g(x) = x^2$ in the interval $[a, b]$
- $f(x) = \ln x, g(x) = \frac{1}{x}$ in $[1, e]$.

Solution: CMV theorem states that $\frac{f(b)-f(a)}{g(b)-g(a)} = \frac{f'(c)}{g'(c)}$

- $f(x) = x^4, g(x) = x^2, [a, b]$
 $f' = 4x^3, g' = 2x$

2.22 — HIGHER ENGINEERING MATHEMATICS—II

By CMV theorem,

$$\frac{b^4 - a^4}{b^2 - a^2} = \frac{f'(c)}{g'(c)} = \frac{4c^3}{2c}$$

$$\therefore c^2 = \frac{1}{2}(a^2 + b^2) \quad \therefore c = \frac{1}{\sqrt{2}}\sqrt{a^2 + b^2} \in (a, b)$$

ii. $f' = \ln x, g(x) = \frac{1}{x}, [1, e]$

$$f' = \frac{1}{x}, \quad g' = -\frac{1}{x^2}$$

By CMV theorem,

$$\frac{\ln e - \ln 1}{\frac{1}{e} - 1} = \frac{1}{c} \cdot (-c^2) = -c$$

$$\therefore c = \frac{e}{e-1} \in (1, e)$$

Example 2: If $0 \leq a < b < \pi/2$ show that

$$0 < \cos a - \cos b < b - a.$$

Solution: Apply CMV theorem to functions $f(x) = \cos x$ and $g(x) = x$ in $[a, b]$. Then by CMV theorem

$$\frac{\cos b - \cos a}{b - a} = -\sin c$$

$$\cos a - \cos b = (b - a) \sin c$$

Since $\cos$ is decreasing in $(0, \pi/2)$, so $\cos a > \cos b$ for $a < b$. Thus $\cos a - \cos b > 0$. Also in $(0, \pi/2)$ maximum value of $\sin x$ is 1. So since $c \in (a, b)$, and $\sin c < 1$

so $(b - a) \sin c < (b - a)$

Thus

$$0 < \cos a - \cos b < (b - a).$$

Example 3: Show that there exists a number $c \in (a, b)$ such that

$$2c[f(a) - f(b)] = f'(c) \cdot [a^2 - b^2]$$

when f is continuous in $[a, b]$ and derivable in (a, b) .

Solution: By applying CMV theorem to the two functions $f(x)$ and $g(x) = x^2$ in $[a, b]$,

$$\frac{f(b) - f(a)}{b^2 - a^2} = \frac{f'(c)}{2c}$$

for some c in (a, b) . Hence the result.

EXERCISE

Verify Cauchy's mean value theorem for the following pair of functions in the indicated interval:

1. e^x, e^{-x} , in the interval (a, b)

Ans. $c = \frac{a+b}{2}$

2. x^2, x in (a, b)

Ans. $c = \frac{a+b}{2}$

3. $\sin x, \cos x$ in (a, b)

Hint:

$$\begin{aligned} -\cot c &= \frac{\cos c}{\sin c} = \frac{\sin b - \sin a}{\cos b - \cos a} \\ &= \frac{2 \sin\left(\frac{b-a}{2}\right) \cdot \cos\left(\frac{b+a}{2}\right)}{-2 \sin\left(\frac{b-a}{2}\right) \cdot \sin\left(\frac{b+a}{2}\right)} \\ &= -\cot\left(\frac{b+a}{2}\right) \end{aligned}$$

Ans. $c = \frac{a+b}{2}$

4. $\sqrt{x}, \frac{1}{\sqrt{x}}$ in (a, b) Ans. $c = \sqrt{ab}$

5. $\frac{1}{x^2}, \frac{1}{x}$ in (a, b) Ans. $c = \frac{2ab}{a+b}$

6. x^3, x^2 in (a, b) Ans. $c = \frac{2(b^2+ab+a^2)}{3(a+b)}$

7. $2x + 1, 3x - 4$ in $(1, 3)$

Ans. CMV theorem is satisfied for every point in the interval $(1, 3)$

8. $x^3 - 3x^2 + 2x, x^3 - 5x^2 + 6x$ in $(0, \frac{1}{2})$

Ans. $c = \frac{5-\sqrt{13}}{6}$

9. $\frac{x^3}{4} - 4x, x^2$ in $(0, 3)$ Ans. $c = \frac{-1+\sqrt{37}}{3}$

10. $x^2, \sqrt{x}$ in $(1, 4)$ Ans. $c = \left(\frac{15}{4}\right)^{\frac{2}{3}}$

11. Show that $\sin b - \sin a < b - a$ if $0 < a < b < \frac{\pi}{2}$.

Hint: Take $f(x) = \sin x, g(x) = x$ in CMV theorem.

12. Show that $\sqrt{\frac{1-x}{1+x}} < \frac{\ln(1+x)}{\sin^{-1}x} < 1$ if $0 \leq x < 1$.

Hint: $f(x) = \ln(1+x), g(x) = \sin^{-1}x$.

2.7 GENERALIZED MEAN VALUE THEOREM

Taylor's Theorem

Let $f^{(n-1)}$ the $(n-1)$ th derivative of f is continuous in $[a, a+h]$, $f^{(n)}$ the n th derivative exists in $(a, a+h)$ and p be a given positive integer. Then there exists at least one number θ lying between 0 and 1 such that

$$f(a+h) = f(a) + h \frac{f'(a)}{1!} + \frac{h^2}{2!} f''(a) + \dots + \frac{h^{n-1}}{(n-1)!} f^{(n-1)}(a) + R_n \quad (1)$$

$$\text{where } R_n = \frac{h^n (1-\theta)^{n-p}}{(n-1)!p} f^{(n)}(a+\theta h) \quad (2)$$

and $0 < \theta < 1$

Proof: $f, f', f'', \dots, f^{(n-2)}$ are continuous in $[a, a+h]$ by the hypothesis that $f^{(n-1)}$ is continuous in $[a, a+h]$.

Define

$$\begin{aligned} \phi(x) = f(x) + (a+h-x)f'(x) + \frac{(a+h-x)^2}{2!} f''(x) \\ + \frac{(a+h-x)^3}{3!} f'''(x) + \dots \\ + \frac{(a+h-x)^{n-2}}{(n-2)!} f^{(n-2)}(x) + \frac{(a+h-x)^{n-1}}{(n-1)!} \times \\ f^{(n-1)}(x) + (a+h-x)^p A \end{aligned} \quad (3)$$

where A is unknown constant. Put $x = a+h$ in (3), we get

$$\phi(a+h) = f(a+h) + 0 + 0 \dots + 0 \quad (4)$$

Put $x = a$ in (3), we get

$$\begin{aligned} \phi(a) = f(a) + \frac{h}{1!} f'(a) + \frac{h^2}{2!} f''(a) \\ + \frac{h^3}{3!} f'''(a) + \dots + \frac{h^{n-2}}{(n-2)!} f^{(n-2)}(a) \\ + \frac{h^{n-1}}{(n-1)!} f^{(n-1)}(a) + h^p A \end{aligned} \quad (5)$$

Choose the constant A such that $\phi(a) = \phi(a+h)$

Equating (3) and (4),

$$\begin{aligned} f(a+h) = \phi(a+h) = \phi(a) = f(a) + hf'(a) \\ + \frac{h^2}{2!} f''(a) + \dots + \frac{h^{n-2}}{(n-2)!} f^{(n-2)}(a) \\ + \frac{h^{n-1}}{(n-1)!} f^{(n-1)}(a) + h^p A \end{aligned} \quad (6)$$

The new function ϕ is continuous in $[a, a+h]$, derivable in $(a, a+h)$ and $\phi(a) = \phi(a+h)$ thus satisfying all the conditions of Rolle's theorem. Therefore it follows from Rolle's theorem that there exists at least one c between a and $a+h$ where

$$\phi'(c) = \phi'(a+\theta h) = 0.$$

Differentiating (3) w.r.t. x , we get

$$\begin{aligned} \phi' = f' - f' + (a+h-x)f'' + \frac{2(a+h-x)}{2!} (-1)f'' \\ + \frac{(a+h-x)^2}{2!} f''' + \frac{3(a+h-x)^2}{3!} (-1)f''' + \dots \\ + \frac{(n-2)(a+h-x)^{n-3}}{(n-2)!} f^{(n-2)} \\ + \frac{(a+h-x)^{n-2}}{(n-2)!} \cdot f^{(n-1)} \\ + \frac{(n-1) \cdot (a+h-x)^{n-2}}{(n-1)!} (-1)f^{(n-1)} \\ + \frac{(a+h-x)^{n-1}}{(n-1)!} f^n + p(a+h-x)^{p-1} A \cdot (-1). \end{aligned}$$

or

$$\phi'(x) = \frac{(a+h-x)^{n-1}}{(n-1)!} f^{(n)}(x) - pA \cdot (a+h-x)^{p-1}$$

Thus

$$\begin{aligned} 0 = \phi'(a+\theta h) = \frac{h^{n-1}}{(n-1)!} (1-\theta)^{n-1} f^{(n)}(a+\theta h) \\ - pA(1-\theta)^{p-1} h^{p-1} \end{aligned}$$

$$\text{Solving, } A = \frac{h^{n-p}(1-\theta)^{n-p}}{(n-1)!p} f^{(n)}(a+\theta h) \quad (7)$$

with $h \neq 0$ and $1-\theta \neq 0$. Substituting A from (7) in (6), we get

2.24 — HIGHER ENGINEERING MATHEMATICS—II

$$\begin{aligned}
 f(a+h) &= f(a) + hf'(a) + \frac{h^2}{2!} f''(a) \\
 &+ \frac{h^3}{3!} f'''(a) + \cdots + \frac{h^{n-1}}{(n-1)!} f^{(n-1)}(a) \\
 &+ \frac{h^n(1-\theta)^{n-p}}{(n-1)!p} f^{(n)}(a+\theta h) \quad (8)
 \end{aligned}$$

with $0 < \theta < 1$.

Taylor's remainder after n terms R_n due to

1. Schlomilch & Roche: $R_n = \frac{h^n(1-\theta)^{n-p} f^{(n)}(a+\theta h)}{(n-1)!p}$
2. Cauchy: $p = 1$: $R_n = \frac{h^n(1-\theta)^{n-1}}{(n-1)!} f^{(n)}(a+\theta h)$
3. Lagrange's: $p = n$: $R_n = \frac{h^n}{n!} f^{(n)}(a+\theta h)$

Putting $a+h=x$ or $h=x-a$ in (8) we get another convenient form of Taylor's theorem as

$$\begin{aligned}
 f(x) &= f(a) + (x-a) \frac{f'(a)}{1!} + \frac{(x-a)^2}{2!} f''(a) \\
 &+ \frac{(x-a)^3}{3!} f'''(a) + \cdots + \frac{(x-a)^{n-1}}{(n-1)!} f^{(n-1)}(a) \\
 &+ \frac{(x-a)^n(1-\theta)^{n-p}}{(n-1)!p} f^{(n)}(a+\theta(x-a)) \quad (9)
 \end{aligned}$$

with $0 < \theta < 1$.

Maclaurin's theorem is a special case of Taylor's theorem when $a = 0$. Thus putting $a = 0$ in (9)

$$\begin{aligned}
 f(x) &= f(0) + xf'(0) + \frac{x^2}{2!} f''(0) + \frac{x^3}{3!} f'''(0) + \cdots \\
 &+ \frac{x^{n-1}}{(n-1)!} f^{(n-1)}(0) + \frac{x^n(1-\theta)^{n-p}}{(n-1)!p} f^{(n)}(\theta x) \quad (10)
 \end{aligned}$$

Schlomilch remainder is given by $\frac{x^n(1-\theta)^{n-p}}{(n-1)!p} \cdot f^{(n)}(\theta x)$

Lagrange's Remainder for Maclaurin's Theorem: (Put $p=n$ in Schlomilch Remainder)

$$\frac{x^n}{n!} f^{(n)}(\theta x)$$

Cauchy's Remainder for Maclaurin's Theorem: (Put $p=1$ in Schlomilch Remainder)

$$\frac{x^n(1-\theta)^{n-1}}{(n-1)!} f^{(n)}(\theta x)$$

WORKED OUT EXAMPLES

Example 1: State Maclaurin's theorem with Lagrange's form of remainder for $f(x) = \cos x$.

Solution: Maclaurin's theorem with Lagrange's form of remainder is given by

$$\begin{aligned}
 f(x) &= f(0) + xf'(0) + \frac{x^2}{2!} f''(0) + \frac{x^3}{3!} f'''(0) + \cdots + \\
 &+ \frac{x^{n-1}}{(n-1)!} f^{(n-1)}(0) + \frac{x^n}{n!} f^{(n)}(\theta x).
 \end{aligned}$$

We know that $\frac{d^n}{dx^n} \{\cos(ax+b)\} = a^n \cdot \cos(ax+b+n\frac{\pi}{2})$.

Here $f(x) = \cos x$

$$\text{so } f^{(n)}(x) = \frac{d^n}{dx^n} (\cos x) = \cos(x + \frac{n\pi}{2})$$

At $a = 0$, $f^{(n)}(0) = \cos(\frac{n\pi}{2})$

Thus $f(0) = \cos 0 = 1$,

$$f^{(2n)}(0) = \cos\left(2\frac{n\pi}{2}\right) = \cos(n\pi) = (-1)^n$$

$$f^{(2n+1)}(0) = \cos\left((2n+1)\frac{\pi}{2}\right) = 0$$

So coefficients of even powers of x will be $(-1)^n$ while coefficients of odd powers of x are all zero. Substituting these values of the $f^{(n)}(0)$ we have

$$\begin{aligned}
 \cos x &= f(x) = 1 + 0 + \frac{x^2}{2!}(-1) + 0 + \frac{x^4}{4!}(+1) + \cdots + \\
 &+ \frac{x^{2n}}{(2n)!}(-1)^n + \frac{x^{2n+1}}{(2n+1)!}(-1)^n(-1) \cos(\theta x)
 \end{aligned}$$

so

$$\begin{aligned}
 \cos x &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots + (-1)^n \frac{x^{2n}}{(2n)!} \\
 &+ \frac{(-1)^{n+1} x^{2n+1}}{(2n+1)!} \cos(\theta x).
 \end{aligned}$$

Example 2: Verify Taylor's theorem for $f(x) = (1-x)^{\frac{5}{2}}$ with Lagrange's form of remainder up to 2 terms in the interval $[0, 1]$.

Solution: $f(x) = (1-x)^{\frac{5}{2}}$ and $f'(x)$ are continuous in $[0, 1]$ while $f''(x)$ is differentiable in $(0, 1)$. Thus $f(x)$ satisfies the conditions of Taylor's

theorem. In Taylor's theorem with Lagrange's form of remainder up to 2 terms, $n = \text{number of terms in the remainder} = 2 = p$ (since Lagrange's) and $a = 0$ and $x = 1$ (since interval is $[0, 1]$).

Thus

$$f(x) = f(0) + xf'(0) + \frac{x^2}{2!} f''(\theta x) \quad \text{with } 0 < \theta < 1$$

$$f'(x) = -\frac{5}{2}(1-x)^{\frac{3}{2}}, f''(x) = \frac{5}{2} \cdot \frac{3}{2}(1-x)^{\frac{1}{2}}$$

$$\text{so } f(0)=1, f'(0)=-\frac{5}{2}, f''(\theta h)=f''(\theta)=\frac{15}{4}(1-\theta)^{\frac{1}{2}}, f(1)=0$$

Substituting these values,

$$0 = 1 + 1 \cdot \left(\frac{-5}{2}\right) + \frac{1^2}{2!} \frac{15}{4}(1-\theta)^{\frac{1}{2}}$$

Solving for θ , we get $\theta = \frac{9}{25} = 0.36$ which lies between 0 and 1, thus verifying the Taylor's theorem.

Example 3: For every $x \geq 0$, show that

$$1 + x + \frac{x^2}{2} \leq e^x \leq 1 + x + \frac{x^2}{2} e^x.$$

Solution: The Maclaurin's theorem with Lagrange's form of remainder for the function $f(x) = e^x$ gives

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^{n-1}}{(n-1)!} + \frac{x^n}{n!} e^{\theta x}$$

where $0 < \theta < 1$. Note that e^x and all its derivatives are continuous for any x . Taking remainder up to 2 terms i.e., $n = 2$, we have

$$e^x = 1 + x + \frac{x^2}{2!} e^{\theta x}$$

For $x \geq 0$ and $0 < \theta < 1$, $e^{\theta x} \leq e^x$ so that

$$1 + x + \frac{x^2}{2!} e^{\theta x} \leq 1 + x + \frac{x^2}{2!} e^x$$

Also for $x \geq 0$ and $0 < \theta < 1$, $e^{\theta x} > 1$ so that

$$1 + x + \frac{x^2}{2!} \leq 1 + x + \frac{x^2}{2!} e^{\theta x}$$

Thus

$$1 + x + \frac{x^2}{2!} \leq 1 + x + \frac{x^2}{2!} e^{\theta x} = e^x \leq 1 + x + \frac{x^2}{2!} e^x.$$

EXERCISE

1. Show that for any x

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} + \cdots + (-1)^{n-1} \cdot \frac{x^{2n-1}}{(2n-1)!} + (-1)^n \frac{x^{2n}}{(2n)!} \sin \theta x$$

where $0 < \theta < 1$

Hint: Apply Maclaurin's theorem for $f(x) = \sin x$ with Lagrange's remainder.

Note: $f^{(n)}(x) = \sin\left(x + \frac{n\pi}{2}\right)$ and $f^{2n}(\theta x) = \sin(\theta x + n\pi) = (-1)^n \sin \theta x$.

2. Calculate the first four terms and the remainder after n terms of the Maclaurin's expression of $e^{ax} \cos bx$.

Hint:

$$\begin{aligned} \frac{d^n}{dx^n} \{e^{ax} \cos bx\} \\ &= (a^2 + b^2)^{n/2} e^{ax} \cdot \cos\left(bx + c + n \tan^{-1} \frac{b}{a}\right) \\ \tan \theta &= \frac{b}{a}, \cos \theta = a/\sqrt{a^2 + b^2}. \end{aligned}$$

$$\begin{aligned} \text{Ans. } e^{ax} \cos bx &= 1 + ax + \frac{a^2 - b^2}{2!} x^2 + \frac{a(a^2 - 3b^2)}{3!} x^3 \\ &+ \cdots + \frac{x^n}{n!} (a^2 + b^2)^{n/2} e^{a\theta x} \times \\ &\times \cos\left(b\theta x + n \tan^{-1} \frac{b}{a}\right). \end{aligned}$$

3. Verify Maclaurin's theorem for $f(x) = (1-x)^{5/2}$ with Lagrange's remainder up to 3 terms when $x = 1$

$$\text{Hint: } f(x) = f(0) + xf'(0) + \frac{x^2}{2!} f''(0) + \frac{x^3}{3!} f'''(\theta h).$$

$$\text{Ans. } \theta = \frac{11}{36} = 0.25 \in (0, 1)$$

4. Verify Taylor's theorem for $f(x) = x^3 - 3x^2 + 2x$ in $[0, \frac{1}{2}]$ with Lagrange's remainder up to 2 terms.

$$\text{Hint: } f\left(\frac{1}{2}\right) = f(0) + \frac{1}{2} f'(0) + \frac{(1/2)^2}{2!} f''(\theta).$$

$$\text{Ans. } \theta = \frac{1}{6} \in \left(0, \frac{1}{2}\right)$$

2.26 — HIGHER ENGINEERING MATHEMATICS—II

Using Taylor's theorem prove the following:

5. $\ln(1+x) < x - \frac{x^2}{2} + \frac{x^3}{3}$ for $x > 0$

Hint: For Lagrange's with 3 terms

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3(1+\theta x)^3}; 0 < \theta < 1$$

and $(1+\theta x)^3 > 1$ for $x > 0$

Note: $\frac{d^n}{dx^n} \ln(1+x) = \frac{(-1)^{n-1}(n-1)!}{(1+x)^n}$.

6. $x - \frac{x^3}{6} < \sin x < x - \frac{x^3}{6} + \frac{x^5}{120}$, for $x > 0$

Hint: Maclaurin's with 2 and 5 terms

$$\sin x = x - \frac{x^3}{3!} \cos \theta_1 x, 0 < \theta_1 < 1$$

and

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} \cos \theta_2 x, 0 < \theta_2 < 1$$

and $\cos \theta_1 x \leq 1$ and $\cos \theta_2 x \leq 1$.

7. $1 - \frac{x^2}{2} \leq \cos x \leq 1 - \frac{x^2}{2} + \frac{x^2}{24}$, for any x

8. $x - \frac{x^2}{2} \leq \sin x \leq x$, for $x > 0$

9. Show that for any $x > 0$ and $a > 0$

$$a^x = 1 + x \cdot \ln a + \frac{x^2}{2!} (\ln a)^2 + \dots + \frac{x^{n-1}}{(n-1)!} (\ln a)^{n-1} + \frac{x^n}{n!} a^{\theta x} (\ln a)^n$$

9. Show that for any $x > 0$ and $a > 0$

$$a^x = 1 + x \cdot \ln a + \frac{x^2}{2!} (\ln a)^2 + \dots + \frac{x^{n-1}}{(n-1)!} (\ln a)^{n-1} + \frac{x^n}{n!} a^{\theta x} (\ln a)^n$$

10. Find the first 3 terms and the Lagrange's remainder after n terms of the function $f(x) = e^{ax} \sin bx$.

Hint:

$$\frac{d^n}{dx^n} \{e^{ax} \sin bx\} = (a^2 + b^2)^{n/2} e^{ax} \sin(bx + n\alpha)$$

so $f^{(n)}(0) = (a^2 + b^2)^{n/2} \cdot \sin n\alpha$.

Ans.

$$bx + abx^2 + \frac{b(3a^2 - b^2)}{3!} x^3 + \dots$$

$$+ \frac{x^n}{n!} (a^2 + b^2)^{n/2} \cdot e^{a\theta x} \sin(b\theta x + n\alpha)$$

where $\tan \alpha = \frac{b}{a}, \sin \alpha = \frac{b}{\sqrt{a^2 + b^2}},$

$$\cos \alpha = \frac{a}{\sqrt{a^2 + b^2}}$$

2.8 TAYLOR'S SERIES AND MACLAURIN'S SERIES EXPANSIONS

From the Taylor's theorem with Lagrange's form of remainder, we get the Taylor's formula

$$\begin{aligned} f(x) = f(a) + (x-a) \frac{f'(a)}{1!} + \frac{(x-a)^2}{2!} f''(a) \\ + \frac{(x-a)^3}{3!} f'''(a) + \dots \\ + \frac{(x-a)^{n-1}}{(n-1)!} f^{n-1}(a) \\ + \frac{(x-a)^n}{n!} f^{(n)}(a + \theta(x-a)) \end{aligned} \quad (1)$$

where $0 < \theta < 1$.

Note: Taylor's formula for $n = 1$, reduces to the Lagrange's mean value theorem (the law of means). Denote the first n terms of R.H.S. of (1) by $P_n(x)$ which is a polynomial of $(n-1)$ th degree in the variable $(x-a)$ and the last term on R.H.S. of (1) by $R_n(x)$ which is the Lagrange's form of remainder after n terms i.e.,

$$\begin{aligned} P_n(x) = f(a) + (x-a) \frac{f'(a)}{1!} + \frac{(x-a)^2}{2!} f''(a) + \dots \\ + \frac{(x-a)^{n-1}}{(n-1)!} f^{n-1}(a) \end{aligned} \quad (2)$$

and

$$R_n(x) = \frac{(x-a)^n}{n!} f^n(a + \theta(x-a)) \quad (3)$$

Then $f(x) = P_n(x) + R_n(x)$

or $R_n(x) = f(x) - P_n(x)$

i.e., $BC = AC - AB$

Thus for those values of x , for which $R_n(x)$ is small, the polynomial $P_n(x)$ yields an approximate

Fig. 2.7

representation of $f(x)$. When $a = 0$, the Taylor's formula (1) at origin $(0, 0)$ reduces to

$$f(x) = f(0) + x \frac{f'(0)}{1!} + \frac{x^2}{2!} f''(0) + \frac{x^3}{3!} f'''(0) + \cdots + \frac{x^{n-1}}{(n-1)!} f^{(n-1)}(0) + \frac{x^n}{n!} f^{(n)}(\theta x) \quad (4)$$

(4) is known as Maclaurin's formula.

In (1) as $n \rightarrow \infty$ if $R_n(x) \rightarrow 0$, then $f(x)$ is represented by infinite series in powers of $(x - a)$ and is given by

$$f(x) = f(a) + \frac{(x-a)}{1!} f'(a) + \frac{(x-a)^2}{2!} f''(a) + \cdots + \frac{(x-a)^n}{n!} f^{(n)}(a) + \cdots \quad (5)$$

The power series (5) is known as Taylor's series. Rewriting in the summation form

$$f(x) = f(a) + \sum_{n=1}^{\infty} \frac{f^{(n)}(a)}{n!} (x-a)^n \quad (6)$$

Thus (5) or (6) is the Taylor's series expansion of $f(x)$ about the point ' a ' (or in powers of $x - a$). When $a = 0$, (6) reduces to

$$f(x) = f(0) + \sum_{n=1}^{\infty} \frac{f^{(n)}(0)}{n!} x^n \quad (7)$$

The infinite series in powers of x given by (7) is called the Maclaurin's series expansion of $f(x)$ or simply Maclaurin's series of $f(x)$ (about origin).

Maclaurin Series Expansion of Some Elementary Functions

1. Exponential function $f(x) = e^x$.

Differentiating n times, $f^{(n)}(x) = e^x$. So at $x = 0$, $f^{(n)}(0) = 1$. Substituting in the Maclaurin's formula (4), we obtain

$$f(x) = e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^{n-1}}{(n-1)!} + \frac{x^n}{n!} e^{\theta x}$$

where $0 < \theta < 1$.

For $0 < \theta < 1$, $e^{\theta x}$ is bounded for any x ($< e^x$ for $x > 0$ and < 1 for $x < 0$). Thus the Lagrange's remainder

$$R_n = \frac{x^n}{n!} e^{\theta x} \rightarrow 0 \text{ as } n \rightarrow \infty \text{ for any } x.$$

Hence the Maclaurin series expansion of e^x is

$$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^n}{n!} + \cdots; -\infty < x < \infty$$

Therefore e^x can be evaluated to any degree of accuracy by taking sufficient number of terms.

2. Expansion of $f(x) = \cos x$

Differentiating n times, $f^{(n)}(x) = \cos(x + \frac{n\pi}{2})$, so $f^{(n)}(0) = \cos n \frac{\pi}{2}$. The remainder

$$R_n(x) = \frac{x^n}{n!} f^{(n)}(\theta x) = \frac{x^n}{n!} \cos\left(\theta x + \frac{n\pi}{2}\right) \rightarrow 0 \text{ as } n \rightarrow \infty$$

since $|\cos(\theta x + \frac{n\pi}{2})| \leq 1$, for all values of x .

At $x = 0$, $f(0) = 1$, $f^{(1)}(0) = \cos \frac{\pi}{2} = 0$, $f^{(2)}(0) = \cos \pi = -1$, $f^{(3)}(0) = \cos \frac{3\pi}{2} = 0$, $f^{(4)}(0) = \cos 2\pi = 1$ and so on. Substituting these values in the Maclaurin series given by (7), we get

$$\begin{aligned} f(x) = \cos x &= 1 + 0 - \frac{x^2}{2!} + 0 + \frac{x^4}{4!} + 0 - \frac{x^6}{6!} + \cdots \\ &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots; -\infty < x < \infty. \end{aligned}$$

3. Expansion of $f(x) = \sin x$.

We know that $f^{(n)}(x) = \sin(x + n \frac{\pi}{2})$. So $f^{(n)}(0) = \sin n \frac{\pi}{2}$ then $f(0) = 0$, $f'(0) = \sin \frac{\pi}{2} = 1$, $f^{(2)}(0) = \sin \pi = 0$, $f^{(3)}(0) = \sin \frac{3\pi}{2} = -1$, $f^{(4)}(0) = \sin 2\pi = 0$ etc.

Substituting these values in (7), we get the Maclaurin series expansion of $f(x)$ valid for any

2.28 — HIGHER ENGINEERING MATHEMATICS—II

x as

$$f(x) = \sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots, \quad -\infty < x < \infty$$

Fig. 2.8

Figure 2.8 shows the graphs of the function $f(x) = \sin x$ and the first three approximations

$$y = x, \quad y = x - \frac{x^3}{3!}, \quad y = x - \frac{x^3}{3!} + \frac{x^5}{5!}$$

4. Expansion of $f(x) = \sinh x$.

We know that $f^{(2n+1)}(x) = \cosh x$ and $f^{(2n)}(x) = \sinh x$ so $f^{(2n+1)}(0) = 1$, $f^{(2n)}(0) = 0$, $f(0) = 0$. Substituting in (7),

$$f(x) = \sinh x = x + \frac{x^3}{3!} + \frac{x^5}{5!} + \frac{x^7}{7!} + \dots; \quad -\infty < x < \infty$$

5. Expansion of $f(x) = \cosh x$.

Since $f^{(2n)}(x) = \cosh x$ and $f^{(2n+1)}(x) = \sinh x$, we have $f^{(2n)}(0) = 1$, $f^{(2n+1)}(0) = 0$, $f(0) = 1$. From (7),

$$f(x) = \cosh x = 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \frac{x^6}{6!} + \dots; \quad -\infty < x < \infty$$

6. Expansion of $f(x) = (ax + b)^m$ where m is any real number and $x > -\frac{b}{a}$ (i.e., $ax + b > 0$) and $a \neq 0$. The n th derivative of f is

$$f^{(n)}(x) = m(m-1)(m-2) \dots (m-n+1)a^n(ax+b)^{m-n}$$

At $x = 0$, $f^{(n)}(0) = m(m-1)(m-2) \dots (m-n+1)a^n \cdot b^{m-n}$ and $f(0) = b^m$.

Substituting in (7), we obtain

$$\begin{aligned} f(x) &= (ax + b)^m = b^m + m \cdot a \cdot b^{m-1}x \\ &\quad + m(m-1)a^2 \cdot b^{m-2} \frac{x^2}{2!} + \\ &\quad + m(m-1)(m-2) \cdot a^3 b^{m-3} \cdot \frac{x^3}{3!} + \dots \end{aligned}$$

$$\begin{aligned} \text{or} \quad (ax + b)^m &= b^m \left[1 + m \left(\frac{a}{b} \right) \frac{x}{1!} \right. \\ &\quad + m(m-1) \left(\frac{a}{b} \right)^2 \frac{x^2}{2!} + \\ &\quad \left. + m(m-1)(m-2) \left(\frac{a}{b} \right)^3 \frac{x^3}{3!} + \dots \right] \end{aligned}$$

valid for any real m and for any $x > -\frac{b}{a}$, $a \neq 0$.

Corollary 1: When $a = b = 1$,

$$\begin{aligned} f(x) &= (1+x)^m = 1 + m \frac{x}{1!} + m(m-1) \frac{x^2}{2!} \\ &\quad + m(m-1)(m-2) \frac{x^3}{3!} + \dots \end{aligned}$$

valid for any real m and for any $x > -1$.

7. Expansion of $f(x) = \ln(1+x)$. We know that

$$f^{(n)}(x) = \frac{(-1)^{n-1}(n-1)!}{(1+x)^n} \quad \text{so}$$

$$f^{(n)}(0) = (-1)^{n-1} \cdot (n-1)! \quad \text{and} \quad f(0) = 0. \quad \text{From (7),}$$

$$\begin{aligned} f(x) &= \ln(1+x) = 0 + x - \frac{x^2}{2!} + 2! \frac{x^3}{3!} - 3! \frac{x^4}{4!} + \dots \\ &\quad + (-1)^{n-1}(n-1)! \frac{x^n}{n!} + \dots \end{aligned}$$

$$\begin{aligned} \text{or} \quad \ln(1+x) &= x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} \dots \\ &\quad + (-1)^{n-1} \frac{x^n}{n} + \dots \end{aligned}$$

valid for $1+x > 0$ i.e., $x > -1$.

8. Expansion of $f(x) = \ln(1-x)$.

$$\text{Here } f^{(n)}(x) = \frac{(-1)^{n-1} \cdot (n-1)! \cdot (-1)^n}{(1-x)^n}, \quad \text{so } f^{(n)}(0) = -(n-1)!$$

From (7),

$$\begin{aligned} f(x) &= \ln(1-x) = -x - \frac{x^2}{2} - \frac{x^3}{3} - \frac{x^4}{4} - \frac{x^5}{5} - \dots - \frac{x^n}{n} - \dots \\ &= - \left(x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \dots + \frac{x^n}{n} + \dots \right) \end{aligned}$$

valid for $x < 1$.

Note: For any given function $f(x)$, in general, the n th derivative $f^{(n)}(x)$ can not be determined and therefore the nature of R_n not known. Therefore by assuming that $R_n \rightarrow 0$ as $n \rightarrow \infty$, formal Maclaurin's expansions of any given function is obtained

from (7) by substituting f and its derivatives evaluated at $x = 0$. If the n th derivative is not obtainable, first few (5 to 6) terms are determined. Sometimes $f(x)$ can be expressed as sum or product of two or more infinite series.

WORKED OUT EXAMPLES

Example 1: Expand the polynomial

$$f(x) = x^5 + 2x^4 - x^2 + x + 1$$

in powers of $x + 1$.

Or

Obtain the Taylor's series expansion of $f(x)$ about the point $x = -1$.

Solution: $f(-1) = -1 + 2 - 1 - 1 + 1 = 0$

$$f'(x) = 5x^4 + 8x^3 - 2x + 1, f'(-1) = 5 - 8 + 2 + 1 = 0$$

$$f''(x) = 20x^3 + 24x^2 - 2, f''(-1) = -20 + 24 - 2 = 2$$

$$f'''(x) = 60x^2 + 48x, f'''(-1) = 60 - 48 = 12$$

$$f^{(4)}(x) = 120x + 48, f^{(4)}(-1) = -120 + 48 = -72$$

$$f^{(5)}(x) = 120, f^{(5)}(-1) = 120$$

$$f^n(x) = 0 \quad \text{for } n > 5.$$

The Taylor series expansion of $f(x)$ about $x = a$.

$$\begin{aligned} f(x) &= f(a) + (x-a)f'(a) + (x-a)^2 \frac{f''(a)}{2!} \\ &\quad + \frac{(x-a)^3}{3!} f'''(a) + \dots \end{aligned}$$

Here $a = -1$. Substituting the above values

$$f(x) = x^5 + 2x^4 - x^2 + x + 1$$

$$= 0 + 0 + (x+1)^2 \cdot \frac{2}{2!} + 12 \cdot \frac{(x+1)^3}{3!}$$

$$- 72 \cdot \frac{(x+1)^4}{4!} + 120 \frac{(x+1)^5}{5!}$$

$$f(x) = (x+1)^2 + 2(x+1)^3 - 3(x+1)^4 + (x+1)^5.$$

Example 2: Write Taylor's formula for the function $y = \sqrt{x}$ with Lagrange's remainder with $a=1, n=3$.

Solution:

$$y = f(x) = \sqrt{x}, f(a) = f(1) = 1$$

$$f'(x) = \frac{1}{2\sqrt{x}}, f'(1) = \frac{1}{2}$$

$$f''(x) = -\frac{1}{4} \frac{1}{x^{\frac{3}{2}}} = -\frac{1}{4}$$

$$f'''(x) = \frac{3}{8} \frac{1}{x^{\frac{5}{2}}} = \frac{1}{8}$$

$$f^{(4)}(x) = -\frac{15}{16} \frac{1}{x^{\frac{7}{2}}}$$

Taylor's formula with Lagrange's remainder up to 4 terms (i.e., $n = 3$)

$$\begin{aligned} f(x) &= f(a) + (x-a) \frac{f'(a)}{1!} + (x-a)^2 \frac{f''(a)}{2!} \\ &\quad + (x-a)^3 \frac{f'''(a)}{3!} + \frac{(x-a)^4}{4!} f^{(4)}(a + \theta(x-a)) \end{aligned}$$

Substituting f and its derivatives at $a = 1$,

$$\begin{aligned} f(x) &= 1 + (x-1) \cdot \frac{1}{2} + (x-1)^2 \left(-\frac{1}{4}\right) \frac{1}{2!} \\ &\quad + (x-1)^3 \cdot \frac{3}{8} \cdot \frac{1}{3!} + (x-1)^4 \cdot \left(-\frac{15}{16}\right) \times \\ &\quad \times \frac{1}{[1 + \theta(x-1)]^{\frac{7}{2}}} \cdot \frac{1}{4!} \\ &= 1 + \frac{1}{2}(x-1) - \frac{1}{8}(x-1)^2 + \frac{1}{16}(x-1)^3 \\ &\quad - \frac{5}{128}(x-1)^4 [1 + \theta(x-1)]^{-\frac{7}{2}}. \end{aligned}$$

Example 3: Expand $\sin x$ in powers of $(x - \frac{\pi}{2})$.

Solution:

$$\begin{aligned} \sin(x) &= \sin\left(x - \frac{\pi}{2} + \frac{\pi}{2}\right) = \sin\left(\left(x - \frac{\pi}{2}\right) + \frac{\pi}{2}\right) \\ &= \sin\left(x - \frac{\pi}{2}\right) \cdot \cos \frac{\pi}{2} + \sin \frac{\pi}{2} \cdot \cos\left(x - \frac{\pi}{2}\right) \\ &= 0 + 1 \cdot \cos\left(x - \frac{\pi}{2}\right). \end{aligned}$$

2.30 — HIGHER ENGINEERING MATHEMATICS—II

We know that $\cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!}$ so

$$\sin x = +\cos\left(x - \frac{\pi}{2}\right) = +\sum_{n=0}^{\infty} (-1)^n \frac{\left(x - \frac{\pi}{2}\right)^{2n}}{(2n)!}$$

The Taylor series expansion of $\sin x$ about $x = \frac{\pi}{2}$ is

$$\begin{aligned}\sin x &= 1 - \left(x - \frac{\pi}{2}\right)^2 \frac{1}{2!} + \left(x - \frac{\pi}{2}\right)^4 \cdot \frac{1}{4!} \\ &\quad - \left(x - \frac{\pi}{2}\right)^6 \frac{1}{6!} + \dots\end{aligned}$$

Example 4: Obtain the first 4 terms of the Taylor's series of $\cos x$ about $x = \frac{\pi}{4}$.

Solution: $\cos x = \cos\left(x - \frac{\pi}{4} + \frac{\pi}{4}\right) = \cos\left(t + \frac{\pi}{4}\right)$
where $t = x - \frac{\pi}{4}$

$$\begin{aligned}\cos x &= \cos t \cdot \cos \frac{\pi}{4} - \sin t \cdot \sin \frac{\pi}{4} = \frac{1}{\sqrt{2}}(\cos t - \sin t) \\ &= \frac{1}{\sqrt{2}} \left[\left(1 - \frac{t^2}{2!} + \frac{t^4}{4!} - \frac{t^6}{6!} + \dots\right) \right. \\ &\quad \left. - \left(t - \frac{t^3}{3!} + \frac{t^5}{5!} - \frac{t^7}{7!} + \dots\right) \right] \\ &= \frac{1}{\sqrt{2}} \left[1 - t + \frac{t^2}{2!} + \frac{t^3}{3!} + \frac{t^4}{4!} - \frac{t^5}{5!} - \frac{t^6}{6!} + \frac{t^7}{7!} + \dots \right] \\ &= \frac{1}{\sqrt{2}} \left[1 - \left(x - \frac{\pi}{4}\right) - \left(x - \frac{\pi}{4}\right)^2 \cdot \frac{1}{2!} + \left(x - \frac{\pi}{4}\right)^3 \cdot \frac{1}{3!} + \right. \\ &\quad \left. + \left(x - \frac{\pi}{4}\right)^4 \cdot \frac{1}{4!} - \left(x - \frac{\pi}{4}\right)^5 \cdot \frac{1}{5!} + \dots \right].\end{aligned}$$

Example 5: Using Taylor's series expansion calculate an approximate value of $\sqrt{10}$.

Solution: Let $\sqrt{10} = \sqrt{9+1} = 3\left(1 + \frac{1}{9}\right)^{\frac{1}{2}}$ using,

$$\begin{aligned}(1+x)^m &= 1 + mx + \frac{m(m-1)}{2!}x^2 \\ &\quad + \frac{m(m-1)(m-2)}{3!}x^3 + \dots\end{aligned}$$

with $x = \frac{1}{9}$, $m = \frac{1}{2}$, we get

$$3\left(1 + \frac{1}{9}\right)^{\frac{1}{2}} = 3\left[1 + \frac{1}{2} \cdot \frac{1}{9} + \frac{\frac{1}{2}\left(\frac{1}{2} - 1\right)}{2!} \left(\frac{1}{9}\right)^2\right]$$

$$+ \frac{\frac{1}{2}\left(\frac{1}{2} - 1\right)\left(\frac{1}{2} - 2\right)}{3!} \left(\frac{1}{9}\right)^3 - \dots\right]$$

considering the first four terms,

$$\approx 3\left[1 + \frac{1}{18} - \frac{1}{8} \cdot \frac{1}{81} + \frac{1}{16} \cdot \frac{1}{729}\right] \approx 3.1629.$$

Example 6: Find the first seven terms of the Maclaurin series of $f(x) = \ln \sec x$.

Solution: $f(0) = \ln \sec 0 = \ln 1 = 0$
Differentiating w.r.t. x ,

$$\begin{aligned}f'(x) &= \frac{1}{\sec x} \cdot \sec x \cdot \tan x = \tan x, f'(0) = \tan 0 = 0 \\ f''(x) &= \sec^2 x, f''(0) = \sec^2 0 = 1 \\ f'''(x) &= 2 \sec x \cdot \sec x \cdot \tan x = 2 \sec^2 x \cdot \tan x, f'''(0) = 0 \\ f^{(4)}(x) &= 4 \sec x \cdot \sec x \cdot \tan x \cdot x + 2 \sec^2 x \cdot \sec^2 x \\ f^{(5)}(x) &= 4 \sec^2 x \cdot \tan^2 x + 2 \sec^4 x, f^{(5)}(0) = 0 + 2 = 2 \\ f^{(6)}(x) &= 8 \sec^2 x \cdot \tan^3 x + 16 \sec^4 x \cdot \tan x, f^{(6)}(0) = 0 \\ f^{(7)}(x) &= 16 \sec^2 x \cdot \tan^4 x + 88 \sec^4 x \cdot \tan^2 x \\ &\quad + 16 \sec^6 x, f^{(7)}(0) = 16\end{aligned}$$

The Maclaurin series is

$$\begin{aligned}f(x) &= f(0) + f'(0) \cdot \frac{x}{1!} + f''(0) \cdot \frac{x^2}{2!} \\ &\quad + f^{(3)}(0) \cdot \frac{x^3}{3!} + \dots\end{aligned}$$

Substituting the above values

$$\begin{aligned}f(x) &= \ln \sec x = 0 + 1 \cdot \frac{x^2}{2!} + 0 + 2 \cdot \frac{x^4}{4!} + 0 \\ &\quad + \frac{16x^6}{6!} + \dots \\ f(x) &= \frac{x^2}{2} + \frac{x^4}{12} + \frac{x^6}{45} + \dots\end{aligned}$$

Example 7: If $y = \sin \ln(x^2 + 2x + 1)$, expand y in ascending powers of x up to x^6 .

Solution: Differentiating y w.r.t. x ,

$$\begin{aligned}y_1 &= +\cos \ln(x^2 + 2x + 1) \cdot \left(\frac{1}{x^2 + 2x + 1}\right) \cdot (2x + 2) \\ y_1 &= \frac{2}{x + 1} \cdot \cos \ln(x^2 + 2x + 1)\end{aligned}$$

$$(x+1)y_1 = 2 \cos \ln(x^2 + 2x + 1)$$

Differentiating again w.r.t. x ,

$$(x+1)y_2 + y_1 = -2 \cdot \sin \ln(x^2 + 2x + 1) \times$$

$$\times \left(\frac{1}{x^2 + 2x + 1} \right) \cdot (2x + 2)$$

$$= -\frac{4}{x+1} \cdot \sin \ln(x^2 + 2x + 1) = -\frac{4y}{(x+1)}$$

or $(x+1)^2 y_2 + (x+1)y_1 + 4y = 0$.

Differentiate ' n ' times using Leibnitz's rule,

$$\left[(x+1)^2 y_{n+2} + n \cdot 2(x+1)y_{n+1} + \frac{n(n-1)}{2} \cdot 2 \cdot 1 \cdot y_n \right] +$$

$$+ [(x+1)y_{n+1} + n \cdot 1 \cdot y_n] + 4y_n = 0$$

or

$$(x+1)^2 y_{n+2} + (x+1)(2n+1)y_{n+1} + (4+n^2)y_n = 0.$$

Recurrence relation: At $x = 0$

$$y_{n+2}(0) = -[(2n+1)y_{n+1}(0) + (4+n^2)y_n(0)]$$

Now $y(0) = 0$, $y_1(0) = 2$,

Using recurrence relation

$$y_2(0) = -[y_1(0) + 4y_0(0)] = -[2 + 4 \cdot 0] = -2$$

$$y_3(0) = -[3y_2(0) + 5y_1(0)] = -[3(-2) + 5 \cdot 2] = -4$$

$$y_4(0) = -[5y_3(0) + 8y_2(0)] = -[5(-4) + 8(-2)] = 36$$

$$y_5(0) = -[7y_4(0) + 13y_3(0)] = -[7(36) + 13(-4)] = -200$$

$$y_6(0) = -[9y_5(0) + 20y_4(0)] = -[9(-200) + 20(36)] = 1080$$

Substituting these values in the Maclaurin series,

$$y = \sin \ln(x^2 + 2x + 1) = 0 + 2 \cdot \frac{x}{1!} - 2 \frac{x^2}{2!} - 4 \cdot \frac{x^3}{3!}$$

$$+ 36 \cdot \frac{x^4}{4!} - 200 \cdot \frac{x^5}{5!} + 1080 \cdot \frac{x^6}{6!} + \dots$$

$$= 2x - x^2 - \frac{2}{3}x^3 + \frac{3}{2}x^4 - \frac{5}{3}x^5 + \frac{3}{2}x^6 + \dots$$

Example 8: Prove that

$$e^x \cos x = 1 + x - \frac{2x^3}{3!} - 2^2 \frac{x^4}{4!} - 2^2 \frac{x^5}{5!} + 2^3 \frac{x^7}{7!} + \dots$$

Solution: R.H.S. in a Maclaurin series expansion of $y = f(x) = e^x \cos x$. We know that

$$y_n = f^{(n)}(x) = \frac{d^n}{dx^n} \{e^x \cos x\} = 2^{\frac{n}{2}} e^x \cdot \cos \left(x + n \frac{\pi}{4} \right).$$

$$\text{For } n=4, y_4(x) = 2^2 \cdot e^x \cdot \cos(x + \pi) = -4e^x \cos x = -4y \text{ i.e., } y_4 = -4y$$

Differentiating n times by Leibnitz's rule, we get the recurrence relation

$$y_{n+4}(x) = -4y_n(x)$$

$$\text{At } x = 0, \quad y_{n+4}(0) = -4y_n(0).$$

Also $y(0) = f(0) = e^0 \cdot \cos 0 = 1$; $y_1(0) = 1$, $y_2(0) = 0$; $y_3(0) = -2$, $y_4(0) = -4$, $y_5(0) = -4$, $y_6(0) = 0$, $y_7(0) = 8$ etc.

With these values, the Maclaurin series expansion of $e^x \cos x = 1 + x - \frac{2}{3!}x^3 - \frac{4}{4!}x^4 - \frac{4}{5!}x^5 + \frac{8}{7!}x^7 + \dots$

Example 9: Expand $e^x \sin^2 x$ in ascending powers of x upto x^5 .

Solution: Let $f(x) = e^x \cdot \sin^2 x$.

We know that

$$e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!} \text{ and } \sin x = \sum_{n=1}^{\infty} \frac{(-1)^{n+1} x^{2n-1}}{(2n-1)!}$$

$$f(x) = e^x \cdot \sin^2 x = \left(\sum_{n=0}^{\infty} \frac{x^n}{n!} \right) \left(\sum_{n=1}^{\infty} \frac{(-1)^{n+1} \cdot x^{2n-1}}{(2n-1)!} \right)$$

$$= \left(1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \dots \right) \times$$

$$\times \left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots \right)^2$$

$$= \left(1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots \right) \times$$

$$\times \left(x^2 + \dots - 2 \frac{x^4}{3!} + \dots \right)$$

Both the series are truncated, because we are considering terms upto x^5 . Multiplying the series term by term, we get

$$f(x) = e^x \sin^2 x = x^2 - \frac{2x^4}{3!} + x^3 - 2 \frac{x^5}{3!} + \frac{x^4}{2!} + \frac{x^5}{3!} + \dots$$

$$= x^2 + x^3 + \frac{1}{6}x^4 + \frac{1}{6}x^5 + \dots$$

Example 10: Using Maclaurin series show that

$$e^{x \cos x} = 1 + x + \frac{x^2}{2} - \frac{x^3}{3} + \dots$$

2.32 — HIGHER ENGINEERING MATHEMATICS—II

Solution: We know that $e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!}$

$$e^{x \cos x} = \sum_{n=0}^{\infty} \frac{(x \cos x)^n}{n!}$$

$$= 1 + x \cos x + \frac{(x \cos x)^2}{2!} + \frac{(x \cos x)^3}{3!} + \dots$$

But $x \cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n)!}$ so

$$e^{x \cos x} = 1 + \left(\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n)!} \right) + \frac{1}{2!} \left(\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n)!} \right)^2$$

$$+ \frac{1}{3!} \left(\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n)!} \right)^3 + \dots$$

$$= 1 + \left(x - \frac{x^3}{2!} + \frac{x^5}{4!} - \frac{x^7}{6!} + \dots \right)$$

$$+ \frac{1}{2!} \left(x - \frac{x^3}{2!} + \frac{x^5}{4!} - \frac{x^7}{6!} + \dots \right)^2$$

$$+ \frac{1}{3!} \left(x - \frac{x^3}{2!} + \frac{x^5}{4!} - \frac{x^7}{6!} + \dots \right)^3 + \dots$$

$$= 1 + x + \frac{1}{2!} x^2 + \left(-\frac{1}{2!} + \frac{1}{3!} \right) x^3 + \dots$$

$$= 1 + x + \frac{x^2}{2} - \frac{x^3}{3} + \dots$$

EXERCISE

1. Expand the polynomial $x^4 - 5x^3 + 5x^2 + x + 2$ in powers of $x - 2$.

Ans. $-7(x-2) - (x-2)^2 + 3(x-2)^3 + (x-2)^4$

2. Expand $2x^3 + 7x^2 + x - 1$ about $x = 2$.

Ans. $45 + 53(x-2) + 19(x-2)^2 + 2(x-2)^3$

3. Find Taylor series expansion of $f(x)$ about 'a' where

i. $f(x) = \ln x, a = 1$

ii. $f(x) = \tan x, a = \frac{\pi}{4}$

iii. $f(x) = \ln \cos x, a = \frac{\pi}{3}$

iv. $f(x) = e^x, a = 3$

Ans. i. $(x-1) - \frac{(x-1)^2}{2!} + \frac{2!}{3!}(x-1)^3 - \frac{3!}{4!}(x-1)^4 + \dots$

ii. $1 + 2(x - \frac{\pi}{4}) + 2(x - \frac{\pi}{4})^2 + \dots$

iii. $-\ln 2 - \sqrt{3}(x - \frac{\pi}{3}) - 2(x - \frac{\pi}{3})^2 + \dots$

iv. $e^{x-3+3} = e^3 \left[\sum_{n=0}^{\infty} \frac{(x-3)^n}{n!} \right]$

4. Prove that

$$f(x) = f(a) + 2 \frac{(x-a)}{2} f' \left(\frac{x+a}{2} \right)$$

$$+ \frac{(x-a)^3}{8(3!)} f''' \left(\frac{x+a}{2} \right)$$

$$+ \frac{(x-a)^5}{32(5!)} f^{(5)} \left(\frac{x+a}{2} \right) + \dots$$

Hint: Expand $f(x) = f\left(\frac{x+a}{2} + \frac{x-a}{2}\right)$ and $f(a) = f\left(\frac{x+a}{2} + \frac{a-x}{2}\right)$ and subtract.

5. Show that

$$\tan^{-1}(x+h) = \tan^{-1} x$$

$$= h \sin z \cdot \frac{\sin z}{1} - (h \sin z)^2 \frac{\sin 2z}{2}$$

$$+ (h \sin z)^2 \frac{\sin 3z}{3} + \dots$$

where $z = \cot^{-1} x$.

Hint: Use Taylor's series, $x = \cot z$, $\frac{dz}{dx} = -\sin^2 z$, take $f(x) = \tan^{-1} x$.

6. Calculate the approximate value of $\cos 32^\circ$ using Taylor series.

Hint: Expand $f(30+2) = \cos(30+2)$

Ans. 0.8482

7. Obtain the Maclaurin series of a^x

Hint: $f^{(n)}(x) = a^x (\log a)^n, f^{(n)}(0) = (\log a)^n$

Ans. $a^x = 1 + x \log a + \frac{1}{2!} (x \log a)^2 + \frac{1}{3!} (x \log a)^3 + \dots + \frac{1}{n!} (x \log a)^n + \dots$

8. If $f(x) = x^3 + 3x^2 + 15x - 10$, calculate the approximate value of $f(\frac{11}{10})$.

Hint: Use Taylor's series and expand $f(\frac{11}{10}) = f(1+h) = f(1 + \frac{1}{10})$; $f(1) = 9, f'(1) = 24,$

$$f''(1) = 12, f'''(1) = 6.$$

Ans. 11.461

9. Determine the approximate value of π using the Maclaurin series expansion of $\sin^{-1} x$.

$$\text{Hint: } y = \sin^{-1} x = x + \frac{1^2}{3!}x^2 + \frac{1^2 \cdot 3^2}{5!}x^5 + \frac{1^2 \cdot 3^2 \cdot 5^2}{7!}x^7 + \dots, (1-x^2)y_{n+2} - (2n+1)xy_{n+1} - (n^2+1)xy_{n+1} - n^2y_n = 0, y_{n+2}(0) = n^2y_n(0).$$

Ans. $\pi = 3.1386$

10. Expand $f(x) = e^{ax} \cdot \sin bx$ in ascending powers of x .

Hint:

$$f^{(n)}(0) = (a^2 + b^2)^{\frac{n}{2}} \sin n\theta; \\ \sin \theta = \frac{b}{\sqrt{a^2 + b^2}}; \quad \cos \theta = \frac{a}{\sqrt{a^2 + b^2}}$$

Ans. $e^{ax} \sin bx = bx + abx^2 + \frac{b(3a^2 - b^2)}{3!}x^3 + \dots$

11. Obtain the Maclaurin series of $\tan x$.

$$\text{Hint: } f(x) = \tan x, f(0) = 0, f'(x) = 1 + \tan^2 x, \\ f'(0) = 1, f'' = 2(\tan x + \tan^3 x); f''(0) = 0, \\ f''' = 2 + 8\tan^2 x + 6\tan^4 x, f'''(0) = 2, \\ f'''' = 16\tan x + 40\tan^3 x + 24\tan^5 x, f''''(0) = 0 \\ f''''' = 16\sec^2 x + 120\tan^2 x \sec^2 x + \\ 120\tan^4 x \sec^2 x, f'''''(0) = 16$$

Ans. $\tan x = x + \frac{1}{3}x^3 + \frac{2}{15}x^5 + \dots$

12. Find the Maclaurin series of $y = e^x \ln(1+x)$.

$$\text{Hint: } (1+x)y_{n+2} + (n-x)y_{n+1} - (n+1)y_n - e^x = 0, y(0) = 0, y_1(0) = 1, y_2(0) = 1, \\ y_{n+2}(0) = -ny_{n+1}(0) + (n+1)y_n(0) + 1$$

Ans. $x + \frac{x^2}{2!} + \frac{2x^3}{3!} + \frac{9x^5}{5!} - \frac{35x^6}{6!} + \dots$

13. Write the Maclaurin formula for $y = \sqrt{1+x}$ when $n = 2$ and with Lagrange's remainder

Ans. $\sqrt{1+x} = 1 + \frac{1}{2}x - \frac{1}{8}x^2 + \frac{x^3}{16} \cdot (1+\theta x)^{-\frac{5}{2}}, \\ 0 < \theta < 1.$

14. Show that

$$e^{a \sin^{-1} x} = 1 + ax + \frac{a^2}{2!}x^2 + \frac{a(1^2 + a^2)}{3!}x^3 \\ + \frac{a^2(2^2 + a^2)}{4!}x^4 + \dots$$

$$\text{Hint: } y = e^{a \sin^{-1} x}, y(0) = 1, y_1(0) = a, y_2(0) = a^2, (1-x^2)y_{n+2} - (2n+1)xy_{n+1} - (n^2+a^2)y_n = 0 \text{ and } y_{n+2}(0) = (n^2+a^2)y_n(0)$$

15. Show that $\tan^{-1} x = x - \frac{1}{3}x^3 + \frac{1}{5}x^5 + \dots$ for $|x| < 1$. (This series is known as **Gregory's series**).

$$\text{Hint: } (1+x^2)y_1 = 1, (1+x^2)y_{n+1} + 2nxy_n + n(n-1)y_{n-1} = 0, y_{n+1}(0) = -n(n-1)y_{n-1}(0).$$

2.9 INDETERMINATE FORMS

If two functions $f(x)$ and $g(x)$ are both zero at $x = a$, the fraction $\frac{f(a)}{g(a)}$ is said to assume the indeterminate form $\frac{0}{0}$. Although the function $F(x) = \frac{f(x)}{g(x)}$ is undefined (indeterminate) at $x = a$, it may however approach a limit as x approaches a . The process of determining such a limit, if it exists, is known as the evaluation of indeterminate forms. The L'Hospital's rule (theorem) allows the evaluation of indeterminate forms.

L'Hospital's Rule

Let $f(x)$ and $g(x)$ be continuous in an interval (c, d) containing $x = a$. Suppose $f(a) = 0$ and $g(a) = 0$. Also the derivatives of f and g exist and $g'(x) \neq 0$ in (c, d) except possibly at $x = a$. Then

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \lim_{x \rightarrow a} \frac{f'(x)}{g'(x)} \quad (1)$$

provided the limit on R.H.S. of (1) exists.

Proof: Since $f(x)$ and $g(x)$ satisfy conditions of Cauchy's mean value theorem in (c, d) , we have

$$\frac{f(x) - f(a)}{g(x) - g(a)} = \frac{f'(e)}{g'(e)}$$

where $e \in (c, d)$ such that $x < e < a$ or $a < e < x$. From hypothesis $f(a) = 0, g(a) = 0$. So

$$\frac{f(x)}{g(x)} = \frac{f'(e)}{g'(e)}$$

As $x \rightarrow a, e \rightarrow a$, we have

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \lim_{x \rightarrow a} \frac{f'(x)}{g'(x)}$$

2.34 — HIGHER ENGINEERING MATHEMATICS—II

Note: In R.H.S. of (1) the functions $f(x)$ and $g(x)$ are differentiated w.r.t. x , separately, not by using the quotient rule.

Corollary 1: Suppose $f'(a) = 0$, and $g'(a) = 0$ in addition to $f(a) = 0$ and $g(a) = 0$. Then applying Cauchy's mean value theorem to $f'(x)$ and $g'(x)$, we get the L'Hospital's rule as

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \lim_{x \rightarrow a} \frac{f''(a)}{g''(a)}$$

Corollary 2: If $f(a) = 0$, $g(a) = 0$, $f'(a) = 0$, $g'(a) = 0$, ..., $f^{(n-1)}(a) = 0$, $g^{(n-1)}(a) = 0$, and $g^{(n)}(a) \neq 0$ then

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \lim_{x \rightarrow a} \frac{f^{(n)}(a)}{g^{(n)}(a)}$$

Corollary 3: As $x \rightarrow \infty$ if $\frac{f(x)}{g(x)}$ assumes indeterminate form $\frac{0}{0}$ then the L'Hospital's rule is

$$\lim_{x \rightarrow \infty} \frac{f(x)}{g(x)} = \lim_{x \rightarrow \infty} \frac{f'(x)}{g'(x)}$$

Results similar to Corollary 1, and Corollary 2 are valid as $x \rightarrow \infty$.

Indeterminate Forms of the Type $\frac{\infty}{\infty}$

Suppose $f(x) = \infty$ and $g(x) = \infty$ as $x \rightarrow a$ (or as $x \rightarrow \pm\infty$). Then $\frac{f(x)}{g(x)}$ assumes the indeterminate form $\frac{\infty}{\infty}$ which can also be evaluated by L'Hospital's rule.

$$\lim_{\substack{x \rightarrow a \\ (\text{or } x \rightarrow \pm\infty)}} \frac{f(x)}{g(x)} = \lim_{\substack{x \rightarrow a \\ (\text{or } x \rightarrow \pm\infty)}} \frac{f'(x)}{g'(x)}$$

Results similar to Corollary 1 and Corollary 2 are valid in this case also.

Important Note: While evaluating the indeterminate form $\frac{\infty}{\infty}$, in many cases, it is advised to convert the indeterminate form $\frac{\infty}{\infty}$ to the form $\frac{0}{0}$ as early as possible (say by rewriting as $\frac{1}{\frac{1}{g(x)}}$). Otherwise the process of differentiation of the numerator $f(x)$ and denominator $g(x)$ may *never* terminate, thus complicating the problem.

Indeterminate Form $0 \cdot \infty$

As $x \rightarrow a$ (or $x \rightarrow \pm\infty$) if $f(x) \rightarrow 0$ and $g(x) \rightarrow \infty$ then the product $f(a) \cdot g(a)$ is undefined and is said

to assume the indeterminate form $0 \cdot \infty$. This can be converted to the indeterminate form $\frac{0}{0}$ or $\frac{\infty}{\infty}$ by rewriting

$$f(x) \cdot g(x) = \frac{f(x)}{\left(\frac{1}{g(x)}\right)} \quad \text{or} \quad \frac{g(x)}{\left(\frac{1}{f(x)}\right)}$$

and apply L'Hospital's rule.

Indeterminate Form $\infty - \infty$

As $x \rightarrow a$ (or $x \rightarrow \pm\infty$) if $f(x) \rightarrow \infty$ and $g(x) \rightarrow \infty$ then the difference $f(a) - g(a)$ is indeterminate of the form $\infty - \infty$. Rewriting the difference into a fraction of algebraic means, we get

$$f(x) - g(x) = \frac{\frac{1}{g(x)} - \frac{1}{f(x)}}{\frac{1}{f(x)g(x)}}$$

which $\frac{0}{0}$ form. Applying L'Hospital's rule, the indeterminate form $\infty - \infty$ is evaluated.

Indeterminate Forms of the Type 0^0 , ∞^0 , 1^∞

As $x \rightarrow a$ (or $x \rightarrow \neq \infty$), the expression $f(a)^{g(a)}$ is said to be (i) indeterminate form of type 0^0 if $f(x) \rightarrow 0$ and $g(x) \rightarrow 0$ (ii) indeterminate form of type ∞^0 if $f(x) \rightarrow \infty$ and $g(x) \rightarrow 0$ (iii) indeterminate form of type 1^∞ if $f(x) \rightarrow 1$ and $g(x) \rightarrow \infty$. To evaluate these forms consider.

$$y(x) = f(x)^{g(x)}$$

Taking logarithm

$$\ln y = g(x) \ln f(x)$$

which is of the form $0 \cdot \infty$ and can be evaluated as in *Indeterminate Form* $0 \cdot \infty$. Taking the limit as $x \rightarrow a$ (or $x \rightarrow \pm\infty$)

$$\lim_{x \rightarrow a} \ln y = k \text{ (say).}$$

Then

$$k = \lim_{x \rightarrow a} (\ln y) = \ln \left(\lim_{x \rightarrow a} y \right) = \ln \left(\lim_{x \rightarrow a} f(x)^{g(x)} \right)$$

$$\therefore \lim_{x \rightarrow a} f(x)^{g(x)} = e^k.$$

Notes:

- i. Maclaurin series expansion may be used to simplify the expressions.

- ii. Standard limits such as $\lim_{x \rightarrow 0} \frac{\sin x}{x} = 1$,
 $\lim_{x \rightarrow 0} \frac{\tan x}{x} = 1$, $\lim_{x \rightarrow 0} (1+x)^{\frac{1}{x}} = e$ may also be used.

WORKED OUT EXAMPLES

Type $\frac{0}{0}$ form

Example 1: Evaluate

$$\begin{aligned} \text{(a)} \quad & \lim_{x \rightarrow 1} \frac{1 + \ln x - x}{1 - 2x + x^2} & \text{(b)} \quad & \lim_{x \rightarrow 0} \frac{e^{ax} - e^{-ax}}{\ln(1 + bx)} \\ \text{(c)} \quad & \lim_{x \rightarrow \frac{\pi}{4}} \frac{(\sec^2 x - 2 \tan x)}{1 + \cos 4x} \end{aligned}$$

Solution:

- a. At $x = 1$, $\frac{1 + \ln x - x}{1 - 2x + x^2} = \frac{1 + \ln 1 - 1}{1 - 2 \cdot 1 + 1^2} = \frac{0}{0}$, indeterminate. Applying L'Hospital's rule

$$\begin{aligned} \lim_{x \rightarrow 1} \frac{1 + \ln x - x}{1 - 2x + x^2} &= \lim_{x \rightarrow 1} \frac{(1 + \ln x - x)^i}{(1 - 2x + x^2)^i} \\ &= \lim_{x \rightarrow 1} \frac{0 + \frac{1}{x} - 1}{-2 + 2x} \end{aligned}$$

which is again of the $\frac{0}{0}$ form. Applying L'Hospital's rule again, we get

$$\begin{aligned} \lim_{x \rightarrow 1} \frac{1 + \ln x - x}{1 - 2x + x^2} &= \lim_{x \rightarrow 1} \frac{(\frac{1}{x} - 1)^i}{(-2 + 2x)^i} \\ &= \lim_{x \rightarrow 1} \frac{-\frac{1}{x^2}}{2} = -\frac{1}{2}. \end{aligned}$$

- b. At $x = 0$, $\frac{e^{ax} - e^{-ax}}{\ln(1 + bx)} = \frac{1 - 1}{\ln 1} = \frac{0}{0}$ form.

Applying L'Hospital's rule

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{e^{ax} - e^{-ax}}{\ln(1 + bx)} &= \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(e^{ax} - e^{-ax})}{\frac{d}{dx}(\ln(1 + bx))} \\ &= \lim_{x \rightarrow 0} \frac{ae^{ax} + ae^{-ax}}{\frac{b}{1 + bx}} = \frac{a + a}{\frac{b}{1}} = \frac{2a}{b} \end{aligned}$$

- c. $\lim_{x \rightarrow \frac{\pi}{4}} \frac{\sec^2 x - 2 \tan x}{1 + \cos 4x} : \frac{0}{0}$ form. Applying the rule

$$= \lim_{x \rightarrow \frac{\pi}{4}} \frac{\frac{d}{dx}(\sec^2 x - 2 \tan x)}{\frac{d}{dx}(1 + \cos 4x)}$$

$$\begin{aligned} &= \lim_{x \rightarrow \frac{\pi}{4}} \frac{2 \sec x \cdot \sec x \cdot \tan x - 2 \sec^2 x}{-4 \sin 4x} \\ &= \lim_{x \rightarrow \frac{\pi}{4}} \frac{\sec^2 x (\tan x - 1)}{-2 \sin 4x} : \frac{0}{0} \\ &= \lim_{x \rightarrow \frac{\pi}{4}} \frac{2 \sec x \cdot \sec x \cdot \tan x (\tan x - 1) + \sec^2 x \cdot \sec^2 x}{-8 \cos 4x} \\ &= \frac{2 \cdot 2 \cdot 1 \cdot (1 - 1) + 2 \cdot 2}{-8 \cdot (-1)} = \frac{1}{2} \end{aligned}$$

(since $\cos 4 \frac{\pi}{4} = -1$, $\sec^2 \frac{\pi}{4} = 2$, $\tan \frac{\pi}{4} = 1$).

Example 2: Evaluate

- i. $\lim_{x \rightarrow 0} \frac{\cos x - \ln(1+x) - 1 + x}{\sin^2 x}$
 ii. $\lim_{x \rightarrow 0} \frac{x^2 + 2 \cos x - 2}{x \sin^3 x}$
 iii. $\lim_{x \rightarrow 0} \frac{\sin 2x + a \sin x}{x^3}$ is finite. Find a and the limit.

Solution:

- i. $\frac{0}{0}$ form use Maclaurin series expansions for $\cos x$, $\ln(1 + x)$ and $\sin x$. Then

$$\begin{aligned} & \lim_{x \rightarrow 0} \frac{\cos x - \ln(1 + x) - 1 + x}{\sin^2 x} \\ &= \lim_{x \rightarrow 0} \frac{\left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots\right) - \left(x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots\right) - 1 + x}{\left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots\right)^2} \\ &= \lim_{x \rightarrow 0} \frac{-\frac{x^3}{3} + \frac{7}{24}x^4 + \dots}{x^2 - \frac{x^6}{(3!)^2} + \frac{x^{10}}{(5!)^2} + \dots - \frac{2x^4}{3!} + \frac{2x^6}{5!} + \dots} \\ &= \lim_{x \rightarrow 0} \frac{-\frac{1}{3}x + \frac{7}{24}x^3 + \dots}{1 - \frac{1}{3}x^2 - \frac{1}{36}x^4 + \dots} = \frac{0}{1} = 0. \end{aligned}$$

$$\begin{aligned} \text{ii.} \quad & \lim_{x \rightarrow 0} \frac{x^2 + 2 \cos x - 2}{x \cdot \sin^3 x} \\ &= \lim_{x \rightarrow 0} \frac{x^2 + 2 \cos x - 2}{x \cdot x^3 \cdot \sin^3 x} \\ &= \lim_{x \rightarrow 0} \frac{x^2 + 2 \cos x - 2}{x^4} \cdot \lim_{x \rightarrow 0} \left(\frac{x}{\sin x}\right)^3 \\ &= \lim_{x \rightarrow 0} \frac{x^2 + 2 \cos x - 2}{x^4} \cdot 1 = \frac{0}{0} \end{aligned}$$

since $\lim_{x \rightarrow 0} \frac{\sin x}{x} = 1$. Now applying L'Hospital's rule

$$= \lim_{x \rightarrow 0} \frac{2x - 2 \sin x}{4x^3} = \lim_{x \rightarrow 0} \frac{1 - \cos x}{6x^2} = \lim_{x \rightarrow 0} \frac{\sin x}{12x}$$

2.36 — HIGHER ENGINEERING MATHEMATICS—II

$$= \frac{1}{12} \lim_{x \rightarrow 0} \frac{\sin x}{x} = \frac{1}{12} \cdot 1 = \frac{1}{12}.$$

iii. At $x = 0$, $\frac{\sin 2x + a \sin x}{x^3}$ is $\frac{0}{0}$ for any a .

Applying L'Hospital's rule

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{\sin 2x + a \sin x}{x^3} \\ = \lim_{x \rightarrow 0} \frac{2 \cdot \cos 2x + a \cos x}{3x^2} = \infty. \end{aligned}$$

In order that the limit is finite, choose $a = -2$ in which case it reduces to $\frac{0}{0}$ form. Applying L'Hospital's rule

$$\begin{aligned} &= \lim_{x \rightarrow 0} \frac{-4 \sin 2x + 2 \sin x}{6x} = \frac{0}{0} \\ &= \lim_{x \rightarrow 0} \frac{-4 \cos 2x + \cos x}{3} = \frac{-4 + 1}{3} = -1. \end{aligned}$$

Type $\frac{\infty}{\infty}$ form

Example 3: Evaluate (i) $\lim_{x \rightarrow \infty} \frac{x^n}{e^x}$

(ii) $\lim_{x \rightarrow \infty} \frac{x}{\sqrt{1+x^2}}$ (iii) $\lim_{x \rightarrow 0} \log_{\tan x} \tan 2x$.

Solution:

i. $\frac{\infty}{\infty}$ form. Applying L'Hospital's rule repeatedly n times

$$\lim_{x \rightarrow \infty} \frac{x^n}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d^n}{dx^n} x^n}{\frac{d^n}{dx^n} e^x} = \lim_{x \rightarrow \infty} \frac{n!}{e^x} = 0.$$

ii. $\frac{\infty}{\infty}$ form. Applying L'Hospital's rule

$$\begin{aligned} \lim_{x \rightarrow \infty} \frac{x}{\sqrt{1+x^2}} &= \frac{1}{\frac{1}{2}(1+x^2)^{-\frac{1}{2}} \cdot 2x} \\ &= \frac{\sqrt{1+x^2}}{x} : \frac{\infty}{\infty} \text{ form.} \end{aligned}$$

Again applying L'Hospital's rule

$$\begin{aligned} &= \lim_{x \rightarrow \infty} \frac{\frac{1}{2}(1+x^2)^{-\frac{1}{2}} \cdot 2x}{1} \\ &= \lim_{x \rightarrow \infty} \frac{x}{\sqrt{1+x^2}} : \frac{\infty}{\infty} : \text{which is the original function.} \end{aligned}$$

Instead introduce $z = \frac{1}{x^2}$ then

$$\begin{aligned} \lim_{x \rightarrow \infty} \frac{x}{\sqrt{1+x^2}} &= \lim_{z \rightarrow 0} \frac{x}{x \sqrt{\frac{1}{x^2} + 1}} \\ &= \lim_{z \rightarrow 0} \frac{1}{\sqrt{z+1}} = 1. \end{aligned}$$

iii. $\frac{\infty}{\infty}$ form.

$$\lim_{x \rightarrow 0} \log_{\tan x} \tan 2x = \lim_{x \rightarrow 0} \frac{\log \tan 2x}{\log \tan x} : \frac{\infty}{\infty}$$

Applying L'Hospital's rule

$$\begin{aligned} &= \lim_{x \rightarrow 0} \frac{1}{\tan 2x} \cdot 2 \cdot \sec^2 2x \cdot \frac{\tan x}{\sec^2 x} : \frac{0}{0} \text{ form} \\ &= \lim_{x \rightarrow 0} \frac{\sin x \cdot \cos x \cdot 2}{\sin 2x \cdot \cos 2x} = \lim_{x \rightarrow 0} \frac{2 \cdot \frac{1}{2} \sin 2x}{\frac{1}{2} \sin 4x} \\ &= \lim_{x \rightarrow 0} \frac{\sin 2x}{2x} \cdot \frac{4x}{\sin 4x} = 1 \cdot 1 = 1. \end{aligned}$$

Type $0 \cdot \infty$ form

Example 4: Evaluate

i. $\lim_{x \rightarrow 1} \log(1-x) \cdot \cot \frac{\pi x}{2}$
ii. $\lim_{x \rightarrow a} (a-x) \cdot \tan \frac{\pi x}{2a}$.

Solution:

i. $\infty \cdot 0$ forms. Rewriting in $\frac{\infty}{\infty}$ form

$$\lim_{x \rightarrow 1} \log(1-x) \cdot \cot \frac{\pi x}{2} = \lim_{x \rightarrow 1} \frac{\ln(1-x)}{\tan \frac{\pi x}{2}}.$$

Applying L'Hospital's rule

$$= \lim_{x \rightarrow 1} \frac{\frac{1}{1-x} \cdot (-1)}{\frac{\pi}{2} \cdot \sec^2 \frac{\pi x}{2}} : \frac{\infty}{\infty} \text{ form.}$$

Rewriting in $\frac{0}{0}$ form

$$= \lim_{x \rightarrow 1} \frac{-2 \cos^2 \frac{\pi x}{2}}{\pi (1-x)} : \frac{0}{0} \text{ form.}$$

Applying L'Hospital's rule

$$= \lim_{x \rightarrow 1} -\frac{2}{\pi} \cdot \frac{2 \cdot \cos \frac{\pi x}{2} \cdot (-\sin \frac{\pi x}{2}) \cdot \frac{\pi}{2}}{-1} = 0.$$

ii. $0 \cdot \infty$ form. Rewriting

$$\lim_{x \rightarrow a} (a - x) \cdot \tan \frac{\pi x}{2a} = \lim_{x \rightarrow a} \frac{\tan \frac{\pi x}{2a}}{\left(\frac{1}{a-x}\right)} : \frac{\infty}{\infty} \text{ form.}$$

Applying L'Hospital's rule

$$= \lim_{x \rightarrow a} \frac{\frac{2a}{\pi} \cdot \sec^2 \frac{\pi x}{2a}}{\frac{1}{(a-x)^2}(-1)} : \frac{\infty}{\infty} \text{ form.}$$

Rewriting in $\frac{0}{0}$ form

$$\begin{aligned} &= \lim_{x \rightarrow a} \frac{2a}{\pi} \cdot \frac{(a-x)^2}{\cos^2\left(\frac{\pi x}{2a}\right)} = \\ &= \lim_{x \rightarrow a} \frac{2a}{\pi} \cdot \frac{(-2)(a-x)}{2 \cdot \cos\left(\frac{\pi x}{2a}\right) \cdot \left(-\sin \frac{\pi x}{2a}\right) \cdot \frac{\pi}{2a}} : \frac{0}{0} \\ &= \lim_{x \rightarrow a} \frac{-1}{\frac{2a}{\pi} \cdot \cos^2 \frac{\pi x}{2a} - \frac{\pi}{2a} \sin^2 \frac{\pi x}{2a}} \\ &= \frac{-1}{0 - \frac{\pi}{2a}} = \frac{2a}{\pi}. \end{aligned}$$

Type $\infty - \infty$ form

Example 5: Evaluate

- i. $\lim_{x \rightarrow \frac{\pi}{2}} (\sec x - \tan x)$
- ii. $\lim_{x \rightarrow 1} \left[\frac{x}{x-1} - \frac{1}{\ln x} \right]$
- iii. $\lim_{x \rightarrow 0} \left(\frac{1}{x^2} - \cot^2 x \right).$

Solution:

 i. $\infty - \infty$ form. Rewriting

$$\begin{aligned} \lim_{x \rightarrow \frac{\pi}{2}} (\sec x - \tan x) &= \lim_{x \rightarrow \frac{\pi}{2}} \left(\frac{1}{\cos x} - \frac{\sin x}{\cos x} \right) \\ &= \lim_{x \rightarrow \frac{\pi}{2}} \left(\frac{1 - \sin x}{\cos x} \right) : \frac{0}{0} \end{aligned}$$

Applying L'Hospital's rule

$$\lim_{x \rightarrow \frac{\pi}{2}} \frac{\cos x}{\sin x} = \frac{0}{1} = 0.$$

 ii. $\infty - \infty$ form. Rewriting

$$\lim_{x \rightarrow 1} \left[\frac{x}{x-1} - \frac{1}{\ln x} \right] = \lim_{x \rightarrow 1} \frac{x \ln x - (x-1)}{(x-1) \ln x} : \frac{0}{0} \text{ form.}$$

$$= \lim_{x \rightarrow 1} \frac{x \cdot \frac{1}{x} + \ln x - 1}{1 \cdot \ln x + (x-1) \cdot \frac{1}{x}} : \frac{0}{0} \text{ form}$$

$$= \lim_{x \rightarrow 1} \frac{\frac{1}{x}}{\frac{1}{x} + \frac{1}{x^2}} = \frac{1}{1+1} = \frac{1}{2}.$$

 iii. $\infty - \infty$ form. Rewriting

$$\lim_{x \rightarrow 0} \left(\frac{1}{x^2} - \cot^2 x \right) = \lim_{x \rightarrow 0} \left(\frac{1}{x^2} - \frac{\cos^2 x}{\sin^2 x} \right)$$

$$= \lim_{x \rightarrow 0} \left(\frac{\sin^2 x - x^2 \cos^2 x}{x^2 \sin^2 x} \right) : \frac{0}{0}$$

$$= \lim_{x \rightarrow 0} \frac{\sin^2 x - x^2 \cos^2 x}{x^4} \cdot \lim_{x \rightarrow 0} \frac{x^2}{\sin^2 x}.$$

$$\cdot \text{Since } \lim_{x \rightarrow 0} \frac{\sin x}{x} = 1,$$

$$= \lim_{x \rightarrow 0} \left[\frac{1}{x^2} \cdot \frac{\sin^2 x}{x^2} - \frac{\cos^2 x}{x^2} \right] \cdot 1$$

$$= \lim_{x \rightarrow 0} \left(\frac{1}{x^2} \cdot 1 - \frac{\cos^2 x}{x^2} \right) : \infty - \infty$$

$$= \lim_{x \rightarrow 0} \left(\frac{1 - \cos^2 x}{x^2} \right) : \frac{0}{0} \text{ form. Applying rule}$$

$$= \lim_{x \rightarrow 0} \frac{-2 \cos x \cdot (-\sin x)}{2x}$$

$$= \lim_{x \rightarrow 0} \cos x \cdot \lim_{x \rightarrow 0} \frac{\sin x}{x} = 1 \cdot 1 = 1.$$

Types 0^0 , ∞^0 , 1^∞

Example 6: Evaluate (0^0 form)

- (i) $\lim_{x \rightarrow 0} (x)^x$
- (ii) $\lim_{x \rightarrow \frac{\pi}{2}} (\cos x)^{\left(\frac{\pi}{2}-x\right)}$
- (iii) $\lim_{x \rightarrow 0} (x + \sin x)^{\tan x}.$

Solution:

 i. 0^0 form. Put $y = x^x$. Take logarithm, then

$$\lim_{x \rightarrow 0} \ln y = \lim_{x \rightarrow 0} x \ln x = 0 \cdot \infty \text{ form. Rewriting}$$

$$= \lim_{x \rightarrow 0} \frac{\ln x}{\frac{1}{x}} : \frac{\infty}{\infty} \text{ form} = \lim_{x \rightarrow 0} \frac{\frac{1}{x}}{-\frac{1}{x^2}} = \lim_{x \rightarrow 0} -x = 0$$

$$\therefore \lim_{x \rightarrow 0} x^x = \lim_{x \rightarrow 0} y = e^0 = 1.$$

2.38 — HIGHER ENGINEERING MATHEMATICS—II

ii. 0^0 form. Put $y = (\cos x)^{(\frac{\pi}{2}-x)}$. Take logarithm, then

$$\lim_{x \rightarrow \frac{\pi}{2}} \ln y = \lim_{x \rightarrow \frac{\pi}{2}} \left(\frac{\pi}{2} - x \right) \ln \cos x : 0 \cdot \infty \text{ form}$$

$$= \lim_{x \rightarrow \frac{\pi}{2}} \frac{\frac{\ln \cos x}{1}}{\left(\frac{\pi}{2} - x \right)} : \frac{\infty}{\infty} \text{ form. Applying rule}$$

$$= \lim_{x \rightarrow \frac{\pi}{2}} \frac{-\sin x}{\cos x} \cdot \frac{1}{\left(\frac{\pi}{2} - x \right)^2 (-1)}$$

$$= \lim_{x \rightarrow \frac{\pi}{2}} \frac{\left(\frac{\pi}{2} - x \right)^2}{\cot x} : \frac{0}{0} \text{ form}$$

$$= \lim_{x \rightarrow \frac{\pi}{2}} \frac{2\left(\frac{\pi}{2} - x \right) \cdot (-1)}{-\operatorname{cosec}^2 x} = 0$$

$$\therefore \lim_{x \rightarrow \frac{\pi}{2}} (\cos x)^{(\frac{\pi}{2}-x)} = e^0 = 1$$

iii. 0^0 form. Put $y = (x + \sin x)^{\tan x}$. Take log

$$\lim_{x \rightarrow 0} \ln y = \lim_{x \rightarrow 0} \tan x \cdot \ln(x + \sin x) : 0 \cdot \infty \text{ form.}$$

$$= \lim_{x \rightarrow 0} \frac{\ln(x + \sin x)}{\cot x} : \frac{\infty}{\infty} \text{ form}$$

$$= \lim_{x \rightarrow 0} \frac{1 + \cos x}{x + \sin x} \cdot \frac{1}{(-\operatorname{cosec}^2 x)}$$

$$= \lim_{x \rightarrow 0} -\frac{\sin^2 x \cdot (1 + \cos x)}{(x + \sin x)} : \frac{0}{0}$$

$$= \lim_{x \rightarrow 0} -\frac{[2 \sin x \cdot \cos x (1 + \cos x) + \sin^2 x \cdot (-\sin x)]}{1 + \cos x}$$

$$= \frac{0}{2} = 0.$$

$$\lim_{x \rightarrow 0} (x + \sin x)^{\tan x} = e^0 = 1.$$

Example 7: Evaluate (∞^0 form)

$$(i) \lim_{x \rightarrow \infty} (e^x + x)^{\frac{1}{x}} \quad (ii) \lim_{x \rightarrow \frac{\pi}{2}} (\tan x)^{\tan 2x}$$

$$(iii) \lim_{x \rightarrow \infty} (\cosh x)^{\frac{1}{x}}$$

Solution:

i. Put $y = (e^x + x)^{\frac{1}{x}}$. Take log

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{1}{x} \cdot \ln(e^x + x) : 0 \cdot \infty \text{ form}$$

$$= \lim_{x \rightarrow \infty} \frac{\ln(e^x + x)}{x} : \frac{\infty}{\infty} \text{ form}$$

$$= \lim_{x \rightarrow \infty} \frac{\frac{e^x + 1}{e^x + x}}{1} : \frac{\infty}{\infty} \text{ form}$$

$$= \lim_{x \rightarrow \infty} \frac{e^x}{e^x + 1} = \lim_{x \rightarrow \infty} \frac{e^x}{e^x} = 1.$$

$$\therefore \lim_{x \rightarrow \infty} (e^x + x)^{\frac{1}{x}} = e^1 = e.$$

ii. Put $y = (\tan x)^{\tan 2x}$. Take log

$$\lim_{x \rightarrow \frac{\pi}{2}} \ln y = \lim_{x \rightarrow \frac{\pi}{2}} \tan 2x \cdot \ln(\tan x) : 0 \cdot \infty$$

$$= \lim_{x \rightarrow \frac{\pi}{2}} \frac{\ln(\tan x)}{\cot 2x} = \lim_{x \rightarrow \frac{\pi}{2}} \frac{\sec^2 x}{\tan x} \cdot \frac{1}{-2 \cdot \operatorname{cosec}^2 2x} : \frac{\infty}{\infty}$$

$$= \lim_{x \rightarrow \frac{\pi}{2}} \frac{\sin^2 2x}{(-2) \tan x \cos^2 x} = \lim_{x \rightarrow \frac{\pi}{2}} \frac{\sin^2 2x}{-\sin 2x}$$

$$= \lim_{x \rightarrow \frac{\pi}{2}} -\sin 2x = 0.$$

$$\therefore \lim_{x \rightarrow \frac{\pi}{2}} (\tan x)^{\tan 2x} = e^0 = 1.$$

iii. Put $y = (\cosh x)^{\frac{1}{x}}$. Take log

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln \cosh x}{x} = \lim_{x \rightarrow \infty} \frac{\sinh x}{\cosh x} \cdot \frac{1}{x} : \frac{\infty}{\infty}$$

$$= \lim_{x \rightarrow \infty} \frac{e^x - e^{-x}}{e^x + e^{-x}} = \lim_{x \rightarrow \infty} \frac{e^{2x} - 1}{e^{2x} + 1} = \lim_{x \rightarrow \infty} \frac{2e^{2x}}{2e^{2x}} = 1 : \frac{\infty}{\infty}$$

$$\therefore \lim_{x \rightarrow \infty} (\cosh x)^{\frac{1}{x}} = e^1 = e.$$

Example 8: Evaluate (1^∞ form)

$$(i) \lim_{x \rightarrow 1} \left(\tan \frac{\pi x}{4} \right)^{\tan \frac{\pi x}{2}} \quad (ii) \lim_{x \rightarrow 0} \left(\frac{2x + 1}{x + 1} \right)^{\frac{1}{x}}$$

$$(iii) \lim_{x \rightarrow 0} \left(\frac{\sinh x}{x} \right)^{\frac{1}{x^2}} \quad (iv) \lim_{x \rightarrow 0} \left(\frac{a^x + b^x + c^x}{3} \right)^{\frac{1}{x}}$$

Solution:

i. Put $y = \left(\tan \frac{\pi x}{4} \right)^{\tan \frac{\pi x}{2}}$. Take log

$$\lim_{x \rightarrow 1} \ln y = \lim_{x \rightarrow 1} \tan \left(\frac{\pi x}{2} \right) \cdot \ln \tan \left(\frac{\pi x}{4} \right)$$

$$: \infty \cdot 0 \text{ form}$$

$$= \lim_{x \rightarrow 1} \frac{\ln \tan \left(\frac{\pi x}{4} \right)}{\cot \left(\frac{\pi x}{2} \right)} =$$

$$= \lim_{x \rightarrow 1} \frac{\frac{\pi}{4} \sec^2 \left(\frac{\pi x}{4} \right)}{\tan \frac{\pi x}{4}} \cdot \frac{1}{\left(-\frac{\pi}{2} \right) \operatorname{cosec}^2 \frac{\pi x}{2}} : \frac{0}{0} \text{ form}$$

$$= \frac{\frac{\pi}{4} \cdot (\sqrt{2})^2}{1} \cdot \frac{1}{\frac{-\pi}{2} \cdot 1} = -1$$

$$\therefore \lim_{x \rightarrow 1} \left(\tan \frac{\pi x}{4} \right)^{\tan \frac{\pi x}{2}} = e^{-1} = \frac{1}{e}.$$

ii. Put $y = \left(\frac{2x+1}{x+1} \right)^{\frac{1}{x}}$. Take log

$$\begin{aligned} \lim_{x \rightarrow 0} \ln y &= \lim_{x \rightarrow 0} \frac{1}{x} \cdot \ln \left(\frac{2x+1}{x+1} \right) : 0 \cdot \infty \text{ form} \\ &= \lim_{x \rightarrow 0} \frac{\ln \left(\frac{2x+1}{x+1} \right)}{x} = \frac{x+1}{2x+1} \cdot \frac{(x+1)2 - (2x+1) \cdot 1}{(x+1)^2} \cdot \frac{1}{1} \\ &= 2 - 1 = 1 \end{aligned}$$

$$\therefore \lim_{x \rightarrow 0} \left(\frac{2x+1}{x+1} \right)^{\frac{1}{x}} = e^1.$$

iii. Expanding $\sinh x$ in Maclaurin series

$$\begin{aligned} \lim_{x \rightarrow 0} \left(\frac{\sinh x}{x} \right)^{\frac{1}{x^2}} &= \lim_{x \rightarrow 0} \left(\frac{x + \frac{x^3}{3!} + \frac{x^5}{5!} + \frac{x^7}{7!} + \dots}{x} \right)^{\frac{1}{x^2}} \\ &= \lim_{x \rightarrow 0} \left[1 + x^2 \left(\frac{1}{3!} + \frac{x^2}{4!} + \frac{x^2}{5!} + \dots \right) \right]^{\frac{1}{x^2}} \end{aligned}$$

$$\text{Put } t = \frac{1}{3!} + \frac{x^2}{4!} + \frac{x^2}{5!} + \dots, \text{ so } \lim_{x \rightarrow 0} t = \frac{1}{6}.$$

Now

$$\begin{aligned} \lim_{x \rightarrow 0} \left(\frac{\sinh x}{x} \right)^{\frac{1}{x^2}} &= \lim_{x \rightarrow 0} \left\{ [1 + tx^2]^{\frac{1}{tx^2}} \right\}^t = \lim_{x \rightarrow 0} e^t \\ &= e^{\lim_{x \rightarrow 0} t} = e^{\frac{1}{6}} \end{aligned}$$

iv. Put $y = \left(\frac{a^x + b^x + c^x}{3} \right)^{\frac{1}{x}}$. Take log

$$\lim_{x \rightarrow 0} \ln y = \lim_{x \rightarrow 0} \frac{1}{x} \cdot \ln \left(\frac{a^x + b^x + c^x}{3} \right) : \frac{0}{0} \text{ form}$$

Apply rule

$$\begin{aligned} &= \lim_{x \rightarrow 0} \frac{3}{a^x + b^x + c^x} \times \\ &\quad \times \frac{(a^x \log_e a + b^x \log_e b + c^x \log_e c) \cdot \frac{1}{x}}{3} \\ &= \frac{3}{1+1+1} \frac{(1 \cdot \log_e a + 1 \cdot \log_e b + 1 \cdot \log_e c)}{3} \\ &= \frac{1}{3} \log_e abc \end{aligned}$$

$$\therefore \lim_{x \rightarrow 0} \left(\frac{a^x + b^x + c^x}{3} \right)^{\frac{1}{x}} = e^{\frac{1}{3} \log_e abc} = (abc)^{\frac{1}{3}}.$$

2.10 DERIVATIVES OF ARCS

Arc Length

The graph AB of a function $y = f(x)$ defined in the interval (a, b) be the arc of the curve AB . Join the $(n+1)$ points $a_0, a_1, a_2, \dots, a_n$ on AB by broken lines $a_0a_1, a_1a_2, a_2a_3, \dots, a_{n-1}a_n$.

Fig. 2.9

Length of arc AB is defined to be the limit of the sum of the lengths of the n broken lines as the largest broken line $a_{i-1}a_i \rightarrow 0$.

Result:

$$\lim_{AB \rightarrow 0} \frac{\text{Length of arc } AB}{\text{Length of chord } AB} = \lim_{AB \rightarrow 0} \frac{\widehat{AB}}{AB} = 1.$$

Derivative of Arc

Equation of the curve in the cartesian form

Let $A(x_0, y_0)$ be a fixed point of the curve $y = f(x)$. Let $P(x, y)$ and $Q(x + \Delta x, y + \Delta y)$ be any two neighbouring points on curve AB . Let s be the arc length AP measured from the fixed point A along the curve AB and denoted by $\widehat{AP}$. As P moves to Q , x changes to $x + \Delta x$, y changes to $y + \Delta y$, so the arc length s changes to $s + \Delta s$ where $\Delta s = \widehat{PQ}$. Thus s is a function of x .

From the right angled triangle PQR

$$\overline{PQ}^2 = (\Delta x)^2 + (\Delta y)^2$$

$$\left(\frac{\overline{PQ}}{\Delta s}\right)^2 \left(\frac{\Delta s}{\Delta x}\right)^2 = 1 + \left(\frac{\Delta y}{\Delta x}\right)^2$$

As $Q \rightarrow P, \Delta x \rightarrow 0$ then chord $PQ \rightarrow 0$ and

$$\lim_{Q \rightarrow P} \frac{\widehat{PQ}}{\overline{PQ}} = 1.$$

$$\left(\frac{ds}{dx}\right)^2 = 1 + \left(\frac{dy}{dx}\right)^2$$

Here positive sign is taken before the radical, assuming that s increases as x increases, so $\frac{ds}{dx} > 0$. Thus the *differential of arc* is

or $ds = \sqrt{(dx)^2 + (dy)^2}$ (2*)

$$\frac{ds}{dy} = \frac{ds}{dx} \cdot \frac{dx}{dy} = \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \cdot \left(\frac{dx}{dy}\right)$$

$$\frac{ds}{dy} = \sqrt{1 + \left(\frac{dx}{dy}\right)^2} \quad (3)$$

$$\frac{ds}{dx} = \sqrt{1 + \left(\frac{dy}{dx}\right)^2} = \sqrt{1 + \tan^2 \psi} = \sec \psi \quad \text{so}$$

$$\cos \psi = \frac{dx}{ds} \text{ and } \sin \psi = \tan \psi \cdot \cos \psi = \frac{dy}{dx} \cdot \frac{dx}{ds} = \frac{dy}{ds}.$$

$x = x(t), \quad y = y(t)$, then

$$= \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dx}\right)^2 \left(\frac{dx}{dt}\right)^2}$$

$$\frac{ds}{dt} = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}. \quad (4)$$

On the curve AB , consider $P(r, \theta)$ and $Q(r + \Delta r, \theta + \Delta \theta)$ two neighbouring points. Let A be a fixed point. Assume that $\widehat{AP} = s$, $\widehat{PQ} = \Delta s$.

2.42 — HIGHER ENGINEERING MATHEMATICS—II

Draw $\perp^r PN$ from P on to OQ . From the right angled triangle OPQ ,

$$PN = r \sin \Delta\theta, \quad ON = r \cos \Delta\theta$$

$$NQ = OQ - ON = (r + \Delta r) - r \cos \Delta\theta$$

$$= \Delta r + 2r \sin^2 \left(\frac{\Delta\theta}{2} \right).$$

From the right angled triangle PNQ ,

$$PQ^2 = PN^2 + NQ^2$$

$$PQ^2 = (r \sin \Delta\theta)^2 + \left(\Delta r + 2r \sin^2 \frac{\Delta\theta}{2} \right)^2$$

Rewriting and dividing by $(\Delta\theta)^2$, we get

$$\begin{aligned} \left(\frac{\widehat{PQ}}{\widehat{PQ}} \cdot \frac{\widehat{PQ}}{\Delta\theta} \right)^2 &= r^2 \left(\frac{\sin \Delta\theta}{\Delta\theta} \right)^2 \\ &+ \left(\frac{\Delta r}{\Delta\theta} + r \cdot \frac{\sin \frac{\Delta\theta}{2}}{\left(\frac{\Delta\theta}{2} \right)} \cdot \sin \left(\frac{\Delta\theta}{2} \right) \right)^2 \end{aligned}$$

As $Q \rightarrow P$, $\widehat{PQ} \rightarrow 0$ so $\frac{\widehat{PQ}}{\widehat{PQ}} \rightarrow 1$. Also as $Q \rightarrow P$,

$\Delta\theta \rightarrow 0$ so $\lim_{\Delta\theta \rightarrow 0} \frac{\sin \Delta\theta}{\Delta\theta} = 1$. With this

$$\begin{aligned} \lim_{Q \rightarrow P} \left(\frac{\widehat{PQ}}{\Delta\theta} \right)^2 &= \lim_{\Delta\theta \rightarrow 0} \left(\frac{\Delta s}{\Delta\theta} \right)^2 \\ &= r^2 \cdot 1 + \left(\frac{dr}{d\theta} + r \cdot 1 \cdot 0 \right)^2 \end{aligned}$$

$$\text{Thus} \quad \left(\frac{ds}{d\theta} \right)^2 = r^2 + \left(\frac{dr}{d\theta} \right)^2$$

$$\text{or} \quad \frac{ds}{d\theta} = \sqrt{r^2 + \left(\frac{dr}{d\theta} \right)^2} \quad (5)$$

Here positive sign is taken before the radical, since it is assumed that s increases as θ increases so that $\frac{ds}{d\theta} > 0$.

Corollary 1: Equation of the curve is $\theta = \theta(r)$. Then,

$$\begin{aligned} \frac{ds}{dr} &= \frac{ds}{d\theta} \cdot \frac{d\theta}{dr} = \sqrt{r^2 + \left(\frac{dr}{d\theta} \right)^2} \cdot \frac{d\theta}{dr} \\ &= \sqrt{r^2 \left(\frac{d\theta}{dr} \right)^2 + \left(\frac{dr}{d\theta} \cdot \frac{d\theta}{dr} \right)^2} \end{aligned}$$

$$\text{Thus} \quad \frac{ds}{dr} = \sqrt{1 + r^2 \left(\frac{d\theta}{dr} \right)^2} \quad (6)$$

Corollary 2: Let ϕ be the angle between the tangent PT at P and the radius vector OP . Then

$$r \frac{d\theta}{dr} = \tan \phi.$$

$$\text{So} \quad \frac{ds}{dr} = \sqrt{1 + \left(r \frac{d\theta}{dr} \right)^2} = \sqrt{1 + \tan^2 \phi} = \sec \phi.$$

Then

$$\cos \phi = \frac{dr}{ds}, \quad \sin \phi = \tan \phi \cdot \cos \phi = r \frac{d\theta}{dr} \cdot \frac{dr}{ds} = r \frac{d\theta}{ds}.$$

WORKED OUT EXAMPLES

Example 1: Find $\frac{ds}{dx}$ when $y = c \cosh \frac{x}{c}$.

$$\begin{aligned} \text{Solution:} \quad \frac{dy}{dx} &= c \cdot \frac{1}{c} \cdot \sinh \frac{x}{c} \\ \frac{ds}{dx} &= \sqrt{1 + \left(\frac{dy}{dx} \right)^2} = \sqrt{1 + \left(\sinh \frac{x}{c} \right)^2} = \cosh \frac{x}{c}. \end{aligned}$$

Example 2: Find $\frac{ds}{dy}$ when $ax^2 = y^3$.

$$\begin{aligned} \text{Solution:} \quad 2ax &= 3y^2 \frac{dy}{dx}. \text{ So } \frac{dx}{dy} = \frac{3y^2}{2ax} \\ \frac{ds}{dy} &= \sqrt{1 + \left(\frac{dx}{dy} \right)^2} = \sqrt{1 + \frac{9}{4} \frac{y^4}{a^2 x^2}} = \sqrt{1 + \frac{9}{4} \frac{y}{a}}. \end{aligned}$$

Example 3: Find $\frac{ds}{dt}$ for the curve $x = e^t \sin t$, $y = e^t \cos t$.

$$\text{Solution:} \quad \frac{dx}{dt} = e^t \sin t + e^t \cos t, \quad \frac{dy}{dt} = e^t \cos t - e^t \sin t$$

$$\begin{aligned} \left(\frac{ds}{dt} \right)^2 &= \left(\frac{dx}{dt} \right)^2 + \left(\frac{dy}{dt} \right)^2 \\ &= e^{2t} (\sin t + \cos t)^2 + e^{2t} (\cos t - \sin t)^2 \\ &= e^{2t} [1 + 2 \sin t \cos t + 1 - 2 \sin t \cos t] = 2e^{2t} \\ \therefore \frac{ds}{dt} &= \sqrt{2} e^t. \end{aligned}$$

Example 4: Find $\frac{ds}{d\theta}$ for $r = a(1 - \cos \theta)$.

$$\text{Solution:} \quad \frac{dr}{d\theta} = +a \sin \theta$$

$$\frac{ds}{d\theta} = \sqrt{r^2 + \left(\frac{dr}{d\theta} \right)^2} = \sqrt{a^2(1 - \cos \theta)^2 + a^2 \sin^2 \theta}$$

$$\begin{aligned}
 &= a\sqrt{1 + \cos^2 \theta - 2 \cos \theta + \sin^2 \theta} \\
 &= a \cdot \sqrt{2} \sqrt{1 - \cos \theta} \\
 &= 2a \sin \frac{\theta}{2}.
 \end{aligned}$$

Example 5: Find $\frac{ds}{dr}$ for the curve $r\theta = a$.

Solution: $\theta = \frac{a}{r}$, so $\frac{d\theta}{dr} = -\frac{a}{r^2}$

$$\begin{aligned}
 \frac{ds}{dr} &= \sqrt{1 + r^2 \left(\frac{d\theta}{dr} \right)^2} = \sqrt{1 + r^2 \cdot \frac{a^2}{r^4}} \\
 &= \sqrt{1 + \frac{a^2}{r^2}} = \sqrt{1 + \theta^2}.
 \end{aligned}$$

Example 6: For the curve

$$\theta = \cos^{-1} \frac{r}{k} - \sqrt{\frac{k^2 - r^2}{r^2}}$$

Show that $r \frac{ds}{dr}$ is a constant.

Solution: Differentiating

$$\theta = \cos^{-1} \frac{r}{k} - \sqrt{\frac{k^2 - r^2}{r^2}}$$

w.r.t. r , we get

$$\begin{aligned}
 \frac{d\theta}{dr} &= \frac{-1}{\sqrt{1 - \left(\frac{r}{k}\right)^2}} \cdot \frac{1}{k} - \frac{1}{2} \sqrt{\frac{r^2}{k^2 - r^2}} \times \\
 &\quad \times \frac{r^2(-2r) - (k^2 - r^2)2r}{r^4} \\
 &= -\frac{1}{\sqrt{k^2 - r^2}} + \frac{1}{\sqrt{k^2 - r^2}} \cdot \frac{k^2}{r^2} \\
 &= \frac{(k^2 - r^2)}{r^2 \sqrt{k^2 - r^2}} = \frac{\sqrt{k^2 - r^2}}{r^2}
 \end{aligned}$$

Now

$$\frac{ds}{dr} = \sqrt{1 + \left(\frac{rd\theta}{dr} \right)^2} = \sqrt{1 + r^2 \cdot \frac{k^2 - r^2}{r^4}} = \frac{k}{r}$$

Then $r \frac{ds}{dr} = k = \text{constant}$.

EXERCISE

1. Find $\frac{ds}{dx}$ for the curve

$$\begin{aligned}
 &\text{(i) } y^2 = 4ax \quad \text{(ii) } 3ay^2 = x^2(a - x) \\
 &\text{(iii) } y = \ln \frac{e^x - 1}{e^x + 1} \quad \text{(iv) } y = a \ln \left\{ \frac{a^2}{a^2 - x^2} \right\}
 \end{aligned}$$

Ans. (i) $\sqrt{1 + \frac{a}{x}}$ (ii) $\sqrt{1 + \frac{(2a-3x)^2}{12a(x-a)}}$ (iii) $\frac{e^{2x}+1}{e^{2x}-1}$
 (iv) $\frac{a^2+x^2}{a^2-x^2}$

2. Find $\frac{ds}{dy}$ for the curve $a^2 y^2 = a^3 - x^3$ at $(a, 0)$.

Hint: $\frac{dx}{dy} = \frac{2a^2 y}{3x^2}$ at $(a, 0)$ is zero.

Ans. 1

3. Find $\frac{ds}{dx}$ and $\frac{ds}{dy}$ for the curve $x^3 + xy^2 - 6y^2 = 0$ at $(3, 3)$.

Hint: $3x^2 + (x - 6)2yy_1 + y^2 = 0$, At $(3, 3)$,
 $y_1 = \frac{dy}{dx} = 2$

Ans. $\frac{ds}{dx} = \sqrt{5}$, $\frac{ds}{dy} = \sqrt{\frac{5}{2}}$

4. Find $\frac{ds}{dx}$, $\frac{ds}{dy}$ and $\frac{ds}{d\theta}$ for the cycloid
 $x = a(\theta - \sin \theta)$, $y = a(1 - \cos \theta)$.

Hint: $\frac{dy}{dx} = \frac{\dot{y}}{\dot{x}} = \frac{a \sin \theta}{a(1 - \cos \theta)} = \cot \frac{\theta}{2}$,
 $\frac{dx}{dy} = \tan \frac{\theta}{2}$

$$\begin{aligned}
 \frac{ds}{dx} &= \sqrt{\frac{2}{1 - \cos \theta}} = \sqrt{\frac{2a}{y}}, \quad \frac{ds}{dy} = \sec \frac{\theta}{2}, \\
 \frac{ds}{dt} &= \sqrt{2a(1 - \cos \theta)} = \sqrt{2ay}
 \end{aligned}$$

Ans. $\sqrt{\frac{2a}{y}}$, $\sqrt{\frac{2a}{2a-y}}$, $\sqrt{2ay}$

5. Find $\frac{ds}{dt}$ for the astroid $x = a \cos^3 t$,
 $y = a \sin^3 t$.

Hint: $\frac{dx}{dt} = -3a \cos^2 t \sin t$,
 $\frac{dy}{dt} = 3a \sin^2 t \cos t$

Ans. $3a \sin t \cdot \cos t$

6. Determine $\frac{ds}{dt}$ for the ellipse $x = a \cos t$,
 $y = b \sin t$.

Hint: $\dot{x} = -a \sin t$, $\dot{y} = b \cos t$

Ans. $a\sqrt{1 - e^2 \cos^2 t}$ where $e = \text{eccentricity}$,

2.44 — HIGHER ENGINEERING MATHEMATICS—II

$$e = \frac{a^2 - b^2}{a^2}$$

7. Find $\frac{ds}{d\theta}$ for (i) $r = a(1 + \cos \theta)$
(ii) $r = ae^{\theta \cot \alpha}$ (iii) $r^2 \sin 2\theta = 2a^2$.

Hint: (iii) $\frac{dr}{d\theta} = -r \cot 2\theta$

Ans. (i) $2a \cos \frac{\theta}{2}$ (ii) $r \operatorname{cosec} \alpha$ (iii) $\frac{r^3}{2a^2}$

8. Find $\frac{ds}{dr}$ for (i) $r = a\theta$ (ii) $r^2 = a^2 \cos 2\theta$

Ans. (i) $\sqrt{1 + \theta^2}$ (ii) $\sqrt{1 + \cot^2 2\theta} = \operatorname{cosec} 2\theta$.

2.11 CURVATURE

The shape of a plane curve c is characterized by the degree of bentness or curvedness. A straight line has no bending while a circle has constant bending. Curvature of a curve is a measure of rate of change of bentness.

Angle of contingence of the arc AB of a curve c is the angle between the tangents at A and B to the curve c (see Fig. 2.12).

Given two arcs of the same length, the arc with greater angle of contingence is said to be more curved.

Fig. 2.12

Average curvature of an arc AB is

$$k_{av} = \frac{\Delta \alpha}{\widehat{AB}} = \frac{\text{angle of contingence}}{\text{length of the arc}}$$

Curvature of a curve c at a point A is denoted by k and is given by

$$k = \lim_{B \rightarrow A} k_{av} = \lim_{AB \rightarrow 0} \frac{\Delta \alpha}{\widehat{AB}} = \lim_{\Delta S \rightarrow 0} \frac{\Delta \alpha}{\Delta S} = \left| \frac{d\alpha}{ds} \right|.$$

Calculation of Curvature

Cartesian form Let the equation of the curve be given in cartesian form $y = f(x)$:

$$y = f(x) \text{ so } \tan \alpha = \frac{dy}{dx} = y_1$$

$$\text{Then } \alpha = \tan^{-1} \frac{dy}{dx} = \tan^{-1} y_1$$

$$\frac{d\alpha}{dx} = \frac{1}{1 + y_1^2} \cdot y_2 \quad \text{where } y_2 = \frac{d^2y}{dx^2}$$

$$\text{we know that } \frac{ds}{dx} = \sqrt{1 + y_1^2}$$

Thus

$$k = \frac{d\alpha}{ds} = \frac{(d\alpha/dx)}{(ds/dx)} = \frac{y_2}{(1 + y_1^2)} \cdot \frac{1}{\sqrt{1 + y_1^2}}$$

$$\therefore k = \left| \frac{y_2}{(1 + y_1^2)^{3/2}} \right| > 0$$

Cartesian form when $x = f(y)$:

$$k = \frac{\frac{d^2x}{dy^2}}{\left[1 + \left(\frac{dx}{dy} \right)^2 \right]^{3/2}}$$

Note: Useful when tangent is $\perp$ to x -axis i.e., $\frac{dy}{dx} = \infty$ or $\frac{dx}{dy} = 0$.

Parametric form When equation of the curve is $x = x(t)$, $y = y(t)$ where t is the parameter:

$$\dot{x} = \frac{dx}{dt}, \dot{y} = \frac{dy}{dt} \text{ so } \frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} = \frac{\dot{y}}{\dot{x}}$$

$$\frac{d^2y}{dx^2} = \frac{d}{dx} \left(\frac{\dot{y}}{\dot{x}} \right) = \frac{d}{dt} \left(\frac{\dot{y}}{\dot{x}} \right) \frac{dt}{dx} = \frac{1}{\dot{x}} \left[\frac{\dot{x}\ddot{y} - \dot{y}\ddot{x}}{\dot{x}^2} \right]$$

Substituting y_1 and y_2

$$k = \frac{|\dot{x}\ddot{y} - \dot{y}\ddot{x}|}{(\dot{x}^2 + \dot{y}^2)^{3/2}}$$

Polar form When equation of the curve is $r = f(\theta)$, where r, θ are the polar coordinates given by $x = r \cos \theta$, $y = r \sin \theta$. Then

$$k = \frac{|r^2 + 2r_1^2 - rr_2|}{(r^2 + r_1^2)^{3/2}}$$

where $r_1 = \frac{dr}{d\theta}$ and $r_2 = \frac{d^2r}{d\theta^2}$.

Example: Curvature of a straight line $y = mx + c$.

Solution: $y_1 = \frac{dy}{dx} = m$, $y_2 = \frac{d^2y}{dx^2} = 0$, so $k = 0$
i.e., straight line has zero curvature.

Example: Curvature of a circle of given radius r (see Fig. 2.13).

Fig. 2.13

Solution:

$$k_{av} = \frac{\text{angle of contingence}}{\text{length of arc}} = \frac{\alpha}{\alpha r}$$

k = curvature at any point A.

$$k = \lim_{B \rightarrow A} k_{av} = \lim_{B \rightarrow A} \frac{1}{r} = \lim_{AB \rightarrow 0} \frac{1}{r} = \frac{1}{r} = \text{constant}$$

The curvature of a circle is constant and is the reciprocal of the radius of the circle.

Implicit equation

Equation of the curve is $f(x, y) = 0$:

we know that $\frac{dy}{dx} = -\frac{f_x}{f_y}$ with $f_y \neq 0$.

$$\text{and } \frac{d^2y}{dx^2} = -\frac{[f_{xx}f_y^2 - 2f_{xy}f_xf_y + f_{yy}f_x^2]}{f_y^3}$$

with $f_y \neq 0$

Here f_x, f_y, f_{xx} etc. are partial derivatives of f . Substituting y_1 and y_2 we get

$$k = \frac{f_{xx}f_y^2 - 2f_{xy}f_xf_y + f_{yy}f_x^2}{(f_y^2 + f_x^2)^{\frac{3}{2}}}$$

Definition

Radius of curvature to a curve at a point is denoted by R and is the reciprocal of the curvature at that point. Thus

$$R = \frac{1}{k}$$

Cartesian form $y = f(x)$

$$R = \frac{(1 + y_1^2)^{\frac{3}{2}}}{y_2}$$

Cartesian form $x = f(y)$

$$R = \frac{[1 + (dx/dy)^2]^{\frac{3}{2}}}{\left(\frac{d^2x}{dy^2}\right)}$$

Parametric form $x = x(t), y = y(t)$

$$R = \frac{(\dot{x}^2 + \dot{y}^2)^{\frac{3}{2}}}{|\dot{x}\ddot{y} - \ddot{x}\dot{y}|}$$

Polar form $r = f(\theta)$

$$R = \frac{(r^2 + r_1^2)^{\frac{3}{2}}}{|r^2 + 2r_1^2 - rr_2|}$$

Implicit equation $f(x, y) = 0$

$$R = \frac{(f_x^2 + f_y^2)^{\frac{3}{2}}}{|f_{xx}f_y^2 - 2f_{xy}f_xf_y + f_{yy}f_x^2|}$$

WORKED OUT EXAMPLES

Radius of curvature: Cartesian form

Example 1: Find the radius of curvature $y^2 = 2x(3 - x^2)$ at the points where the tangents are parallel to x -axis.

Solution: Differentiating the equation w.r.t. x ,

$$2yy_1 = 6 - 6x^2 = 6(1 - x^2) \quad (1)$$

At the points where the tangents are parallel to

$$x\text{-axis, } y_1 = 0 \text{ i.e., } x = \pm 1 \quad (2)$$

Differentiating (1). $y_1^2 + yy_2 = -6x$

$$\text{At } x = \pm 1, y_2 = -\frac{6x}{y}$$

Take $x = 1$, so that $y^2 = 4$ or $y = \pm 2$, then

$$y_2 = -\frac{6}{\pm 2}$$

Thus

$$R = \frac{(1 + y_1^2)^{\frac{3}{2}}}{y_2} = \frac{(1 + 0)^{\frac{3}{2}}}{\pm 3} = \left| \pm \frac{1}{3} \right| = \frac{1}{3}.$$

Example 2: Calculate R at $(a, 0)$ for $a^2y^2 = a^3 - x^3$.

2.46 — HIGHER ENGINEERING MATHEMATICS—II

Solution:

$$2a^2 y y_1 = -3x^2 \quad \text{so} \quad y_1 = -\frac{3x^2}{2a^2 y}$$

$$\text{At } (a, 0), y_1 = \infty. \quad \text{or} \quad \frac{dx}{dy} = 0$$

So consider x as the dependent variable and y as the independent variable. i.e., $x = f(y)$.

Differentiating $a^2 y^2 = a^3 - x^3$ w.r.t. y , we get

$$2a^2 y = 0 - 3x^2 \frac{dx}{dy} \quad (1)$$

$$\frac{dx}{dy} = \frac{2a^2 y}{3x^2}$$

$$\text{At } (a, 0): \quad \frac{dx}{dy} = 0 \quad (2)$$

Differentiating (1) again w.r.t. y , we get

$$2a^2 = -6x \frac{dx}{dy} - 3x^2 \frac{d^2 x}{dy^2}$$

Using (2),

$$\frac{d^2 x}{dy^2} = -\frac{2a^2}{3x^2}$$

$$\text{At } (a, 0), \quad \frac{d^2 x}{dy^2} = -\frac{2}{3}$$

Then

$$R = \frac{\left[1 + \left(\frac{dx}{dy}\right)^2\right]^{\frac{3}{2}}}{\left|\frac{d^2 x}{dy^2}\right|} = \frac{(1+0)^{\frac{3}{2}}}{\left|-\frac{2}{3}\right|} = \frac{3}{2}.$$

Example 3: Find R at $(3, 3)$ for the implicit equation $x^3 + x y^2 - 6y^2 = 0$.

Solution: Differentiating implicitly w.r.t. x ,

$$3x^2 + (x - 6) \cdot 2y y_1 + 1 \cdot y^2 = 0$$

$$\text{At } (3, 3), \quad 27 - 6 \cdot 3y_1 + 9 = 0, \quad \therefore y_1 = 2$$

Differentiating again w.r.t. x ,

$$6x + 2y y_1 + (x - 6)[2y_1^2 + 2y y_2] + 2y y_1 = 0$$

$$\text{At } (3, 3), \quad 18 + 12 + (-3)[8 + 6y^2] + 12 = 0$$

$$\therefore y_2 = 1$$

$$\text{Then} \quad R = \frac{(1 + 2^2)^{\frac{3}{2}}}{1} = 5^{\frac{3}{2}}.$$

Example 4: Determine the point on $y = 4x - x^2$ where the curvature is maximum.

Solution:

$$y_1 = 4 - 2x, y_2 = -2, k = \frac{|-2|}{[1 + (4 - 2x)^2]^{\frac{3}{2}}}$$

k is maximum when $1 + (4 - 2x)^2$ is minimum. The stationary point $\frac{d}{dx}[1 + (4 - 2x)^2] = 0$, $2(4 - 2x)(-2) = 0$ i.e., $x = 2$. Thus curvature is maximum at $(2, 4)$.

EXERCISE

Find the radius of curvature of the following curves at the indicated point:

$$1. \quad x^3 + y^3 = 3axy \text{ at } \left(\frac{3a}{2}, \frac{3a}{2}\right)$$

$$\text{Ans. } 3a/(8\sqrt{2})$$

$$2. \quad y^2 = 4ax \text{ at } (x, y)$$

$$\text{Ans. } \frac{2}{\sqrt{a}}(x + a)^{\frac{3}{2}}$$

$$3. \quad y = c \ln \sec\left(\frac{x}{c}\right) \text{ at } (x, y)$$

$$\text{Ans. } c \sec(x/c)$$

$$4. \quad x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}} \text{ at } (x, y)$$

Hint: Use parametric equations $x = a \cos^3 t$, $y = a \sin^3 t$.

$$\text{Ans. } 3a^{\frac{2}{3}} x^{\frac{1}{3}} y^{\frac{1}{3}}$$

$$5. \quad \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \text{ at } (a, 0) \text{ and } (0, b)$$

$$\text{Ans. } \frac{b^2}{a} \text{ and } \frac{a^2}{b}$$

$$6. \quad x^2 y = a(x^2 + y^2) \text{ at } (-2a, 2a)$$

Hint: $\frac{dy}{dx}$ at $(-2a, 2a)$ is ∞ . Treat $x = f(y)$.

$$\text{Ans. } |-2a|$$

$$7. \quad xy^2 = a^3 - x^3 \text{ at } (a, 0)$$

Hint: Since $\frac{dy}{dx}$ is ∞ , take $x = f(y)$.

$$\text{Ans. } \left|\frac{-3a}{2}\right|$$

$$8. \quad y = c \cosh(x/c) \text{ at } (x, y)$$

$$\text{Ans. } \frac{y^2}{c}$$

$$9. \quad xy = c^2 \text{ at } (x, y)$$

$$\text{Ans. } (x^2 + y^2)^{\frac{3}{2}}/2xy$$

10. $\sqrt{x} + \sqrt{y} = \sqrt{a}$ at $(\frac{a}{4}, \frac{a}{4})$

Ans. $a/\sqrt{2}$

11. $x^{\frac{1}{3}} + y^{\frac{1}{3}} = 1$ at $(1/8, 1/8)$

Ans. $32/3$

12. $y^2(2-x) = x^3$ at $(1, 1)$

Ans. $25/(3\sqrt{5})$

13. $x^3 + y^3 = 2a^3$ at (a, a)

Ans. $a/\sqrt{2}$

14. Find the point of greatest curvature on the curve $y = \ln x$

Hint: Stationary points: $\frac{dk}{dx} = \frac{1-2x^2}{(1+x^2)^{\frac{5}{2}}} = 0$.

Ans. $(\frac{1}{\sqrt{2}}, -\frac{1}{2} \ln 2)$

15. Prove that the ratio of the radii of curvature of the curves $xy = a^2$, $x^3 = 3a^2y$ at points which have the same abscissa varies as the square root of the ratio of the ordinates.

Hint: $R_1 = \frac{(x_1^4 + a^4)^{\frac{3}{2}}}{2a^2x_1^3}$, Radius of curvature to the first curve $xy = a^2$ with (x_1, y_1) point. R_2 at (x_2, y_2) on second curve $x^3 = 3a^2y$ is $\frac{(x_1^4 + a^4)^{\frac{3}{2}}}{2x_1a^4}$

$$\frac{R_1}{R_2} = \frac{a^2}{x_1^2} = \frac{1}{\sqrt{3}} \sqrt{\frac{y_1}{y_2}}$$

16. Find the point where the radius of curvature of the curve $x^2y = a(x^2 + a^2/\sqrt{5})$ is minimum.

Ans. $x = a$, minimum curvature is $9a/10$

17. Show that $R_1^{-\frac{2}{3}} + R_2^{-\frac{2}{3}} = L^{-\frac{2}{3}}$ where R_1 and R_2 are the radii of curvature at the extremities of a focal chord of a parabola with latus rectum $2L$.

Hint: $y^2 = 4ax$ or $x = at^2$, $y = 2at$,

Latus rectum $L = 2a$

Extremities P (at t_1) and Q (at t_2) of focal chord

$$R = 2a(1 + t_1^2)^{\frac{3}{2}}$$

18. Prove that $(\frac{2R}{a})^{\frac{2}{3}} = (\frac{y}{x})^2 + (\frac{x}{y})^2$ where R is the radius of curvature of the curve $y = ax/(a+x)$

Hint: $R = -[1 + (y/x)^4]^{\frac{3}{2}} / [(\frac{2}{a})(\frac{y}{x})^3]$.

19. Show that $(R_1^{\frac{2}{3}} + R_2^{\frac{2}{3}})(ab)^{\frac{2}{3}} = a^2 + b^2$ where R_1 and R_2 are the radii of curvature at the extremities of the conjugate diameters of an ellipse $(x^2/a^2) + (y^2/b^2) = 1$.

Hint: $R = (b^4x^2 + a^4y^2)^{\frac{3}{2}}/(a^4b^4)$.

Coordinates of the conjugate diameters are $(a \cos \theta, b \sin \theta)$ and $(-a \sin \theta, b \cos \theta)$.

20. The radius of curvature $R = \frac{ds}{d\psi}$ for a curve $s = s(\psi)$ where ψ is the angle the tangent to the curve makes with the x -axis. Find R for

i. catenary $S = c \tan \psi$

Ans. $c \sec^2 \psi$

ii. cycloid $S = 4a \sin \psi$

Ans. $4a \cos \psi$

iii. cardioid $S = 4a \sin \frac{\psi}{3}$

Ans. $\frac{4}{3}a \cos \frac{\psi}{3}$

iv. parabola $S = a \ln(\tan \psi + \sec \psi) +$

$a \tan \psi \sec \psi$

Ans. $2a \sec^3 \psi$

v. $S = c \ln \sec \psi$

Ans. $\frac{1}{c} \cot \psi$.

WORKED OUT EXAMPLES

Radius of curvature for parametric curve

Find the radius of curvature for the following curves in the parametric form.

Example 1: $x = 6t^2 - 3t^4$, $y = 8t^3$.

Solution: Differentiating w.r.t. t

$$\dot{x} = 12t - 12t^3, \ddot{x} = 12 - 36t^2, \dot{y} = 24t^2, \ddot{y} = 48t$$

$$\dot{x}^2 + \dot{y}^2 = 12^2t^2(1 - t^2)^2 + 24^2t^4 = 12^2t^2(1 + t^2)^2$$

$$\dot{x}\ddot{y} - \ddot{x}\dot{y} = 12t(1 - t^2)(48t) - 12(1 - 3t^2)(24t^2)$$

$$= 12 \cdot 24 \cdot t^2(1 + t^2)$$

$$R = \frac{(\dot{x}^2 + \dot{y}^2)^{\frac{3}{2}}}{(\dot{x}\ddot{y} - \ddot{x}\dot{y})} = \frac{12^3t^3(1 + t^2)^3}{12 \cdot 24 \cdot t^2(1 + t^2)} = 6t(1 + t^2)^2.$$

Example 2: $x = e^t + e^{-t}$, $y = e^t - e^{-t}$ at $t = 0$.

Solution:

$$\dot{x} = e^t - e^{-t}, \ddot{x} = e^t + e^{-t}$$

2.48 — HIGHER ENGINEERING MATHEMATICS—II

$$\dot{y} = e^t + e^{-t}, \ddot{y} = e^t - e^{-t}$$

$$\text{At } t = 0, \dot{x} = 0, \ddot{x} = 2, \dot{y} = 2, \ddot{y} = 0$$

$$R = \frac{(0 + 2^2)^{\frac{3}{2}}}{|-2 \cdot 2|} = 2.$$

Example 3: $x = \frac{a \cos t}{t}, y = \frac{a \sin t}{t}.$

Solution:

$$\begin{aligned}\dot{x} &= \frac{a[-\sin t - \cos t \cdot 1]}{t^2} \\ \dot{y} &= \frac{a[t \cos t - \sin t \cdot 1]}{t^2} \\ \dot{x}^2 + \dot{y}^2 &= \frac{(1 + t^2)a^2}{t^4} \\ \ddot{x} &= a(-t^2 \cos t + 2t \sin t + 2 \cos t)/t^3 \\ \ddot{y} &= a(-t^2 \sin t - 2t \cos t + 2 \sin t)/t^3 \\ \dot{x}\ddot{y} - \ddot{x}\dot{y} &= a^2/t^2 \\ R &= \frac{a^3(1 + t^2)^{\frac{3}{2}}}{t^6} \cdot \frac{t^2}{a^2} = \frac{a(1 + t^2)^{\frac{3}{2}}}{t^4}.\end{aligned}$$

Example 4: $x = a \ln(\sec t + \tan t), y = a \sec t.$

Solution:

$$\begin{aligned}\dot{x} &= \frac{a}{\sec t + \tan t} \cdot (\sec t \tan t + \sec^2 t) \\ \dot{x} &= a \sec t \\ \dot{y} &= a \sec t \tan t \\ \ddot{x} &= a \sec t \cdot \tan t, \ddot{y} = a[\sec t \cdot \tan^2 t + \sec t \cdot \sec^2 t] \\ \ddot{y} &= a \sec t [\tan^2 t + \sec^2 t] \\ \dot{x}^2 + \dot{y}^2 &= a^2 \sec^2 t + a^2 \sec^2 t \tan^2 t \\ &= a^2 \sec^2 t (1 + \tan^2 t) = a^2 \sec^4 t \\ \dot{x}\ddot{y} - \ddot{x}\dot{y} &= (a \sec t)(a \sec t)[\tan^2 t + \sec^2 t] \\ &\quad - (a^2 \sec^2 t \tan^2 t) \\ &= a^2 \sec^4 t \\ R &= \frac{(\dot{x}^2 + \dot{y}^2)^{\frac{3}{2}}}{\dot{x}\ddot{y} - \ddot{x}\dot{y}} = \frac{(a^2 \sec^4 t)^{\frac{3}{2}}}{a^2 \sec^4 t} = a \sec^2 t.\end{aligned}$$

EXERCISE

Find the radius of curvature of the following parametric curves:

1. $x = 1 - t^2, y = t - t^3$ at $t = \pm 1$

Ans. $2\sqrt{2}$

2. $x = 2t^2 - t^4, y = 4t^3$ at $t = 1$

Ans. 18

3. $x = a(t - t^3/3), y = at^2$

Ans. $\frac{a}{2}(1 + t^2)^2$

4. $x = \ln t, y = \frac{1}{2}(t + t^{-1})$

Ans. $\frac{t}{4}(1 + t^2)^2$

5. Cycloid $x = a(t + \sin t), y = a(1 - \cos t)$

Hint: $y_1 = \tan \frac{t}{2}, y_2 = \frac{\sec^4 t/2}{4a}.$

Ans. $4a \cos \frac{t}{2}$

6. Cycloid $x = t - \sin t, y = 1 - \cos t$ at the highest point of the arch

Hint: At $t = \pi$, highest point of arch.

Ans. 4

7. (a) Ellipse $x = a \cos t, y = b \sin t$, (b) circle

Ans. (a) $(a^2 \sin^2 \theta + b^2 \cos^2 \theta)^{\frac{3}{2}}/ab,$

(b) $a = b, R = \frac{a^3}{a^2} = a$

8. Tractrix $x = a[\cos t + \ln \tan(t/2)], y = a \sin t$

Hint: $y_1 = \tan t, y_2 = (\sec^4 t \cdot \sin t)/a.$

Ans. $a \cot t$

9. $x = 3a \cos t - a \cos 3t, y = 3a \sin t - a \sin 3t$

Hint:

$$y_1 = \tan 2t$$

$$y_2 = 1/(3a \cos^2 2t \cdot \sin t).$$

Ans. $3a \sin t$

10. $x = 3 \sin t + \sin 3t, y = 3 \cos t + \cos 3t$

Ans. $3 \cot t$

11. $x = a(\cos t + t \sin t), y = a(\sin t - t \cos t)$

Hint: $\dot{x}^2 + \dot{y}^2 = a^2 t^2, \dot{x}\ddot{y} - \ddot{x}\dot{y} = a^2 t^2.$

Ans. at

12. $x = a(\cos t + \ln \tan \frac{t}{2}), y = a \sin t$

Hint: $y_1 = a \cos t, y_2 = \sin t / (a \cos^4 t)$.

Ans. $a \cot t$

13. The tangents at two points
- A, B
- on the cycloid
- $x = a(t - \sin t), y = a(1 - \cos t)$
- are perpendicular. Show that
- $R_1^2 + R_2^2 = 16a^2$
- where
- R_1
- and
- R_2
- are the radii of curvature at these points
- A
- and
- B
- .

Hint: $\dot{x}^2 + \dot{y}^2 = 4a^2 \sin^2 \frac{t}{2}$,

$$\ddot{x}\ddot{y} - \dot{x}\dot{y} = -2a^2 \sin^2 \frac{t}{2}.$$

$$R = -4a \sin \frac{t}{2}$$

Slope of tangent at t is $\cot t/2$

use perpendicularity: $\cot \frac{t_1}{2} \cdot \cot \frac{t_2}{2} = -1$.

- 14.
- $x = a \cos t(1 + \sin t), y = a \sin t(1 + \cos t)$
-
- at
- $t = -\pi/4$

Hint: $\dot{x} = \frac{a}{\sqrt{2}}, \dot{y} = \frac{a}{\sqrt{2}}, \ddot{x} = \frac{a(2\sqrt{2}-1)}{\sqrt{2}},$

$$\ddot{y} = \frac{a(2\sqrt{2}+1)}{\sqrt{2}}, \dot{x}^2 + \dot{y}^2 = a^2, \dot{x}\ddot{y} - \ddot{x}\dot{y} = a^2.$$

Ans. a

15. $x = a \ln \tan \left(\frac{\pi}{4} + \frac{\theta}{2} \right), y = a \sec \theta$

Ans. $a \sec^2 \theta$

16. Astroid $x = a \cos^3 t, y = a \sin^3 t$

Hint: $\dot{x}^2 + \dot{y}^2 = 9a^2 \sin^2 t \cos^2 t, \dot{x}\ddot{y} - \ddot{x}\dot{y} = -9a^2 \sin^2 t \cos^2 t$.

Ans. $|-3a \sin t \cos t|$.

$$r = 4$$

$$R = \frac{(16 + 64)^{\frac{3}{2}}}{16 + 128 - 64} = \sqrt{80}.$$

Example 2: Show that the radius of curvature at any point (r, θ) on the curve $r^2 = a^2 \sec 2\theta$, is proportional to r^3 .

Solution: Taking $\log: 2 \ln r = \ln a^2 + \ln \sec 2\theta$.
Differentiating w.r.t. θ ,

$$2 \cdot \frac{1}{r} \cdot \frac{dr}{d\theta} = 0 + \frac{1}{\sec 2\theta} \cdot \sec 2\theta \cdot \tan 2\theta \cdot 2$$

$$r_1 = \frac{dr}{d\theta} = r \tan 2\theta$$

$$\text{so } r_2 = \frac{d^2r}{d\theta^2} = \tan 2\theta \cdot \frac{dr}{d\theta} + r \cdot 2 \cdot \sec^2 2\theta$$

$$r_2 = r \cdot \tan^2 2\theta + 2r \sec^2 2\theta$$

$$\text{Then } r^2 + r_1^2 = r^2 + r^2 \tan^2 2\theta = r^2 \sec^2 2\theta$$

$$r^2 + 2r_1^2 - rr_2 = r^2 + 2 \cdot r^2 \tan^2 2\theta$$

$$-r(r \tan^2 2\theta + 2r \sec^2 2\theta)$$

$$= -r^2 \sec^2 2\theta$$

$$R = \frac{(r^2 \sec^2 2\theta)^{\frac{3}{2}}}{|-r^2 \sec^2 2\theta|} = r \sec 2\theta = r \cdot \frac{r^2}{a^2} = \frac{r^3}{a^2}.$$

Example 3: Determine the radius of curvature R at any point (r, θ) on the curve $r^n = a^n \sin n\theta$. Deduce R for the curves (i) $r = a \sin \theta$ and (ii) $r^2 = a^2 \sin 2\theta$.

Solution: Taking $\log$

$$n \ln r = \ln a^n + \ln \sin n\theta$$

Differentiating w.r.t. θ ,

$$n \cdot \frac{1}{r} \frac{dr}{d\theta} = 0 + \frac{1}{\sin n\theta} \cdot n \cdot \cos n\theta$$

$$r_1 = \frac{dr}{d\theta} = r \cot n\theta$$

Differentiating again w.r.t. θ ,

$$\frac{d^2r}{d\theta^2} = \frac{dr}{d\theta} \cdot \cot n\theta + r \cdot (-\operatorname{cosec}^2 n\theta) \cdot n$$

$$r_2 = \frac{d^2r}{d\theta^2} = r \cot^2 n\theta - nr \operatorname{cosec}^2 n\theta$$

WORKED OUT EXAMPLES

Radius of curvature for polar curve

Example 1: Find the radius of curvature $r = e^{2\theta}$ at $\theta = \ln 2$.

Solution: $r_1 = \frac{dr}{d\theta} = 2e^{2\theta}, r_2 = \frac{d^2r}{d\theta^2} = 4e^{2\theta}$

$$R = \frac{(r^2 + r_1^2)^{\frac{3}{2}}}{|r^2 + 2r_1^2 - rr_2|} = \frac{(e^{4\theta} + 4e^{4\theta})^{\frac{3}{2}}}{(e^{4\theta} + 8e^{4\theta} - 4e^{4\theta})} = \frac{e^{6\theta} 5^{\frac{3}{2}}}{e^{4\theta} 5}$$

$$R = \sqrt{5}e^{2\theta} = \sqrt{5} \cdot 4 = \sqrt{80}$$

$$\text{or at } \theta = \ln 2, r_1 = 2e^{2 \ln 2} = 8, r_2 = 4e^{2 \ln 2} = 16,$$

2.50 — HIGHER ENGINEERING MATHEMATICS—II

So

$$\begin{aligned} r^2 + 2r_1^2 - rr_2 &= r^2 + 2 \cdot (r^2 \cot^2 n\theta) \\ &\quad - r(r \cot^2 n\theta - nr \operatorname{cosec}^2 n\theta) \\ &= r^2[(1 + \cot^2 n\theta) + n \operatorname{cosec}^2 n\theta] \\ &= r^2(1 + n) \cdot \operatorname{cosec}^2 n\theta \end{aligned}$$

Also

$$(r^2 + r_1^2)^{\frac{3}{2}} = [r^2 + r^2 \cot^2 n\theta]^{\frac{3}{2}} = r^3 \operatorname{cosec}^3 n\theta$$

Thus

$$\begin{aligned} R &= \frac{(r^2 + r_1^2)^{\frac{3}{2}}}{|r^2 + 2r_1^2 - rr_2|} = \frac{r^3 \operatorname{cosec}^3 n\theta}{r^2(1 + n) \operatorname{cosec}^2 n\theta} \\ &= \frac{r}{(1 + n)} \cdot \frac{1}{\sin n\theta} \\ R &= \frac{r}{(1 + n)} \cdot \frac{a^n}{r^n} = \frac{a^n}{(1 + n)r^{n-1}} \end{aligned}$$

For $n = 1$: Radius of curvature of $r = a \sin \theta$ is

$$r = \frac{a}{2} = \text{constant}$$

For $n = 2$: Radius of curvature of $r^2 = a^2 \sin 2\theta$ is

$$r = \frac{a^2}{2r}.$$

Example 4: Prove that at the points in which the Archimedean spiral $r = a\theta$ intersects the hyperbolic spiral $r\theta = a$, their curvatures are in the ratio 3 : 1.

Solution: For the curve $r = a\theta$,

$$r_1 = a, \quad r_2 = 0$$

Let curvature of the curve $r = a\theta$ be k_1

$$\begin{aligned} k_1 &= \frac{r^2 + 2r_1^2 - rr_2}{(r^2 + r_1^2)^{\frac{3}{2}}} = \frac{a^2\theta^2 + 2a^2 - 0}{(a^2\theta^2 + a^2)^{\frac{3}{2}}} \\ k_1 &= \frac{\theta^2 + 2}{a(\theta^2 + 1)^{\frac{3}{2}}} \quad (1) \end{aligned}$$

Let curvature of the curve $r\theta = a$ be k_2 .

Then $r = \frac{a}{\theta}$, $r_1 = -\frac{a}{\theta^2}$, $r_2 = \frac{2a}{\theta^3}$ so

$$k_2 = \frac{\left(\frac{a}{\theta}\right)^2 + 2\left(-\frac{a}{\theta^2}\right)^2 - \left(\frac{a}{\theta}\right)\left(\frac{2a}{\theta^3}\right)}{\left[\left(\frac{a}{\theta}\right)^2 + \left(-\frac{a}{\theta^2}\right)^2\right]^{\frac{3}{2}}} = \frac{\theta^4}{a(\theta^2 + 1)^{\frac{3}{2}}} \quad (2)$$

The points of intersection of the two curves $r = a\theta$ and $r = \frac{a}{\theta}$ are given by

$$a\theta = r = \frac{a}{\theta}$$

or $\theta^2 = 1$ or $\theta = \pm 1$

Now from (1) and (2)

$$k_1|_{\theta=\pm 1} = \frac{3}{a2^{\frac{3}{2}}} \quad (3)$$

$$k_2|_{\theta=\pm 1} = \frac{1}{a2^{\frac{3}{2}}} \quad (4)$$

Thus k_1 and k_2 are in the ratio 3 : 1.

Example 5: For the cardioid $r = a(1 + \cos \theta)$ show that the square of the radius of curvature at any point (r, θ) is proportional to r . Also find the radius of curvature when $\theta = 0, \frac{\pi}{4}, \frac{\pi}{2}$.

Solution: The pedal equation or $p - r$ equation (see Pages 2.51-2.52)

$$\frac{1}{p^2} = \frac{1}{r^2} + \frac{1}{r^4} \left(\frac{dr}{d\theta} \right)^2$$

For the cardioid $r = a(1 + \cos \theta)$,

$$\frac{dr}{d\theta} = -a \sin \theta$$

So the pedal equation for cardioid is

$$\begin{aligned} \frac{1}{p^2} &= \frac{1}{r^2} + \frac{1}{r^4} (a^2 \sin^2 \theta) = \frac{1}{r^4} [r^2 + a^2 \sin^2 \theta] \\ &= \frac{1}{r^4} [a^2(1 + \cos \theta)^2 + a^2 \sin^2 \theta] = \frac{2a^2}{r^4} (1 + \cos \theta) \end{aligned}$$

$$\frac{1}{p^2} = \frac{2a^2}{r^4} \cdot \frac{r}{a} = \frac{2a}{r^3}$$

$$\text{or} \quad 2ap^2 = r^3$$

Differentiating w.r.t., 'r',

$$4ap \frac{dp}{dr} = 3r^2$$

Radius of curvature in pedal form is (see Pages 2.51-2.52)

$$\begin{aligned} R &= r \frac{dr}{dp} = r \cdot \left(\frac{4ap}{3r^2} \right) = \frac{4}{3} \frac{a}{r} p = \frac{4}{3} \frac{a}{r} \cdot \left(\frac{r^3}{2a} \right)^{\frac{1}{2}} \\ \therefore R &= \frac{2}{3} \sqrt{(2ar)} \end{aligned}$$

Thus $R^2 \propto r$

$$\text{At } \theta = 0, r = 2a, \quad \text{so } R = \frac{2}{3}\sqrt{2a} \cdot \sqrt{2a} = \frac{4}{3}a$$

$$\text{At } \theta = \frac{\pi}{4}, r = a\left(1 + \frac{1}{\sqrt{2}}\right),$$

$$\text{so } R = \frac{2}{3}\sqrt{2a} \left[a \left(1 + \frac{1}{\sqrt{2}} \right) \right]^{\frac{1}{2}}$$

$$\text{At } \theta = \frac{\pi}{2}, r = a, \quad \text{so } R = \frac{2}{3}\sqrt{2a} \cdot \sqrt{a} = \frac{2\sqrt{2}}{3}a.$$

EXERCISE

Find the radius of curvature R for the following curves at the indicated points

1. $r = \tan \theta$ at $\theta = \frac{3\pi}{4}$

Ans. $\sqrt{5}$

2. $r = 2 \sin 3\theta$ at $\theta = \frac{\pi}{6}$

Ans. $1/5$

3. $r = 2 \cos 2\theta$ at $\theta = \frac{\pi}{6}$

Ans. $13\sqrt{13}/58$

4. $r^2 = a^2 \cos 2\theta$

Hint: Convert to pedal equation $\frac{dp}{dr} = 3r^2/a^2$.

$$R = r \frac{dr}{dp} = r \left(\frac{a^2}{3r^2} \right) = \frac{a^2}{3r}.$$

Ans. $a^2/3r$

5. $r^2 \cos 2\theta = a^2$

Hint: Pedal equation $p = a^2/r$, $R = \frac{rdr}{dp} = r \cdot \left(\frac{-r^2}{a^2} \right)$.

Ans. r^3/a^2

6. $\sqrt{r} \cos \frac{\theta}{2} = \sqrt{a}$

Hint: Rewrite $r = a \sec^2 \frac{\theta}{2}$.

Ans. $2r\sqrt{r/a}$

7. $r = ae^{\theta \cot \alpha}$

Hint: Pedal equation: $p = r \sin \alpha$.

Ans. $r \operatorname{cosec} \alpha$

8. $r(1 + \cos \theta) = 2a$

Hint: Pedal equation $p^2 = ar$.

Ans. $2r\sqrt{r/a}$

9. $\theta = \frac{\sqrt{r^2 - a^2}}{a} - \cos^{-1} \frac{a}{r}$

Hint: Pedal equation $p^2 = r^2 - a^2$.

Ans. $\sqrt{r^2 - a^2}$

10. $r = a(1 - \cos \theta)$

Aliter: Pedal equation $2ap^2 = r^3$.

Ans. $\frac{2\sqrt{2a}}{3}\sqrt{(r/a)}$

11. $r^m = a^m \cos m\theta$

Ans. $a^m / [(m+1)r^{m-1}]$

Deduce cases when,

i. $m = -1$, straight line $a = r \cos \theta$

ii. $m = 2$, $r^2 = a^2 \cos 2\theta$ (Lemniscate of Bernoulli)

iii. $m = -2$, $r^2 \cos 2\theta = a^2$ (Rectangular hyperbola)

iv. $m = 1$, $r = a \cos \theta$ (Circle of diameter a)

v. $m = \frac{1}{2}$, $r = \frac{a}{2}(1 + \cos \theta)$ (Cardioid)

vi. $m = -\frac{1}{2}$, $r(1 + \cos \theta) = 2a$ (Parabola)

vii. $m = \frac{1}{3}$, Cardioid.

12. Show that $9(R_1^2 + R_2^2) = 16a^2$, where R_1 and R_2 are the radii of curvature at the extremities of the chord through the pole of the cardioid $r = a(1 + \cos \theta)$.

Hint:

$$R = \frac{2\sqrt{2a}}{3} r^{\frac{1}{2}} = \frac{2\sqrt{2a}}{3} (1 + \cos \theta)^{\frac{1}{2}} = \frac{4a}{3} \cos \frac{\theta}{2}$$

$$R_2 = R|_{\theta+\pi} = \frac{4a}{3} \cos \left(\frac{\theta + \pi}{2} \right) = -\frac{4a}{3} \sin \frac{\theta}{2}$$

$$R_1 = R|_{\theta} = \frac{4a}{3} \cos \frac{\theta}{2}.$$

Pedal Equation:

Radius of Curvature for Pedal Curve

Let O be the pole and OX be the initial line (refer Fig. 2.14). Let $P(r, \theta)$ be any point on the curve c whose polar equation is $r = f(\theta)$. Let PT be the tangent at P to the curve. Draw ON perpendicular to PT and let $ON =$ length of the perpendicular from

2.52 — HIGHER ENGINEERING MATHEMATICS—II

pole O to the tangent at $P = p$. Let ϕ be the angle between the tangent PT and the radius vector OP . Then from the right angled triangle ONP ,

Fig. 2.14

$$\sin \phi = \frac{ON}{OP} = \frac{p}{r}$$

$$\therefore p = r \sin \phi \quad (1)$$

Then

$$\frac{1}{p^2} = \frac{1}{r^2 \sin^2 \theta} = \frac{\operatorname{cosec}^2 \phi}{r^2} = \frac{1 + \cot^2 \theta}{r^2} = \frac{1}{r^2} + \frac{1}{r^2 \tan^2 \phi}$$

we know that $\tan \phi = r \frac{d\theta}{dr} = \frac{r}{(dr/d\theta)}$

Thus

$$\frac{1}{p^2} = \frac{1}{r^2} + \frac{1}{r^2 \left(\frac{r}{dr/d\theta} \right)^2} = \frac{1}{r^2} + \frac{1}{r^4} \left(\frac{dr}{d\theta} \right)^2 \quad (2)$$

Pedal equation of curve c is the relation between p and r given by (1) or (2). It is also known as $p - r$ equation to the curve.

Note: If the polar equation of the curve is known, the pedal equation can be obtained by eliminating θ between $r = f(\theta)$ and (2). Sometimes it is more convenient to eliminate θ and ϕ between $r = f(\theta)$, $\tan \phi = r \frac{d\theta}{dr}$ and $p = r \sin \phi$.

Radius of curvature R , for pedal curve

$$\text{Let } p = f(r) = r \sin \theta \quad (1)$$

be the pedal equation and

$$\psi = \theta + \phi \quad (2)$$

Differentiating (1) w.r.t. ' r ', we get

$$\begin{aligned} \frac{dp}{dr} &= r \cos \phi \frac{d\phi}{dr} + \sin \phi \\ &= r \frac{dr}{ds} \frac{d\phi}{dr} + r \frac{d\theta}{ds} \end{aligned}$$

since $\cos \phi = \frac{dr}{ds}$ and $\sin \phi = r \frac{d\theta}{ds}$

Thus

$$\frac{dp}{dr} = r \frac{d}{ds} (\phi + \theta) = r \frac{d\psi}{ds} \quad \text{by (2)}$$

$$= r \frac{1}{R}$$

$$\therefore R = r \frac{dr}{dp}$$

WORKED OUT EXAMPLES

Example 1: Find the radius of curvature at any point (r, θ) of the conic section $\frac{L}{r} = 1 + e \cos \theta$.

Solution: Differentiating w.r.t. θ ,

$$-\frac{L}{r^2} \frac{dr}{d\theta} = 0 - e \sin \theta$$

$$\text{so } \frac{dr}{d\theta} = \frac{r^2 e \sin \theta}{L}$$

The pedal equation is

$$\frac{1}{p^2} = \frac{1}{r^2} + \frac{1}{r^4} \left(\frac{dr}{d\theta} \right)^2 = \frac{1}{r^2} + \frac{1}{r^4} \frac{r^4 e^2 \sin^2 \theta}{L^2} = \frac{1}{r^2} + \frac{e^2 \sin^2 \theta}{L^2}$$

From the given conic equation, $\cos \theta = \frac{L-r}{er}$, so

$$\sin^2 \theta = 1 - \cos^2 \theta = 1 - \left(\frac{L-r}{er} \right)^2 = \frac{e^2 r^2 - (L-r)^2}{e^2 r^2}$$

Thus

$$\frac{1}{p^2} = \frac{1}{r^2} + \frac{1}{L^2} \left[e^2 - \frac{L^2}{r^2} - 1 + \frac{2L}{r} \right] = \frac{e^2 - 1}{L^2} + \frac{2}{Lr}$$

Differentiating p w.r.t. r ,

$$-\frac{2}{p^3} \cdot \frac{dp}{dr} = 0 - \frac{2}{L} \frac{1}{r^2}$$

$$R = \text{Radius of curvature} = r \frac{dr}{dp} = r \cdot \frac{Lr^2}{p^3} = L \left(\frac{r}{p} \right)^3.$$

Example 2: Determine R for $r \cos 2\theta = a$.

Solution: Differentiating w.r.t. θ ,

$$\frac{dr}{d\theta} \cdot \cos 2\theta - r \cdot 2 \cdot \sin 2\theta = 0$$

$$\frac{dr}{d\theta} = 2r \tan 2\theta$$

The pedal equation is

$$\begin{aligned} \frac{1}{p^2} &= \frac{1}{r^2} + \frac{1}{r^4} \left(\frac{dr}{d\theta} \right)^2 = \frac{1}{r^2} + \frac{1}{r^4} (4r^2 \tan^2 2\theta) \\ &= \frac{1}{r^2} [1 + 4(\sec^2 2\theta - 1)] = \frac{1}{r^2} \left[-3 + 4\left(\frac{r}{a}\right)^2 \right] \end{aligned}$$

since $\sec 2\theta = \frac{r}{a}$ from the given equation.

Thus

$$\frac{1}{p^2} = \frac{4}{a^2} - \frac{3}{r^2}$$

Differentiating w.r.t. 'r',

$$-\frac{2}{p^3} \frac{dp}{dr} = 0 - \frac{3 \cdot (-2)}{r^3}$$

$$R = r \frac{dr}{dp} = r \cdot \left(\frac{r^3}{-3p^3} \right) = \left| -\frac{r^4}{3p^3} \right|.$$

Example 3: Find the pedal equation of the curve $r = a \sec t$, $\theta = \tan t - t$ and find the radius of curvature at any point (r, θ) .

Solution: $\frac{r}{a} = \sec t$, so $\cos t = \frac{a}{r}$ or $t = \cos^{-1} \frac{a}{r}$.

$$\text{Then } \tan^2 t = \sec^2 t - 1 = \frac{r^2}{a^2} - 1 = \frac{r^2 - a^2}{a^2}$$

$$\text{or } \tan t = \frac{\sqrt{r^2 - a^2}}{a}$$

Thus eliminating t , the polar equation is

$$\theta = \tan t - t = \frac{\sqrt{r^2 - a^2}}{a} - \cos^{-1} \frac{a}{r}.$$

Differentiating θ w.r.t. r ,

$$\frac{d\theta}{dr} = \frac{1}{a} \cdot \frac{1}{2} \cdot \frac{1}{\sqrt{r^2 - a^2}} \cdot 2r - (-1) \cdot \frac{1}{\sqrt{1 - \left(\frac{a}{r}\right)^2}} \cdot \left(-\frac{a}{r^2}\right) \times$$

$$r \frac{d\theta}{dr} = \frac{\sqrt{r^2 - a^2}}{a} = \tan \phi$$

$$\text{So } \sin \phi = \frac{\sqrt{r^2 - a^2}}{\sqrt{a^2 + (r^2 - a^2)}} = \frac{\sqrt{r^2 - a^2}}{r}$$

The pedal equation of the curve is

$$p = r \sin \phi = \sqrt{r^2 - a^2}$$

$$\text{or } p^2 = r^2 - a^2$$

Differentiating w.r.t. r , $2p \frac{dp}{dr} = 2r$ or $\frac{dp}{dr} = \frac{r}{p}$.

The radius of curvature R is

$$R = r \cdot \frac{dr}{dp} = r \cdot \frac{p}{r} = p.$$

Example 4: Write the $p - r$ equation of the polar curve $r^n = a^n \sin n\theta$ and find the radius of curvature to the curve.

Solution: Taking log

$$n \ln r = n \ln a + \ln \sin n\theta$$

Differentiating w.r.t. θ ,

$$n \cdot \frac{1}{r} \frac{dr}{d\theta} = 0 + \frac{1}{\sin n\theta} \cdot n \cdot \cos n\theta$$

$$\frac{dr}{d\theta} = r \cot n\theta$$

we know that

$$\tan \phi = r \frac{d\theta}{dr} = r \cdot \frac{1}{r \cdot \cot n\theta} = \tan n\theta$$

Thus

$$\phi = n\theta$$

The required $p - r$ equation to the curve is

$$p = r \sin \phi = r \sin n\theta = r \cdot \left(\frac{r^n}{a^n} \right) = \frac{r^{n+1}}{a^n}$$

since $\sin n\theta = \frac{r^n}{a^n}$ from the equation of curve.

Differentiating w.r.t. r ,

$$a^n \cdot \frac{dp}{dr} = (n+1)r^n$$

$$R = r \frac{dr}{dp} = r \cdot \frac{a^n}{(n+1)r^n} = \frac{a^n}{(n+1)r^{n-1}}.$$

Example 5: Find the pedal equation of $r = a\theta$ and find R .

Solution:

$$\frac{dr}{d\theta} = a$$

so pedal equation is

2.54 — HIGHER ENGINEERING MATHEMATICS—II

$$\frac{1}{p^2} = \frac{1}{r^2} + \frac{1}{r^4} \left(\frac{dr}{d\theta} \right)^2 = \frac{1}{r^2} + \frac{1}{r^4} (a^2) = \frac{r^2 + a^2}{r^4}$$

$$\text{Thus } p^2 = \frac{r^4}{r^2 + a^2}$$

Differentiating w.r.t. r ,

$$2p \frac{dp}{dr} = \frac{(r^2 + a^2)4r^3 - r^4(2r)}{(r^2 + a^2)^2}$$

$$\frac{dp}{dr} = \frac{r(r^2 + 2a^2)}{(r^2 + a^2)^{\frac{3}{2}}}$$

$$\text{so } R = r \frac{dr}{dp} = \frac{(r^2 + a^2)^{\frac{3}{2}}}{(r^2 + 2a^2)}.$$

EXERCISE

Find the pedal curve of the polar curve $r = f(\theta)$ and find the radius of curvature R at any point (r, θ) :

1. Ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$
 $(x = a \cos \theta, y = b \sin \theta)$

Ans. Pedal equation $\frac{1}{p^2} = \frac{1}{a^2} + \frac{1}{b^2} - \frac{r^2}{a^2 b^2}$

$$R = a^2 b^2 / p^3$$

2. Parabola: $y^2 = 4a(x + a)$ or $\frac{2a}{r} = 1 - \cos \theta$

Ans. Pedal equation: $p^2 = ar$

$$R = 2r^{\frac{3}{2}} / \sqrt{a}$$

3. Cardioid: $r = a(1 + \cos \theta)$

Ans. Pedal equation: $r^3 = 2ap^2$

$$R = \frac{2}{3} \sqrt{2ar}$$

4. Hyperbola: $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$

Ans. Pedal equation: $r^2 = \frac{a^2 b^2}{p^2} + a^2 - b^2$

$$R = a^2 b^2 / p^3$$

5. Rectangular hyperbola: $r^2 \cos 2\theta = a^2$

Ans. Pedal equation: $p = a^2 / r$

$$R = r^3 / a^2$$

6. Equiangular spiral: $r = ae^{\theta \cot \alpha}$

Ans. Pedal equation: $p = r \sin \alpha$

$$R = r \operatorname{cosec} \alpha$$

7. Lemniscate $r^2 = a^2 \cos 2\theta$

Ans. Pedal equation: $r^3 = a^2 p$

$$R = a^2 / 3r$$

8. $x^2 + y^2 = 2ay$

Ans. Pedal equation: $r^2 = 2ap$

$$R = a$$

9. $r^m = a^m \cos m\theta$

Ans. Pedal equation: $r^{m+1} = a^m p$

$$R = a^m / [(m+1)r^{m-1}]$$

10. Astroid: $x = a \cos^3 t, y = a \sin^3 t$

$$\text{or } x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}}$$

with pedal equation: $r^2 = a^2 - 3p^2$

Ans. $R = |-3p|$.

Newton's Method:

To Find Radius of Curvature at the Origin

Let the given curve pass through the origin O (0, 0).

Case 1: If the x -axis is tangent to the curve at O then radius of curvature at origin is given by

$$R|_{\text{at}(0,0)} = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \left\{ \frac{x^2}{2y} \right\}.$$

Proof: Since x -axis is tangent to the curve at 0,

$$y_1(0) = \frac{dy}{dx}|_{\text{at}(0,0)} = 0 \quad (1)$$

Now

$$\lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \left\{ \frac{x^2}{2y} \right\} = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \left\{ \frac{2x}{2y_1} \right\} = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \left\{ \frac{1}{y_2} \right\} = \frac{1}{y_2(0)} \quad (2)$$

where we have applied L'Hospital's rule as the limit is 0/0 indeterminate form.

Substituting $y_1(0)$ and $y_2(0)$ from (1) and (2) in

$$R|_{(0,0)} = \frac{[1 + y_1^2(0)]^{\frac{3}{2}}}{y_2(0)} = \frac{(1 + 0)^{\frac{3}{2}}}{y_2(0)}$$

$$= \frac{1}{y_2(0)} = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \left\{ \frac{x^2}{2y} \right\}$$

Case 2: If the y -axis is a tangent to the curve at the origin O then

$$R \Big|_{(0,0)} = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \left\{ \frac{y^2}{2x} \right\}$$

Case 3: Both x -axis and y -axis are not tangents to the curve $y = f(x)$ at origin $O(0, 0)$.

By Maclaurin's theorem

$$y = f(0) + \frac{x}{1!} f_1(0) + \frac{x^2}{2!} f_2(0) + \dots$$

$f(0) = 0$ since curve passes through the origin.

Then

$$R = \frac{(1 + y_1^2)^{\frac{3}{2}}}{y_2} = \frac{(1 + p^2)^{\frac{3}{2}}}{q}$$

where $p = f_1(0) = y_1(0)$ and $q = f_2(0) = y_2(0)$.

Note: Tangents at the origin to a curve are obtained by equating the lowest degree terms in the equation of the curve to zero.

Case 4: Radius of curvature at the pole (origin) when equation is in polar form: If the initial line is tangent at pole then

$$R_{\text{at pole}} = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \left[\frac{x^2}{2y} \right] = \lim_{\substack{x \rightarrow 0 \\ \theta \rightarrow 0}} \left[\frac{r \cos^2 \theta}{2r \sin \theta} \right]$$

$$= \lim_{\substack{r \rightarrow 0 \\ \theta \rightarrow 0}} \left[\frac{r}{2\theta} \right] = \lim_{\theta \rightarrow 0} \left[\frac{dr/d\theta}{2} \right]$$

$$R_{\text{at pole}} = \frac{1}{2} \lim_{\substack{r \rightarrow 0 \\ \theta \rightarrow 0}} \left(\frac{dr}{d\theta} \right).$$

WORKED OUT EXAMPLES

Example 1: Find the radius of curvature at the origin for $x^4 - y^4 + x^3 - y^3 + x^2 - y^2 + y = 0$.

Solution: Equating to zero, the lowest term in the equation we get $y = 0$ (x -axis) is a tangent to the curve at the origin.

Divide the equation throughout by y , we get

$$x^2 \cdot \frac{x^2}{y} - y^3 + x \cdot \frac{x^2}{y} - y^2 + \frac{x^2}{y} - y + 1 = 0$$

We know that $\lim_{y \rightarrow 0} \frac{x^2}{y}$ as $x \rightarrow 0$ is $2R$

Taking the limit as $x \rightarrow 0, y \rightarrow 0$

$$0 \cdot 2R - 0 + 0 \cdot 2R - 0 + 2R - 0 + 1 = 0$$

$$\therefore R = \left| -\frac{1}{2} \right|.$$

Example 2: Determine R at $(0, 0)$ to the curve

$$x^3 y - x y^3 + 2x^2 y - 2x y^2 + 2y^2 - 3x^2 + 3x y - 4x = 0.$$

Solution: Observe that $x = 0$ (y -axis) is a tangent to the curve at origin. Divide the equation throughout by x , we get

$$x^2 y - y^3 + 2xy - 2y^2 + \frac{2y^2}{x} - 3x + 3y - 4 = 0$$

As $x \rightarrow 0$ and $y \rightarrow 0$

$$0 - 0 + 0 - 0 + 2 \cdot 2R - 0 + 0 - 4 = 0$$

$$\therefore R = 1.$$

Example 3: Calculate the radius of curvature at origin to the curve $a(y^2 - x^2) = x^3$.

Solution: Equating the lowest terms $y^2 - x^2$ to zero, note that $y = \pm x$ are the tangents to the curve at origin.

Substituting $y = px + q \frac{x^2}{2} + \dots$ in the given equation

$$a \left[\left(px + q \frac{x^2}{2} + \dots \right)^2 - x^2 \right] = x^3$$

To find the unknowns p and q , equate to zero coefficients of x^2 on both sides

$$ap^2 - a = 0 \therefore p = \pm 1$$

Similarly equating to zero coefficients of x^3 , we get

$$apq = 1, \quad q = \pm \frac{1}{a}$$

Now

$$R = \frac{(1 + y_1^2)^{\frac{3}{2}}}{y_2} = \frac{(1 + p^2)^{\frac{3}{2}}}{q} = \frac{(1 + 1)^{\frac{3}{2}}}{\pm \frac{1}{a}}$$

$$R = \pm 2\sqrt{2}a.$$

2.56 — HIGHER ENGINEERING MATHEMATICS—II

Example 4: Find the radius of curvature to the curve $x = at^2$, $y = 2at$ at the origin.

Solution: The curve is a parabola $y^2 = 4ax$ with y-axis as tangent at origin (0, 0).

$$R \text{ at origin} = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \left(\frac{y^2}{2x} \right) = \lim_{t \rightarrow 0} \left(\frac{4a^2 t^2}{2at^2} \right) \\ = \lim_{t \rightarrow 0} 2a = 2a.$$

EXERCISE

Find the radius of curvature at origin to the following curves:

1. $y^4 + x^3 + a(x^2 + y^2) - a^2 y = 0$

Hint: $y = 0$ (x-axis) is tangent to curve at origin.

Ans. $a/2$

2. $x^3 + y^3 - 2x^2 + 6y = 0$

Hint: $y = 0$ is tangent to curve at origin.

Ans. $3/2$

3. $2x^4 + 3y^4 + 4x^2 y + xy - y^2 + 2x = 0$

Hint: $x = 0$ (y-axis) is tangent to curve at origin.

Ans. 1

4. $y^2 = x^2(a + x)/(a - x)$

Hint: $y = \pm x$ are tangents. $p = \pm 1$, $q = \pm \frac{2}{a}$.

Ans. $\sqrt{2}a$

5. $x^3 - 2x^2 y + 3xy^2 - 4y^3 + 5x^2 - 6xy + 7y^2 - 8y = 0$

Hint: x-axis is tangent.

Ans. $4/5$

6. $y = x^4 - 4x^3 - 18x^2$

Hint: x-axis is tangent.

Ans. $1/36$

7. $x^3 + 3x^2 y - 4y^3 + y^2 - 6x = 0$

Hint: y-axis is tangent.

Ans. 3

8. $3x^2 y - 3xy^2 + 2y^3 + 3x^2 - 3y^2 - 9y = 0$

Hint: x-axis is tangent.

Ans. $3/2$

9. $y^2 - 3xy - 4x^2 + x^3 + x^4 y + y^5 = 0$

Ans. $\frac{85\sqrt{17}}{2}, 5\sqrt{2}$

10. $xy^2 = 4a^2(2a - x)$ at vertex (2a, 0)

Hint: Put $x = 2a + X$, $y = Y$.

New equation $(2a + X)Y^2 = -4a^2 X$ has y-axis as tangent at origin.

Ans. $|-a|$

11. $5x^3 + 7y^3 + 4x^2 y + xy^2 + 2x^2 + 3xy + y^2 + 4x = 0$

Ans. $|-2|$

12. $x^3 + y^3 = 3axy$

Hint: Both x-axis and y-axis are tangents.

Ans. $3a/2$

13. $x = a(t + \sin t)$, $y = a(1 - \cos t)$

Hint: Curve passes through origin. x-axis is tangent to the curve at origin.

$$R = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x^2}{2y} = \lim_{\theta \rightarrow 0} \frac{a^2(0 + \sin \theta)^2}{2a(1 - \cos \theta)} = 4a.$$

Ans. $4a$

14. $r = a \sin n\theta$ at pole

Hint: Curve passes through origin (pole)

Initial line is tangent to the curve at pole

$$R = \lim_{\substack{x \rightarrow 0 \\ \theta \rightarrow 0}} \left(\frac{1}{2} \frac{dr}{d\theta} \right) = \lim_{\theta \rightarrow 0} \frac{1}{2} (na \cos n\theta) = \frac{na}{2}.$$

Ans. $\frac{na}{2}$

15. $2x^4 + 4x^3 y + xy^2 + 6y^3 - 3x^2 - 2xy + y^2 - 4x = 0$

Hint: y-axis is tangent.

Ans. 2

16. $y - x = x^2 + 2xy + y^2$

Hint: $y = x$ is tangent, $p = 1$, $q = 8$.

Ans. $a/2$.

Radius of Curvature, Centre of Curvature and Circle of Curvature

Let $P(x, y)$ be any point on a curve $y = f(x)$. Let the tangent L at P makes an angle α with the x -axis (see Fig. 2.15). Construct a circle such that circle is tangent to L at P , lies on the same side of L as the curve and has the same curvature k at P . Then this circle is known as circle of curvature and its radius R is known as radius of curvature and c is known as the centre of circle of curvature with coordinates x and y . Thus

Radius of curvature to the curve at the point P is $R = \frac{1}{k}$

In cartesian form

$$R = \frac{1}{k} = \frac{(1 + y_1^2)^{\frac{3}{2}}}{y_2}$$

Centre of circle of curvature

$$X = x - R \sin \alpha = x - R \cdot \frac{y_1}{\sqrt{1 + y_1^2}}$$

$$X = x - y_1 \frac{(1 + y_1^2)}{y_2}$$

Similarly

$$Y = y + R \cos \alpha = y + R \cdot \frac{1}{\sqrt{1 + y_1^2}}$$

$$Y = y + \frac{(1 + y_1^2)}{y_2}$$

The equation of the **circle of curvature** to the given

Fig. 2.15

curve at the point P is the circle of radius R and with centre $C(x, y)$ given by

$$(x - X)^2 + (y - Y)^2 = R^2.$$

Parametric Form

Radius of curvature in parametric form is

$$R = \frac{1}{k} = \frac{(\dot{x}^2 + \dot{y}^2)^{\frac{3}{2}}}{(\dot{x}\ddot{y} - \ddot{x}\dot{y})}$$

Centre of circle of curvature is

$$X = x(t) - \frac{\dot{y}(\dot{x}^2 + \dot{y}^2)}{(\dot{x}\ddot{y} - \ddot{x}\dot{y})}$$

$$Y = y(t) + \frac{\dot{x}(\dot{x}^2 + \dot{y}^2)}{\dot{x}\ddot{y} - \ddot{x}\dot{y}}.$$

WORKED OUT EXAMPLES

Example 1: Find the centre of circle of curvature for $xy(x + y) = 2$ at $(1, 1)$.

Solution: The given curve is $x^2y + xy^2 = 2$
Differentiating w.r.t. x ,

$$2xy + x^2y_1 + y^2 + 2xyy_1 = 0$$

$$y_1 = -\frac{(2xy + y^2)}{(x^2 + 2xy)}, \quad y_1|_{(1,1)} = \frac{-(2+1)}{(1+2)} = -1$$

Differentiating again w.r.t. x ,

$$2y + 2xy_1 + 2xy_1 + x^2y_2 + 2yy_1 + 2yy_1 + 2xy_1^2 + 2xyy_2 = 0$$

$$y_2 = \frac{2(y + 2xy_1 + 2yy_1 + xy_1^2)}{-(2xy + x^2)}, \quad y_2|_{(1,1)} = \frac{4}{3}$$

Centre of curvature

$$X = x - \frac{y_1(1 + y_1^2)}{y_2} = 1 - \frac{(-1)(1+1)}{4/3} = \frac{5}{2}$$

$$Y = y + \frac{(1 + y_1^2)}{y_2} = 1 + \frac{(1+1)}{4/3} = \frac{5}{2}$$

Coordinates of centre of curvature to the given curve at $(1, 1)$ are $(\frac{5}{2}, \frac{5}{2})$.

Example 2: Determine the centre of curvature to the curve in parametric form $x = 3t^2, y = 3t - t^3$.

2.58 — HIGHER ENGINEERING MATHEMATICS—II

Solution: Differentiating x and y w.r.t. t ,

$$\dot{x} = 6t, \ddot{x} = 6, \dot{y} = 3(1 - t^2), \ddot{y} = -6t$$

$$\dot{x}^2 + \dot{y}^2 = 36t^2 + 9(1 - t^2)^2 = 9(t^2 + 1)^2$$

$$\dot{x}\ddot{y} - \ddot{x}\dot{y} = 6t(-6t) - 6(3)(1 - t^2) = -18(t^2 + 1)$$

Coordinates of the centre of curvature

$$\begin{aligned} X &= x(t) - \frac{\dot{y}(\dot{x}^2 + \dot{y}^2)}{\dot{x}\ddot{y} - \ddot{x}\dot{y}} \\ &= 3t^2 - 3(1 - t^2) \frac{9(t^2 + 1)^2}{-18(t^2 + 1)} \end{aligned}$$

$$X(t) = \frac{3}{2}[1 + 2t^2 - t^4]$$

$$\begin{aligned} Y &= y + \frac{\dot{x}(\dot{x}^2 + \dot{y}^2)}{\dot{x}\ddot{y} - \ddot{x}\dot{y}} \\ &= (3t - t^3) + 6t \cdot \frac{9(t^2 + 1)^2}{-18(t^2 + 1)} \end{aligned}$$

$$Y = 3t - t^3 - 3t(t^2 + 1) = -4t^3$$

Centre of curvature $\left(\frac{3}{2}(1 + 2t^2 - t^4), -4t^3\right)$.

EXERCISE

Find the centre of curvature of the following curve at the indicated point:

I. Cartesian form

1. $y^2 = 4ax$ at (x, y)

Ans. $(3x + 2a, -2x^{\frac{3}{2}}/\sqrt{a})$

2. $y = e^x$ at $(0, 1)$

Ans. $(-2, 3)$

3. $y^2 = x^3$ at $(1, 1)$

Ans. $\left(-\frac{11}{2}, \frac{16}{3}\right)$

4. $y = \ln \sec x$ at $(\pi/3, \ln 2)$

Ans. $\left(\frac{\pi}{3} - \sqrt{3}, 1 + \ln 2\right)$

5. $y = (x^2 + 9)/x$ at $(3, 6)$

Ans. $(3, 15/2)$

6. $y = x^3 - 6x^2 + 3x + 1$ at $(1, -1)$

Ans. $(-36, -43/6)$

7. $x^3 + xy^2 - 6y^2 = 0$ at $(3, 3)$

Ans. $(-7, 8)$

8. $y = c \cosh(x/c)$ at (x, y)

Ans. $\left(x - y \frac{\sqrt{y^2 - c^2}}{c}, 2y\right)$

9. $x^3 + y^3 = 2$ at $(1, 1)$

Ans. $\left(\frac{1}{2}, \frac{1}{2}\right)$

10. $xy = c^2$ at (c, c)

Ans. $(2c, 2c)$

11. $y^3 = a^2x$ at (x, y)

Ans. $\left(\frac{a^4 + 15y^4}{6a^2y}, \frac{a^4y + 9y^5}{2a^4}\right)$

12. $y = x^4 - x^2$ at $(0, 0)$

Ans. $\left(0, -\frac{1}{2}\right)$

13. $y = x/(x + 1)$ at $(0, 0)$

Ans. $(1, -1)$

14. $y = e^{-x^2}$ at $(0, 1)$

Ans. $\left(0, \frac{1}{2}\right)$

15. $y = x \ln x$ at the point where tangent is parallel to x -axis

Ans. $(1/e, (e^2 - 1)/e)$

II. Parametric form

1. $x = a(\theta - \sin \theta), y = a(1 - \cos \theta)$

Ans. $X = a(\theta + \sin \theta), Y = -a(1 - \cos \theta)$

2. $x = t^2, y = t^3$

Ans. $X = -t^2 - 9t^{\frac{4}{3}}, Y = 4t^3 + 4t/3$

3. $x = 3t, y = t^2 - 6$ at (a, b)

Ans. $X = -4a(20 + a^2), Y = b + (81 + 4a^2)/18$

4. $x = a(\cos t + t \sin t), y = a(\sin t - t \cos t)$

Ans. $X = a \cos t, Y = a \sin t$

5. $x = (1 - at) \cos t + a \sin t,$

$y = (1 - at) \sin t - a \cos t$

Ans. $X = a \sin t, Y = -a \cos t.$

WORKED OUT EXAMPLES

Circle of curvature

Example 1: Find the circle of curvature of the curve $x + y = ax^2 + by^2 + cx^3$ at the origin.

Solution: Differentiating the given curve

$$x + y = ax^2 + by^2 + cx^3$$

w.r.t. 'x' implicitly, we get

$$1 + \frac{dy}{dx} = 2ax + 2by \frac{dy}{dx} + 3cx^2 \quad (1)$$

$$\frac{dy}{dx} = y_1 = \frac{1 - 2ax - 3cx^2}{2by - 1} \quad (2)$$

Differentiating (1) w.r.t. x,

$$0 + \frac{d^2y}{dx^2} = 2a + 2b \left(\frac{dy}{dx} \right)^2 + 2by \cdot \frac{d^2y}{dx^2} + 6cx$$

$$\frac{d^2y}{dx^2} = y_2 = + \frac{2a + 2by_1^2 + 6cx}{1 - 2by} \quad (3)$$

At origin (0, 0), $y_1 = -1$, $y_2 = 2(a + b)$

$$\begin{aligned} R = \text{Radius of curvature} &= \frac{[1 + (-1)^2]^{\frac{3}{2}}}{y_2} \\ &= \frac{2\sqrt{2}}{2(a+b)} = \frac{\sqrt{2}}{a+b} \end{aligned} \quad (4)$$

The centre of circle of curvature is given by

$$X = x - \frac{y_1(1 + y_1^2)}{y_2} = 0 - \frac{(-1)(1 + (-1)^2)}{2(a+b)} = \frac{1}{a+b} \quad (5)$$

$$Y = y + \frac{(1 + y_1^2)}{y_2} = 0 + \frac{(1 + (-1)^2)}{2(a+b)} = \frac{1}{a+b} \quad (6)$$

The equation of the circle of curvature with centre given by (5) and (6) and radius by (4) is

$$\left(x - \frac{1}{a+b} \right)^2 + \left(y - \frac{1}{a+b} \right)^2 = \left(\frac{\sqrt{2}}{a+b} \right)^2$$

$$\text{or } (a+b)(x^2 + y^2) = 2(x+y).$$

Example 2: Determine the circle of curvature of the folium $x^3 + y^3 = 3axy$ at the point $P(3a/2, 3a/2)$.

Solution: By implicit differentiation

$$3x^2 + 3y^2 y_1 = 3ay + 3axy_1$$

$$y_1 = \frac{ay - x^2}{y^2 - ax}$$

Differentiating w.r.t. x again

$$2x + 2yy_1^2 + y^2 y_2 = ay_1 + ay_1 + axy_2$$

$$y_2 = \frac{2ay_1 - 2x - 2yy_1^2}{y^2 - ax}$$

At the point $P(3a/2, 3a/2)$

$$y_1 = \frac{a \cdot \frac{3a}{2} - \left(\frac{3a}{2} \right)^2}{\left(\frac{3a}{2} \right)^2 - a \cdot \frac{3a}{2}} = -1$$

$$y_2 = -\frac{32}{3a}$$

$$\begin{aligned} R = \text{Radius of curvature} &= \left| \frac{[1 + (-1)^2]^{\frac{3}{2}}}{(-32/3a)} \right| \\ R &= \frac{3\sqrt{2}a}{16} \end{aligned} \quad (1)$$

The centre of curvature

$$X = x - \frac{y_1(1 + y_1^2)}{y_2} = \frac{3a}{2} - \frac{(-1)(2)}{(-32)} \cdot 3a = \frac{21a}{16} \quad (2)$$

$$Y = y + \frac{(1 + y_1^2)}{y_2} = \frac{3a}{2} + \frac{2}{(-32)} \cdot 3a = \frac{21a}{16} \quad (3)$$

The required circle of curvature with centre given by (1) and (2) and radius (3) is

$$\left(x - \frac{21a}{16} \right)^2 + \left(y - \frac{21a}{16} \right)^2 = \left(\frac{3\sqrt{2}a}{16} \right)^2$$

$$\text{or } (x^2 + y^2) - \frac{21}{8}a(x+y) + \frac{432}{128}a^2 = 0.$$

Example 3: Show that the parabolas $y = -x^2 + x + 1$, $x = -y^2 + y + 1$ have the same circle of curvature at the point (1, 1).

Solution: For the parabola

$$y = -x^2 + x + 1 \quad (1)$$

$$\frac{dy}{dx} = -2x + 1, \quad \frac{d^2y}{dx^2} = -2. \text{ At } (1, 1), \frac{dy}{dx} = -1, \quad \frac{d^2y}{dx^2} = -2$$

$R_1 = \text{Radius of curvature of parabola (1) at } (1, 1)$

$$= \left| \frac{[1 + (-1)^2]^{\frac{3}{2}}}{-2} \right|$$

$$R_1 = \frac{\sqrt{8}}{2} = \sqrt{2}$$

2.60 — HIGHER ENGINEERING MATHEMATICS—II

Centre of circle for parabola (1) at (1, 1) is

$$X_1 = 1 - (-1) \frac{(1+1)}{-2} = 1 - 1 = 0,$$

$$Y_1 = 1 + \frac{(1+1)}{-2} = 1 - 1 = 0$$

Thus the equation of circle of curvature for the parabola (1) at the point (1,1) is

$$(x-0)^2 + (y-0)^2 = (\sqrt{2})^2 \text{ or } x^2 + y^2 = 2 \quad (2)$$

Similarly for the parabola

$$x = -y^2 + y + 1 \quad (3)$$

$$\frac{dx}{dy} = -2y + 1, \frac{d^2x}{dy^2} = -2 \text{ so at } P(1, 1) \frac{dx}{dy} = -1, \frac{d^2x}{dy^2} = -2$$

R_2 = Radius of curvature for parabola (2) at (1, 1)

$$= \left| \frac{[1 + (-1)^2]^{\frac{3}{2}}}{-2} \right| = \frac{\sqrt{8}}{2} = \sqrt{2}$$

Centre of curvature for parabola (2) at (1, 1) is

$$X = 1 - \frac{(-1)(1+1)}{-2} = 1 - 1 = 0, Y = 1 + \frac{(1+1)}{-2} = 0$$

So the equation of circle of curvature to the second parabola (2) at point (1, 1) is same as (2) given by

$$(x-0)^2 + (y-0)^2 = (\sqrt{2})^2 \text{ or } x^2 + y^2 = 2.$$

Example 4: Determine the circles of curvature at the vertices of an ellipse with semi-axes a, b .

Solution: Equation of ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

In the parametric form $x = a \cos t, y = b \sin t$
Differentiating w.r.t. the parameter 't'

$$\dot{x} = -a \sin t, \ddot{x} = -a \cos t, \dot{y} = b \cos t, \ddot{y} = -b \sin t$$

$$R = \frac{(\dot{x}^2 + \dot{y}^2)^{\frac{3}{2}}}{|\dot{x}\ddot{y} - \ddot{x}\dot{y}|} = \frac{(a^2 \sin^2 t + b^2 \cos^2 t)^{\frac{3}{2}}}{ab \sin^2 t + ab \cos^2 t}$$

$$R = \frac{(a^2 \sin^2 t + b^2 \cos^2 t)^{\frac{3}{2}}}{ab} \quad (1)$$

Centre of curvature

$$X = x - \frac{\dot{x}^2 + \dot{y}^2}{\dot{x}\ddot{y} - \ddot{x}\dot{y}} \cdot \dot{y}$$

$$= a \cos t - \frac{b \cdot \cos t (a^2 \sin^2 t + b^2 \cos^2 t)}{ab}$$

$$X = \frac{a^2 b \cos t + a^2 b \cos^3 t - a^2 b \cos t - b^3 \cos^3 t}{ab}$$

$$X = \frac{(a^2 - b^2) \cos^3 t}{a} \quad (2)$$

Similarly

$$Y = y + \frac{\dot{x}(\dot{x}^2 + \dot{y}^2)}{\dot{x}\ddot{y} - \ddot{x}\dot{y}} = \frac{-(a^2 - b^2) \sin^3 t}{b}$$

The vertex A(a, 0) corresponds to $t = 0$.

So at A

$$R|_{t=0} = \frac{b^2}{a}, X|_{t=0} = \frac{a^2 - b^2}{a}, Y|_{t=0} = 0$$

The circle of curvature at the vertex A(a, 0) is

$$\left(x - \frac{a^2 - b^2}{a}\right)^2 + (y - 0)^2 = \left(\frac{b^2}{a}\right)^2$$

$$\text{or } x^2 + y^2 + 2x \left(\frac{b^2 - a^2}{a}\right) = (2b^2 - a^2)$$

Similarly the vertex B(0, b) corresponds to $t = \frac{\pi}{2}$

$$R = \frac{a^2}{b}, X = 0, Y = \frac{-(a^2 - b^2)}{b}$$

The circle of curvature at B is

$$(x - 0)^2 + \left(y + \frac{(a^2 - b^2)}{b}\right)^2 = \left(\frac{a^2}{b}\right)^2$$

$$\text{or } x^2 + y^2 + \frac{2(a^2 - b^2)y}{b} = (2a^2 - b^2)$$

EXERCISE

Circle of curvature

Determine the circle of curvature of the curve at the indicated point:

$$1. \ 2xy + x + y = 4 \text{ at } (1, 1)$$

$$\text{Ans. } \left(x - \frac{5}{2}\right)^2 + \left(y - \frac{5}{2}\right)^2 = \frac{9}{2}$$

$$2. \ y^2 = 12x \text{ at } (3, 6) \text{ and } (0, 0)$$

$$\text{Ans. At } (3, 6) : (x - 15)^2 + (y - (-6))^2 = (12\sqrt{2})^2$$

$$\text{At } (0, 0) : (x - 6)^2 + (y - 0)^2 = 6^2$$

$$3. \sqrt{x} + \sqrt{y} = \sqrt{a} \quad \text{at } (a/4, a/4)$$

$$\text{Ans. } \left(x - \frac{3a}{4}\right)^2 + \left(y - \frac{3a}{4}\right)^2 = \left(\frac{a}{\sqrt{2}}\right)^2$$

$$4. y^2 = 4ax \quad \text{at } (at^2, 2at)$$

$$\text{Ans. } x^2 + y^2 - 6at^2x - 4ax + 4at^3y = 3a^2t^4$$

$$5. y = mx + \frac{x^2}{a} \quad \text{at } (0, 0)$$

$$\text{Ans. } x^2 + y^2 = a(1 + m^2)(y - mx)$$

$$6. x^3 + y^3 = 2xy \quad \text{at } (1, 1)$$

$$\text{Ans. } \left(x - \frac{7}{8}\right)^2 + \left(y - \frac{7}{8}\right)^2 = \left(\frac{\sqrt{2}}{8}\right)^2$$

$$7. xy(x + y) = 2 \quad \text{at } (1, 1)$$

$$\text{Ans. } x^2 + y^2 + 5x - 5y + 8 = 0$$

$$8. y = x^3 + 2x^2 + x + 1 \quad \text{at } (0, 1)$$

$$\text{Ans. } x^2 + y^2 + x - 3y + 2 = 0$$

$$9. y^2 = 4ax \quad \text{at } (a, 2a)$$

$$\text{Ans. } x^2 + y^2 - 10ax + 4ay = 3a^2$$

10. Determine the values of a, b, c if $y = a + bx + cx^2$ and $xy = 12$ have same circle of curvature at the point $(3, 4)$

$$\text{Ans. } a = -12, b = -4, c = 4/9.$$

2.12 EVOLUTE

As a point P moves along a given curve c_1 , the centre of curvature corresponding to P describes another curve c_2 . The curve c_2 is known as the **Evolute** of the given curve c_1 and c_1 is known as the **Involute** of c_2 .

Thus *Evolute* of a curve is the locus of the centres of curvature corresponding to points on the curve c .

Determination of Evolute

I. Cartesian form Let $y = f(x)$ be the equation of the given curve c in cartesian form. Then the coordinates of the centre of curvature given by

$$X = x - y_1(1 + y_1^2)/y_2 \quad (1)$$

$$Y = y(x) + (1 + y_1^2)/y_2 \quad (2)$$

form the parametric equations of the evolute of C expressed in terms of the parameter x .

In many cases, the parameter x can be eliminated between (1) and (2). This results in a relation between X and Y of the form $f(X, Y) = 0$ which is the equation of the required evolute.

II. Parametric form Let the equation of the curve be in parametric form $x = x(t)$, $y = y(t)$ where t is the parameter. Then the parametric equations of the evolute are

$$X(t) = x(t) - \frac{\dot{y}(\dot{x}^2 + \dot{y}^2)}{\dot{x}\ddot{y} - \ddot{x}\dot{y}}$$

$$Y(t) = y(t) + \frac{\dot{x}(\dot{x}^2 + \dot{y}^2)}{\dot{x}\ddot{y} - \ddot{x}\dot{y}}$$

where $\dot{}$ denotes differentiation w.r.t. ' t '.

Result 1: The length of the arc of the evolute E between two points P_1 and P_2 equals to $R_1 - R_2$ where R_1 and R_2 are the radius of curvatures of the given curve c (involute) at the two points on c corresponding to P_1 and P_2 .

Result 2: Normal to a curve c (involute) is the tangent to its evolute.

WORKED OUT EXAMPLES

Example 1: Determine the parametric equations for the evolute of the curve $x = \frac{t^4}{4}$, $y = \frac{t^5}{5}$.

Solution: $\dot{x} = \frac{dx}{dt} = t^3$, $\ddot{x} = 3t^2$, $\dot{y} = t^4$, $\ddot{y} = 4t^3$. The coordinates of the centre of curvature in parametric form is

$$\begin{aligned} X &= x(t) - \frac{\dot{y}(\dot{x}^2 + \dot{y}^2)}{\dot{x}\ddot{y} - \ddot{x}\dot{y}} \\ &= \frac{t^4}{4} - \frac{t^4(t^6 + t^8)}{4t^6 - 3t^6} = -\frac{3}{4}t^4 - t^6 \end{aligned} \quad (1)$$

$$\begin{aligned} Y &= y(t) + \frac{\dot{x}(\dot{x}^2 + \dot{y}^2)}{\dot{x}\ddot{y} - \ddot{x}\dot{y}} \\ &= \frac{t^5}{5} + \frac{t^3(t^6 + t^8)}{4t^6 - 3t^6} = \frac{6}{5}t^5 + t^3 \end{aligned} \quad (2)$$

Note that the parameter t can not be eliminated between (1) and (2). Therefore the equation of the

2.62 — HIGHER ENGINEERING MATHEMATICS—II

required evolute in the parametric equations $X = x(t)$ and $Y = y(t)$ are given by (1) and (2).

Example 2: Find the evolute of the hyperbola $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$. Deduce the evolute of a rectangular hyperbola.

Solution: Differentiating the equation of hyperbola

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1 \quad (1)$$

w.r.t. x , we get

$$\frac{2x}{a^2} - \frac{2y}{b^2} \frac{y_1}{x} = 0$$

$$\text{or } y_1 = \frac{dy}{dx} = \frac{b^2 x}{a^2 y} \quad (2)$$

so

$$y_2 = y'' = \frac{d^2 y}{dx^2} = \frac{b^2}{a^4 y^3} (a^2 y^2 - b^2 x^2) = -\frac{b^4}{a^2} \frac{1}{y^3} \quad (3)$$

since from (1)

$$\frac{y^2}{b^2} = \frac{x^2 - a^2}{a^2} \text{ or } a^2 y^2 - b^2 x^2 = -b^2 a^2$$

Now the centre of curvature is

$$\begin{aligned} X &= x - \left(\frac{b^2 x}{a^2 y} \right) \cdot \left(1 + \frac{b^4 x^2}{a^4 y^2} \right) \cdot \left(\frac{a^2 y^3}{-b^4} \right) \\ X &= x \left[\frac{b^2 a^4 + a^2 b^2 x^2 - a^4 b^2 + b^4 x^2}{b^2 a^4} \right] \\ &= \frac{x^3 (b^2 + a^2)}{a^4} \end{aligned} \quad (4)$$

Similarly,

$$\begin{aligned} Y &= y + \left(1 + \frac{b^4 x^2}{a^4 y^2} \right) \cdot \left(\frac{-a^2 y^3}{b^4} \right) \\ Y &= y \left[\frac{-b^4 a^2 + a^4 y^2 + b^4 x^2}{-b^4 a^2} \right] = \frac{-y^3 (a^2 + b^2)}{b^4} \end{aligned} \quad (5)$$

$$\text{From (4): } x^2 = \left(\frac{a^4 X}{a^2 + b^2} \right)^{\frac{2}{3}} \quad (6)$$

$$\text{From (5): } y^2 = \left(\frac{b^4 Y}{a^2 + b^2} \right)^{\frac{2}{3}} \quad (7)$$

Then

$$1 = \frac{x^2}{a^2} - \frac{y^2}{b^2} = \frac{1}{a^2} \left(\frac{a^4 X}{a^2 + b^2} \right)^{\frac{2}{3}} - \frac{1}{b^2} \left(\frac{b^4 Y}{a^2 + b^2} \right)^{\frac{2}{3}}$$

Thus the required envelope is

$$(aX)^{\frac{2}{3}} - (bY)^{\frac{2}{3}} = (a^2 + b^2)^{\frac{2}{3}}$$

For a rectangular hyperbola with $a = b$ the envelope reduces to

$$X^{\frac{2}{3}} - Y^{\frac{2}{3}} = (2a)^{\frac{2}{3}}$$

Example 3: Show that the evolute of the deltoid $x = 2 \cos t + \cos 2t$, $y = 2 \sin t - \sin 2t$ is another deltoid three times the size of the given deltoid and has the equations

$$x = 3(2 \cos t - \cos 2t), \quad y = 3(2 \sin t + \sin 2t)$$

Solution: Differentiating x and y w.r.t. ' t ',

$$\dot{x} = -2 \sin t - 2 \sin 2t, \quad \ddot{x} = -2 \cos t - 4 \cos 2t$$

$$\dot{y} = -2 \cos t - 2 \cos 2t, \quad \ddot{y} = -2 \sin t + 4 \sin 2t$$

$$\text{so } \dot{x}^2 + \dot{y}^2 = 4(\sin^2 t + \sin^2 2t) + 4(\cos^2 t - \cos^2 2t)^2$$

$$= 4(\sin^2 t + \sin^2 2t + 2 \sin t \cdot \sin 2t)$$

$$+ 4(\cos^2 t + \cos^2 2t - 2 \cos t \cdot \cos 2t)$$

$$\dot{x}^2 + \dot{y}^2 = 8(1 + \sin t \cdot \sin 2t - \cos t \cdot \cos 2t)$$

Also

$$\dot{x} \ddot{y} - \dot{y} \ddot{x} = -2(\sin t + \sin 2t)(-2 \sin t + 4 \sin 2t)$$

$$- 2(\cos t - \cos 2t)(-2 \cos t - 4 \cos 2t)$$

$$= 4[\sin^2 t - 2 \sin^2 2t - \sin t \cdot \sin 2t]$$

$$+ 4[\cos^2 t - 2 \cos^2 2t + \cos t \cdot \cos 2t]$$

$$\dot{x} \ddot{y} - \dot{y} \ddot{x} = -4[1 + \sin t \cdot \sin 2t - \cos t \cdot \cos 2t]$$

$$\text{so that } (\dot{x}^2 + \dot{y}^2)/(\dot{x} \ddot{y} - \dot{y} \ddot{x}) = -2$$

Now the coordinates of the centre of curvature are

$$X = x(t) - \frac{\dot{y}(\dot{x}^2 + \dot{y}^2)}{\dot{x} \ddot{y} - \dot{y} \ddot{x}}$$

$$X = (2 \cos t + \cos 2t) - (2 \cos t - 2 \cos 2t)(-2)$$

$$X = 3(2 \cos t - \cos 2t)$$

Similarly

$$Y = y(t) + \frac{\dot{x}(\dot{x}^2 + \dot{y}^2)}{\dot{x} \ddot{y} - \dot{y} \ddot{x}}$$

$$= (2 \sin t - \sin 2t) + (-2 \sin t - 2 \sin 2t)(-2)$$

$$Y = 3(2 \sin t + \sin 2t)$$

Thus the evolute given by $X(t)$ and $Y(t)$ is the required deltoid.

Example 4: Calculate the total length of the evolute of the astroid $x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}}$.

Solution: $x = a \cos^3 t$, $y = a \sin^3 t$ are the parametric equations of the given astroid (also known as four-cusped hypo-cycloid (refer Fig. 2.16).

$$y_1 = \frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{3a \sin^2 t \cos t}{-3a \cos^2 t \sin t} = -\tan t$$

$$y_2 = \frac{d^2y}{dx^2} = \frac{d}{dt}(-\tan t) \frac{dt}{dx} \\ = -\sec^2 t \times \frac{1}{-3a \cos^2 t \sin t}$$

so $y_2 = \frac{1}{3a \cos^4 t \sin t}$

Now the centre of curvature (X, Y) are

$$X = x - y_1 \frac{(1 + y_1^2)}{y_2} \\ = a \cos^3 t + \tan t (1 + \tan^2 t) 3a \cos^4 t \sin t \\ X = a \cos^3 t + 3a \sin^2 t \cos t$$

Similarly

$$Y = y + \frac{1 + y_1^2}{y_2} = a \sin^3 t + 3a \cos^2 t \sin t$$

To eliminate the parameter t , consider

$$(X + Y)^{\frac{2}{3}} + (X - Y)^{\frac{2}{3}} \\ = a^{\frac{2}{3}} [(\cos t + \sin t)^2 + (\cos t - \sin t)^2]$$

Thus the required evolute for the astroid is given by

$$(X + Y)^{\frac{2}{3}} + (X - Y)^{\frac{2}{3}} = 2a^{\frac{2}{3}}$$

The radius of curvature R at any point of the given astroid is

$$R = \frac{(1 + y_1^2)^{\frac{3}{2}}}{y_2} \\ = (1 + \tan^2 t)^{\frac{3}{2}} \cdot 3a \cos^4 t \sin t = \frac{3a}{2} \sin 2t$$

Total length of the evolute $= L = 8$ times the length of arc of the evolute AB in the 1st quadrant. Radius of curvature of the astroid at the point A with $t = 0$ is $R_1 = \frac{3a}{2} \cdot \sin 2 \cdot 0 = 0$.

Fig. 2.16

Radius of curvature at B (with $t = \frac{\pi}{4}$) is $R_2 = \frac{3a}{2}$. Since the length of the arc of the evolute between two points is the difference between the radii of curvatures of the curve at the corresponding points, the length of the arc AB of the evolute $= R_2 - R_1 = \frac{3a}{2} - 0 = \frac{3a}{2}$.

Thus the total length of the evolute $= 8 \cdot \frac{3a}{2} = 12a$.

Example 5: Show that $R_1^2 + R_2^2 = \text{constant}$ if R_1 and R_2 are the radii of curvatures at the corresponding points of a cycloid and its evolute.

Solution: Consider a cycloid

$$x = a(t + \sin t), y = -a(1 - \cos t) \quad (1)$$

$$\dot{x} = a(1 + \cos t), \dot{y} = -a \sin t$$

$$y_1 = \frac{\dot{y}}{\dot{x}} = -\frac{a \sin t}{a(1 + \cos t)} = -\frac{2 \sin \frac{t}{2} \cdot \cos \frac{t}{2}}{2 \cdot \cos^2 \frac{t}{2}} = -\tan \frac{t}{2}$$

$$y_2 = -\sec^2 \frac{t}{2} \cdot \frac{1}{2} \cdot \frac{1}{a(1 + \cos t)} = -\frac{1}{2} \frac{\sec^2 \frac{t}{2}}{2 \cdot \cos^2 \frac{t}{2}}$$

$$y_2 = \frac{-1}{4a \cos^4 \frac{t}{2}}$$

The centre of curvature of the given cycloid is

$$X = x - \left(-\tan \frac{t}{2}\right) \cdot \left(1 + \tan^2 \frac{t}{2}\right) \cdot \left(-4a \cos^4 \frac{t}{2}\right)$$

$$X = a(t + \sin t) - 2a \cdot \sin 2 \frac{t}{2} = a(t - \sin t)$$

Similarly

$$Y = y + \left(1 + \tan^2 \frac{t}{2}\right) \left(-4a \cos^4 \frac{t}{2}\right)$$

2.64 — HIGHER ENGINEERING MATHEMATICS—II

$$= -a(1 - \cos t) - 4a \cdot \left(\frac{1 + \cos t}{2} \right)$$

$$Y = -a(3 + \cos t)$$

$$Y + 2a = -a(1 + \cos t)$$

Evolute of the given cycloid (1) is

$$X = a(t - \sin t), Y = -a(3 + \cos t) \quad (2)$$

R_1 = Radius of curvature of the cycloid (1)

$$R_1 = \left(1 + \tan^2 \frac{\theta}{2} \right)^{\frac{3}{2}} \cdot \left(-4a \cdot \cos^4 \frac{t}{2} \right) = -4a \cos \frac{t}{2} \quad (3)$$

R_2 = Radius of curvature of the evolute (2)

$$\dot{X} = a(1 - \cos t), \dot{Y} = a \sin t$$

$$Y_1 = \frac{dY}{dX} = \frac{\dot{Y}}{\dot{X}} = \frac{a \sin t}{a(1 - \cos t)}$$

$$= \frac{2 \sin \frac{t}{2} \cdot \cos \frac{t}{2}}{2 \cdot \sin^2 \frac{t}{2}} = \cot \frac{t}{2}$$

$$Y_2 = \frac{d^2 Y}{dX^2} = \frac{d}{dt} \left(\cot \frac{t}{2} \right) \cdot \frac{dt}{dX}$$

$$= -\operatorname{cosec}^2 \frac{t}{2} \cdot \frac{1}{2} \cdot \frac{1}{a(1 - \cos t)}$$

$$Y_2 = -\frac{1}{2a} \frac{\operatorname{cosec}^2 \frac{t}{2}}{2 \cdot \sin^2 \frac{t}{2}} = \frac{-1}{4a \sin^4 \frac{t}{2}}$$

$$\therefore R_2 = \left(1 + \cot^2 \frac{t}{2} \right)^{\frac{3}{2}} \cdot \left(-4a \sin^4 \frac{t}{2} \right) = -4a \sin \frac{t}{2} \quad (4)$$

From (3) and (4)

$$R_1^2 + R_2^2 = 16a \cos^2 \frac{t}{2} + 16a \sin^2 \frac{t}{2} = 16a = \text{constant.}$$

EXERCISE

Find the evolute of the following curves:

1. $y = x^3$

Ans. $X(x) = \frac{x}{2} - \frac{9}{2}x^5, Y(x) = \frac{5}{2}x^3 - \frac{1}{6x}$

2. $y = e^x$

Ans. $X(x) = x - 1 - e^{2x}, Y(x) = 2e^{2x} + e^{-x}$

3. Cycloid $x = a(t - \sin t), y = a(1 - \cos t)$

Hint: $y_1 = \cot(t/2), y_2 = 1/(4a \sin^4(t/2))$.

Ans. $X(t) = a(t + \sin t), Y(t) = -a(1 - \cos t)$

4. Cycloid $x = a(t + \sin t), y = a(1 + \cos t)$

Ans. $X(t) = a(t - \sin t), Y(t) = -a(1 + \cos t)$

5. Cardioid $x = 2 \cos t \pm \cos 2t, y = 2 \sin t \pm \sin 2t$

Hint: $\frac{\dot{x}^2 + \dot{y}^2}{x\ddot{y} - \dot{x}\ddot{y}} = \frac{8(1 - \cos t)}{12(1 - \cos t)}$ (for $-$ sign).

Ans. Cardioid $X = \frac{1}{3}(2 \cos t \mp \cos 2t),$
 $Y = \frac{1}{3}(2 \sin t \mp \sin 2t)$

6. Nephroid $x = 3 \cos t + \cos 3t,$
 $y = 3 \sin t - \sin 3t$

Hint: $y_1 = \frac{+12 \sin^2 t \cos t}{-12 \cos^2 t \sin t} = -\tan t,$
 $y_2 = -1/(12 \cos^4 t \cdot \sin t)$

Ans. Nephroid $X = 2(3 \cos t - \cos 3t),$
 $Y = 2(3 \sin t + \sin 3t)$

Note: In the above problems from 1 to 6 it is not possible to eliminate the parameter t between X and Y . Therefore the equation of the evolute is given in the parametric form $X = X(t), Y = Y(t)$.

7. Show that the evolute of the curve

$x = a(\cos t + t \sin t), y = a(\sin t - t \cos t)$ is a circle $x^2 + y^2 = a^2$.

Hint: $y_1 = \tan t, y_2 = 1/(at \cos^3 t)$.

Find the evolute of the following curves:

8. $y^2 = 4ax$ or in the parametric form
 $x = a \cot^2 t, y = 2a \cot t$

Ans. $27aY^2 = 4(X - 2a)^3$

9. $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

Hint: $y_1 = -b \cot t, y_2 = -b/(a^2 \sin^3 t)$

Ans. $(aX)^{\frac{2}{3}} + (bY)^{\frac{2}{3}} = (a^2 - b^2)^{\frac{2}{3}}$

10. $xy = c^2/2$

Ans. $(X + Y)^{\frac{2}{3}} - (X - Y)^{\frac{2}{3}} = 2C^{\frac{2}{3}}$

11. Calculate the length of the arc of the evolute of the parabola $y^2 = 4ax$ which is intercepted by the parabola.

Hint: Evolute is $27ay^2 = 4(x - 2a^3)$. Centre of curvature at any point (x, y) on parabola is $(3x + 2a, -y^3/4a^2)$. Points of intersection of parabola and evolute are $B(8a, -4\sqrt{2}a)$ and $C(8a, 4\sqrt{2}a)$. Length of evolute = $2(\text{arc } AC) = 2(R_2 - R_1) = 2(6\sqrt{3}a - 2a)$

Ans. $4a(3\sqrt{3} - 1)$

12. Prove that the whole length of the evolute of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ is $4\left(\frac{a^2}{b} - \frac{b^2}{a}\right)$

Hint: Radius of curvature

$R = \frac{(a^2 \sin^2 t + b^2 \cos^2 t)^{3/2}}{ab}$. Length of evolute of ellipse = $4(R_2 - R_1)$ where R_2, R_1 are the radii of curvature at $t = 0$, and $t = \pi/2$.

2.13 ENVELOPES

One-parameter Family of Curves

Let $f(x, y, \alpha)$ be a function of the three independent variables x, y and α . For a particular given value of α , the equation

$$f(x, y, \alpha) = 0 \quad (1)$$

represents a plane curve in the xy -plane. Thus the one-parameter family of curves is the totality of all the curves having one common property obtained from (1) by assigning different values to α . The variable α is known as the parameter and the equation (1) $f(x, y, \alpha) = 0$ represents a one-parameter family (or system or group) of curves.

Example: $y = mx + 6$ represents a family of straight lines all passing through the point $(0, 6)$ but having different slopes assigned by the parameter m .

Example: $(x - a)^2 + y^2 = 4$ represents a family of circles all with radius 2 but with different centers lying on x -axis for different values of the parameter a .

In a similar way, a two-parameter family of curves is represented by the equation $f(x, y, \alpha, \beta) = 0$ where α, β are the two parameters.

Example: Family of concentric and coaxial ellipses given by $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ with a, b as the parameters.

Note: If the two parameters α, β are connected by a relation, then the two-parameter family reduces to a one-parameter family of curves.

Envelope E of a given family of curves c is a curve which touches every member of the family of curves c and at each point of the envelope E is touched by some member of the family of curves c .

Example: The x -axis $y = 0$ is the envelope of the family of semicubical parabolas $y^2 - (x + b)^3 = 0$ with b as the parameter (see Fig. 2.17).

Fig. 2.17

Example: The two lines $x = a$ and $x = -a$ are the two envelopes to the family of circles

$$x^2 + (y - b)^2 = a^2$$

with centres on y -axis and of given radius a . Here b is the parameter (see Fig. 2.18).

Fig. 2.18

Example: The family of circles $x^2 + (y - b)^2 = b^2$ with centres lying on y -axis, have no envelope (refer Fig. 2.19).

Thus a family of curves may have no envelope or unique envelope or several envelopes.

Envelope may be defined in a rigorous way as the locus of the limiting position of point of intersection of one member of the family with a neighbouring member as the latter tends to the former.

Fig. 2.19

Method of Obtaining Envelope

- I. Envelope is obtained generally by eliminating the parameter α between the equation of the given family curves

$$f(x, y, \alpha) = 0 \quad (1)$$

$$\text{and} \quad \frac{\partial f}{\partial \alpha} = f_{\alpha}(x, y, \alpha) = 0 \quad (2)$$

where $\frac{\partial f}{\partial \alpha}$ is the partial derivative of f w.r.t. α .

- II. In case α can not be eliminated between (1) and (2) then solve (1) and (2) for x and y in terms of α . Then the envelope is given in the parametric form by the equations

$$x = x(\alpha) \quad \text{and} \quad y = y(\alpha)$$

- III. If the equation (1) is a quadratic in the parameter α or quadratic in some parameter λ which is a function of α , then the envelope is given by discriminant equated to zero.

Suppose $f(x, y, \alpha) = 0$ is rewritten as a quadratic equation

$$A\lambda^2 + B\lambda + C = 0 \quad (3)$$

where A, B, C are functions of x, y while λ is either α or function of α . Differentiating (3) w.r.t. λ ,

$$2A\lambda + B = 0 \quad \text{or} \quad \lambda = -\frac{B}{2A} \quad (4)$$

Eliminating λ from (3) by using (4) we get the equation of the required envelope as

$$A \left(-\frac{B}{2A} \right)^2 + B \left(-\frac{B}{2A} \right) + C = 0$$

$$\text{i.e.,} \quad B^2 - 4AC = \text{discriminant} = 0$$

- IV. Envelope of the family of normals to a given curve C is the evolute of the curve C .

- V. For a given two parameter family of curves

$$f(x, y, \alpha, \beta) = 0 \quad (5)$$

with a given relation $g(\alpha, \beta) = 0$ between the parameters α, β , (5) can be reduced to a one parameter family by elimination of one of the parameters say β in terms of α by using the given relation $g(\alpha, \beta)$. Then proceed as in I.

WORKED OUT EXAMPLES

Example 1: Find the envelope of the one parameter family of curves $y = mx + am^p$ where m is the parameter and a, p are constants.

Solution: Differentiate the given curves

$$y = mx + am^p \quad (1)$$

with respect to the parameter ' m '

$$0 = x + apm^{p-1}$$

$$\text{solving} \quad m = \left(-\frac{x}{pa} \right)^{\frac{1}{(p-1)}} \quad (2)$$

using (2) eliminate m from (1)

$$y = \left(\frac{-x}{pa} \right)^{\frac{1}{(p-1)}} \cdot x + a \left(\frac{-x}{pa} \right)^{\frac{p}{(p-1)}}$$

$$y^{(p-1)} = \left(\frac{-x}{pa} \right) \cdot x^{(p-1)} + a^{(p-1)} \cdot \left(\frac{-x}{pa} \right)^p$$

$$\text{or} \quad ap^p y^{p-1} = -x^p \cdot p^{p-1} + (-x)^p \quad (3)$$

(3) is the equation of the required envelope of (1).

Example 2: Show that the family of straight lines $2y - 4x + \alpha = 0$ has no envelope, where α being the parameter.

Solution: Differentiating the given equation w.r.t. ' α ' we get $0 + 0 + 1 = 0$ which is a contradiction. Note that the given family of straight lines $y = 2x - \frac{\alpha}{2}$ are all parallel with common slope

$m = 2$. Therefore no curve (envelope) exists which touches each member of this parallel straight lines.

Example 3: Determine the envelope of

$$x \sin t - y \cos t = at \quad (1)$$

where t is the parameter.

Solution: Differentiating (1) w.r.t. ' t ', we get

$$x \cos t + y \sin t = a \quad (2)$$

As ' t ' the parameter can not be eliminated between (1) and (2). Solve (1) and (2), for x and y in terms of t . For this, multiply (1) by $\sin t$ and (2) by $\cos t$

$$x \sin^2 t - y \sin t \cos t = at \sin t$$

$$x \cos^2 t + y \sin t \cos t = a \cos t$$

Adding, $x(t) = a(t \sin t + \cos t)$. Similarly multiplying (1) by $\cos t$ and (2) by $\sin t$ and subtracting, we get

$$y(t) = a(\sin t - t \cos t).$$

Example 4: (Leibnitz's problem) calculate the envelope of family of circles whose centres lie on the x -axis and radii are proportional to the abscissa of the centre.

Solution: Let $(b, 0)$ be the centre of any one of the family of circles with b as the parameter. Then the equation of the family of circles with centres on x -axis and radius proportional to the abscissa of the centre is

$$(x - b)^2 + y^2 = ab$$

where a is the proportionality constant.

Differentiating the above equation w.r.t. ' b ',

$$-2(x - b) + 0 = a \quad \therefore b = x + \frac{a}{2}$$

Eliminating the parameter b

$$\left(-\frac{a}{2}\right)^2 + y^2 = a\left(x + \frac{a}{2}\right) \quad \text{or} \quad y^2 = a\left(x + \frac{a}{4}\right)$$

The required envelope is the parabola.

Example 5: Prove that every member of the family of parabolas given by $y^2 = 4b(x - b)$ with b as the parameter is touched by one or the other of the straight lines $y = \pm x$.

Solution: Differentiating

$$y^2 = 4b(x - b)$$

w.r.t. ' b ', we get

$$0 = 4x - 8b$$

$$b = \frac{x}{2}$$

Substituting b in the given equation

$$y^2 = 4\left(\frac{x}{2}\right)\left(x - \frac{x}{2}\right) = x^2$$

The required envelopes are the straight lines $y = \pm x$ which touch every parabola of the given family.

Example 6: Determine the envelope of the two parameter family of parabolas

$$\sqrt{\frac{x}{a}} + \sqrt{\frac{y}{b}} = 1$$

where the two parameters a and b are connected by the relation $a + b = c$ where c is a given constant.

Solution: Using the given relation

$$a + b = c$$

eliminate $b = c - a$ from the given family

$$\sqrt{\frac{x}{a}} + \sqrt{\frac{y}{c-a}} = 1 \quad (1)$$

which is now a one-parameter family of parabolas with a as the parameter.

Differentiating (1) w.r.t. ' a ',

$$\begin{aligned} \sqrt{x} \cdot \left(-\frac{1}{2}\right) \frac{1}{a^{\frac{3}{2}}} + \sqrt{y} \cdot \left(-\frac{1}{2}\right) \\ \times \frac{1}{(c-a)^{\frac{3}{2}}} (-1) = 0 \\ \left(\frac{c-a}{a}\right)^{\frac{3}{2}} = \left(\frac{y}{x}\right)^{\frac{1}{2}} \\ \frac{c}{a} = \frac{x^{\frac{1}{3}} + y^{\frac{1}{3}}}{x^{\frac{1}{3}}} \\ \text{or} \quad a = \frac{cx^{\frac{1}{3}}}{x^{\frac{1}{3}} + y^{\frac{1}{3}}} \quad (2) \end{aligned}$$

Substituting (2) in (1), we get the required envelope as

$$\left[x \cdot \frac{x^{\frac{1}{3}} + y^{\frac{1}{3}}}{cx^{\frac{1}{3}}}\right]^{\frac{1}{2}} + \left[y \cdot \frac{1}{\left\{c - \frac{cx^{\frac{1}{3}}}{x^{\frac{1}{3}} + y^{\frac{1}{3}}}\right\}}\right]^{\frac{1}{2}} = 1$$

2.68 — HIGHER ENGINEERING MATHEMATICS—II

$$\left[x^{\frac{2}{3}} \left(x^{\frac{1}{3}} + y^{\frac{1}{3}} \right) \right]^{\frac{1}{2}} + \left[y^{\frac{2}{3}} \left(x^{\frac{1}{3}} + y^{\frac{1}{3}} \right) \right]^{\frac{1}{2}} = c^{\frac{1}{2}}$$

$$\text{or } \left(x^{\frac{1}{3}} + y^{\frac{1}{3}} \right) \left[\left(x^{\frac{2}{3}} \right)^{\frac{1}{2}} + \left(y^{\frac{2}{3}} \right)^{\frac{1}{2}} \right] = c^{\frac{1}{2}}$$

$$\left(x^{\frac{1}{3}} + y^{\frac{1}{3}} \right)^{\frac{3}{2}} = c^{\frac{1}{2}}$$

Thus the envelope is the astroid given by

$$x^{\frac{1}{3}} + y^{\frac{1}{3}} = c^{\frac{1}{3}}.$$

Example 7: If $a^2 + b^2 = c$ show that the envelopes of the family of ellipses

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad (1)$$

with a, b as parameters are the straight lines $\pm x \pm y = \sqrt{c}$.

Solution: Unlike the previous problem 6, where one parameter b is eliminated in terms of the other parameter a , in this problem treat b as a function of a . Thus differentiating equation of ellipses (1) w.r.t. ' a ', we get

$$-\frac{2x^2}{a^3} - \frac{2y^2}{b^3} \cdot \frac{db}{da} = 0 \quad (2)$$

Differentiating the given relation

$$a^2 + b^2 = c \quad (3)$$

w.r.t. ' a ', we have

$$2a + 2b \frac{db}{da} = 0 \quad (4)$$

or

$$\frac{db}{da} = -\frac{a}{b} \quad (5)$$

Substituting (5) in (2)

$$\frac{x^2}{a^4} = \frac{y^2}{b^4}$$

Rewriting

$$\frac{(x^2/a^2)}{a^2} = \frac{(y^2/b^2)}{b^2} = \frac{(x^2/a^2) + (y^2/b^2)}{(a^2 + b^2)} = \frac{1}{c}$$

where equations (1) and (3) are used.

$$\therefore \frac{x^2}{a^4} = \frac{1}{c} \quad \text{and} \quad \frac{y^2}{b^4} = \frac{1}{c}$$

$$\text{or } a^2 = \pm\sqrt{cx}, \quad b^2 = \pm\sqrt{cy}$$

Using (3) again

$$c = a^2 + b^2 = \pm\sqrt{cx} \pm \sqrt{cy}$$

so the required envelopes are

$$\pm x \pm y = \sqrt{c}.$$

Example 8: Find the envelope of the family of circles passing through the origin and with their centres lying on the ellipse (in Fig. 2.20)

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

Fig. 2.20

Solution: Any point $P(x, y)$ lying on the given ellipse in the parametric form is $P(a \cos t, b \sin t)$ with t as the parameter. Since the family of circles pass through the origin $O(0, 0)$ and have their centres as a point $P(x, y)$ on the ellipse, the equation of such family of circles is given by (with x, y as general point)

$$\begin{aligned} (x - a \cos t)^2 + (y - b \sin t)^2 &= (\text{radius})^2 = (OP)^2 \\ &= (a \cos t - 0)^2 + (b \sin t - 0)^2 \end{aligned} \quad (1)$$

Differentiating (1) w.r.t. the parameter ' t '

$$\begin{aligned} 2(x - a \cos t)(+a \sin t) + 2(y - b \sin t)(-b \cos t) \\ = 2a^2 \cdot \cos t(-\sin t) + 2b^2 \sin t \cdot \cos t \end{aligned}$$

Dividing throughout by $\sin t \cdot \cos t$

$$\frac{ax}{\cos t} - a^2 - \frac{by}{\sin t} + b^2 = b^2 - a^2$$

so

$$\tan t = \frac{by}{ax} \quad (\text{refer Fig. 2.21})$$

Fig. 2.21

Then

$$\sin t = \frac{by}{\sqrt{a^2 x^2 + b^2 y^2}} = \frac{by}{h} \quad (2)$$

and

$$\cos t = \frac{ax}{\sqrt{a^2 x^2 + b^2 y^2}} = \frac{ax}{h} \quad (3)$$

where

$$h = \sqrt{a^2 x^2 + b^2 y^2}$$

using (2) and (3) eliminate the parameter 't' from (1)

$$\begin{aligned} & \left(x - a \cdot \frac{ax}{h}\right)^2 + \left(y - b \cdot \frac{by}{h}\right)^2 \\ &= a^2 \cdot \left(\frac{ax}{h}\right)^2 + b^2 \left(\frac{by}{h}\right)^2 \\ & [x^2 h^2 + a^4 x^2 - 2a^2 x^2 h] + [y^2 h^2 + b^4 y^2 - 2b^2 y^2 h] \\ &= a^4 x^2 + b^4 y^2 \\ & (x^2 + y^2)(h^2) = 2h(a^2 x^2 + b^2 y^2) = 2h \cdot h^2 \\ \text{so } & x^2 + y^2 = 2h = 2(a^2 x^2 + b^2 y^2)^{\frac{1}{2}} \end{aligned}$$

Thus the required envelope is

$$(x^2 + y^2)^2 = 4(a^2 x^2 + b^2 y^2).$$

Example 9: Determine the evolute of the hyperbola $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$.

Solution: We know that the evolute of a curve c is the envelope of the family of normals to the given curve c .

Let $P(a \cosh t, b \sinh t)$ be any point on the given hyperbola. Then

$$\frac{dx}{dt} = \dot{x} = \frac{d}{dt}(a \cosh t) = a \sinh t, \dot{y} = b \cosh t \quad \text{so}$$

$$\frac{dy}{dx} = \frac{\dot{y}}{\dot{x}} = \frac{a \cosh t}{a \sinh t} = \frac{b}{a} \coth t$$

Thus the equation to (any) normal to hyperbola at a point P is

$$(y - b \sinh t) = \frac{-a}{b \coth t}(x - a \cosh t) \quad (1)$$

$$\text{or } \frac{by}{\sinh t} - b^2 = -\frac{ax}{\cosh t} + a^2 \quad (2)$$

Differentiating (2) w.r.t. the parameter 't', we get

$$-\frac{by \cosh t}{\sinh^2 t} - 0 = -ax \cdot \frac{\sinh t}{\cosh^2 t} + 0$$

$$\tanh t = -\left(\frac{by}{ax}\right)^{\frac{1}{3}}$$

Then

$$\sinh t = \mp \frac{(by)^{\frac{1}{3}}}{h} \quad \text{and} \quad \cosh t = \pm \frac{(ax)^{\frac{1}{3}}}{h} \quad (3)$$

$$\text{where } h = \sqrt{(ax)^{\frac{2}{3}} - (by)^{\frac{2}{3}}}$$

Using (3) eliminate 't' from (2). Thus

$$\begin{aligned} & \frac{by}{-(by)^{\frac{1}{3}}} \cdot h + \frac{ax}{(ax)^{\frac{1}{3}}} \cdot h = a^2 + b^2 \\ & \left[(ax)^{\frac{2}{3}} - (by)^{\frac{2}{3}}\right] \left[(ax)^{\frac{2}{3}} - (by)^{\frac{2}{3}}\right]^{\frac{1}{2}} = a^2 + b^2 \end{aligned}$$

The required envelope of the normals to the given hyperbola

$$(ax)^{\frac{2}{3}} - (by)^{\frac{2}{3}} = (a^2 + b^2)^{\frac{2}{3}}$$

is the evolute of the hyperbola.

Example 10: Find the envelope of

$$x \sec^2 \theta + y \operatorname{cosec}^2 \theta = a$$

where θ is the parameter.

Solution: The given equation is rewritten as

$$x(1 + \tan^2 \theta) + y(1 + \cot^2 \theta) = a$$

$$\text{or } x \cdot \tan^4 \theta + (x + y - a) \tan^2 \theta + y = 0$$

which is a quadratic equation in the parameter $\lambda = \tan^2 \theta$. Therefore the required envelope is given by discriminant $= B^2 - 4AC = 0$

$$\text{i.e., } (x + y - a)^2 - 4(x)(y) = 0$$

The envelope is

$$(x - y)^2 - 2ax - 2ay + a^2 = 0$$

2.70 — HIGHER ENGINEERING MATHEMATICS—II

Example 11: Show that the envelope of the family of circles described on the double ordinates of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ as diameters, is the ellipse $\frac{x^2}{a^2+b^2} + \frac{y^2}{b^2} = 1$.

Solution: The double ordinates on the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

are $(a \cos t, b \sin t)$ and $(a \cos t, -b \sin t)$ with ' t ' as the parameter. The equation of the family of circles described on the double ordinates as diameter is

$$(x - a \cos t)(x - a \cos t) + (y - b \sin t)(y + b \sin t) = 0.$$

[Note: $(x - x_1)(x - x_2) + (y - y_1)(y - y_2) = 0$ is equation of circle]

Rewriting the equation

$$x^2 + y^2 - 2ax \cos t + a^2 \cos^2 t - b^2 \sin^2 t = 0$$

or

$$(a^2 + b^2) \cos^2 t - 2ax \cos t + (x^2 + y^2 - b^2) = 0$$

which is a quadratic in the parameter $\lambda = \cos t$. Therefore the envelope to this family of circle is $B^2 - 4AC = 0$

$$\text{i.e., } (-2ax)^2 - 4(a^2 + b^2)(x^2 + y^2 - b^2) = 0$$

$$a^2 x^2 = (a^2 x^2 + b^2 x^2) + (a^2 + b^2)y^2 - b^2(a^2 + b^2)$$

Thus the envelope is the ellipse

$$\frac{x^2}{a^2 + b^2} + \frac{y^2}{b^2} = 1.$$

obtained by dividing throughout by $b^2(a^2 + b^2)$.

Example 12: Find the envelope of the family of straight lines drawn through the extremities of and at right angles to the radii vectors of the limaçon $r = a + b \cos \theta$ (see Fig. 2.22)

Fig. 2.22

Solution: Let $P(L, \alpha)$ be any point on the limaçon

$$r = a + b \cos \theta \quad (1)$$

$$\text{so } L = a + b \cos \alpha \quad (2)$$

since P lies on (1). Let $Q(r, \theta)$ be any point on the line PQ , which is drawn through the extremity P of the radius vector OP and is at right angles to OP i.e., $\angle OPQ = 90^\circ$. The problem is to find the envelope of the family of straight lines PQ . From the right angled triangle OPQ ,

$$\cos(\theta - \alpha) = \frac{L}{r}$$

or

$$L = r \cos(\theta - \alpha) \quad (3)$$

Thus the equation of line PQ is (3), with L and α as parameters. Eliminate L , using (2) and (3).

$$a + b \cos \alpha = L = r \cos(\theta - \alpha). \quad (4)$$

So (4) is the equation of the family of straight lines passing through extremity of and perpendicular to the radius vectors. In (4) α is the only parameter. Differentiating (4) w.r.t. ' α ', we get

$$0 + b(-1) \sin \alpha = -r \sin(\theta - \alpha) \cdot (-1)$$

Solving for α

$$\tan \alpha = \frac{r \sin \theta}{r \cos \theta - b} \quad (5)$$

$$\text{Let } h = \sqrt{(r \sin \theta)^2 + (r \cos \theta - b)^2} \quad (6)$$

$$\begin{aligned} h &= \sqrt{r^2 \sin^2 \theta + r^2 \cos^2 \theta + b^2 - 2rb \cos \theta} \\ &= \sqrt{r^2 - 2rb \cos \theta + b^2} \end{aligned}$$

$$\text{Then } \cos \alpha = \frac{r \cos \theta - b}{h} \quad (7)$$

Rewrite (4) as

$$\frac{a}{\cos \alpha} + b = r \cos \theta + r \sin \theta \cdot \tan \alpha. \quad (8)$$

Eliminate the parameter ' α ' from (8) using (5) and (7)

$$a \cdot \left(\frac{h}{r \cos \theta - b} \right) + b = r \cos \theta + r \sin \theta \left(\frac{r \sin \theta}{r \cos \theta - b} \right)$$

$$ah = (r \cos \theta - b)^2 + r^2 \sin^2 \theta$$

$$ah = r^2 - 2rb \cos \theta + b^2 = h^2$$

$$a = h = \sqrt{r^2 - 2rb \cos \theta + b^2}$$

Thus the required envelope is obtained by squaring

$$r^2 - 2b \cos \theta + (b^2 - a^2) = 0.$$

Example 13: Find the envelope of the system of straight lines $2y - 3tx + at^3 = 0$ where t is the parameter. Find the coordinates of the point of contact of the envelope and the particular member of the system when $t = 2$.

Solution: Differentiating the given system

$$2y - 3tx + at^3 = 0 \quad (1)$$

w.r.t. ' t ', we get

$$0 - 3x + 3at^2 = 0 \quad (2)$$

Multiplying (2) by t and subtracting from (1) we get $t = \frac{y}{x}$. Substituting this value of t in (1) we get the required envelope as

$$2y - 3x \left(\frac{y}{x} \right) + a \frac{y^3}{x^3} = 0$$

or

$$ay^2 = x^3 \quad (3)$$

From (2)

$$x = at^2$$

For

$$t = 2, \quad x = a(2)^2 = 4a \quad (4)$$

Substituting x in (3)

$$ay^2 = 64a^3 \quad \therefore y = 8a$$

Thus the point of contact of the envelope with the given family when $t = 2$ is $(x = 4a, y = 8a)$.

EXERCISE

Find the envelope of the following family of curves with m as the parameter:

1. $y = mx + \frac{a}{m}$

Ans. parabola $y^2 = 4ax$

2. $y = mx + \sqrt{1 + m^2}$

Ans. circle $x^2 + y^2 = 1$

3. $y = mx + \sqrt{a^2 m^2 + b^2}$

Ans. ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

4. $y = mx + am^3$

Ans. $8x^3 + 27ay^2 = 0$

5. $y = mx - 2am - am^3$

Ans. $27ay^2 = 4(x - 2a)^3$

Determine the envelope of following family of curves with t as the parameter:

6. $x \cos t - y \cot t = c$

Ans. $x^2 - y^2 = c^2$

7. $x \cos^n t + y \cdot \sin^n t = c$

Ans. $x^{\frac{2}{2-n}} + y^{\frac{2}{2-n}} = c^{\frac{2}{2-n}}$

8. $x \cos t + y \sin t = c \sin t \cos t$

Ans. $x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}}$

9. $\frac{x}{a} \cos t + \frac{y}{b} \sin t = 1$

Ans. $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

10. $\frac{ax}{\cos t} + \frac{by}{\sin t} = a^2 - b^2$

Ans. $(ax)^{\frac{2}{3}} + (by)^{\frac{2}{3}} = (a^2 - b^2)^{\frac{2}{3}}$

11. $x \tan t + y \sec t = c$

Ans. $y^2 = a^2 + x^2$

12. $\frac{a^2 \cos t}{x} - \frac{b^2 \sin t}{y} = c$

Ans. $\frac{a^4}{x^2} + \frac{b^4}{y^2} = c^2$

13. Concentric circles of radius α

Hint: Equation $x^2 + y^2 = \alpha^2$, Differentiating $2\alpha = 0, x^2 + y^2 = 0 \Rightarrow x = 0, y = 0$ an isolated point.

Ans. No envelope

14. Show that the envelope of the family of circles which always pass through the vertex of the parabola $y^2 = 4ax$ and with centres of circles lying on the parabola is a cissoid $x^3 + y^2(x + 2a) = 0$.

Hint: Vertex of parabola is origin $(0, 0)$ centre of circle $(-f, -g)$ lies on parabola, so $f^2 = -4ag$ or $g = -f^2/4a$.

Equation of circle is $x^2 + y^2 + 2gx + 2fy = 0$ or $x^2 + y^2 - \frac{f^2}{2a}x + 2fy = 0$ which is a quadratic in the parameter $f : xf^2 - 4ayf - 2a(x^2 + y^2) = 0$.

2.72 — HIGHER ENGINEERING MATHEMATICS—II

15. Find the envelope of the family of circles whose diameter are double ordinates of a parabola $y^2 = 4ax$.

Hint: The Equation of required circle with centre at $(\alpha, 0)$, end points of diameter (α, y_1) , $(\alpha, -y_1)$, diameter $2y$, radius y_1 is $(x - \alpha)^2 + y^2 = y_1^2$. Since $\theta(\alpha, y_1)$ lies on parabola $y_1^2 = 4a\alpha$. So equation of family of circles is

$$(x - \alpha)^2 + y^2 = 4a\alpha$$

which is a quadratic in α

$$\alpha^2 - 2(x + 2a)\alpha + (x^2 + y^2) = 0.$$

Ans. Envelope is another parabola $y^2 = 4a(x + a)$

16. Find the envelope of the family of straight lines obtained by joining the feet of the two perpendiculars drawn from any point on the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ to the two coordinate axes.

Hint: Any point P on ellipse is $(a \cos \theta, b \sin \theta)$. Coordinates of M and N the feet of perpendiculars PM and PN on to the x and y axis are $(a \cos \theta, 0)$ and $(0, b \sin \theta)$ respectively. So equation of family of straight lines MN is $y - 0 = \left(\frac{b \sin \theta - 0}{0 - a \cos \theta}\right)(x - a \cos \theta)$.

Ans. $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$

17. A straight line of given length 2 slides with its extremities on two fixed straight lines which are at right angles. Determine the envelope of the family of circles drawn on the sliding line as diameter.

Hint: The sliding line AB of length L has extremities $A(L \cos \alpha, 0)$ and $B(0, L \sin \alpha)$. Equation of circle with AB as diameter is

$$(x - L \cos t)(x - 0) + (y - 0)(y - L \sin t) = 0.$$

Ans. $x^2 + y^2 = L^2$

18. Find the envelope of the family of straight lines of given length L , whose extremities slide on two fixed straight lines at right angles.

Hint: Equation of line is:

$$x \sec \alpha + y \operatorname{cosec} \alpha = L$$

Ans. $x^{\frac{2}{3}} + y^{\frac{2}{3}} = L^{\frac{2}{3}}$.

Quadratic equation in the parameter α or $\lambda = \lambda(\alpha)$

$A\lambda^2 + B\lambda + c = 0$, envelope is $B^2 - 4AC = 0$. Find the envelope of:

19. $(y - mx)^2 = a^2m^2 + b^2$, with m parameter

Ans. $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

20. $x \cos t + y \sin t = a \sec t$, t is parameter

Ans. $y^2 = 4a(a - x)$

21. $y = x \tan t - \frac{gx^2}{2u^2 \cos t}$, t is the parameter

Hint: Quadratic in $\lambda = \tan t$ is

$$\left(\frac{g^2x^2}{2u^2}\right)\tan^2 t + (-x)\tan t + \left(y + \frac{gx^2}{2u^2}\right) = 0$$

Envelope is

$$B^2 - 4AC = (-x)^2 - 4\left(\frac{g^2x^2}{2u^2}\right)\left(y + \frac{gx^2}{2u^2}\right) = 0.$$

Ans. $u^4 = 2u^2gy + g^2x^2$

22. Straight lines which move such that the product of the intercepts on the two axes is constant.

Hint: $\frac{x}{a} + \frac{y}{b} = 1$ with $ab = c^2 = \text{constant}$. Quadratic in parameter ' a ' is

$$\frac{y}{c^2}a^2 + (-1) \cdot a + x = 0$$

Envelope is:

$$B^2 - 4AC = (-1)^2 - 4\left(\frac{y}{c^2}\right)(x) = 0.$$

Ans. $xy = c^2/4$, rectangular hyperbola

23. $\frac{x^2}{\alpha^2} + \frac{y^2}{k^2 - \alpha^2} = 1$, α is the parameter

Hint: Quadratic in α^2 is

$$\alpha^4 - (x^2 - y^2 + k^2)\alpha^2 + k^2x^2 = 0$$

Envelope:

$$B^2 - 4AC = (x^2 - y^2 + k^2)^2 - 4 \cdot 1 \cdot k^2x^2 = 0.$$

Ans. Square with four lines

$$x + y + k = 0, \quad x + y - k = 0,$$

$$x - y + k = 0, \quad x - y - k = 0$$

24. $tx^3 + t^2y = a$, where t is the parameter

Ans. $x^6 + 4ay = 0$

25. Prove that all circles having for their diameters the radii vectors of a parabola touch a straight line or the curve $r \cos \theta + a \sin^2 \theta = 0$ according as the radii vectors are drawn from the focus or the vertex.

Hint: Parabola $y^2 = 4ax$, vertex $A(0, 0)$, focus $S(a, 0)$, general point $P(at^2, 2at)$. Equation of circle on SP as diameter is (refer Fig. 2.23)

Fig. 2.23

$$(x-a)(x-at^2) + (y-0)(y-at) = 0$$

This is a quadratic in t

$$a(a-x)t^2 - 2ay \cdot t + (x^2 + y^2 - ax) = 0$$

Envelope:

$$x[(x-a)^2 + y^2] = 0 \quad \therefore x = 0$$

Equation circle on AP as diameter

$$(x-0)(x-at^2) + (y-0)(y-2at) = 0$$

Quadratic in t :

$$axt^2 + 2ayt - (x^2 + y^2) = 0$$

Envelope:

$$ay^2 + x(x^2 + y^2) = 0$$

In polar coordinate:

$$r \cos \theta + a \sin^2 \theta = 0.$$

Evolute as envelope of normals

Evolute of a curve c is the envelope of the normals to that curve c . Using this, find the evolute of the following curves:

26. Parabola $y^2 = 4ax$

Hint: Equation of any normal to the parabola is

$$y = mx - 2am - am^3$$

where m is the parameter.

Ans. $27ay^2 = 4(x-2a)^3$

27. Ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

Hint: Equation of normal at any point $(a \cos t, b \sin t)$ is

$$\frac{ax}{\cos t} - \frac{by}{\sin t} = a^2 - b^2.$$

Ans. $(ax)^{\frac{2}{3}} + (by)^{\frac{2}{3}} = (a^2 - b^2)^{\frac{2}{3}}$

28. $x = a(3 \cos t - 2 \cos^3 t)$,
 $y = a(3 \sin t - 2 \sin^3 t)$.

Hint: Equation of normal at ' t ' is

$$\frac{x}{\cos t} + \frac{y}{\sin t} = 4a.$$

Ans. $x^{\frac{2}{3}} + y^{\frac{2}{3}} = (4a)^{\frac{2}{3}}$

29. Cycloid: $x = a(\cos t + t \sin t)$;
 $y = a(\sin t - t \cos t)$

Ans. $x^2 + y^2 = a^2$

30. Hyperbola $xy = c^2$

Ans. $(x+y)^{\frac{2}{3}} + (x-y)^{\frac{2}{3}} = (2a)^{\frac{2}{3}}$

31. Tractrix $x = a(\cos t + \ln \tan \frac{t}{2})$, $y = a \sin t$

Ans. $y = a \cosh \frac{x}{a}$

Two-parameter family of curves

32. If $ab = 1$, find the envelope of $ax + by = 1$.

Ans. $4xy = 1$

33. Find the envelope of a system of concentric and coaxial ellipses of constant area.

Hint: Equation of ellipses $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ with the two parameters a, b connected by $ab = c^2$ (since area $\pi ab = \text{constant}$).

Ans. $2xy = c^2$

34. If $a + b = c$, determine the envelope of the family of ellipses $x^2/a^2 + y^2/b^2 = 1$

Ans. $x^{\frac{2}{3}} + y^{\frac{2}{3}} = c^{\frac{2}{3}}$

35. Determine the envelop of the two parameter family of straight lines $\frac{x}{a} + \frac{y}{b} = 1$ when a and b are related by

i. $a^n + b^n = c^n$

ii. $a^m b^n = c^{m+n}$

iii. $\frac{a}{c} + \frac{b}{d} = 1$

2.74 — HIGHER ENGINEERING MATHEMATICS—II

- Ans. i. $x^{\frac{n}{n+1}} + y^{\frac{n}{n+1}} = c^{\frac{n}{n+1}}$
 ii. $(m+n)^{m+n} \cdot x^m y^n = m^n n^m c^{m+n}$
 iii. $(x/c)^{\frac{1}{2}} + (y/d)^{\frac{1}{2}} = 1$

36. Find the envelope of the family of parabolas
 $\sqrt{\frac{x}{a}} + \sqrt{\frac{y}{b}} = 1$ when $ab = c^2$.

Ans. $16xy = c^2$, rectangular hyperbola

37. If $a^n + b^n = c^n$ determine the envelop of the family of curves $\frac{x^m}{a^m} + \frac{y^m}{b^m} = 1$.

Ans. $x^p + y^p = c^p$ where $p = mn/(m+n)$

Polar form

38. Prove that the envelopes of circles described on the central radii of a rectangular hyperbola is a lemniscate $r^2 = a^2 \cos 2\theta$.

Hint: General point on $x^2 - y^2 = a^2$ is $P(a \cosh t, a \sinh t)$. Equation of circle with $(0, 0)$ and P as ends of a diameter is

$$(x-0)(x-a \cosh t) + (y-0)(y-a \sinh t) = 0$$

Envelope:

$$a^2(x^2 - y^2) = (x^2 + y^2)^2$$

In polar coordinates:

$$r^2 = a^2 \cos 2\theta.$$

39. Determine the envelope of the straight lines drawn through the extremities of and at right angles to the radii vectors of the equi-angular spiral $r = a e^{\theta \cot \alpha}$.

Hint: If (R, ϕ) is any point on the straight line through (r, θ) and at right angles to radius vector is

$$R \cos(\phi - \theta) = r.$$

Ans. $r \sin \alpha = a e^{(\alpha - \pi/2) \cot \alpha} \cdot e^{(\theta \cot \alpha)}$

40. Show that the envelope of circles described on the radii vectors of $r = 2a \cos \theta$ as diameter is the cardioid $r = a(1 + \cos \theta)$.

Hint: Equation circle drawn on radius vector corresponding to the point (r, θ) on the curve $r = 2a \cos \theta$ as diameter is

$$R = r \cos(\phi - \theta) = 2a \cos \theta \cdot \cos(\phi - \theta)$$

41. Find the envelope of the family of circles whose centres lie on the rectangular hyperbola $x^2 - y^2 = a^2$ and which pass through the origin.

Hint: Any point on hyperbola is $P(a \sec \theta, a \tan \theta)$. Equation of circle with P as centre and OP as radius is

$$(x - a \sec \theta)^2 + (y - a \tan \theta)^2 = OP^2$$

$$= a^2 \sec^2 \theta + a^2 \tan^2 \theta$$

Envelope:

$$(x^2 + y^2)^2 = 4a^2(x^2 - y^2)$$

In polar coordinates is:

$$r^2 = 4a^2 \cos 2\theta$$

Ans. Envelope is lemniscate of Bernoulli
 $r^2 = 4a^2 \cos 2\theta$

42. Prove that the envelope of the circles whose centres lie on the rectangular hyperbola $xy = c^2$ and which pass through the origin is the lemniscate $r^2 = 8c^2 \sin 2\theta$.

43. Determine the envelope of the straight lines drawn through extremities of and at right angles to the radii vectors of the curve $r^n = a^n \cos n\theta$.

Hint: $P(L, \alpha)$ be any point on $r^n = a^n \cos n\theta$ so

$$L^n = a^n \cos n\alpha \quad \text{or} \quad L = a(\cos n\alpha)^{\frac{1}{n}}$$

$Q(r, \theta)$ be any point on the line PQ drawn at right angles to the radius vector OP , so

$$\frac{L}{r} = \cos(\theta - \alpha) \quad \text{or} \quad L = r \cos(\theta - \alpha).$$

Eliminating L , Equation of required line PQ is

$$r \cos(\theta - \alpha) = a(\cos n\alpha)^{\frac{1}{n}}.$$

Ans. $r^p = a^p \cdot \cos p\theta$ where $p = \frac{n}{1-n}$

Determine the envelope of the circles described on the radii vectors as diameter of the curve:

$$44. \quad r^n = a^n \cos n\theta$$

Ans. $r^p = a^p \cos p\theta$ where $p = \frac{n}{1+n}$

$$45. \quad r = L/(L + e \cos \theta)$$

Ans. $r^2(e^2 - 1) - 2Le r, \cos \theta + 2L^2 = 0.$

Chapter 3

Partial Differentiation

INTRODUCTION

Real world can be described in mathematical terms using parametric equations and functions such as trigonometric functions which describe cyclic, repetitive activity; exponential, logarithmic and logistic functions which describe growth and decay and polynomial functions which approximate these and most other functions. The problems in operations research, computer science, probability, statistics, fluid dynamics, economics, electricity etc. deal with functions of two or more independent variables. In this chapter we study the limit, continuity, partial derivative of such functions, Euler's theorem, Jacobians which determine the functional dependence and determination of errors and approximations of calculations.

3.1 FUNCTIONS OF SEVERAL VARIABLES: LIMIT AND CONTINUITY

The area of an ellipse is πab . It depends on two variables a and b ; The total surface area of a rectangular parallelopiped is $2(xy + yz + zx)$ and it depends on 3 variables x, y, z ; The velocity u of a fluid particle moving in space depends on 4 variables x, y, z, t . In transportation problem in operations research the cost function to be minimized is a function of several ($m \cdot n$: running into hundreds) variables (where m is the number of origins and n is the number of destinations). Thus functions of several variables plays a vital role in advanced Mathematics.

If $u = f(x, y, z, t)$ then x, y, z, t are known as the independent variables or arguments and u is known as the 'dependent variable' or 'value' of the function. In this section, we restrict to functions of two and three variables, although the analysis can easily be extended to several variables.

Function of Two Variables

If for every x and y a unique value $f(x, y)$ is associated, then f is said to be a function of the two independent variables x and y and is denoted by

$$z = f(x, y) \quad (1)$$

Geometrically, in three dimensional xyz -coordinate space (1) represents a surface. The values of x and y for which the function is defined is known as the domain of definition of the function:

Example: $z = \sqrt{a^2 - x^2 - y^2}$

$$\text{domain : } x^2 + y^2 \leq a^2$$

Function not defined when $x^2 + y^2 > a^2$.

Example: $z = x^y + y^x$

$$\text{domain : } x > 0 \quad \text{and} \quad y > 0$$

δ -neighbourhood of a point (a, b) in the xy -plane is a square with centre at (a, b) bounded by the four lines $x = a - \delta, x = a + \delta, y = b - \delta, y = b + \delta$ i.e.,

$$a - \delta \leq x \leq a + \delta$$

$$b - \delta \leq y \leq b + \delta.$$

3.2 — HIGHER ENGINEERING MATHEMATICS—II

Note: Neighbourhood of a point (a, b) may also be defined as a circular disk with centre at (a, b) and of radius δ given by

$$(x - a)^2 + (y - b)^2 < \delta^2$$

concept of limit is paramount in defining continuity and differentiability of a function. Note that all the three concepts of limit, continuity and differentiability are point concepts i.e., defined at a point.

Limit: A function $f(x, y)$ is said to have a limit L as the point (x, y) approaches (a, b) and is denoted as

$$\lim_{(x,y) \rightarrow (a,b)} f(x, y) = L$$

if the value of $f(x, y)$ can be made as close (as we please) to the given finite number L for all those (x, y) in an appropriately chosen δ -neighbourhood of (a, b) , i.e., for a given $\epsilon > 0$ we can find a δ such that

$$|f(x, y) - L| < \epsilon$$

for all (x, y) in the δ -neighbourhood

$$|x - a| < \delta \quad \text{and} \quad |y - b| < \delta$$

(or alternatively when $(x - a)^2 + (y - b)^2 < \delta^2$).

Important Note: The limit of a function $f(x, y)$ of two variables is said to exist *only when the same* value is obtained for the limit along any path in the xy -plane from (x, y) to (a, b) say along $x \rightarrow a$ and $y \rightarrow b$ or along $y \rightarrow b$ and $x \rightarrow a$, etc.

Limit may or may not exist. If it exists limit must be unique.

Method of Obtaining Limit

Step I: Evaluate $\lim f(x, y)$ along path I: $x \rightarrow a$ and $x \rightarrow b$

Step II: Evaluate $\lim f(x, y)$ along path II: $y \rightarrow b$ and $x \rightarrow a$

If the limit values along path I and II are same, the limit exist. Otherwise not.

Step III: If $a = 0, b = 0$, evaluate limit along say path $y = mx$ or $y = mx^n$ also.

Results: If $\lim_{(x,y) \rightarrow (a,b)} f(x, y) = L$ and $\lim_{(x,y) \rightarrow (a,b)} g(x, y) = M$. Then

$$1. \quad \lim_{(x,y) \rightarrow (a,b)} (f \pm g) = L \pm M$$

$$2. \quad \lim_{(x,y) \rightarrow (a,b)} (f \cdot g) = L \cdot M$$

$$3. \quad \lim_{(x,y) \rightarrow (a,b)} (f/g) = L/M, \quad \text{provided } M \neq 0.$$

Continuity A function $f(x, y)$ is said to be continuous at a point (a, b) if

$$\lim_{(x,y) \rightarrow (a,b)} f(x, y) = f(a, b) \quad (2)$$

i.e., the limit of f as (x, y) tends to (a, b) = the value of f at (a, b) .

A function is said to be continuous in a domain if it is continuous at every point of the domain.

(2) can also be written as

$$\lim_{(h,k) \rightarrow (0,0)} f(a + h, b + k) = f(a, b)$$

If f is not continuous at (a, b) , it is said to be discontinuous at (a, b) .

Result: If $f(x, y)$ and $g(x, y)$ are continuous at (a, b) then $f \pm g, f \cdot g$ and f/g are continuous at (a, b) .

Test for Continuity at a Point (a, b)

Step I: $f(a, b)$ should be well defined

Step II: $\lim f(x, y)$ as $(x, y) \rightarrow (a, b)$ should exist (must be unique and same along any path)

Step III: The limit of f = value of f at (a, b) .

WORKED OUT EXAMPLES

Limits

Example 1: Evaluate $\lim_{(x,y) \rightarrow (0,0)} (x^2 + y^2)$

Solution:

$$\lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} (x^2 + y^2) = \lim_{y \rightarrow 0} (y^2) = 0$$

$$\lim_{\substack{y \rightarrow 0 \\ x \rightarrow 0}} (x^2 + y^2) = \lim_{x \rightarrow 0} (x^2) = 0$$

Along $y = mx$

$$\begin{aligned}\lim_{\substack{y \rightarrow mx \\ x \rightarrow 0}} (x^2 + y^2) &= \lim_{x \rightarrow 0} (x^2 + m^2 x^2) \\ &= \lim_{x \rightarrow 0} (1 + m^2)x^2 = (1 + m^2) \lim_{x \rightarrow 0} (x^2) = 0\end{aligned}$$

Along $y = mx^2$

$$\lim_{\substack{y \rightarrow mx^2 \\ x \rightarrow 0}} (x^2 + y^2) = \lim_{x \rightarrow 0} x^2(1 + m^2 x^2) = 0.$$

Since the value of the limit along any path is same, the limit exists and the limit value is zero.

Example 2: If $f(x, y) = \frac{y^2 - x^2}{x^2 + y^2}$, show that

$$\lim_{x \rightarrow 0} \left\{ \lim_{y \rightarrow 0} f(x, y) \right\} \neq \lim_{y \rightarrow 0} \left\{ \lim_{x \rightarrow 0} f(x, y) \right\}$$

Solution: L.H.S. of the inequality:

$$\begin{aligned}\lim_{x \rightarrow 0} \left\{ \lim_{y \rightarrow 0} f(x, y) \right\} &= \lim_{x \rightarrow 0} \left\{ \lim_{y \rightarrow 0} \frac{y^2 - x^2}{x^2 + y^2} \right\} \\ &= \lim_{x \rightarrow 0} \frac{-x^2}{x^2} = \lim_{x \rightarrow 0} -1 = -1\end{aligned}$$

R.H.S. of the inequality:

$$\begin{aligned}\lim_{y \rightarrow 0} \left\{ \lim_{x \rightarrow 0} f(x, y) \right\} &= \lim_{y \rightarrow 0} \left\{ \lim_{x \rightarrow 0} \frac{y^2 - x^2}{x^2 + y^2} \right\} \\ &= \lim_{y \rightarrow 0} \left\{ \frac{y^2}{y^2} \right\} = \lim_{y \rightarrow 0} 1 = 1\end{aligned}$$

Thus L.H.S. $= -1 \neq 1 =$ R.H.S.

[**Note:** Since the limits along two different paths are not same, the limit does not exist.]

Example 3: Evaluate $\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 y}{x^4 + y^2}$

Solution:

$$\begin{aligned}\text{I. } \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x^2 y}{x^4 + y^2} &= \lim_{y \rightarrow 0} 0 = 0 \\ \text{II. } \lim_{\substack{y \rightarrow 0 \\ x \rightarrow 0}} \frac{x^2 y}{x^4 + y^2} &= \lim_{x \rightarrow 0} 0 = 0 \\ \text{III. } \lim_{\substack{y=mx \\ x \rightarrow 0}} \frac{x^2 y}{x^4 + y^2} &= \lim_{x \rightarrow 0} \frac{mx^3}{x^4 + m^2 x^2}\end{aligned}$$

$$= \lim_{x \rightarrow 0} \frac{mx}{x^2 + m^2} = 0$$

$$\begin{aligned}\text{IV. } \lim_{\substack{y=mx^2 \\ x \rightarrow 0}} \frac{x^2 y}{x^4 + y^2} &= \lim_{x \rightarrow 0} \frac{mx^4}{x^4 + m^2 x^4} \\ &= \lim_{x \rightarrow 0} \frac{m}{1 + m^2} = \frac{m}{1 + m^2}\end{aligned}$$

Since the limit along the last path $y = mx^2$ depends on m , $\therefore$ limit does not exist.

Continuity

Example 4: If $f(x, y) = \frac{x^3 - y^3}{x^2 + y^2}$ when $x \neq 0, y \neq 0$ and $f(x, y) = 0$ when $x = 0, y = 0$, find out whether the function $f(x, y)$ is continuous at origin.

Solution: First calculate the limit of the function:

$$\text{I. } \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x^3 - y^3}{x^2 + y^2} = \lim_{y \rightarrow 0} \left(\frac{-y^3}{y^2} \right) = \lim_{y \rightarrow 0} (-y) = 0$$

$$\text{II. } \lim_{\substack{y \rightarrow 0 \\ x \rightarrow 0}} \frac{x^3 - y^3}{x^2 + y^2} = \lim_{x \rightarrow 0} \left(\frac{x^3}{x^2} \right) = \lim_{x \rightarrow 0} (x) = 0$$

$$\begin{aligned}\text{III. } \lim_{\substack{y=mx \\ x \rightarrow 0}} \frac{x^3 - y^3}{x^2 + y^2} &= \lim_{x \rightarrow 0} \frac{x^3 - m^3 x^3}{x^2 + m^2 x^2} \\ &= \lim_{x \rightarrow 0} \frac{(1 - m^3)}{(1 + m^2)} \cdot x = 0\end{aligned}$$

$$\begin{aligned}\text{IV. } \lim_{\substack{y=mx^2 \\ x \rightarrow 0}} \frac{x^3 - y^3}{x^2 + y^2} &= \lim_{x \rightarrow 0} \frac{x^3(1 - m^3 x^3)}{x^2(1 + m^2 x^2)} \\ &= \lim_{x \rightarrow 0} \frac{(1 - m^3 x^3)}{(1 + m^2 x^2)} \cdot x = 0.\end{aligned}$$

Since the limit along any path is same, the limit exists and equal to zero which is the value of the function $f(x, y)$ at the origin. Hence the function f is continuous at the origin.

Example 5: Discuss the continuity of the function $f(x, y) = \frac{x}{\sqrt{x^2 + y^2}}$ when $(x, y) \neq (0, 0)$ and $f(x, y) = 2$ when $(x, y) = (0, 0)$.

Solution: At first, evaluate the limit

$$\text{I. } \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x}{\sqrt{x^2 + y^2}} = 0$$

3.4 — HIGHER ENGINEERING MATHEMATICS—II

$$\text{II. } \lim_{\substack{y \rightarrow 0 \\ x \rightarrow 0}} \frac{x}{\sqrt{x^2 + y^2}} = \lim_{x \rightarrow 0} \frac{x}{\sqrt{x^2}} = \lim_{x \rightarrow 0} 1 = 1$$

Since the limits along paths I and II are different, the limit itself does not exist. Therefore the function is discontinuous at the origin.

Example 6: Examine for continuity at origin of the function defined by

$$f(x, y) = \frac{x^2}{\sqrt{x^2 + y^2}}, \quad \text{for } (x \neq 0, y \neq 0)$$

$$= 3, \quad \text{for } (x = 0, y = 0)$$

Redefine the function to make it continuous.

Solution: Initially, find the limit

$$\text{I. } \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x^2}{\sqrt{x^2 + y^2}} = \lim_{y \rightarrow 0} 0 = 0$$

$$\text{II. } \lim_{\substack{y \rightarrow 0 \\ x \rightarrow 0}} \frac{x^2}{\sqrt{x^2 + y^2}} = \lim_{x \rightarrow 0} \frac{x^2}{\sqrt{x^2}} = \lim_{x \rightarrow 0} x = 0$$

$$\text{III. } \lim_{\substack{y=mx \\ x \rightarrow 0}} \frac{x^2}{\sqrt{x^2 + y^2}} = \lim_{x \rightarrow 0} \frac{x^2}{x\sqrt{1+m^2}}$$

$$= \frac{1}{\sqrt{1+m^2}} \lim_{x \rightarrow 0} x = 0$$

$$\text{IV. } \lim_{\substack{y=mx^n \\ x \rightarrow 0}} \frac{x^2}{\sqrt{x^2 + y^2}} = \lim_{x \rightarrow 0} \frac{x^2}{x\sqrt{1+m^2x^{2n-2}}}$$

$$= \frac{0}{\sqrt{1+0}} = 0$$

Thus the limit along any path exists and is the same and the common value equals to zero i.e.,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2}{\sqrt{x^2 + y^2}} = 0$$

However the value of the functions at origin is 3 i.e.,

$$f(0, 0) = 3$$

Therefore f is discontinuous at origin because

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2}{\sqrt{x^2 + y^2}} = 0 \neq 3 = f(0, 0)$$

The function can be 'made' continuous at origin by redefining the function as $f(0, 0) = 0$, since in this

case

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2}{\sqrt{x^2 + y^2}} = 0 = f(0, 0).$$

EXERCISE

Limits

Evaluate the following limits:

$$1. \lim_{\substack{x \rightarrow 2 \\ y \rightarrow 3}} \frac{x^2 + y^3}{2x^2y} \quad \text{Ans. } \frac{31}{24}$$

$$2. \lim_{\substack{x \rightarrow 1 \\ y \rightarrow 2}} \frac{x^2 + y}{3x + y^2} \quad \text{Ans. } \frac{3}{7}$$

$$3. \lim_{(x,y) \rightarrow (0,0)} \frac{xy}{y^2 - x^2}$$

Hint: Along path $y = mx$, limit $= \frac{m}{m^2 - 1}$ which is different for different values of m .

Ans. does not exist

$$4. \lim_{\substack{x \rightarrow 1 \\ y \rightarrow 2}} \frac{2x^2y}{x^2 + y^2 + 1} \quad \text{Ans. } \frac{2}{3}$$

$$5. \lim_{\substack{x \rightarrow 1 \\ y \rightarrow 1}} \frac{x(y-1)}{y(x-1)} \quad \text{Ans. does not exist}$$

$$6. \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{xy}{x^2 + y^2} \quad \text{Ans. does not exist}$$

$$7. \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x-y}{x^2 + y^2} \quad \text{Ans. does not exist}$$

$$8. \lim_{\substack{x \rightarrow \infty \\ y \rightarrow 3}} \frac{2xy-3}{x^3+4y^3} \quad \text{Ans. } 0$$

Show that $\lim_{x \rightarrow 0} \left[\lim_{y \rightarrow 0} f(x, y) \right] \neq \lim_{y \rightarrow 0} \left[\lim_{x \rightarrow 0} f(x, y) \right]$ if

$$9. f(x, y) = \frac{x-y}{2x+y} \quad \text{Ans. } \frac{1}{2} \neq -1$$

$$10. f(x, y) = \frac{x-y}{x+y} \quad \text{Ans. } 1 \neq -1.$$

Continuity

$$11. \text{ If } f(x, y) = \frac{(x^2 - y^2)}{(x^2 + y^2)} \quad \text{when } x \neq 0, y \neq 0$$

$$= 0 \quad \text{when } (x = 0, y = 0)$$

show that f is discontinuous at origin.

12. (a) Is the function $f(x, y) = \frac{xy(x^2 - y^2)}{x^2 + y^2}$ when $(x, y) \neq (0, 0)$ and $f(0, 0) = 4$ continuous at origin. (b) Redefine if necessary to make it continuous at $(0, 0)$.

Ans. **a.** not continuous: $\lim = 0 \neq 4 = f(0, 0)$
b. continuous if $f(0, 0) = 0$

13. If $f(x, y) = x^3 + y^2$ determine where the function is continuous.

Ans. continuous for every x and y i.e., everywhere

14. If $f(x, y) = \frac{x^3 - y^3}{x^3 + y^3}$, for $(x, y) \neq (0, 0)$
 $= 15$, at $(0, 0)$

show that f is discontinuous at origin.

15. Find whether $f(x, y) = \frac{x^3 y^3}{x^3 + y^3}$ is continuous at $(0, 0)$ when (a) $f(0, 0) = -15$, (b) $f(0, 0) = 0$.

Ans. **a.** not continuous: $\lim = 0 \neq -15 = f(0, 0)$
b. continuous since $\lim = 0 = 0 = f(0, 0)$

16. Given $f(x, y) = x^3 + 3y^2 + 2x + y$ for every (x, y) except at $(2, 3)$ where $f(2, 3) = 10$. Examine whether f is continuous at (a) point $(2, 3)$ (b) at any other points (c) can the function be made continuous at $(2, 3)$ by redefining f at $(2, 3)$.

Ans. **a.** discontinuous at $(2, 3)$
b. continuous for every x and y i.e., everywhere except at $(2, 3)$
c. f becomes continuous by redefining f at $(2, 3)$ as $f(2, 3) = 42$

17. **a.** Show that $f(x, y) = \frac{xy}{x^2 + y^2}$, $x = y \neq 0$ is discontinuous at origin when $f(0, 0) = 0$.
b. Can it be made continuous by defining f ?

Ans. **a.** since limit along $y = mx$ is $\frac{m}{1+m^2}$, not unique, the limit does not exist, so discontinuous

b. can not make f continuous by redefining f at $(0, 0)$ i.e., for any choice of $f(0, 0)$, since the limit at $(0, 0)$ does not exist.

18. Prove that $f(x, y) = \frac{x^2 - y^3}{x^2 + y^2}$ when $(x, y) \neq (0, 0)$ and $f(0, 0) = 0$ is discontinuous at origin.

Hint: $\lim f$ along $y = mx$ is not unique, depends on m . So limit does not exist.

Find out (and give reason) whether $f(x, y)$ is continuous at $(0, 0)$ if $f(0, 0) = 0$ and for $(x, y) \neq (0, 0)$ the function f is equal to:

19. $y/\sqrt{x^2 + y^2}$

Ans. discontinuous

20. $x/(1 + \sqrt{x^2 + y^2})$

Ans. continuous

21. $xy/(x^2 + y^2)^{\frac{1}{2}}$

Ans. continuous

22. $(x^2 - y^2)/\sqrt{x^2 + y^2}$

Hint: continuous.

3.2 PARTIAL DIFFERENTIATION

A partial derivative of a function of several variables is the ordinary derivative with respect to one of the variables when all the remaining variables are held constant. Partial differentiation is the process of finding partial derivatives. All the rules of differentiation applicable to function of a single independent variable are also applicable in partial differentiation with the only difference that while differentiating (partially) with respect to one variable, all the *other* variables are treated (temporarily) as constants.

Consider a function u of three independent variables x, y, z , (refer Fig. 3.1)

$$u = f(x, y, z) \quad (1)$$

Keeping y, z constant and varying only x , the partial derivative of u with respect to x is denoted by $\frac{\partial u}{\partial x}$ and is defined as the limit

$$\frac{\partial u(x, y, z)}{\partial x} = \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x, y, z) - f(x, y, z)}{\Delta x}.$$

Partial derivatives of u w.r.t. y and z can be defined similarly and are denoted by $\frac{\partial u}{\partial y}$ and $\frac{\partial u}{\partial z}$.

Notation: The partial derivative $\frac{\partial u}{\partial x}$ is also denoted by $\frac{\partial f}{\partial x}$ or $f_x(x, y, z)$ or f_x or $D_x f$ or $f_1(x, y, z)$ where the subscripts x and 1 denote the variable w.r.t. which the partial differentiation is carried out. Thus

Fig. 3.1

we can have $\frac{\partial u}{\partial y} = \frac{\partial f}{\partial y} = f_y(x, y, z) = f_y = D_y f = f_2(x, y, z)$ etc. The value of a partial derivative at a point (a, b, c) is denoted by

$$\left. \frac{\partial u}{\partial x} \right|_{x=a, y=b, z=c} = \left. \frac{\partial u}{\partial x} \right|_{(a,b,c)} = f_x(a, b, c)$$

Geometrical interpretation of a partial derivative of a function of two variables: $z = f(x, y)$ represents the equation of a surface in xyz -coordinate system. Let APB the curve, which a plane through any point P on the surface parallel to the xz -plane, cuts. As point P moves along this curve APB , its coordinates z and x vary while y remains constant. The slope of the tangent line at P to APB represents the rate at which z changes w.r.t. x .

Thus

$$\frac{\partial z}{\partial x} = \tan \alpha = \text{slope of the curve } APB \text{ at the point } P$$

Similarly,

$$\frac{\partial z}{\partial y} = \tan \beta = \text{slope of the curve } CPD \text{ at } P.$$

Higher Order Partial Derivatives

Partial derivatives of higher order, of a function $f(x, y, z)$ are calculated by successive differentiation. Thus if $u = f(x, y, z)$ then

$$\frac{\partial^2 u}{\partial x^2} = \frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) = f_{xx} = f_{11}$$

$$\frac{\partial^2 u}{\partial x \partial y} = \frac{\partial^2 f}{\partial x \partial y} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) = f_{yx} = f_{21}$$

$$\frac{\partial^2 u}{\partial y \partial x} = \frac{\partial^2 f}{\partial y \partial x} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) = f_{xy} = f_{12}$$

$$\frac{\partial^2 u}{\partial y^2} = \frac{\partial^2 f}{\partial y^2} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right) = f_{yy} = f_{22}$$

$$\begin{aligned} \frac{\partial^3 u}{\partial z^2 \partial y} &= \frac{\partial}{\partial z} \left(\frac{\partial^2 f}{\partial z \partial y} \right) = \frac{\partial}{\partial z} \left(\frac{\partial}{\partial z} \left(\frac{\partial f}{\partial y} \right) \right) \\ &= f_{yzz} = f_{233} \end{aligned}$$

$$\begin{aligned} \frac{\partial^4 u}{\partial x \partial y \partial z^2} &= \frac{\partial}{\partial x} \left(\frac{\partial^3 f}{\partial y \partial z^2} \right) = \frac{\partial}{\partial x} \left(\frac{\partial}{\partial y} \left(\frac{\partial^2 f}{\partial z^2} \right) \right) \\ &= f_{zzyx} = f_{3321}. \end{aligned}$$

The partial derivative $\frac{\partial f}{\partial x}$ obtained by differentiating once is known as first order partial derivative, while $\frac{\partial^2 f}{\partial x^2}$, $\frac{\partial^2 f}{\partial y^2}$, $\frac{\partial^2 f}{\partial x \partial y}$, $\frac{\partial^2 f}{\partial y \partial x}$ which are obtained by differentiating twice are known as second-order derivatives. 3rd order, 4th order derivatives involve 3, 4 times differentiation respectively.

Note 1: The crossed or mixed partial derivatives $\frac{\partial^2 f}{\partial y \partial x}$ and $\frac{\partial^2 f}{\partial x \partial y}$ are in general, equal

$$\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial^2 f}{\partial x \partial y}$$

i.e., the order of differentiation is immaterial if the derivatives involved are continuous.

Note 2: In the subscript notation, the subscripts are written in the *same* order in which differentiation is carried out, while in the ‘ ∂ ’ notation the order is opposite, for example,

$$\frac{\partial^2 u}{\partial y \partial x} = \frac{\partial}{\partial y} \left(\frac{\partial u}{\partial x} \right) = f_{xy}$$

Note 3: A function of 2 variables has two first order derivatives, four second order derivatives and 2^n of n th order derivatives. A function of m independent variables will have m^n derivatives of order n .

WORKED OUT EXAMPLES

Example 1: Find the first order partial derivatives $\frac{\partial w}{\partial x}$ and $\frac{\partial w}{\partial y}$ when:

$$(a) w = e^x \cos y \quad (b) w = \tan^{-1} \frac{y}{x} \quad (c) w = \ln \sqrt{x^2 + y^2}$$

Solution:

$$\text{a. } \frac{\partial w}{\partial x} = \cos y \frac{\partial}{\partial x}(e^x) = e^x \cos y$$

$$\frac{\partial w}{\partial y} = e^x \frac{\partial}{\partial y}(\cos y) = -e^x \sin y$$

$$\text{b. } \frac{\partial w}{\partial x} = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{\partial}{\partial x}\left(\frac{y}{x}\right) = \frac{x^2}{x^2 + y^2} \cdot \left(-\frac{y}{x^2}\right)$$

$$= \frac{-y}{x^2 + y^2}$$

$$\frac{\partial w}{\partial y} = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{\partial}{\partial y}\left(\frac{y}{x}\right) = \frac{x^2}{x^2 + y^2} \cdot \frac{1}{x}$$

$$= \frac{x}{x^2 + y^2}$$

$$\text{c. } \frac{\partial w}{\partial x} = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2}(x^2 + y^2)^{-\frac{1}{2}} \cdot \frac{\partial}{\partial x}(x^2) = \frac{x}{x^2 + y^2}$$

$$\frac{\partial w}{\partial y} = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2}(x^2 + y^2)^{-\frac{1}{2}} \cdot \frac{\partial}{\partial y}(y^2) = \frac{y}{x^2 + y^2}$$

Example 2: Find partial derivative of f with respect to each of the independent variable:

$$\text{a. } f(x, y, z, w) = x^2 e^{2y+3z} \cos(4w)$$

$$\text{b. } f(r, \theta, z) = r(2 - \cos 2\theta)/(r^2 + z^2).$$

Solution:

$$\text{a. } f_x = \frac{\partial f}{\partial x} = e^{2y+3z} \cdot \cos(4w) \cdot \frac{\partial}{\partial x}(x^2)$$

$$f_x = 2x e^{2y+3z} \cos(4w) = 2f/x$$

$$f_y = x^2 e^{3z} \cos(4w) \frac{\partial}{\partial y} e^{2y} = x^2 e^{3z} \cos(4w) \cdot 2e^{2y}$$

$$f_y = 2f$$

$$f_z = x^2 e^{2y} \cos(4w) \frac{\partial}{\partial z} e^{3z} = x^2 e^{2y} \cos(4w) 3e^{3z}$$

$$f_z = 3f$$

$$f_w = x^2 e^{2y+3z} \frac{\partial}{\partial w}(\cos(4w))$$

$$= x^2 e^{2y+3z} \cdot (-\sin 4w) \cdot 4$$

$$f_w = -4x^2 e^{2y+3z} \sin 4w$$

$$\text{b. } f = \frac{r(2 - \cos 2\theta)}{r^2 + z^2}$$

$$\frac{\partial f}{\partial r} = f_r = \frac{(r^2 + z^2)(2 - \cos 2\theta) - r(2 - \cos 2\theta) \cdot 2r}{(r^2 + z^2)^2}$$

$$f_r = \frac{(z^2 - r^2)(2 - \cos 2\theta)}{(r^2 + z^2)^2}$$

$$\frac{\partial f}{\partial \theta} = f_\theta = \frac{r}{r^2 + z^2} \cdot 2 \sin 2\theta$$

$$\frac{\partial f}{\partial z} = f_z = \frac{r(2 - \cos 2\theta)}{(r^2 + z^2)^2}(-2z).$$

Example 3: Find $\frac{\partial^3 u}{\partial x \partial y \partial z}$ if $u = e^{x^2+y^2+z^2}$

Solution: $\frac{\partial u}{\partial z} = 2z e^{x^2+y^2+z^2}$

$$\frac{\partial^2 u}{\partial y \partial z} = \frac{\partial}{\partial y} \left(\frac{\partial u}{\partial z} \right) = \frac{\partial}{\partial y} (2z e^{x^2+y^2+z^2})$$

$$\frac{\partial^2 u}{\partial y \partial z} = 2z \cdot e^{x^2+y^2+z^2} \cdot 2y = 4yz e^{x^2+y^2+z^2}$$

$$\frac{\partial^3 u}{\partial x \partial y \partial z} = \frac{\partial}{\partial x} \left(\frac{\partial^2 u}{\partial y \partial z} \right) = \frac{\partial}{\partial x} (4yz e^{x^2+y^2+z^2})$$

$$= 4yz e^{x^2+y^2+z^2} \cdot 2x = 8xyz e^{x^2+y^2+z^2}$$

Thus $\frac{\partial^3 u}{\partial x \partial y \partial z} = 8xyz u.$

Example 4: Show that

$$V(x, y, z) = \cos 3x \cos 4y \sinh 5z$$

satisfies Laplace's equation

$$\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} + \frac{\partial^2 V}{\partial z^2} = 0.$$

Solution:

$$V_x = -3 \sin 3x \cdot \cos 4y \sinh 5z$$

$$V_{xx} = -9 \cos 3x \cos 4y \sinh 5z = -9V \quad (1)$$

$$V_y = -4 \cos 3x \sin 4y \cdot \sinh 5z$$

$$V_{yy} = -16 \cos 3x \cos 4y \sinh 5z = -16V \quad (2)$$

$$V_z = 5 \cos 3x \cos 4y \cosh 5z$$

$$V_{zz} = 25 \cos 3x \cos 4y \sinh 5z = 25V \quad (3)$$

Adding (1), (2) and (3), we get

$$V_{xx} + V_{yy} + V_{zz} = -9V - 16V + 25V = 0$$

Example 5: If $u = e^{a\theta} \cos(a \ln r)$ show that

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} + \frac{1}{r^2} \frac{\partial^2 u}{\partial \theta^2} = 0$$

3.8 — HIGHER ENGINEERING MATHEMATICS—II

Solution:

$$u_r = e^{a\theta} \cdot (-\sin(a \ln r)) \frac{a}{r} \quad (1)$$

$$u_{rr} = -ae^{a\theta} \left[-\frac{1}{r^2} \sin(a \ln r) + \frac{1}{r} \cos(a \ln r) \cdot \frac{a}{r} \right]$$

$$u_{rr} = \frac{-ae^{a\theta}}{r^2} [-\sin(a \ln r) + a \cos(a \ln r)] \quad (2)$$

$$u_\theta = a e^{a\theta} \cos(a \ln r),$$

$$u_{\theta\theta} = a^2 e^{a\theta} \cos(a \ln r) = a^2 u \quad (3)$$

using (1), (2) and (3)

$$\begin{aligned} u_{rr} + \frac{1}{r}u_r + \frac{1}{r^2}u_{\theta\theta} &= \left[\frac{ae^{a\theta}}{r^2} \sin(a \ln r) - \frac{a^2}{r^2}u \right] \\ &+ \left(\frac{-a}{r^2}e^{a\theta} \sin(a \ln r) \right) \\ &+ \left(\frac{a^2}{r^2}u \right) \\ &= 0 \end{aligned}$$

Example 6: If $u = \ln(x^3 + y^3 - x^2y - xy^2)$ then show that $u_{xx} + 2u_{xy} + u_{yy} = -\frac{4}{(x+y)^2}$

Solution:

$$u_x = \frac{3x^2 - 2xy - y^2}{(x^3 + y^3 - x^2y - xy^2)}, \quad (1)$$

$$u_y = \frac{3y^2 - x^2 - 2xy}{(x^3 + y^3 - x^2y - xy^2)} \quad (2)$$

Adding (1) and (2), we get

$$\begin{aligned} u_x + u_y &= \frac{(3x^2 - 2xy - y^2) + (3y^2 - x^2 - 2xy)}{(x^3 + y^3 - x^2y - xy^2)} \\ &= \frac{2(x - y)^2}{(x^3 + y^3 - x^2y - xy^2)} \\ u_x + u_y &= \frac{2(x - y)^2}{(x + y)(x^2 + y^2 - 2xy)} \\ &= \frac{2(x - y)^2}{(x + y)(x - y)^2} = \frac{2}{x + y} \quad (3) \end{aligned}$$

Now

$$u_{xx} + 2u_{xy} + u_{yy} = \frac{\partial^2 u}{\partial x^2} + \frac{2\partial^2 u}{\partial x \partial y} + \frac{\partial^2 u}{\partial y^2}$$

$$\begin{aligned} &= \left(\frac{\partial}{\partial x} + \frac{\partial}{\partial y} \right) \left(\frac{\partial}{\partial x} + \frac{\partial}{\partial y} \right) u \\ &= \left(\frac{\partial}{\partial x} + \frac{\partial}{\partial y} \right) \left(\frac{2}{x + y} \right) \quad \text{using (3)} \\ &= \frac{\partial}{\partial x} \left(\frac{2}{x + y} \right) + \frac{\partial}{\partial y} \left(\frac{2}{x + y} \right) \\ &= \frac{-2}{(x + y)^2} - \frac{2}{(x + y)^2} = \frac{-4}{(x + y)^2}. \end{aligned}$$

EXERCISE

1. Find the first order partial derivatives of:

a. $u = \frac{x-y}{x+y}$ c. $e^x \sin y$

b. $u = \ln(x + \sqrt{x^2 - y^2})$ d. $u = x^{xy}$

Ans. a. $u_x = \frac{2y}{(x+y)^2}, u_y = \frac{-2x}{(x+y)^2}$

b. $u_x = (1 + x(x^2 - y^2)^{-\frac{1}{2}})/(x + \sqrt{x^2 - y^2})$
 $u_y = y(x^2 - y^2)^{-\frac{1}{2}}/(x + \sqrt{x^2 - y^2})$

c. $u_x = e^x \sin y, u_y = e^x \cos y$

d. $u_x = x^{xy}(y \log x + y); u_y = x^{xy+1} \log x$

2. Find the partial derivative of the given function w.r.t. each variable:

a. $f(x, y, z) = z \sin^{-1}(y/x)$

b. $f(u, v, w) = (u^2 - v^2)/(v^2 + w^2)$

c. $f(x, y, r, s) = \sin 2x \cosh 3r + \sinh 3y \cos 4s$

Ans. a. $f_x = \frac{-yz}{\sqrt{x^4 - x^2y^2}}, f_y = \frac{|x|z}{x\sqrt{x^2 - y^2}},$

$f_z = \sin^{-1}(y/x)$

b. $f_u = \frac{2u}{v^2 + w^2}, f_v = \frac{-2v(u^2 + w^2)}{(v^2 + w^2)^2},$

$f_w = \frac{-2w(u^2 - v^2)}{(v^2 + w^2)^2}$

c. $f_x = 2 \cos 2x \cosh 3r,$

$f_y = 3 \cosh 3y \cos 4s$

$f_r = 3 \sin 2x \sinh 3r,$

$f_s = -4 \sinh 3y \sin 4s$

3. If $w = \ln(2x + 2y) + \tan(2x - 2y)$ prove that

$$\frac{\partial^2 w}{\partial x^2} = \frac{\partial^2 w}{\partial y^2}$$

4. Verify that $w_{xy} = w_{yx}$ when

a. $w = \ln(2x + 3y)$

b. $w = xy^2 + x^2y^3 + x^3y^4$

c. $w = \tan^{-1} y/x$

d. $w = \ln(y \sin x + x \sin y)$.

5. Show that $u_x + u_y = u$ if $u = e^{x+y}/(e^x + e^y)$.

6. Prove that $w = f(x + ct) + g(x - ct)$ satisfies the wave equation $\frac{\partial^2 w}{\partial t^2} = c^2 \frac{\partial^2 w}{\partial x^2}$ where c is a constant. Verify this when

$$w = 7 \sin(3x + 3ct) + 9 \cosh(5x - 5ct).$$

7. Show that $w_x + w_y + w_z = 0$ if

$$w = (y - z)(z - x)(x - y).$$

8. If $w = x^2y + y^2z + z^2x$, prove that

$$w_x + w_y + w_z = (x + y + z)^2.$$

9. Verify that V satisfies Laplace's equation

$$\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} + \frac{\partial^2 V}{\partial z^2} = 0$$

if (a) $V = x^2 + y^2 - 2z^2$, (b) $V = e^{3x+4y} \cos 5z$,

(c) $V = (x^2 + y^2 + z^2)^{-\frac{1}{2}}$.

10. Find $\frac{\partial^3 w}{\partial x \partial y \partial z}$ if $w = e^{xyz}$.

Ans. $e^{xyz}(x^2y^2z^2 + 3xyz + 1)$

11. Show that $xw_x + yw_y + zw_z = 0$ when

$$w = \frac{y}{z} + \frac{z}{x}$$

12. If $w = r^m$ prove that

$$w_{xx} + w_{yy} + w_{zz} = m(m+1)r^{m-2}$$

where $r^2 = x^2 + y^2 + z^2$.

13. For $n = 2$ or -3 show that $u = r^n(3 \cos^2 \theta - 1)$ satisfies the differential equation

$$\frac{\partial}{\partial r} \left(r^2 \frac{\partial u}{\partial r} \right) + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial u}{\partial \theta} \right) = 0$$

14. Prove that $\left(\frac{\partial}{\partial x} + \frac{\partial}{\partial y} + \frac{\partial}{\partial z} \right)^2 u = \frac{-9}{(x+y+z)^2}$ if

$$u = \ln(x^3 + y^3 + z^3 - 3xyz)$$

Hint: Prove and use the result $u_x + u_y + u_z = \frac{3}{(x+y+z)}$

15. Prove (the Cauchy-Riemann equations in polar coordinates) $ru_r = v_\theta$, $rv_r + u_\theta = 0$ when

$$u = e^{r \cos \theta} \cos(r \sin \theta), v = e^{r \cos \theta} \sin(r \sin \theta).$$

16. Show that $yz_x + xz_y = x^2 - y^2$ if

$$e^{-z/(x^2-y^2)} = (x - y)$$

Hint: Solve for $z = (y^2 - x^2) \ln(x - y)$.

17. If $u = (x^2 + y^2 + z^2)^{-\frac{1}{2}}$ show that

$$(u_x)^2 + (u_y)^2 + (u_z)^2 = u^4.$$

18. Prove that $f(x, t) = a \sin bx \cdot \cos bt$ satisfies

$$\frac{\partial^2 f}{\partial x^2} = b^2 \frac{\partial^2 f}{\partial t^2}.$$

19. Show that $\frac{\partial^3 u}{\partial x^2 \partial y} = \frac{\partial^3 u}{\partial x \partial y \partial x}$ if $u = x^y$.

3.3 VARIABLE TREATED AS CONSTANT

Consider $z = x^2 - y^2$. Introducing polar coordinates $x = r \cos \theta$, $y = r \sin \theta$, we have $r^2 = x^2 + y^2$ and $\theta = \tan^{-1} \frac{y}{x}$. To find $\frac{\partial z}{\partial \theta}$ with different variable treated as constant i.e., to find $\left(\frac{\partial z}{\partial \theta} \right)_r$, $\left(\frac{\partial z}{\partial \theta} \right)_x$, $\left(\frac{\partial z}{\partial \theta} \right)_y$.
Variable treated as constant: $\left(\frac{\partial z}{\partial \theta} \right)_r$ usually read as "partial derivative of z w.r.t. θ , with r held constant". However the important point is that z has been written as a function of the variables θ and r only and then differentiated w.r.t. θ , keeping r constant. Thus

$$\begin{aligned} z &= x^2 - y^2 = r^2 \cos^2 \theta - r^2 \sin^2 \theta \\ \left(\frac{\partial z}{\partial \theta} \right)_r &= 2r^2 (\cos \theta (-\sin \theta) - \sin \theta \cos \theta) \\ &= -4r^2 \sin \theta \cos \theta \end{aligned} \quad (1)$$

To find $\left(\frac{\partial z}{\partial \theta} \right)_x$ express z in terms of θ and x as $z^2 = x^2 - y^2 = x^2 - x^2 \tan^2 \theta$.

$$\text{Now} \quad \left(\frac{\partial z}{\partial \theta} \right)_x = x^2 (0 - 2 \tan \theta \cdot \sec^2 \theta) \quad (2)$$

To find $\left(\frac{\partial z}{\partial \theta} \right)_y$ express z in terms of θ and y as $z = x^2 - y^2 = y^2 \cot^2 \theta - y^2$

$$\text{Now} \quad \left(\frac{\partial z}{\partial \theta} \right)_y = y^2 (2 \cdot \cot \theta \cdot (-\operatorname{cosec}^2 \theta)) \quad (3)$$

3.10 — HIGHER ENGINEERING MATHEMATICS—II

These three expressions (1), (2), (3) for $\frac{\partial z}{\partial \theta}$ have different values and are derivatives of three different functions.

WORKED OUT EXAMPLES

Example 1: If $z = x^2 + 2y^2$, $x = r \cos \theta$, $y = r \sin \theta$, find the partial derivatives:

a. $\left(\frac{\partial z}{\partial x}\right)_y$ b. $\left(\frac{\partial z}{\partial x}\right)_\theta$ c. $\left(\frac{\partial z}{\partial \theta}\right)_r$ d. $\frac{\partial^2 z}{\partial r \partial y}$

Solution: Here $z = x^2 + 2y^2$, $r^2 = x^2 + y^2$,
 $\tan \theta = \frac{y}{x}$

a. To get $\left(\frac{\partial z}{\partial x}\right)_y$, z should be expressed as function of x and y

i.e., $z = x^2 + 2y^2$

Differentiating partially w.r.t. x , with y held constant

$$\left(\frac{\partial z}{\partial x}\right)_y = 2x$$

b. Express z as function of x and θ

$$z = x^2 + 2y^2 = x^2 + 2x^2 \tan^2 \theta$$

Differentiating partially w.r.t. x , keeping θ constant

$$\left(\frac{\partial z}{\partial x}\right)_\theta = 2x + 4x \tan^2 \theta = 2x(1 + 2 \tan^2 \theta)$$

c. Express z as function of r and θ

$$z = r^2 \cos^2 \theta + 2r^2 \sin^2 \theta$$

$$\begin{aligned} \left(\frac{\partial z}{\partial \theta}\right)_r &= 2r^2 \cos \theta (-\sin \theta) + 2r^2 2 \cdot \sin \theta \cdot \cos \theta \\ &= r^2 \cdot \sin 2\theta \end{aligned}$$

d. $z = (r^2 - y^2) + 2y^2 = r^2 + y^2$, $\frac{\partial z}{\partial y} = 2y$,
 $\frac{\partial^2 z}{\partial r \partial y} = 0$.

Example 2: If $x^2 = au + bv$; $y^2 = au - bv$ prove that

$$\left(\frac{\partial u}{\partial x}\right)_y \left(\frac{\partial x}{\partial u}\right)_v = \frac{1}{2} = \left(\frac{\partial v}{\partial y}\right)_x \left(\frac{\partial y}{\partial v}\right)_u$$

Solution: Solving

$$x^2 = au + bv \quad (1)$$

$$y^2 = au - bv \quad (2)$$

we get

$$u = \frac{x^2 + y^2}{2a} \quad (3)$$

$$v = \frac{x^2 - y^2}{2b} \quad (4)$$

Differentiating (3) partially w.r.t. x , keeping y constant, we get

$$\left(\frac{\partial u}{\partial x}\right)_y = \frac{2x}{2a} = \frac{x}{a} \quad (5)$$

Differentiating (1) partially w.r.t. u , keeping v constant, we get

$$2x \left(\frac{\partial x}{\partial u}\right)_v = a \quad \therefore \left(\frac{\partial x}{\partial u}\right)_v = \frac{a}{2x} \quad (6)$$

From (5) and (6)

$$\left(\frac{\partial u}{\partial x}\right)_y \left(\frac{\partial x}{\partial u}\right)_v = \frac{x}{a} \cdot \frac{a}{2x} = \frac{1}{2}$$

Similarly differentiating (4) and (2) partially w.r.t. y and v respectively, we get

$$\left(\frac{\partial v}{\partial y}\right)_u = \frac{-2y}{2b} = \frac{-y}{b} \quad (7)$$

$$2y \left(\frac{\partial y}{\partial v}\right)_u = -b \quad \therefore \left(\frac{\partial y}{\partial v}\right)_u = \frac{-b}{2y} \quad (8)$$

From (7) and (8)

$$\left(\frac{\partial v}{\partial y}\right)_x \cdot \left(\frac{\partial y}{\partial v}\right)_u = \left(\frac{-y}{b}\right) \left(\frac{-b}{2y}\right) = \frac{1}{2}$$

EXERCISE

1. Let $z = x^2 - y^2$ and $x = r \cos \theta$, $y = r \sin \theta$.

Find a. $\left(\frac{\partial z}{\partial r}\right)_\theta$ b. $\left(\frac{\partial z}{\partial r}\right)_x$ c. $\left(\frac{\partial z}{\partial r}\right)_y$

a. **Hint:** $z = r^2 (\cos^2 \theta - \sin^2 \theta)$

b. **Hint:** $z = 2x^2 - r^2$

c. **Hint:** $z = r^2 - 2y^2$

Ans. a. $2r(\cos^2 \theta - \sin^2 \theta)$

b. $-2r$

c. $2r$

2. Let $z = x^2 + 2y^2$ and $x = r \cos \theta$,
 $y = r \sin \theta$.

Find a. $\left(\frac{\partial z}{\partial y}\right)_r$ b. $\left(\frac{\partial z}{\partial \theta}\right)_x$ c. $\left(\frac{\partial z}{\partial r}\right)_x$
 d. $\frac{\partial^2 z}{\partial y \partial \theta}$ e. $\frac{\partial^2 z}{\partial r \partial \theta}$.

Ans. a. $2y$ b. $4r^2 \tan \theta$ c. $2x$ d. $-4x \operatorname{cosec}^2 \theta$
 e. $2r \sin 2\theta$

3. If $u = lx + my$, $v = mx - ly$ show that

$$\left(\frac{\partial u}{\partial x}\right)_y \left(\frac{\partial x}{\partial u}\right)_v = \frac{l^2}{l^2 + m^2},$$

$$\left(\frac{\partial y}{\partial v}\right)_x \left(\frac{\partial v}{\partial y}\right)_u = \frac{l^2 + m^2}{l^2}$$

4. If $f(p, v, t) = 0$ show that

$$\left(\frac{\partial p}{\partial T}\right)_v = -\left(\frac{\partial v}{\partial T}\right)_p \left(\frac{\partial p}{\partial v}\right)_T$$

Hint: $\left(\frac{\partial p}{\partial T}\right)_v = -f_T/f_p$, $\left(\frac{\partial v}{\partial T}\right)_p = -f_T/f_v$,
 $\left(\frac{\partial p}{\partial v}\right)_T = -f_v/f_p$.

5. If $E = f(p, T)$ and $T = g(p, v)$ show that

$$\begin{aligned} \left(\frac{\partial E}{\partial p}\right)_v &= f_p + f_T g_p \\ &= \left(\frac{\partial E}{\partial p}\right)_T + \left(\frac{\partial E}{\partial T}\right)_p \left(\frac{\partial T}{\partial p}\right)_v \end{aligned}$$

6. If $x = r \cos \theta$, $y = r \sin \theta$ find

a. $\left(\frac{\partial x}{\partial r}\right)_\theta$ b. $\left(\frac{\partial x}{\partial \theta}\right)_r$ c. $\left(\frac{\partial \theta}{\partial x}\right)_y$ d. $\left(\frac{\partial \theta}{\partial y}\right)_x$
 e. $\left(\frac{\partial y}{\partial x}\right)_r$ f. $\left(\frac{\partial x}{\partial y}\right)_\theta$ g. $\left(\frac{\partial r}{\partial \theta}\right)_x$ h. $\left(\frac{\partial \theta}{\partial r}\right)_y$

Ans. a. $\cos \theta$ b. $-r \sin \theta$ c. $-r^{-1} \sin \theta$
 d. $r^{-1} \cos \theta$ e. $-\cot \theta$ f. $\cot \theta$
 g. $r \tan \theta$ h. $-r^{-1} \tan \theta$.

3.4 TOTAL DERIVATIVE

Total differential of a function f of three variables x, y, z is denoted by df and is defined as

$$df = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy + \frac{\partial f}{\partial z} dz \quad (1)$$

whether or not x, y and z are independent of each other. Several types of dependence among x, y and z are considered now.

Chain Rules for Partial Differentiation

Total derivative Let $u = f(x, y)$ and x and y are themselves functions of a single independent variable t . Then the dependent variable f may be considered as truly a function of the one independent variable t via the intermediate variables x, y . Now the derivative of f w.r.t. ' t ' is known as the total derivative of f and is given by

$$\frac{df}{dt} = \frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt} \quad (2)$$

Generalizing this, if $u = f(x, y, z)$ and $x = x(t)$, $y = y(t)$, $z = z(t)$ then the total derivative of f is

$$\frac{df}{dt} = \frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt} + \frac{\partial f}{\partial z} \frac{dz}{dt} \quad (3)$$

This can easily be extended to function of several variables.

If $u = f(x, y, z)$ and suppose y and z are function of x , then f is a function of the one independent variable x . Here y and z are intermediate variables. Identifying t with x in (3), we obtain

$$\begin{aligned} \frac{df}{dx} &= \frac{\partial f}{\partial x} \frac{dx}{dx} + \frac{\partial f}{\partial y} \frac{dy}{dx} + \frac{\partial f}{\partial z} \frac{dz}{dx} \\ \frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} \frac{dy}{dx} + \frac{\partial f}{\partial z} \frac{dz}{dx} \end{aligned} \quad (4)$$

WORKED OUT EXAMPLES

Example 1: Find $\frac{du}{dt}$ as a total derivative and verify the result by direct substitution if $u = x^2 + y^2 + z^2$ and $x = e^{2t}$, $y = e^{2t} \cos 3t$, $z = e^{2t} \sin 3t$.

Solution: Here u is a function of x, y, z and x, y, z are in turn functions of t . Thus u is a function ' t ' via the intermediate variables x, y, z . Then

$$\begin{aligned} \frac{du}{dt} &= \frac{\partial u}{\partial x} \frac{dx}{dt} + \frac{\partial u}{\partial y} \frac{dy}{dt} + \frac{\partial u}{\partial z} \frac{dz}{dt} \\ &= 2x \cdot 2e^{2t} + 2y \cdot (2e^{2t} \cos 3t - 3e^{2t} \sin 3t) \\ &\quad + 2z(2e^{2t} \sin 3t + 3e^{2t} \cos 3t) \end{aligned}$$

3.12 — HIGHER ENGINEERING MATHEMATICS—II

Rewriting in terms of x, y, z

$$= 2x \cdot 2 \cdot x + 2 \cdot y(2y - 3 \cdot z) + 2z(2z + 3y) \\ = 4(x^2 + y^2 + z^2)$$

or in terms of t

$$\frac{du}{dt} = 4(e^{4t} + e^{4t}(\cos^2 3t + \sin^2 3t)) = 8e^{4t}$$

verification by direct substitution:

$$u = x^2 + y^2 + z^2 = e^{4t} + e^{4t} \cos^2 3t + e^{4t} \sin^2 3t = 2e^{4t} \\ \frac{du}{dt} = 8e^{4t}.$$

Example 2: Find the total differential coefficient of x^2y w.r.t. x when x, y are connected by

$$x^2 + xy + y^2 = 1.$$

Solution: Let $u = x^2y$, then the total differential is

$$du = \frac{\partial u}{\partial x} dx + \frac{\partial u}{\partial y} dy$$

Thus the total differential coefficient of u w.r.t. x is

$$\frac{du}{dx} = \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} \frac{dy}{dx} \\ \frac{du}{dx} = 2xy + x^2 \frac{dy}{dx}$$

From the implicit relation $f = x^2 + xy + y = 1$, we calculate

$$\frac{dy}{dx} = -\frac{f_x}{f_y} = -\frac{2x + y}{x + 2y}$$

so

$$\frac{du}{dx} = 2xy + x^2 \cdot \frac{dy}{dx} = 2xy + x^2 \left(-\frac{(2x + y)}{(x + 2y)} \right) \\ \frac{du}{dx} = 2xy - \frac{x^2(2x + y)}{(x + 2y)}.$$

Example 3: The altitude of a right circular cone is 15 cm and is increasing at 0.2 cm/sec. The radius of the base is 10 cm and is decreasing at 0.3 cm/sec. How fast is the volume changing?

Solution: Let x be the radius and y be the altitude of the cone. So volume V of the right circular cone is

$$V = \frac{1}{3} \pi x^2 y.$$

Since x and y are changing w.r.t. time t , differentiate V w.r.t. t .

$$\frac{dV}{dt} = \frac{\partial V}{\partial x} \frac{dx}{dt} + \frac{\partial V}{\partial y} \frac{dy}{dt}$$

$$= \frac{1}{3} \pi \left(2xy \frac{dx}{dt} + x^2 \frac{dy}{dt} \right)$$

It is given that at $x = 10$, $y = 15$, $\frac{dx}{dt} = -0.3$ and $\frac{dy}{dt} = 0.2$, substituting these values,

$$\frac{dV}{dt} = \frac{1}{3} \pi [2 \cdot 10 \cdot 15(-0.3) + 10^2(0.2)] \\ = -\frac{70}{3} \pi \text{ cm}^3/\text{sec}$$

i.e., volume is decreasing at the rate of $\frac{70\pi}{3}$.

EXERCISE

- Find $\frac{du}{dt}$ when $u = \sin(x/y)$ and $x = e^t$, $y = t^2$. Verify the result by direct substitution.

Ans. $\frac{t-2}{t^3} e^t \cos\left(\frac{e^t}{t^2}\right)$

- Find $\frac{du}{dt}$ given $u = \sin^{-1}(x - y)$; $x = 3t$, $y = 4t^3$. Verify the result by direct substitution.

Ans. $3(1 - t^2)^{-\frac{1}{2}}$

- If $u = x^3 y e^z$ where $x = t$, $y = t^2$ and $z = \ln t$ find $\frac{du}{dt}$ at $t = 2$.

Ans. $6t^5; 192$

- Find $\frac{du}{dt}$ if $u = \tan^{-1}(y/x)$ and $x = e^t - e^{-t}$ and $y = e^t + e^{-t}$.

Ans. $\frac{-2}{e^{2t} + e^{-2t}}$

- If x, y are related by $x^2 - y^2 = 2$ and $u = \tan(x^2 + y^2)$ find $\frac{du}{dx}$

Ans. $4x \sec^2(2x^2 - 2)$

- If $u = \tan^{-1}(y/x)$ and $y = x^4$ find $\frac{du}{dx}$ at $x = 1$

Ans. $\frac{3x^2}{1+x^6}; \frac{3}{2}$ at $x = 1$

- In order that the function $u = 2xy - 3x^2y$ remains constant, what should be the rate of change of y (w.r.t. t) given that x increases at the rate of 2 cm/sec at the instant when $x = 3$ cm and $y = 1$ cm.

Ans. $\frac{dy}{dt} = -\frac{32}{21}$ cm/sec; y must decrease at the rate of $\frac{32}{21}$ cm/sec.

- Find the rate at which the area of a rectangle is increasing at a given instant when the

sides of the rectangle are 4 ft and 3 ft and are increasing at the rate of 1.5 ft/sec and 0.5 ft/sec respectively.

Ans. 6.5 sq. ft/sec

9. Find **a.** $\frac{dz}{dx}$ and **b.** $\frac{dz}{dy}$ given $z = xy^2 + x^2y$, $y = \ln x$

Ans. **a.** Here x is the independent variable

$$\frac{dz}{dx} = \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y} \frac{dy}{dx} = y^2 + 2xy + 2y + x$$

b. Here y is the independent variable

$$\frac{dz}{dy} = \frac{\partial z}{\partial y} + \frac{\partial z}{\partial x} \frac{dx}{dy} = xy^2 + 2x^2y + 2xy + x^2$$

Find the differential of the following functions:

10. $f(x, y) = x \cos y - y \cos x$

Ans. $df = (\cos y + y \sin x)dx - (x \sin y + \cos x)dy$

11. $u(x, y, z) = e^{xyz}$

Ans. $du = e^{xyz}(yz dx + zx dy + xy dz)$

Find $\frac{du}{dt}$ for the following functions:

12. $u = x^2 - y^2$, $x = e^t \cos t$, $y = e^t \sin t$ at $t = 0$.

Ans. $2e^{2t}(\cos 2t - \sin 2t)$; At $t = 0$, $\frac{du}{dt} = 2$

13. $u = \ln(x + y + z)$; $x = e^{-t}$, $y = \sin t$, $z = \cos t$

Ans. $\frac{\cos t - \sin t - e^{-t}}{\cos t + \sin t + e^{-t}}$

14. $u = \sin(e^x + y)$, $x = f(t)$, $y = g(t)$

Ans. $\frac{du}{dt} = [\cos(e^x + y)]e^x f'(t) + [\cos(e^x + y)]g'(t)$

15. $u = x^y$ when $y = \tan^{-1} t$, $x = \sin t$

Ans. $y \cdot x^{y-1} \cos t + x^y \ln x \cdot \frac{1}{1+t^2}$.

3.5 PARTIAL DIFFERENTIATION OF COMPOSITE FUNCTIONS: CHANGE OF VARIABLES

In the study of heat equation, wave equation and Laplace's equation, it is very often required to transform the representing partial differential equations in cartesian coordinate system to cylindrical, spherical

or orthogonal curvilinear systems by changing the variables through partial differentiation of composite functions (function of a function).

Let $u = f(x, y, z)$ and x, y, z are functions of two (or more) independent variables say s and t as $x = x(s, t)$, $y = y(s, t)$, $z = z(s, t)$. Then f is considered as function of s and t via the intermediate variables x, y, z . Now the derivative of f w.r.t. t is partial but not total. Keeping s constant, Equation (3) is modified as

$$\left(\frac{\partial f}{\partial t}\right)_s = \frac{\partial f}{\partial x} \left(\frac{\partial x}{\partial t}\right)_s + \frac{\partial f}{\partial y} \left(\frac{\partial y}{\partial t}\right)_s + \frac{\partial f}{\partial z} \left(\frac{\partial z}{\partial t}\right)_s \quad (5)$$

The subscript s in (5) indicates the variable which is held constant. With this convention $\frac{\partial f}{\partial x}$ may be written as $\left(\frac{\partial f}{\partial x}\right)_{y,z}$ and so on. However following the convention that $\frac{\partial f}{\partial x}$, without subscripts, indicates the result of differentiating f w.r.t. the explicitly appearing variable x , while holding all other explicitly appearing variables (here y and z) constant. With this convention, the subscript s in (5) may be omitted and rewritten as

$$\frac{\partial f}{\partial t} = \frac{\partial f}{\partial x} \frac{\partial x}{\partial t} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial t} + \frac{\partial f}{\partial z} \frac{\partial z}{\partial t} \quad (6)$$

In a similar way, we get

$$\frac{\partial f}{\partial s} = \frac{\partial f}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial s} + \frac{\partial f}{\partial z} \frac{\partial z}{\partial s} \quad (7)$$

Equations (6) and (7) are known as **chain rules for partial differentiation**.

WORKED OUT EXAMPLES

Example 1: If $u = x^2 - y^2$, $x = 2r - 3s + 4$, $y = -r + 8s - 5$ find $\frac{\partial u}{\partial r}$ and $\frac{\partial u}{\partial s}$.

Solution: Here u is a function of x, y which are functions of s, t . So by chain rule

$$\begin{aligned} \frac{\partial u}{\partial r} &= \frac{\partial u}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial r} \\ &= 2x \cdot 2 + (-2y)(-1) = 2(2x + y) \\ \frac{\partial u}{\partial s} &= \frac{\partial u}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial s} \\ &= 2x \cdot (-3) + (-2y)8 = -6x - 16y. \end{aligned}$$

3.14 — HIGHER ENGINEERING MATHEMATICS—II

Example 2: Find $\frac{\partial w}{\partial \theta}$ and $\frac{\partial w}{\partial \phi}$ given that $w(x, y, z) = f(x^2 + y^2 + z^2)$ where $x = r \cos \theta \cdot \cos \phi$, $y = r \cos \theta \cdot \sin \phi$, $z = r \sin \theta$.

Solution: Put $u = x^2 + y^2 + z^2$. Then $w(x, y, z) = f(u)$ where $u = u(x, y, z)$ and x, y, z are functions of r, θ, ϕ . So

$$\begin{aligned}\frac{\partial w}{\partial \theta} &= \frac{\partial w}{\partial u} \cdot \frac{\partial u}{\partial \theta} = \frac{\partial w}{\partial u} \left(\frac{\partial u}{\partial x} \frac{\partial x}{\partial \theta} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial \theta} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial \theta} \right) \\ &= \frac{\partial w}{\partial u} (2x \cdot (-r \sin \theta \cos \phi) + 2y(-r \sin \theta \sin \phi) \\ &\quad + 2z(r \cos \theta))\end{aligned}$$

Substituting x, y, z in terms of r, θ, ϕ , we get

$$\begin{aligned}&= 2 \frac{\partial w}{\partial u} [-r^2 \sin \theta \cos \theta \cos^2 \phi - r^2 \sin \theta \cos \theta \sin^2 \phi \\ &\quad + r^2 \sin \theta \cos \theta] \\ &= 2r^2 \frac{\partial w}{\partial u} [-\sin \theta \cos \theta + \sin \theta \cos \theta] = 0\end{aligned}$$

Now

$$\begin{aligned}\frac{\partial w}{\partial \phi} &= \frac{\partial w}{\partial u} \left(\frac{\partial u}{\partial x} \frac{\partial x}{\partial \phi} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial \phi} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial \phi} \right) \\ &= \frac{\partial w}{\partial u} (2x \cdot (-r \cos \theta \cdot \sin \phi) \\ &\quad + 2y(r \cos \theta \cos \phi) + 2z \cdot 0) \\ &= 2 \frac{\partial w}{\partial u} (-r^2 \cos^2 \theta \cdot \cos \phi \sin \phi \\ &\quad + r^2 \cos^2 \theta \sin \phi \cos \phi) \\ \frac{\partial w}{\partial \phi} &= 2r^2 \frac{\partial w}{\partial u} (0) = 0.\end{aligned}$$

Example 3: If $V = f(2x - 3y, 3y - 4z, 4z - 2x)$ prove that $6V_x + 4V_y + 3V_z = 0$.

Solution: Put $u = 2x - 3y$, $v = 3y - 4z$, $w = 4z - 2x$. Then $V = f(u, v, w)$ and u, v, w are functions of x, y, z . So

$$\begin{aligned}V_x &= \frac{\partial V}{\partial x} = \frac{\partial V}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial V}{\partial v} \frac{\partial v}{\partial x} + \frac{\partial V}{\partial w} \frac{\partial w}{\partial x} \\ V_x &= V_u \cdot 2 + V_v \cdot 0 + V_w(-2) = 2(V_u - V_w) \quad (1)\end{aligned}$$

$$V_y = \frac{\partial V}{\partial y} = \frac{\partial V}{\partial u} \frac{\partial u}{\partial y} + \frac{\partial V}{\partial v} \frac{\partial v}{\partial y} + \frac{\partial V}{\partial w} \frac{\partial w}{\partial y}$$

$$V_y = V_u(-3) + \frac{\partial V}{\partial v}(3) + \frac{\partial V}{\partial w} \cdot 0 = 3(V_v - V_u) \quad (2)$$

Similarly

$$V_w = V_u \cdot 0 + V_v(-4) + V_w \cdot 4 = 4(V_w - V_v) \quad (3)$$

Multiplying (1), (2) and (3) by 6, 4, 3 respectively and adding, we get

$$\begin{aligned}6V_x + 4V_y + 3V_z &= 6(2(V_u - V_w)) + 4(3(V_v - V_u)) \\ &\quad + 3(4(V_w - V_v)) \\ &= 12(V_u - V_w + V_v - V_u + V_w - V_v) \\ &= 0\end{aligned}$$

Example 4: If V is a function of u, v where $u = x - y$ and $v = xy$ prove that

$$x \frac{\partial^2 V}{\partial x^2} + y \frac{\partial^2 V}{\partial y^2} = (x + y) \left(\frac{\partial^2 V}{\partial u^2} + xy \frac{\partial^2 V}{\partial v^2} \right)$$

Solution: Since $V = f(u, v)$ and u, v are functions of x, y use chain rule, to differentiate V w.r.t. x .

Note that $u_x = 1$, $v_x = y$, $u_y = -1$, $v_y = x$

$$\begin{aligned}\frac{\partial V}{\partial x} &= \frac{\partial V}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial V}{\partial v} \frac{\partial v}{\partial x} = \frac{\partial V}{\partial u} \cdot 1 + \frac{\partial V}{\partial v} \cdot y \\ \frac{\partial^2 V}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial V}{\partial x} \right) = \frac{\partial}{\partial x} \left(\frac{\partial V}{\partial u} + y \frac{\partial V}{\partial v} \right) \\ &= \frac{\partial}{\partial u} \left(\frac{\partial V}{\partial u} + y \frac{\partial V}{\partial v} \right) \frac{\partial u}{\partial x} + \frac{\partial}{\partial v} \left(\frac{\partial V}{\partial u} + y \frac{\partial V}{\partial v} \right) \frac{\partial v}{\partial x} \\ \frac{\partial^2 V}{\partial x^2} &= \left(\frac{\partial^2 V}{\partial u^2} + y \frac{\partial^2 V}{\partial u \partial v} \right) \cdot 1 + \left(\frac{\partial^2 V}{\partial v \partial u} + y \frac{\partial^2 V}{\partial v^2} \right) y \quad (1)\end{aligned}$$

Differentiating V w.r.t. y by chain rule

$$\begin{aligned}\frac{\partial V}{\partial y} &= \frac{\partial V}{\partial u} \frac{\partial u}{\partial y} + \frac{\partial V}{\partial v} \frac{\partial v}{\partial y} = \frac{\partial V}{\partial u}(-1) + \frac{\partial V}{\partial v} x \\ \frac{\partial^2 V}{\partial y^2} &= \frac{\partial}{\partial y} \left(\frac{\partial V}{\partial y} \right) = \frac{\partial}{\partial y} \left(-\frac{\partial V}{\partial u} + x \frac{\partial V}{\partial v} \right) \\ &= \frac{\partial}{\partial u} \left(-\frac{\partial V}{\partial u} + x \frac{\partial V}{\partial v} \right) \frac{\partial u}{\partial y} \\ &\quad + \frac{\partial}{\partial v} \left(-\frac{\partial V}{\partial u} + x \frac{\partial V}{\partial v} \right) \frac{\partial v}{\partial y} \\ \frac{\partial^2 V}{\partial y^2} &= \left(-\frac{\partial^2 V}{\partial u^2} + x \frac{\partial^2 V}{\partial u \partial v} \right)(-1) \\ &\quad + \left(-\frac{\partial^2 V}{\partial v \partial u} + x \frac{\partial^2 V}{\partial v^2} \right) x \quad (2)\end{aligned}$$

Multiply (1) by x and (2) by y and adding, we get

$$\begin{aligned} x \frac{\partial^2 V}{\partial x^2} + y \frac{\partial^2 V}{\partial y^2} &= \left(x \frac{\partial^2 V}{\partial u^2} + xy \frac{\partial^2 V}{\partial u \partial v} + xy \frac{\partial^2 V}{\partial v \partial u} + xy^2 \frac{\partial^2 V}{\partial v^2} \right) \\ &+ \left(+y \frac{\partial^2 V}{\partial u^2} - xy \frac{\partial^2 V}{\partial u \partial v} - xy \frac{\partial^2 V}{\partial v \partial u} + x^2 y \frac{\partial^2 V}{\partial v^2} \right) \end{aligned}$$

Since $\frac{\partial^2 V}{\partial u \partial v} = \frac{\partial^2 V}{\partial v \partial u}$

The R.H.S. gets simplified to

$$\begin{aligned} x \frac{\partial^2 V}{\partial x^2} + y \frac{\partial^2 V}{\partial y^2} &= (x+y) \frac{\partial^2 V}{\partial u^2} + xy(x+y) \frac{\partial^2 V}{\partial v^2} \\ &= (x+y) \left(\frac{\partial^2 V}{\partial u^2} + xy \frac{\partial^2 V}{\partial v^2} \right). \end{aligned}$$

EXERCISE

1. If $V = u^2 v$ and $u = e^{x^2 - y^2}$, $v = \sin(xy^2)$ find $\frac{\partial V}{\partial x}$, $\frac{\partial V}{\partial y}$.

Ans. $V_x = e^{2(x^2 - y^2)} [4x \sin(xy^2) + y^2 \cos(xy^2)]$
 $V_y = 2e^{2(x^2 - y^2)} y [x \cos(xy^2) - 2 \sin(xy^2)]$

2. Find $\frac{\partial V}{\partial s}$ if $V = (x+y)/(1-xy)$ and $x = \tan(2r - s^2)$, $y = \cot(r^2 s)$.

Ans. $-(1+x^2)(1+y^2)(2s+r^2)/(1-xy)^2$

3. If $z = \frac{\sin u}{\cos v}$ where $u = \frac{\cos x}{\sin x}$ and $v = \frac{\cos x}{\sin y}$ find $\frac{\partial z}{\partial x}$.

Ans. $-(u \cot x \cos u \sin y + z \sin v \cdot \sin x) / (\cos v \sin y)$

4. Prove that $\frac{\partial z}{\partial u} - \frac{\partial z}{\partial v} = x \frac{\partial z}{\partial x} - y \frac{\partial z}{\partial y}$ if z is a function of x and y and $x = e^u + e^{-v}$, $y = e^{-u} - e^v$.

5. If $\cos z = u + v$ and $u = \sin x$, $v = \cos x$ find the total derivative of z w.r.t. x i.e., $\frac{dz}{dx}$.

Ans. $\frac{dz}{dx} = \frac{\partial z}{\partial u} \frac{du}{dx} + \frac{\partial z}{\partial v} \frac{dv}{dx} = \frac{\sin x - \cos x}{\sqrt{1 - (u+v)^2}}$

6. Prove that $y \frac{\partial V}{\partial y} - x \frac{\partial V}{\partial x} = x^2 V^3$ if

$$V = (1 - 2xy + y^2)^{-\frac{1}{2}}.$$

7. Show that $\left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial u}{\partial y}\right)^2 = \left(\frac{\partial u}{\partial r}\right)^2 + \frac{1}{r^2} \left(\frac{\partial u}{\partial \theta}\right)^2$ when u is a function of x , y where $x = r \cos \theta$, $y = r \sin \theta$.

8. If $V = f(r, s, t)$ and $r = x/y$, $s = y/z$, $t = z/x$ show that $x \frac{dV}{dx} + y \frac{dV}{dy} + z \frac{dV}{dz} = 0$.

9. Change the Laplacian equation in cartesian coordinates $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$ into polar coordinates.

Hint: Use the change of variables

$x = r \cos \theta$, $y = r \sin \theta$ or $r = \sqrt{x^2 + y^2}$, $\theta = \tan^{-1}(y/x)$, calculate $u_x = u_r r_x + u_\theta \theta_x$ etc.

Ans. $\frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} + \frac{1}{r^2} \frac{\partial^2 u}{\partial \theta^2} = 0$

10. If $V = f(u, v)$ where $u = a \cosh x \cos y$, $v = a \sinh x \sin y$ prove that $\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} = \frac{a^2}{2} (\cosh 2x - \cos 2y) \left(\frac{\partial^2 V}{\partial u^2} + \frac{\partial^2 V}{\partial v^2} \right)$.

11. Transform the Laplacian equation $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$ by change of variables from x, y to r, θ when $x = e^r \cos \theta$, $y = e^r \sin \theta$.

Hint: Use $r = \ln \sqrt{x^2 + y^2}$, $\theta = \tan^{-1}(y/x)$.

Ans. $e^{-2r} \left(\frac{\partial^2 u}{\partial r^2} + \frac{\partial^2 u}{\partial \theta^2} \right) = 0$

12. Transform the Laplacian $\frac{\partial^2 V}{\partial u^2} + \frac{\partial^2 V}{\partial v^2}$ by changing the variables from u, v to x, y when $x = u \cos \theta - v \sin \theta$, $y = u \sin \theta + v \cos \theta$.

Hint: Use chain rule $\frac{\partial V}{\partial u} = \frac{\partial V}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial V}{\partial y} \frac{\partial y}{\partial u}$.

Ans. $\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2}$

13. Express $\nabla f = \frac{\partial f}{\partial x} \bar{i} + \frac{\partial f}{\partial y} \bar{j}$ in plane polar coordinates.

Hint: Use $x = r \cos \theta$, $y = r \sin \theta$, use chain rule.

Ans. $\nabla f = \left(f_r \cos \theta - f_\theta \frac{\sin \theta}{r} \right) \bar{i} + \left(\sin \theta f_r + \frac{\cos \theta}{r} f_\theta \right) \bar{j}$

14. If $x = r \cos \theta$, $y = r \sin \theta$ prove that

$$\left(\frac{\partial^2 r}{\partial x^2} \right) \left(\frac{\partial^2 r}{\partial y^2} \right) = \left(\frac{\partial^2 r}{\partial x \partial y} \right)^2$$

3.16 — HIGHER ENGINEERING MATHEMATICS—II

Hint: $r_{xx} = \frac{1}{r} - \frac{x^2}{r^3}$, $r_{yy} = \frac{1}{r} - \frac{y^2}{r^3}$, $r_{xy} = \frac{-xy}{r^3}$.

15. If $u = x^2 + 2xy - y \ln z$ where

$$x = s + t^2, y = s - t^2, z = 2t$$

find $\frac{\partial u}{\partial s}$, $\frac{\partial u}{\partial t}$ at $(1, 2, 1)$

Ans. $\frac{\partial u}{\partial s} = 4x + 2y - \ln z$, at $(1, 2, 1) : 8$

$$\frac{\partial u}{\partial t} = 4yt + 2t \ln z - \frac{2y}{z}, \text{ at } (1, 2, 1) : 8t - 4.$$

3.6 DIFFERENTIATION OF AN IMPLICIT FUNCTION

An implicit function of x and y is an equation of the form

$$f(x, y) = 0$$

which can not necessarily be solved for one of the variables say x in terms of the other variable say y .

For example

$$x^2 + y^2 + a^2 = 0 \quad (1)$$

is an implicit function which can not be solved for say x in terms of y explicitly. If (1) defines y as a function of x , the derivative of y w.r.t. x can be calculated in terms of f , without solving (1) explicitly for x in the form $y = y(x)$, by differentiating (1) partially w.r.t. to x as

$$\frac{\partial f}{\partial x} \frac{dx}{dx} + \frac{\partial f}{\partial y} \frac{dy}{dx} = 0 \quad (2)$$

solving (2) we get

$$\frac{dy}{dx} = -\frac{\frac{\partial f}{\partial x}}{\frac{\partial f}{\partial y}} = -\frac{f_x}{f_y} \quad \text{provided } f_y \neq 0 \quad (3)$$

Higher derivative $\frac{d^2y}{dx^2}$ of an implicit function (1) can be obtained by differentiating (3) on both sides, keeping in mind that the arguments on the right of (3) are x and y and that y itself is the function of x defined by (1).

Differentiating (3) w.r.t. x , noting that f_x and f_y as composite functions of x , we have

$$\frac{d^2y}{dx^2} = \frac{\left[\frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y \partial x} \frac{dy}{dx} \right] \frac{\partial f}{\partial y} - \left[\frac{\partial^2 f}{\partial x \partial y} + \frac{\partial^2 f}{\partial y^2} \frac{dy}{dx} \right] \frac{\partial f}{\partial x}}{\left(\frac{\partial f}{\partial y} \right)^3} \quad (4)$$

Substituting from (3) $\frac{dy}{dx} = -\frac{f_x}{f_y}$ in (4) and rearranging, we get

$$\frac{d^2y}{dx^2} = -\frac{[f_{xx}(f_y)^2 - 2f_{xy}f_xf_y + f_{yy}(f_x)^2]}{(f_y)^3}, \quad (5)$$

if $f_y \neq 0$

Thus $\frac{dy}{dx}$ and $\frac{d^2y}{dx^2}$, given by (3) and (5) respectively, are expressed in terms of the partial derivatives $f_x, f_y, f_{xx}, f_{xy}, f_{yy}$.

Implicit Function of Three Variables

Let $f(x, y, z) = 0$ be the equation of an implicit function of three variables x, y, z . Suppose y and z are functions of x , then f is a function of one independent variable x and y, z are intermediate variables.

Keeping z constant, differentiating w.r.t. x , we get

$$\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial x} = 0$$

solving $\frac{\partial y}{\partial x} = -\frac{f_x}{f_y}$, provided $f_y \neq 0$

Similarly differentiating w.r.t. x , holding y constant

$$\frac{\partial f}{\partial x} + \frac{\partial f}{\partial z} \frac{\partial z}{\partial x} = 0$$

solving $\frac{\partial z}{\partial x} = -\frac{f_x}{f_z}$, if $f_z \neq 0$.

WORKED OUT EXAMPLES

Implicit function of two variables

Example 1: Find $\frac{dy}{dx}$ from the given implicit function f connecting x and y :

a. $f(x, y) = x \sin(x - y) - (x + y) = 0$

$$\frac{dy}{dx} = -\frac{\frac{\partial f}{\partial x}}{\frac{\partial f}{\partial y}} = -\frac{[\sin(x - y) + x \cdot \sin(x - y) \cdot 1 - 1]}{x \cos(x - y) \cdot (-1) - 1}.$$

b. $x^y = y^x$

Taking log, $f = y \log x - x \log y = 0$

$$\frac{dy}{dx} = -\frac{f_x}{f_y} = -\frac{\frac{y}{x} - \log y}{\log x - \frac{x}{y}}.$$

Example 2: Find $\frac{dy}{dx}$ when $y^{x^y} = \sin x$.

Solution:

$$\text{Taking } \log, f(x, y) = x^y \ln y - \ln \sin x = 0 \quad (1)$$

$$\text{Put } z = x^y, \text{ so } \ln z = y \ln x \quad (2)$$

Differentiating (2) w.r.t. x and y , we get

$$\frac{1}{z} z_x = y \cdot \frac{1}{x} \quad \text{so } z_x = \frac{y}{x} \cdot z = \frac{y}{x} \cdot x^y = yx^{y-1} \quad (3)$$

$$\frac{1}{z} z_y = \ln x \quad \text{so } z_y = z \ln x = x^y \ln x \quad (4)$$

Differentiating (1) partially w.r.t. x and y , we get

$$\frac{\partial f}{\partial x} = f_x = \frac{\partial}{\partial x}(x^y) \ln y - \frac{1}{\sin x} \cdot \cos x$$

using result (3)

$$f_x = yx^{y-1} \cdot \ln y - \cot x \quad (5)$$

$$\frac{\partial f}{\partial y} = f_y = \frac{\partial}{\partial y}(x^y) \ln y + x^y \cdot \frac{1}{y} - 0$$

using result (4)

$$f_y = x^y \ln x \cdot \ln y + \frac{x^y}{y} \quad (6)$$

Substituting (5) and (6) in

$$\frac{dy}{dx} = -\frac{f_x}{f_y} = -\frac{(yx^{y-1} \ln y - \cot x)}{x^y \ln x \cdot \ln y + x^y y^{-1}}$$

Example 3: Find $\frac{d^2y}{dx^2}$ if $x^5 + y^5 = 5a^3x^2$.

Solution: Let $f(x, y) = x^5 + y^5 - 5a^3x^2 = 0$

Differentiating f w.r.t. x , y , we get

$$f_x = 5x^4 - 10a^3x, f_{xy} = 0$$

$$f_{xx} = 20x^3 - 10a^3,$$

$$f_y = 5y^4, f_{yy} = 20y^3$$

Substituting these values in

$$\begin{aligned} \frac{d^2y}{dx^2} &= -\frac{f_{xx}(f_y)^2 - 2f_{xy} \cdot f_x \cdot f_y + f_{yy}(f_x)^2}{(f_y)^3} \\ &= -\frac{(20x^3 - 10a^3)(25y^8) - 0 + 20y^3(5x^4 - 10a^3x)^2}{125y^{12}} \\ &= -\frac{y^5(20x^3 - 10a^3) + 20(x^8 - 4a^3x^5 + 4a^6x^2)}{5y^9} \end{aligned}$$

$$\text{Replace } y^5 = 5a^3x^2 - x^5$$

$$\begin{aligned} &= -\frac{(5a^3x^2 - x^5)(4x^3 - 2a^3) + 4(x^8 - 4a^3x^5 + 4a^6x^2)}{y^9} \\ &= \frac{6a^3x^2(a^3 + x^3)}{y^9}. \end{aligned}$$

Example 4: Compute $\frac{\partial z}{\partial x}$ and $\frac{\partial y}{\partial x}$ at $(1, -1, 2)$ if $x^2 + y^2 + z^2 = a^2$.

Solution: $f(x, y, z) = x^2 + y^2 + z^2 - a^2 = 0$ is the equation of implicit function. Differentiating f partially w.r.t. x ,

$$\frac{\partial f}{\partial x} = 2x, \frac{\partial f}{\partial x} \Big|_{(1, -1, 2)} = 2$$

Differentiating w.r.t. z

$$\frac{\partial f}{\partial z} = 2z, \frac{\partial f}{\partial z} \Big|_{(1, -1, 2)} = 4$$

$$\text{so } \frac{\partial z}{\partial x} \Big|_{(1, -1, 2)} = -\frac{f_x}{f_z} \Big|_{(1, -1, 2)} = \frac{-2}{4} = -\frac{1}{2}$$

Differentiating w.r.t. y

$$\frac{\partial f}{\partial y} = 2y, \frac{\partial f}{\partial y} \Big|_{(1, -1, 2)} = -2$$

$$\text{so } \frac{\partial y}{\partial x} = -\frac{f_x}{f_y} = \frac{-2}{-2} = 1.$$

Example 5: If $xy^3 - yx^3 = 6$ is the equation of a curve, find the slope and the equation of the tangent line at the point $(1, 2)$.

Solution: Differentiating $xy^3 - yx^3 = 6$ implicitly w.r.t. x , we get

$$y^3 + 3xy^2 \frac{dy}{dx} - \frac{dy}{dx} x^3 - 3yx^2 = 0$$

$$\text{At } (x = 1, y = 2), 8 + 12y' - y' - 6 = 0$$

$$\text{slope at } (1, 2) \text{ is } \frac{dy}{dx} = -\frac{2}{11},$$

Equation of the tangent line at $(1, 2)$ is

$$\frac{y - 2}{x - 1} = -\frac{2}{11}$$

$$\text{or } 2x + 11y - 24 = 0.$$

EXERCISE

Find the derivative $\frac{dy}{dx}$ from the given implicit function $f(x, y) = c$. **Hint** : use $\frac{dy}{dx} = \frac{-f_x}{f_y}$:

1. $x^3 + y^3 = 3ax^2$

Ans. $\frac{dy}{dx} = (2ax - x^2)/y^2$

2. $(\cos x)^y = (\sin y)^x$

Ans. $\frac{\sin y(y \sin x + \cos x \ln \sin y)}{\cos x(\sin y \ln \cos x - x \cos y)}$

3. $\sin(xy) = e^{xy} + x^2y$

Ans. $\frac{-y(\cos xy - e^{xy} - 2x)}{x(\cos xy - e^{xy} - x)}$

4. $ax^2 + 2hxy + by^2 = c$

Ans. $-(ax + hy)/(hx + by)$

5. $x^y + y^x = c$

Ans. $-\frac{yx^{y-1} + y^x \ln y}{xy^{x-1} + x^y \ln x}$

Find $\frac{d^2y}{dx^2}$ from the implicit function $f(x, y) = c$

6. $x^4 + y^4 = 4a^2xy$

Ans. $\frac{2a^2xy(3a^4 + x^2y^2)}{(a^2x - y^3)^3}$

7. $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$

Ans. $\frac{abc + 2fgh - af^2 - bg^2 - ch^2}{(hx + by + f)^3}$

8. $x\sqrt{1-y^2} + y\sqrt{1-x^2} = a$

Ans. $\frac{a}{(1-x^2)^{\frac{3}{2}}}$

9. Find $\frac{\partial y}{\partial u}$ and $\frac{\partial y}{\partial x}$ if $\ln uy + y \ln u = x$

Ans. $\frac{\partial y}{\partial u} = -(y^2 + y)/(u + yu \ln u)$

$\frac{\partial y}{\partial x} = y/(1 + y \ln u)$

10. Find $\frac{du}{dx}$ given $u = x \ln xy$ and $x^3 + y^3 + 3xy - 1 = 0$

Ans. $1 + \ln xy - x(x^2 + y)/(y(y^2 + x))$ at $x = y = a$

11. If $z(z^2 + 3x) + 3y = 0$, prove that

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = \frac{2z(x-1)}{(z^2+x)^3}$$

12. Find $\frac{\partial u}{\partial x}$ and $\frac{\partial u}{\partial y}$ if $u = f(x + u, yu)$

Ans. $\frac{\partial u}{\partial x} = f_1/(1 - f_1 - yf_2)$

$\frac{\partial u}{\partial y} = uf_2/(1 - f_1 - yf_2)$

where f_1 is differentiation w.r.t. to the first variable $x + u$; f_2 is w.r.t. yu

13. If $ye^{xy} = \sin x$, find $\frac{dy}{dx}$ and $\frac{d^2y}{dx^2}$ at $(0, 0)$

Ans. $\frac{dy}{dx} = 1, \frac{d^2y}{dx^2} = 0$

14. If $x^y = y^x$ find $\frac{dy}{dx}$ at $(2, 4)$

Ans. $y' = 4(\ln 2 - 1)/(2 \ln 2 - 1)$

15. Find $\frac{\partial y}{\partial x}$ and $\frac{\partial z}{\partial x}$ at $(0, 1, 2)$ if $z^3 + xy - y^2z = 6$

Ans. $\frac{\partial y}{\partial x} = -\frac{y}{x - 2yz} \Big|_{(0,1,2)} = \frac{1}{4}$

$\frac{\partial z}{\partial x} = -\frac{y}{3z^2 - y^2} \Big|_{(0,1,2)} = -\frac{1}{11}$

16. For the curve $xe^y + ye^x = 0$, find the equation of the tangent line at the origin.

Ans. $x + y = 0$.

3.7 EULER'S THEOREM

Homogeneous Function

A polynomial in x and y is said to be homogeneous if all its terms are of the same degree. Generalizing this property to include non-polynomials, a function $f(x, y)$ in two variables x and y is said to be a homogeneous function of degree n if for any positive number λ ,

$$f(\lambda x, \lambda y) = \lambda^n f(x, y)$$

This definition can be further enlarged to include transcendental functions also as follows. A function $f(x, y)$ is said to be homogeneous of degree n if it can be expressed as

$$x^n \phi\left(\frac{y}{x}\right) \quad \text{or} \quad y^n \psi\left(\frac{x}{y}\right)$$

Here n need not be an integer, n could be positive, negative or zero.

Example:

1. $3x^2 - 2xy + \frac{15}{2}y^2$ is homogeneous of degree 2
2. $\frac{\sqrt{y} + \sqrt{x}}{y+x}$ is homogeneous of degree $-\frac{1}{2}$
3. $\sin\left(\frac{y}{x}\right) + \tan^{-1}\left(\frac{x}{y}\right)$ is homogeneous of degree zero
4. $\left(\frac{x+y}{xy} + x^{\frac{2}{3}}e^{\frac{x}{y}}\right)y^{-\frac{5}{3}}$ is not homogeneous
5. $x^{\frac{1}{3}}y^{-\frac{2}{3}} + x^{\frac{2}{3}}y^{-\frac{1}{3}}$ is not homogeneous

Homogeneous function f of three variables x, y, z of degree n can be expressed as

$$f = x^n \phi\left(\frac{y}{x}, \frac{z}{x}\right) \quad \text{or} \quad y^n \psi\left(\frac{x}{y}, \frac{z}{y}\right) \quad \text{or} \quad z^n \chi\left(\frac{x}{z}, \frac{y}{z}\right)$$

Euler's Theorem on Homogeneous Functions

Theorem: If f is a homogeneous function of x, y of degree n then

$$x \frac{\partial f}{\partial x} + y \frac{\partial f}{\partial y} = nf \quad (1)$$

Proof: Since f is a homogeneous function of degree n , f can be written in the form

$$f(x, y) = x^n \phi\left(\frac{y}{x}\right) \quad (2)$$

Differentiating partially w.r.t. x and y , we get

$$\frac{\partial f}{\partial x} = nx^{n-1}\phi + x^n \cdot \phi' \cdot \left(\frac{-y}{x^2}\right) \quad (3)$$

$$\frac{\partial f}{\partial y} = x^n \phi' \cdot \frac{1}{x} \quad (4)$$

Multiplying (3) by x and (4) by y and adding we have

$$\begin{aligned} x \frac{\partial f}{\partial x} + y \frac{\partial f}{\partial y} &= nx^n \phi - x^{n-1} y \phi' + y x^{n-1} \phi' \\ &= \eta x^n \phi = n \cdot f \end{aligned}$$

Thus differential operator $x \frac{\partial}{\partial x} + y \frac{\partial}{\partial y}$ operating on a homogeneous function f of degree n amounts to multiplication of f by n .

Corollary 1: If f is a homogeneous function of degree n , then

$$x^2 \frac{\partial^2 f}{\partial x^2} + 2xy \frac{\partial^2 f}{\partial x \partial y} + y^2 \frac{\partial^2 f}{\partial y^2} = n(n-1)f \quad (5)$$

Proof: Differentiating Euler's result (1) w.r.t. x and y respectively, we get

$$\frac{\partial f}{\partial x} + x \frac{\partial^2 f}{\partial x^2} + y \frac{\partial^2 f}{\partial y \partial x} = n \frac{\partial f}{\partial x} \quad (6)$$

$$x \frac{\partial^2 f}{\partial x \partial y} + \frac{\partial f}{\partial y} + y \frac{\partial^2 f}{\partial y^2} = n \frac{\partial f}{\partial y} \quad (7)$$

Multiplying (6) by x and (7) by y and adding, we have

$$\begin{aligned} x^2 f_{xx} + y^2 f_{yy} + 2xy f_{xy} &= (n-1)(xf_x + yf_y) \\ &= n(n-1)f \end{aligned}$$

where we have used Euler's theorem (1) and assumed that $f_{xy} = f_{yx}$.

Euler's Theorem for Three Variables

Theorem: If f is a homogeneous function of three independent variables x, y, z of order n , then

$$x f_x + y f_y + z f_z = nf \quad (8)$$

Proof: Express f as

$$f = x^n \phi\left(\frac{y}{x}, \frac{z}{x}\right) = x^n \phi(u, v) \quad (9)$$

where $u = y/x, v = z/x$

Differentiating (9) partially w.r.t. x, y, z , respectively

$$f_x = \eta x^{n-1} \phi + x^n \left(\frac{\partial \phi}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial \phi}{\partial v} \frac{\partial v}{\partial x} \right)$$

$$f_x = \eta x^{n-1} \phi + x^n \left[\frac{\partial \phi}{\partial u} \cdot \left(\frac{-y}{x^2}\right) + \frac{\partial \phi}{\partial v} \left(\frac{-z}{x^2}\right) \right] \quad (10)$$

$$f_y = x^n \left[\frac{\partial \phi}{\partial u} \cdot \frac{\partial u}{\partial y} + \frac{\partial \phi}{\partial v} \cdot \frac{\partial v}{\partial y} \right] = x^n \cdot \frac{\partial \phi}{\partial u} \cdot \frac{1}{x} + 0 \quad (11)$$

$$f_z = x^n \left[\frac{\partial \phi}{\partial u} \cdot \frac{\partial u}{\partial z} + \frac{\partial \phi}{\partial v} \cdot \frac{\partial v}{\partial z} \right] = x^n \left[0 + \frac{\partial \phi}{\partial v} \left(\frac{1}{x}\right) \right] \quad (12)$$

Multiplying (10), (11), (12) by x, y, z respectively and adding the resultant equations, we get

$$\begin{aligned} x f_x + y f_y + z f_z &= \eta x^n \phi - x^{n-1} \left(y \frac{\partial \phi}{\partial u} + z \frac{\partial \phi}{\partial v} \right) \\ &\quad + y x^{n-1} \frac{\partial \phi}{\partial u} + z x^{n-1} \frac{\partial \phi}{\partial v} \\ &= \eta x^n \phi = n f. \end{aligned}$$

3.20 — HIGHER ENGINEERING MATHEMATICS—II

WORKED OUT EXAMPLES

Example 1: Find the degree of the following homogeneous functions:

- a. $x^2 - 2xy + y^2$ d. $x^{\frac{1}{3}}y^{-\frac{4}{3}}\tan^{-1}(y/x)$
 b. $\log y - \log x$ e. $3x^2yz + 5xy^2z + 4x^4$
 c. $(\sqrt{x^2 + y^2})^3$ f. $[z^2/(x^4 + y^4)]^{\frac{1}{3}}$

Ans:

- a. 2
 b. $\log y - \log x = \ln\left(\frac{y}{x}\right) = x^0 \ln\left(\frac{y}{x}\right)$ degree zero
 c. $(\sqrt{x^2 + y^2})^3 = x^3 \sqrt{1 + \left(\frac{y}{x}\right)^2}$ degree 3
 d. $x^{\frac{1}{3}}y^{-\frac{4}{3}}\tan^{-1}(y/x) = x^{-1} \cdot x^{-\frac{4}{3}}y^{-\frac{4}{3}}\tan^{-1}\frac{y}{x} = x^{-1}\left(\frac{y}{x}\right)^{\frac{4}{3}}\tan^{-1}\frac{y}{x}$. degree: -1
 e. degree 4
 f. $\left[\frac{z^2}{x^4 + y^4}\right]^{\frac{1}{3}} = \left[\frac{1}{z^2} \frac{z^4}{x^4 + y^4}\right]^{\frac{1}{3}} = z^{-\frac{2}{3}} \left[\frac{1}{\left(\frac{x}{z}\right)^4 + \left(\frac{y}{z}\right)^4}\right]^{\frac{1}{3}}$
 degree = -2/3.

Example 2: Verify Euler's theorem for the following functions by computing both sides of Euler's Equation (1) directly:

- i. $(ax + by)^{\frac{1}{3}}$ ii. $x^{\frac{1}{3}}y^{-\frac{4}{3}}\tan^{-1}(y/x)$

Solution: i. $f = (ax + by)^{\frac{1}{3}}$ is homogeneous function of degree $\frac{1}{3}$

Differentiating f partially w.r.t. x and y , we get

$$f_x = \frac{\partial f}{\partial x} = \frac{1}{3}(ax + by)^{-\frac{2}{3}} \cdot a$$

$$f_y = \frac{\partial f}{\partial y} = \frac{1}{3}(ax + by)^{-\frac{2}{3}} \cdot b$$

Multiplying by x and y and adding, we get the L.H.S. of (1)

$$\begin{aligned} x f_x + y f_y &= \frac{1}{3}(ax + by)^{-\frac{2}{3}} ax + \frac{1}{3}(ax + by)^{-\frac{2}{3}} by \\ &= \frac{1}{3}(ax + by)^{-\frac{2}{3}} (ax + by) \\ &= \frac{1}{3}(ax + by)^{\frac{1}{3}} = \frac{1}{3}f. \end{aligned}$$

Since f is homogeneous function of degree $\frac{1}{3}$ the R.H.S. of (1) is $nf = \frac{1}{3}f$.

Thus

$$x f_x + y f_y = \text{L.H.S.} = \frac{1}{3}f = \text{R.H.S.}$$

ii. $f = x^{\frac{1}{3}}y^{-\frac{4}{3}}\tan^{-1}(y/x)$ is homogeneous function of degree -1

$$f_x = \frac{1}{3}x^{-\frac{2}{3}}y^{-\frac{4}{3}}\tan^{-1}\left(\frac{y}{x}\right) + x^{\frac{1}{3}}y^{-\frac{4}{3}} \cdot \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \left(-\frac{y}{x^2}\right)$$

$$f_y = x^{\frac{1}{3}}\left(-\frac{4}{3}\right)y^{-\frac{7}{3}}\tan^{-1}\left(\frac{y}{x}\right) + x^{\frac{1}{3}}y^{-\frac{4}{3}} \cdot \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{1}{x}$$

so

$$\begin{aligned} x f_x + y f_y &= \frac{1}{3} \cdot x^{\frac{1}{3}}y^{-\frac{4}{3}}\tan^{-1}(y/x) + x^{\frac{4}{3}}y^{-\frac{4}{3}}\left(\frac{-y}{x^2 + y^2}\right) \\ &\quad - \frac{4}{3}x^{\frac{1}{3}}y^{-\frac{4}{3}}\tan^{-1}(y/x) + x^{\frac{4}{3}}y^{-\frac{1}{3}} \cdot \frac{1}{x^2 + y^2} \\ &= -x^{\frac{1}{3}}y^{-\frac{4}{3}}\tan^{-1}(y/x) = -f. \end{aligned}$$

Example 3: If $u = \log \frac{x^2 + y^2}{x + y}$, prove that

$$x u_x + y u_y = 1$$

Solution: Let

$$f = e^u = \frac{x^2 + y^2}{x + y} = \frac{x^2 \left(1 + \left(\frac{y}{x}\right)^2\right)}{x \left(1 + \frac{y}{x}\right)} = x \phi\left(\frac{y}{x}\right)$$

f is a homogeneous function of degree 1.

Applying Euler's theorem for the function f , we get

$$x f_x + y f_y = n \cdot f = f.$$

Since $f = e^u$, $f_x = e^u \cdot u_x$, $f_y = e^u u_y$

$$\text{so } x \cdot e^u u_x + y e^u u_y = f = e^u$$

since $e^u \neq 0$, $x u_x + y u_y = 1$.

Example 4: Show that $x u_x + y u_y + z u_z = -2 \cot u$ when

$$u = \cos^{-1} \left(\frac{x^3 + y^3 + z^3}{ax + by + cz} \right)$$

Solution: Let

$$f = \cos u = \frac{x^3 + y^3 + z^3}{ax + by + cz}$$

Here f is a homogeneous function of degree 2 in the three variables x, y, z . By Euler's theorem

$x f_x + y f_y + z f_z = 2f$. Now differentiating f w.r.t. x, y, z respectively, we get

$$f_x = -\sin u \cdot u_x, f_y = -\sin u u_y, f_z = -\sin u u_z.$$

Substituting

$$\begin{aligned} x f_x + y f_y + z f_z &= -\sin u(x u_x + y u_y + z u_z) = 2f \\ &= 2 \cos u \end{aligned}$$

or

$$x u_x + y u_y + z u_z = \frac{-2 \cos u}{\sin u} = -2 \cot u$$

Example 5: Prove that $x u_x + y u_y = \frac{5}{2} \tan u$ if $u = \sin^{-1} \left(\frac{x^3 + y^3}{\sqrt{x} + \sqrt{y}} \right)$

Solution: Let $f = \sin u = \frac{x^3 + y^3}{\sqrt{x} + \sqrt{y}}$ then f is a homogeneous function of degree $\frac{5}{2}$ since

$$f = \frac{x^3}{\sqrt{x}} \left(\frac{1 + (y/x)^3}{1 + (y/x)^{\frac{1}{2}}} \right) = x^{\frac{5}{2}} \phi(y/x).$$

Applying Euler's theorem for f , we have

$$x f_x + y f_y = n f = \frac{5}{2} f.$$

Since $f = \sin u$, $f_x = \cos u \cdot u_x$, $f_y = \cos u u_y$ so that

$$\begin{aligned} x \cdot \cos u u_x + y \cos u u_y &= \frac{5}{2} f = \frac{5}{2} \sin u \\ x u_x + y u_y &= \frac{5 \sin u}{2 \cos u} = \frac{5}{2} \tan u \end{aligned}$$

Example 6: If $u = x^3 y^2 \sin^{-1}(y/x)$ show that

$$x u_x + y u_y = 5u$$

and $x^2 u_{xx} + 2xy u_{xy} + y^2 u_{yy} = 20u$

Solution: Rewriting $u = \frac{x^2}{x^2} \cdot x^3 y^2 \sin^{-1}(y/x) = x^5 \left(\frac{y}{x} \right)^2 \sin^{-1} \frac{y}{x}$

$u = x^5 \phi \left(\frac{y}{x} \right)$ so u is a homogeneous function of degree 5.

Applying Euler's theorem to u , we get

$$x u_x + y u_y = n u = 5u$$

Differentiating the above equation partially w.r.t. x and y , we have

$$x u_{xx} + u_x + y u_{yx} = 5u_x$$

$$x u_{xy} + u_y + y u_{yy} = 5u_y$$

Multiplying by x and y and adding, we get

$$\begin{aligned} (x^2 u_{xx} + x u_x + xy u_{yx}) + (xy u_{xy} + y u_y + y^2 u_{yy}) \\ = 5(xu_x + yu_y) \end{aligned}$$

or

$$\begin{aligned} x^2 u_{xx} + 2xy u_{xy} + y^2 u_{yy} &= (5 - 1)(x u_x + y u_y) \\ &= (5 - 1) \cdot 5u = 20u \end{aligned}$$

Here we replaced $x u_x + y u_y$ by $5u$ (from Euler's theorem) and assumed $u_{yx} = u_{xy}$.

EXERCISE

1. Determine the degree of the following homogeneous functions:

a. $\sqrt{x^2 - xy}$

b. $\sin^{-1} \left(\frac{y}{x} \right)$

c. $\frac{x^3 - y^3}{x + y}$

d. $\frac{ax + by + cz}{Ax^6 + By^6 + Cz^6}$

e. $x^2(x^2 - y^2)^{\frac{1}{3}} / (x^2 + y^2)^{\frac{2}{3}}$

f. $2x^3y^2 + 3x^2y^3 + 6xy^4 - 8y^5$

Ans. a. 1 b. 0 c. 2 d. -5 e. 4/3 f. 5

2. Verify Euler's theorem

a. $\sqrt{x^2 + y^2}$

b. $\cos^{-1} \left(\frac{x}{y} \right)$

c. $(ax + by)^{\frac{3}{2}}$

d. $x^2(x^2 - y^2)^3 / (x^2 + y^2)^3$

e. $x^2y^2 / (x + y)$

f. $\cos^{-1} \left(\frac{x}{y} \right) + \cot^{-1} \left(\frac{y}{x} \right)$

g. $(x^{\frac{1}{3}} + y^{\frac{1}{3}}) / (x^{\frac{1}{4}} - y^{\frac{1}{4}})$

h. $xy / (x + y)$

i. $(x^2 + xy + y^2)^{-1}$

j. $\frac{1}{x^2} + \frac{1}{xy} + \frac{\log x - \log y}{x^2 + y^2}$

k. $\log \frac{x^4 + y^4}{x + y}$

3.22 — HIGHER ENGINEERING MATHEMATICS—II

3. If $f(x, y) = \sec^{-1} \left(\frac{x^3+y^3}{x-y} \right)$ show that $x f_x + y f_y = 2 \cot f$.
4. If $u = \sin^{-1} \left(\frac{x}{y} \right) + \tan^{-1} \left(\frac{y}{x} \right)$ show that $x u_x + y u_y = 0$.
5. If $f = \ln \left(\frac{x^4+y^4}{x+y} \right)$ then $x f_x + y f_y = 3$.
6. If $u = \sin^{-1} \left(\frac{x^2+y^2}{x+y} \right)$ show that $x u_x + y u_y = \tan u$ and $x^2 u_{xx} + 2xy u_{xy} + y^2 u_{yy} = \tan^3 u$.
7. If $u = \sin^{-1} \left(\frac{x^2 y^2}{x+y} \right)$ then $x u_x + y u_y = 3 \tan u$.
8. If $f = x g \left(\frac{y}{x} \right) + h \left(\frac{y}{x} \right)$ show that $x^2 f_{xy} + 2xy f_{yy} + y^2 f_{yy} = 0$.
9. If $u = y^2 e^{\frac{y}{x}} + x^2 \tan^{-1} \left(\frac{x}{y} \right)$ show that

$$x u_x + y u_y = 2u$$

$$\text{and } x^2 u_{xx} + 2xy u_{xy} + y^2 u_{yy} = 2u.$$

10. If $\tan u = \frac{x^3+y^3}{x-y}$ show that $x u_x + y u_y = \sin 2u$ and $x^2 u_{xx} + 2xy u_{xy} + y^2 u_{yy} = 2 \cos 3u \cdot \sin u$.
11. If $\cos u = \frac{x^2+y^2}{\sqrt{x}+\sqrt{y}}$ then $x u_x + y u_y = -\frac{3}{2} \cot u$.
12. If $\ln u = x^2 y^2 / (x+y)$ then show that

$$x u_x + y u_y = 3u \ln u.$$

13. If $u = 3x^4 \cot^{-1} \left(\frac{y}{x} \right) + 16y^4 \cos^{-1} \left(\frac{x}{y} \right)$ then prove that $x u_{xx} + 2yx u_{xy} + y^2 u_{yy} = 12u$.
14. Show that $x^2 u_{xx} + 2xy u_{xy} + y^2 u_{yy} = \frac{\tan u}{12} \left(\frac{13}{12} + \frac{\tan^2 u}{12} \right)$ when $(\sqrt{x} + \sqrt{y}) \sin^2 u = x^{\frac{1}{3}} + y^{\frac{1}{3}}$.
15. Verify Euler's theorem for

$$f = \frac{z}{x+y} + \frac{y}{z+x} + \frac{x}{y+z}.$$

16. If $u = \cos^{-1} \left(\frac{x^5-2y^5+6z^5}{\sqrt{ax^3+by^3+cz^3}} \right)$ then show that $x u_x + y u_y + z u_z = -\frac{7}{2} \cot u$.

17. Prove that

$$\begin{aligned} \left(x \frac{\partial}{\partial x} + y \frac{\partial}{\partial y} \right)^3 f &= x^3 f_{xxx} + 3x^2 y f_{xxy} \\ &\quad + 3xy^2 f_{xyy} + y^3 f_{yyy} \\ &= n(n-1)(n-2)f \end{aligned}$$

if $f(x, y)$ is a homogeneous function of degree n .

18. Prove that $4x f_x + 4y f_y + \sin 2f = 0$ if $(\sqrt{x} + \sqrt{y}) \cot f - x - y = 0$.
19. Show that $x u_x + y u_y + z u_z = 0$ when $u = \frac{y}{z} + \frac{z}{x}$.

Hint: u is homogeneous function of degree zero.

3.8 JACOBIAN

Jacobian* is a functional determinant (whose elements are functions) which is very useful in transformation of variables from cartesian to polar, cylindrical and spherical coordinates in multiple integrals (Chapter 7). Let $u(x, y)$ and $v(x, y)$ be two given functions of two independent variables x and y .

The **Jacobian** of u, v with respect to x, y denoted by $J \left(\frac{u, v}{x, y} \right)$ or $\frac{\partial(u, v)}{\partial(x, y)}$ is a second order functional determinant defined as

$$J \left(\frac{u, v}{x, y} \right) = \frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix}$$

Note: Obviously $J \left(\frac{u, v}{u, v} \right) = \frac{\partial(u, v)}{\partial(u, v)} = \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} = 1$

Similarly the Jacobian of three functions u, v, w of three independent variables x, y, z is defined as

$$J \left(\frac{u, v, w}{x, y, z} \right) = \frac{\partial(u, v, w)}{\partial(x, y, z)} = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} & \frac{\partial u}{\partial z} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} & \frac{\partial v}{\partial z} \\ \frac{\partial w}{\partial x} & \frac{\partial w}{\partial y} & \frac{\partial w}{\partial z} \end{vmatrix}$$

* Carl Gustav Jacob Jacobi (1804–1851), German mathematician.

In a similar way, Jacobian of n functions in n variables can be defined.

Two Important Properties of Jacobians

BookWork I. If $J = \frac{\partial(u, v)}{\partial(x, y)}$ and $J^* = \frac{\partial(x, y)}{\partial(u, v)}$ then $J J^* = 1$ i.e.,
 i.e., $J = \frac{\partial(u, v)}{\partial(x, y)} = \frac{1}{J^*} = \frac{1}{\frac{\partial(x, y)}{\partial(u, v)}}$

Proof: Let

$$u = f(x, y) \text{ and } v = g(x, y) \quad (1)$$

be two given functions in terms of x and y , which are transformations from u, v to x, y . Solving (1) for x and y , we get x and y as functions in terms of the two independent variables u and v as

$$x = \phi(u, v) \text{ and } y = \psi(u, v) \quad (2)$$

known as inverse transformation from x, y to u, v .

Differentiating partially w.r.t. u and v , we get

$$1 = \frac{\partial u}{\partial u} = \frac{\partial u}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial u} = u_x x_u + u_y y_u \quad (3)$$

$$0 = \frac{\partial u}{\partial v} = \frac{\partial u}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial v} = u_x x_v + u_y y_v \quad (4)$$

$$0 = \frac{\partial v}{\partial u} = \frac{\partial v}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial v}{\partial y} \frac{\partial y}{\partial u} = v_x x_u + v_y y_u \quad (5)$$

$$1 = \frac{\partial v}{\partial v} = \frac{\partial v}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial v}{\partial y} \frac{\partial y}{\partial v} = v_x x_v + v_y y_v \quad (6)$$

Consider

$$\begin{aligned} J \cdot J^* &= \begin{vmatrix} u_x & u_y \\ v_x & v_y \end{vmatrix} \begin{vmatrix} x_u & x_v \\ y_u & y_v \end{vmatrix} \\ &= \begin{vmatrix} u_x & u_y \\ v_x & v_y \end{vmatrix} \begin{vmatrix} x_u & y_u \\ x_v & y_v \end{vmatrix} \text{ By interchanging rows and columns in the second determinant.} \end{aligned}$$

Multiplying the determinant row-wise,

$$J \cdot J^* = \begin{vmatrix} u_x x_u + u_y y_u & u_x x_v + u_y y_v \\ v_x x_u + v_y y_v & v_x x_v + v_y y_v \end{vmatrix}$$

Substituting (3), (4), (5), (6) above, we get

$$J \cdot J^* = \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} = 1$$

Chain Rule for Jacobians

Book Work II. If u, v are functions of r, s and r, s are themselves functions of x, y then

$$\begin{aligned} \frac{\partial(u, v)}{\partial(x, y)} &= \frac{\partial(u, v)}{\partial(r, s)} \frac{\partial(r, s)}{\partial(x, y)} \\ J \left(\frac{u, v}{x, y} \right) &= J \left(\frac{u, v}{r, s} \right) J \left(\frac{r, s}{x, y} \right) \end{aligned}$$

Proof: Differentiating u, v partially w.r.t. x, y

$$\frac{\partial u}{\partial x} = \frac{\partial u}{\partial r} \frac{\partial r}{\partial x} + \frac{\partial u}{\partial s} \frac{\partial s}{\partial x} \quad (1)$$

$$\frac{\partial u}{\partial y} = \frac{\partial u}{\partial r} \frac{\partial r}{\partial y} + \frac{\partial u}{\partial s} \frac{\partial s}{\partial y} \quad (2)$$

$$\frac{\partial v}{\partial x} = \frac{\partial v}{\partial r} \frac{\partial r}{\partial x} + \frac{\partial v}{\partial s} \frac{\partial s}{\partial x} \quad (3)$$

$$\frac{\partial v}{\partial y} = \frac{\partial v}{\partial r} \frac{\partial r}{\partial y} + \frac{\partial v}{\partial s} \frac{\partial s}{\partial y} \quad (4)$$

From definition of Jacobian

$$\frac{\partial(u, v)}{\partial(r, s)} \cdot \frac{\partial(r, s)}{\partial(x, y)} = \begin{vmatrix} u_r & u_s \\ v_r & v_s \end{vmatrix} \begin{vmatrix} r_x & r_y \\ s_x & s_y \end{vmatrix}$$

By interchanging the rows and columns in second determinant

$$= \begin{vmatrix} u_r & u_s \\ v_r & v_s \end{vmatrix} \begin{vmatrix} r_x & s_x \\ r_y & s_y \end{vmatrix}$$

Multiplying the determinant row-wise

$$= \begin{vmatrix} u_r r_x + u_s s_x & u_r r_y + u_s s_y \\ v_r r_x + v_s s_x & v_r r_y + v_s s_y \end{vmatrix}$$

Using (1), (2), (3), (4)

$$\frac{\partial(u, v)}{\partial(r, s)} \cdot \frac{\partial(r, s)}{\partial(x, y)} = \begin{vmatrix} u_x & u_y \\ v_x & v_y \end{vmatrix} = \frac{\partial(u, v)}{\partial(x, y)}$$

Thus Jacobians behave in a certain way like derivatives.

Note: All the above results of Jacobian of two variables can be extended similarly to n (any number of) variables.

Standard Jacobians

Jacobians for change of variables from cartesian coordinates to

- polar coordinate $x = r \cos \theta, y = r \sin \theta$

3.24 — HIGHER ENGINEERING MATHEMATICS—II

- ii. cylindrical coordinates $x = r \cos \theta$,
 $y = r \sin \theta$, $z = z$
- iii. spherical coordinates $x = r \sin \theta \cos \phi$,
 $y = r \sin \theta \sin \phi$ and $z = r \cos \theta$

- i. $x = r \cos \theta$, $y = r \sin \theta$, so $x_r = \cos \theta$,
 $x_\theta = -r \sin \theta$, $y_r = \sin \theta$, $y_\theta = r \cos \theta$

$$\frac{\partial(x, y)}{\partial(r, \theta)} = \begin{vmatrix} x_r & x_\theta \\ y_r & y_\theta \end{vmatrix} = \begin{vmatrix} \cos \theta & -r \sin \theta \\ \sin \theta & r \cos \theta \end{vmatrix}$$

$$= r(\cos^2 \theta + \sin^2 \theta) = r$$

Solving for r, θ we have

$$r = \sqrt{x^2 + y^2}, \theta = \tan^{-1} \left(\frac{y}{x} \right)$$

$$\text{so } r_x = \frac{x}{r}, r_y = \frac{y}{r}, \theta_x = \frac{-y}{r^2}, \theta_y = \frac{x}{r^2}$$

$$\frac{\partial(r, \theta)}{\partial(x, y)} = \begin{vmatrix} r_x & r_y \\ \theta_x & \theta_y \end{vmatrix} = \begin{vmatrix} \frac{x}{r} & \frac{y}{r} \\ \frac{-y}{r^2} & \frac{x}{r^2} \end{vmatrix} = \frac{x^2}{r^3} + \frac{y^2}{r^3} = \frac{r^2}{r^3} = \frac{1}{r}$$

- ii. $x = r \cos \theta$, $y = r \sin \theta$, $z = z$ so $x_r = \cos \theta$,
 $x_\theta = -r \sin \theta$, $x_z = 0$, $y_r = \sin \theta$, $y_\theta = r \cos \theta$,
 $y_z = 0$, $z_r = 0$, $z_\theta = 0$, $z_z = 1$

$$J = \frac{\partial(x, y, z)}{\partial(r, \theta, z)} = \begin{vmatrix} x_r & x_\theta & x_z \\ y_r & y_\theta & y_z \\ z_r & z_\theta & z_z \end{vmatrix} = \begin{vmatrix} \cos \theta & -r \sin \theta & 0 \\ \sin \theta & r \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix}$$

$$= r(\cos^2 \theta + \sin^2 \theta) = r$$

$$J^* = \frac{\partial(r, \theta, z)}{\partial(x, y, z)} = \frac{1}{J} = \frac{1}{r}$$

- iii. $x = r \sin \theta \cos \phi$, $y = r \sin \theta \sin \phi$,
 $z = r \cos \theta$

$$\frac{\partial(x, y, z)}{\partial(r, \theta, \phi)} = \begin{vmatrix} \sin \theta \cos \phi & r \cos \theta \cos \phi & -r \sin \theta \sin \phi \\ \sin \theta \sin \phi & r \cos \theta \sin \phi & r \sin \theta \cos \phi \\ \cos \theta & -r \sin \theta & 0 \end{vmatrix}$$

$$= r^2 \sin \theta \cos^2 \theta + r^2 \sin \theta \sin^2 \theta = r^2 \sin \theta$$

Using property (ii)

$$\frac{\partial(r, \theta, \phi)}{\partial(x, y, z)} = \frac{1}{\frac{\partial(x, y, z)}{\partial(r, \theta, \phi)}} = \frac{1}{r^2 \sin \theta}.$$

WORKED OUT EXAMPLES

Example 1: Find the Jacobian $\frac{\partial(u, v)}{\partial(x, y)}$ in each of the following:

- i. $u = x \sin y$, $v = y \sin x$

- ii. $u = e^x \sin y$, $v = x + \log \sin y$

Solution: By definition

$$\frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix}$$

- i. $u = x \sin y$, $v = y \sin x$ so $u_x = \sin y$, $u_y = x \cos y$, $v_x = y \cos x$, $v_y = \sin x$

$$\text{Jacobian} = \begin{vmatrix} \sin y & x \cos y \\ y \cos x & \sin x \end{vmatrix}$$

$$= \sin x \sin y - xy \cos x \cos y$$

- ii. $u = e^x \sin y$, $v = x + \log \sin y$ so $u_x = e^x \sin y$,
 $u_y = e^x \cos y$, $v_x = 1$, $v_y = \frac{\cos y}{\sin y}$

$$\frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} e^x \sin y & e^x \cos y \\ 1 & \frac{\cos y}{\sin y} \end{vmatrix}$$

$$= e^x \cos y - e^x \cos y = 0.$$

Example 2: Calculate $J = \frac{\partial(u, v)}{\partial(x, y)}$ and $J^* = \frac{\partial(x, y)}{\partial(u, v)}$.
 verify that $J \cdot J^* = 1$ given

- i. $u = x + \frac{y^2}{x}$, $v = \frac{y^2}{x}$

- ii. $x = e^u \cos v$, $y = e^u \sin v$

- i. $u = x + \frac{y^2}{x}$, $v = \frac{y^2}{x}$

$$J = \frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} 1 - \frac{y^2}{x^2} & \frac{2y}{x} \\ -\frac{y^2}{x^2} & \frac{2y}{x} \end{vmatrix}$$

$$= \frac{2y}{x} - \frac{2y^3}{x^3} + \frac{2y^3}{x^3} = \frac{2y}{x}$$

Solving for x, y in terms of u and v , we have
 $u = x + \frac{y^2}{x} = x + v \quad \therefore \quad x = u - v, v = \frac{y^2}{x},$

$$y^2 = vx, y^2 = v(u - v) \quad \therefore y = \sqrt{v(u - v)}$$

$$J^* = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} x_u & x_v \\ y_u & y_v \end{vmatrix} = \begin{vmatrix} 1 & -1 \\ \frac{1}{2} \frac{v}{\sqrt{v(u-v)}} & \frac{1}{2} \frac{(u-2v)}{\sqrt{v(u-v)}} \end{vmatrix}$$

$$J^* = \frac{1}{2} \frac{1}{\sqrt{v(u-v)}} [u - 2v + v] = \frac{1}{2} \frac{u - v}{\sqrt{v(u-v)}} = \frac{1}{2} \frac{x}{y}$$

$$\text{Verification: } J \cdot J^* = \frac{2y}{x} \cdot \frac{1}{2} \frac{x}{y} = 1$$

ii. $x = e^u \cos v, y = e^u \sin v$

$$J = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} e^u \cos v & -e^u \sin v \\ e^u \sin v & e^u \cos v \end{vmatrix}$$

$$= e^{2u} (\cos^2 v + \sin^2 v) = e^{2u}$$

Solving for u, v in terms of x, y

$$\tan v = \frac{e^u \sin v}{e^u \cos v} = \frac{y}{x} \quad \therefore v = \tan^{-1} \frac{y}{x}$$

$$x^2 + y^2 = e^{2u} (\cos^2 v + \sin^2 v) = e^{2u}$$

$$\therefore u = \frac{1}{2} \ln(x^2 + y^2).$$

$$J^* = \frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} \frac{x}{x^2 + y^2} & \frac{y}{x^2 + y^2} \\ \frac{-y}{x^2 + y^2} & \frac{x}{x^2 + y^2} \end{vmatrix}$$

$$J^* = \frac{x^2 + y^2}{(x^2 + y^2)^2} = \frac{1}{x^2 + y^2} = \frac{1}{e^{2u}}$$

$$\text{Verification: } J \cdot J^* = e^{2u} \frac{1}{e^{2u}} = 1.$$

Example 3: Calculate $\frac{\partial(x, y, z)}{\partial(u, v, w)}$ if $u = \frac{2yz}{x}, v = \frac{3zx}{y}, w = \frac{4xy}{z}$.

Solution:

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} x_u & x_v & x_w \\ y_u & y_v & y_w \\ z_u & z_v & z_w \end{vmatrix}$$

$$= \begin{vmatrix} \frac{-2yz}{x^2} & \frac{2z}{x} & \frac{2y}{x} \\ \frac{3z}{y} & \frac{-3zx}{y^2} & \frac{3x}{y} \\ \frac{4y}{z} & \frac{4x}{z} & \frac{-4xy}{z^2} \end{vmatrix}$$

Expanding the determinant

$$= \frac{-2yz}{x^2} \left[\frac{12x^2 yz}{y^2 z^2} - \frac{12x^2}{yz} \right] - \frac{2z}{x} \left[\frac{-12xy z}{yz^2} - \frac{12xy}{yz} \right]$$

$$+ \frac{2y}{x} \left[\frac{12xz}{yz} + \frac{12xyz}{zy^2} \right]$$

$$= 0 + 48 + 48 = 96.$$

Example 4: Calculate $\frac{\partial(u, v)}{\partial(r, \theta)}$ if $u = 2axy, v = a(x^2 - y^2)$ where $x = r \cos \theta, y = r \sin \theta$.

Solution: Since u, v are functions of x, y which are themselves functions of r, θ , use chain rule for Jacobians. Thus

$$\frac{\partial(u, v)}{\partial(r, \theta)} = \frac{\partial(u, v)}{\partial(x, y)} \frac{\partial(x, y)}{\partial(r, \theta)}$$

Given $u = 2axy, v = a(x^2 - y^2), u_x = 2ay, u_y = 2ax, v_x = 2ax, v_y = -2ay$

$$\frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} 2ay & 2ax \\ 2ax & -2ay \end{vmatrix}$$

$$= -4a^2(y^2 + x^2) = -4a^2 r^2$$

Since $x^2 + y^2 = r^2 \cos^2 \theta + r^2 \sin^2 \theta = r^2$

$$\text{Also } \frac{\partial(x, y)}{\partial(r, \theta)} = \begin{vmatrix} \cos \theta & -r \sin \theta \\ \sin \theta & r \cos \theta \end{vmatrix} = r$$

$$\text{Hence } \frac{\partial(u, v)}{\partial(r, \theta)} = \frac{\partial(u, v)}{\partial(x, y)} \frac{\partial(x, y)}{\partial(r, \theta)} = (-4a^2 r^2) r = -4a^2 r^3.$$

Example 5: If $x = \sqrt{vw}, y = \sqrt{wu}, z = \sqrt{uv}$ and $u = r \sin \theta \cdot \cos \phi, v = r \sin \theta \sin \phi, w = r \cos \theta$, calculate $\frac{\partial(x, y, z)}{\partial(r, \theta, \phi)}$.

Solution: Since x, y, z are functions of u, v, w which are in turn functions of r, θ, ϕ , so use chain rule for Jacobians. Thus

$$\frac{\partial(x, y, z)}{\partial(r, \theta, \phi)} = \frac{\partial(x, y, z)}{\partial(u, v, w)} \frac{\partial(u, v, w)}{\partial(r, \theta, \phi)}$$

Consider

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} x_u & x_v & x_w \\ y_u & y_v & y_w \\ z_u & z_v & z_w \end{vmatrix}$$

3.26 — HIGHER ENGINEERING MATHEMATICS—II

$$= \begin{vmatrix} 0 & \frac{1}{2}\sqrt{\frac{w}{v}} & \frac{1}{2}\sqrt{\frac{v}{w}} \\ \frac{1}{2}\sqrt{\frac{w}{u}} & 0 & \frac{1}{2}\sqrt{\frac{u}{w}} \\ \frac{1}{2}\sqrt{\frac{v}{u}} & \frac{1}{2}\sqrt{\frac{u}{v}} & 0 \end{vmatrix}$$

$$= \frac{1}{8} \left[\sqrt{\frac{w}{v} \frac{v}{u} \frac{u}{w}} + \sqrt{\frac{v}{w} \frac{w}{u} \frac{u}{v}} \right] = \frac{2}{8} = \frac{1}{4}$$

We know already that Jacobian for spherical coordinates is

$$\frac{\partial(u, v, w)}{\partial(r, \theta, \phi)} = r^2 \sin \theta$$

$$\text{thus } \frac{\partial(x, y, z)}{\partial(r, \theta, \phi)} = \frac{\partial(x, y, z)}{\partial(u, v, w)} \frac{\partial(u, v, w)}{\partial(r, \theta, \phi)} = \frac{1}{4} r^2 \sin \theta$$

Example 6: Calculate $\frac{\partial(u, v, w)}{\partial(x, y, z)}$ if

$$u = x/\sqrt{(1-r^2)}, v = y/\sqrt{(1-r^2)}, w = z/\sqrt{(1-r^2)}$$

where $r^2 = x^2 + y^2 + z^2$.

Solution: Given $r^2 = x^2 + y^2 + z^2$, $r = \sqrt{x^2 + y^2 + z^2}$,
 $r_x = \frac{1}{2} \frac{2x}{\sqrt{x^2 + y^2 + z^2}} = \frac{x}{r}$. Similarly $r_y = \frac{y}{r}$, $r_z = \frac{z}{r}$.

Differentiating $u = x/\sqrt{(1-r^2)}$ w.r.t. x , we get

$$u_x = \frac{1}{\sqrt{1-r^2}} + x \cdot \left(-\frac{1}{2}\right) \cdot \frac{-2r}{(1-r^2)^{\frac{3}{2}}} \cdot r_x$$

$$u_x = \frac{1}{\sqrt{1-r^2}} + \frac{rx}{(1-r^2)^{\frac{3}{2}}} \cdot \frac{x}{r} = \frac{(1-r^2) + x^2}{(1-r^2)^{\frac{3}{2}}}$$

Put $e = (1-r^2)^{3/2}$, so $u_x = \frac{1-r^2+x^2}{e}$

By symmetry

$$v_y = \frac{(1-r^2) + y^2}{e}, \quad w_z = \frac{(1-r^2) + z^2}{e}$$

Differentiating u w.r.t. y , we get

$$u_y = x \cdot \left(-\frac{1}{2}\right) \cdot \frac{1}{(1-r^2)^{\frac{3}{2}}} (-2r) \cdot r_y = \frac{xr}{(1-r^2)^{\frac{3}{2}}} \cdot \frac{y}{r}$$

$$u_y = \frac{xy}{(1-r^2)^{\frac{3}{2}}} = \frac{xy}{e}$$

In a similar way, we have

$$u_z = \frac{xz}{e}, \quad v_x = \frac{yx}{e}, \quad v_z = \frac{yz}{e}$$

$$w_x = \frac{xz}{e}, \quad w_y = \frac{yz}{e}$$

Thus

$$\frac{\partial(u, v, w)}{\partial(x, y, z)} = \begin{vmatrix} \frac{(1-r^2)+x^2}{e} & \frac{xy}{e} & \frac{xz}{e} \\ \frac{xy}{e} & \frac{(1-r^2)+y^2}{e} & \frac{yz}{e} \\ \frac{xz}{e} & \frac{yz}{e} & \frac{(1-r^2)+z^2}{e} \end{vmatrix}$$

$$= \frac{1}{(1-r^2)^{\frac{9}{2}}} \begin{vmatrix} 1-r^2+x^2 & xy & xz \\ xy & 1-r^2+y^2 & yz \\ xz & yz & 1-r^2+z^2 \end{vmatrix}$$

$$= (1-r^2)^{-\frac{9}{2}} [(1-r^2+x^2)\{(1-r^2+y^2)(1-r^2+z^2) - y^2z^2\} - (1-r^2)x^2y^2 - (1-r^2)x^2z^2]$$

$$= (1-r^2)^{-\frac{9}{2}} [(1-r^2+x^2)(1-r^2+y^2)(1-r^2+z^2) - (1-r^2)(y^2z^2 + x^2y^2 + x^2z^2) - x^2y^2z^2]$$

$$= (1-r^2)^{-\frac{9}{2}} [(1-r^2)^3 + (1-r^2)^2(x^2 + y^2 + z^2)]$$

$$= (1-r^2)^{-\frac{9}{2}} (1-r^2)^2 = (1-r^2)^{-\frac{5}{2}}.$$

Example 7: Verify the chain rule for Jacobians if $x = u$, $y = u \tan v$, $z = w$.

Solution:

$$J = \frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} 1 & 0 & 0 \\ \tan v & u \sec^2 v & 0 \\ 0 & 0 & 1 \end{vmatrix} = u \sec^2 v$$

Solving for u, v, w in terms of x, y, z we have $u=x$,
 $\tan v = \frac{y}{u} = \frac{y}{x}$, $v = \tan^{-1} \frac{y}{x}$, $w = z$

$$J^* = \frac{\partial(u, v, w)}{\partial(x, y, z)} = \begin{vmatrix} 1 & 0 & 0 \\ \frac{-y}{x^2 + y^2} & \frac{x}{x^2 + y^2} & 0 \\ 0 & 0 & 1 \end{vmatrix}$$

$$J^* = \frac{x}{x^2 + y^2} = \frac{1}{x \left[1 + \left(\frac{y}{x}\right)^2\right]} = \frac{1}{u \sec^2 v}$$

$$\text{Thus } J \cdot J^* = u \sec^2 v \cdot \frac{1}{u \sec^2 v} = 1.$$

EXERCISE

Find the Jacobian $\frac{\partial(u,v)}{\partial(x,y)}$ when

1. $u = 3x + 5y, v = 4x - 3y$

Ans. -29

2. $x + y = u, y = uv$

Ans. $(x + y)^{-1}$

Hint: Solving $u = x + y, v = y/(x + y)$

3. $u = (x + y)/(1 - xy), v = \tan^{-1} x + \tan^{-1} y$

Ans. 0

Verify the chain rule for Jacobians

i.e., $J \cdot J^* = \frac{\partial(u,v)}{\partial(x,y)} \frac{\partial(x,y)}{\partial(u,v)} = 1$ for the following

4. $x = u(1 - v), y = uv$

Ans. $J = u, J^* = (x + y)^{-1} = u^{-1}$

5. $u = x + y, v = xy$

Ans. $J = x - y$

6. Show that $\frac{\partial(u,v)}{\partial(r,\theta)} = 6r^3 \sin 2\theta$ given $u = x^2 - 2y^2, v = 2x^2 - y^2$ and $x = r \cos \theta, y = r \sin \theta$.

Hint: use $\frac{\partial(u,v)}{\partial(r,\theta)} = \frac{\partial(u,v)}{\partial(x,y)} \frac{\partial(x,y)}{\partial(r,\theta)}$, Also $\frac{\partial(x,y)}{\partial(r,\theta)} = r$.

7. Calculate Jacobian of u, v, w w.r.t. x, y, z when $u = yz/x, v = zx/y, w = xy/z$

Ans. 4

8. Find $\partial(u,v)/\partial(r,\theta)$ if $u = 2xy, v = x^2 - y^2$ and $x = r \cos \theta, y = r \sin \theta$.

Ans. $4r^3$

9. $u = x^2 + y^2, v = y, x = r \cos \theta, y = r \sin \theta$.

Ans. $2xr$

10. If $X = u^2v, Y = uv^2$ and $u = x^2 - y^2, v = xy$ find $\frac{\partial(X,Y)}{\partial(x,y)}$.

Hint: Use $\frac{\partial(X,Y)}{\partial(x,y)} = \frac{\partial(X,Y)}{\partial(u,v)} \frac{\partial(u,v)}{\partial(x,y)}$ (chain rule).

Ans. $6x^2y^2(x^2 + y^2)(x^2 - y^2)^2$

11. Find $\frac{\partial(u,v,w)}{\partial(x,y,z)}$ if $u = x^2, v = \sin y, w = e^{-3z}$

Ans. $-6e^{-3z}x \cos y$

12. If $u = x + y + z, uv = y + z, uvw = z$ find $\frac{\partial(x,y,z)}{\partial(u,v,w)}$

Ans. u^2v

13. $u = xyz, v = xy + yz + zx, w = x + y + z$

Ans. $(x - y)(y - z)(z - x)$

14. $x = \frac{1}{2}(u^2 - v^2), y = uv, z = w$

Ans. $(u^2 + v^2)^{-1}$

15. $u = 3x + 2y - z, v = x - y + z, w = x + 2y - z$

Ans. -2 .

3.9 FUNCTIONAL DEPENDENCE

Let $u = f(x, y), v = \phi(x, y)$ be two given differentiable functions of the two independent variables x and y . Suppose these functions u and v are connected by a relation $F(u, v) = 0$, where F is differentiable. Then these functions u and v are said to be functionally dependent on one another (i.e., one function say u is a function of the second function v) if the partial derivatives u_x, u_y, v_x and v_y are not all zero simultaneously.

Necessary and sufficient condition for functional dependence can be expressed in terms of a determinant as follows: Differentiating $F(u, v) = 0$ partially w.r.t. x and y , we get

$$\frac{\partial F}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial F}{\partial v} \frac{\partial v}{\partial x} = 0$$

$$\frac{\partial F}{\partial u} \frac{\partial u}{\partial y} + \frac{\partial F}{\partial v} \frac{\partial v}{\partial y} = 0$$

A non-trivial solution $F_u \neq 0, F_v \neq 0$ to this system exists if the coefficient determinant is zero.

$$\begin{vmatrix} u_x & v_x \\ u_y & v_y \end{vmatrix} = \begin{vmatrix} u_x & u_y \\ v_x & v_y \end{vmatrix} = 0$$

Result: Two functions u and v are **functionally dependent** if their Jacobian

3.28 — HIGHER ENGINEERING MATHEMATICS—II

$$J\left(\frac{u}{x}, \frac{v}{y}\right) = \frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} u_x & u_y \\ v_x & v_y \end{vmatrix} = 0$$

If Jacobian is not equal to zero, then u and v are said to be **functionally independent**.

Extending this concept, three given functions $u(x, y, z)$, $v(x, y, z)$, $w(x, y, z)$ of three independent variables x, y, z , connected by the relation $F(u, v, w)$ are functionally dependent if first order derivatives of u, v, w w.r.t. x, y, z are **not** all zero simultaneously or if

$$J\left(\frac{u}{x}, \frac{v}{y}, \frac{w}{z}\right) = \frac{\partial(u, v, w)}{\partial(x, y, z)} = \begin{vmatrix} u_x & u_y & u_z \\ v_x & v_y & v_z \\ w_x & w_y & w_z \end{vmatrix} = 0$$

If Jacobian is non-zero, the functions u, v, w are said to be functionally independent.

Note: m functions of n variables are **always** functionally dependent when $m > n$.

WORKED OUT EXAMPLES

Determine which of the following functions are functionally dependent. Find a functional relation between them in case they are functionally dependent.

Example 1: $u = e^x \sin y$, $v = e^x \cos y$.

Solution:

$$\begin{aligned} \text{Jacobian} &= \frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} u_x & u_y \\ v_x & v_y \end{vmatrix} \\ &= \begin{vmatrix} e^x \sin y & e^x \cos y \\ e^x \cos y & -e^x \sin y \end{vmatrix} \\ &= e^x(-\sin^2 y - \cos^2 y) = -e^x \neq 0 \end{aligned}$$

$\therefore u, v$ are functionally independent.

Example 2: $u = \frac{x}{y}$, $v = \frac{x+y}{x-y}$.

Solution:

$$J = \frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} \frac{1}{y} & \frac{-x}{y^2} \\ \frac{-2y}{(x-y)^2} & \frac{2x}{(x-y)^2} \end{vmatrix}$$

$$= \frac{2xy}{(x-y)^2} - \frac{2xy}{(x-y)^2} = 0$$

$\therefore u, v$ are functionally dependent

$$v = \frac{x+y}{x-y} = \frac{y\left(\frac{x}{y} + 1\right)}{y\left(\frac{x}{y} - 1\right)} = \frac{u+1}{u-1}$$

$\therefore v = \frac{u+1}{u-1}$ is the functional relation between u and v .

Example 3: $u = x^2 e^{-y} \cosh z$, $v = x^2 e^{-y} \sinh z$, $w = 3x^4 e^{-2y}$.

Solution:

$$\begin{aligned} J\left(\frac{u}{x}, \frac{v}{y}, \frac{w}{z}\right) &= \frac{\partial(u, v, w)}{\partial(x, y, z)} = \begin{vmatrix} u_x & u_y & u_z \\ v_x & v_y & v_z \\ w_x & w_y & w_z \end{vmatrix} \\ &= \begin{vmatrix} 2x e^{-y} \cosh z & -x^2 e^{-y} \cosh z & x^2 e^{-y} \sinh z \\ 2x e^{-y} \sinh z & -x^2 e^{-y} \sinh z & x^2 e^{-y} \cosh z \\ 12x^3 e^{-2y} & -6x^4 e^{-2y} & 0 \end{vmatrix} \\ &= 12x^7 e^{-4y} (\cosh^2 z - \sinh^2 z) \\ &\quad - 12x^7 e^{-4y} (\cosh^2 z - \sinh^2 z) = 0 \end{aligned}$$

$\therefore u, v, w$ are functionally dependent

$$\begin{aligned} 3u^2 - 3v^2 &= 3(x^4 e^{-2y} \cosh^2 z - x^4 e^{-2y} \sinh^2 z) \\ &= 3x^4 e^{-2y} = w. \end{aligned}$$

EXERCISE

Determine whether the following functions are functionally dependent or not. If functionally dependent, find the functional relation between them:

$$1. u = \frac{x^2 - y^2}{x^2 + y^2}, v = \frac{2xy}{x^2 + y^2}$$

Ans. dependent, $u^2 + v^2 = 1$

$$2. u = \sin x + \sin y; v = \sin(x + y)$$

Ans. independent

$$3. u = \frac{x+y}{x-y}, v = \frac{xy}{(x-y)^2}$$

Ans. dependent, $u^2 = 1 + 4v$

$$4. u = \frac{x-y}{(x+a)}, v = \frac{(x+a)}{(y+a)}, a = \text{const}$$

Ans. dependent, $v = \frac{1}{1-u}$

$$5. u = x^2 + y^2 + 2xy + 2x + 2y, v = e^x \cdot e^y$$

Ans. dependent, $u = (\log v)^2 + 2 \log v$

$$6. u = x + y + z, v = x^2 + y^2 + z^2, \\ w = x^3 + y^3 + z^3 - 3xyz$$

Ans. dependent, $2w = u(3v - v^2)$

$$7. u = xe^y \sin z, v = xe^y \cos z, w = x^2 e^{2y}$$

Ans. dependent, $u^2 + v^2 = w$

$$8. u = x + y + z, v = x^3 + y^3 + z^3 - 3xyz, \\ w = x^2 + y^2 + z^2 - xy - yz - zx$$

Ans. dependent, $uw = v$

$$9. u = 4x^2 + 9y^2 + 16z^2, v = 2x + 3y + 4z, \\ w = 12xy + 16xz + 24yz$$

Ans. dependent, $v^2 - u - w = 0$

$$10. u = \frac{3x^2}{2(y+z)}, v = \frac{2(y+z)}{3(x-y)^2}, w = \frac{x-y}{x}$$

Ans. dependent, $uvw^2 = 1$

$$11. u = \frac{x}{y-z}, v = \frac{y}{z-x}, w = \frac{z}{x-y}$$

Ans. dependent, $vw + wu + uv + 1 = 0$

$$12. u = \sin^{-1} x + \sin^{-1} y, v = x\sqrt{1-y^2} + \\ y\sqrt{1-x^2}$$

Ans. dependent, $v = \sin u$.

$$\boxed{f(x + \Delta x, y + \Delta y) \approx f(x, y) + \frac{\partial f(x, y)}{\partial x} \Delta x + \frac{\partial f(x, y)}{\partial y} \Delta y} \quad (2)$$

Thus the value of a function at a point can be obtained approximately if the value of the function and its derivatives at a neighbouring point are known.

Errors in measured data will result in error in the estimated value. For example, small error in the measurement of radius of a sphere will introduce a corresponding error in the volume of the sphere $V = \frac{4\pi}{3}r^3$. *Absolute error*, denoted by Δx , is the error in x . Error may be positive or negative. *Relative or proportional error* in x is $\frac{\Delta x}{x}$ or $\frac{dx}{x}$ since $\Delta x = dx$. *Percentage error* in x is given by $100 \frac{dx}{x}$.

Example: If the error is 0.05 cm in measuring a dimension of length of 2 cm, then the absolute error is 0.05 cm, the relative error is $\frac{0.05}{2} = 0.025$ cm and the percentage error is $100 \times 0.025 = 2.5$.

For a function $z = f(x, y)$, the actual error Δz in z can be calculated approximately by using the differential dz , for given errors $\Delta x, \Delta y$ in x and y respectively.

WORKED OUT EXAMPLES

3.10 ERRORS AND APPROXIMATIONS

If $z = f(x, y)$, then the total differential of z , denoted by dz , is given by

$$dz = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy \quad (1)$$

If x increases by an increment Δx and y increases by an increment Δy , then the total increment in z , denoted by Δz , is

$$\Delta z = f(x + \Delta x, y + \Delta y) - f(x, y)$$

$$\text{or} \quad f(x + \Delta x, y + \Delta y) = f(x, y) + \Delta z$$

But $\Delta z \approx dz$.

Replacing dz by (1), we have the approximate formula

Example 1: Using differentials, calculate approximately the value of $f(0.999)$ where $f(x) = 2x^4 + 7x^3 - 8x^2 + 3x + 1$.

Solution: Choose $x = 1$ and $\Delta x = -0.001$ so that $x + \Delta x = 1 + (-0.001) = 0.999$. Thus to calculate

$$f(0.999) = f(x + \Delta x) = f(x) + \Delta f \\ \approx f(x) + f'(x)\Delta x \approx f(1) + f'(1)(-0.001).$$

Here $f(1) = 2.1 + 7.1 - 8.1 + 3.1 + 1 = 5$ and

$$f'(x) = 8x^3 + 21x^2 + 16x + 3 \quad \text{so}$$

$$f'(1) = 8.1 + 21.1 + 16.1 + 3 = 16.$$

Thus the approximate value of

$$f(0.999) \approx 5 + 16(-0.001) = 5 - 0.016 = 4.984.$$

3.30 — HIGHER ENGINEERING MATHEMATICS—II

Example 2: Considering the volume of a spherical shell as an increment of volume of a sphere, calculate approximately the volume of a spherical shell whose inner diameter is 8 inches and whose thickness is $\frac{1}{16}$ inch (Fig. 3.2).

Fig. 3.2

Solution: Volume of a sphere of radius r is $V = \frac{4}{3}\pi r^3$. Now volume of the spherical shell ΔV is the difference between volume V_o of outer sphere and volume V_i of inner sphere. Thus volume of the spherical shell $= \Delta V = V_o - V_i$. Here radius of the outer sphere $r = 4$ in (diameter is 8 inches) choose $r = 4$ and $dr = \frac{1}{16}$. Then

$$\begin{aligned} V\left(4 + \frac{1}{16}\right) - V(4) &= V(r + \Delta r) - V(r) = \\ &= \Delta V \approx dV = \frac{4}{3} \cdot 3\pi r^2 dr \text{ at } r = 4 \text{ and } dr = \frac{1}{16} \\ &= 4\pi(4)^2 \left(\frac{1}{16}\right) = 4\pi \text{ cubic inches.} \end{aligned}$$

Example 3: The time T of a complete oscillation of a simple pendulum of length L is governed by the equation $T = 2\pi\sqrt{\frac{L}{g}}$ where g is a constant.

- Find the approximate error in the calculated value of T corresponding to an error of 2% in the value of L .
- By what percentage should the length be changed in order to correct a loss of 2 minutes per day?

Solution:

$$\text{i. Taking log: } \ln T = \ln 2\pi + \frac{1}{2} \ln \frac{L}{g}.$$

$$\text{Differentiating } \frac{dT}{T} = 0 + \frac{1}{2} \frac{g}{L} \cdot \frac{dL}{g} = \frac{1}{2} \frac{dL}{L}$$

$$\text{Error relation: } \frac{dT}{T} = \frac{1}{2} \frac{dL}{L}$$

Error in value of L is 2% i.e., $\frac{dL}{L} \times 100 = 2$. Then $100 \times \frac{dT}{T} = \frac{1}{2} \frac{dL}{L} \times 100 = \frac{1}{2} 2 = 1$. The percentage error in calculate value of T is 1.

- Loss of error in value of T is 2 minutes per day i.e., $\frac{dT}{T} = (-2) \times \frac{1}{60} \times \frac{1}{24}$
From the error relation

$$\frac{dT}{T} \times 100 = -2 \times \frac{1}{60} \times \frac{1}{24} \times 100 = \frac{1}{2} \frac{dL}{L} \times 100$$

$$\text{or } 100 \times \frac{dL}{L} = -\frac{1}{360} \times 100 = -0.2777 \approx -0.278\%$$

Example 4: The diameter and height of a right circular cylinder are measured to be 5 and 8 inches respectively. If each of these dimensions may be in error by ± 0.1 inch, find the relative percentage error in volume of the cylinder.

Solution: Let x be the diameter and y be the height of the cylinder then

$$\begin{aligned} V &= \text{volume of cylinder} = \pi \left(\frac{x}{2}\right)^2 y \\ &= \frac{1}{4} \pi x^2 y. \quad \left(\because \text{radius} = \frac{x}{2}\right) \end{aligned}$$

$$\text{Differential : } dV = \frac{1}{4} \pi \cdot 2xy \cdot dx + \frac{1}{4} \pi x^2 dy$$

$$100 \times \frac{dV}{V} = 2 \frac{dx}{x} \times 100 + \frac{dy}{y} \times 100$$

Given $x = \text{diameter} = 5$ inches, height $= y = 8$ inches, error $dx = dy = \pm 0.1$. So

$$100 \times \frac{dV}{V} = \pm \left(2 \cdot \frac{0.1}{5} + \frac{0.1}{8}\right) = \pm 0.0525$$

Thus the percentage error in volume is ± 0.0525 .

EXERCISE

- Using differential calculate approximately

$$(a) (2.98)^3 \quad (b) \sqrt{4.05} \quad (c) \frac{1}{2.1} \quad (d) (83.7)^{\frac{1}{4}} \\ (e) y(1.997) \text{ where } y(x) = x^4 - 2x^3 + 9x + 7$$

Hint: Choose $y = f(x)$, x and Δx as follows

$$\text{a. } x^3, x = 3, \Delta x = -0.02$$

$$\text{b. } y = \sqrt{x}, x = 4, \Delta x = 0.5$$

$$\text{c. } y = \frac{1}{x}, x = 2, \Delta x = 0.1$$

$$\text{d. } y = x^{\frac{1}{4}}, x = 81, \Delta x = 2.7$$

Ans. (a) 26.46 (b) 2.13 (c) 0.475 (d) 3.025 (e) 24.949

2. If the radius of a sphere is measured as 5 inches with a possible error of 0.02 inches, find approximately the greatest possible error and percentage error in the computed value of the volume.

Hint: $V = \frac{4}{3}\pi r^3$, $dV = 4\pi r^2 dr$, $r = 5$, $dr = 0.02$, $dV = \pm 2\pi$, $V = \frac{500\pi}{3}$.

Ans. ± 0.012 , $\pm 1.2\%$

3. The quantity Q of water flowing over a V-notch is given by the formula $Q = cH^{\frac{5}{2}}$ where H is the head of water and c is a constant. Find the error in Q if the error in H is 1.5%.

Hint: $\frac{dQ}{Q} = \frac{5}{2} \frac{dH}{H} = \frac{5}{2}(1.5\%)$

Ans. 3.75%

4. Calculate the percentage increase in the pressure p corresponding to a reduction of $\frac{1}{2}\%$ in the volume V , if the p and V are related by $pV^{1.4} = c$ where c is a constant:

Hint: $100 \times \frac{dp}{p} = -1.4 \frac{dV}{V} \times 100 = -(1.4) \times (-\frac{1}{2})$

Ans. 0.7

5. Find the possible error in (a) surface area (b) volume of a sphere of radius r if r is measured as 18.5 inches with a possible error of 0.1 inch.

Ans. (a) 14.8π sq. in (b) 136.9π cubic inch

6. Show that the relative error in c due to a given error in θ is minimum when $\theta = 45^\circ$ if $c = k \tan \theta$.

Hint: $\frac{dc}{c} = \frac{2d\theta}{\sin 2\theta}$ minimum when $\sin 2\theta$ is greatest i.e., $2\theta = 90$.

7. Considering the area of a circular ring as an increment of area of a circle, find approximately the area of a ring whose inner and outer radii are 3 in and 3.02 in respectively.

Hint: $A = \pi r^2$, Area of circular ring $= A(3.02) - A(3) = 2\pi r dr$ with $r=3$, $dr=0.02$

Ans. 0.12π

8. Find the percentage error in calculated value of volume of a right circular cone whose altitude is same as the base radius and is measured as

5 inches with a possible error of 0.02 inches.

Hint: $V = \pi r^2 h = \pi r^3$ ($\because r = h$), $\frac{dV}{V} = 3 \frac{dr}{r}$, $r = 5$, $dr = 0.02$

Ans. 1.2%

9. Calculate the error in R if $RI = E$ and possible errors in E and I are 20% and 10% respectively

Hint: $\frac{dR}{R} \times 100 = (\frac{dE}{E} - \frac{dI}{I}) \times 100 = 20 - 10 = 10$

Ans. 10%

10. The diameter and the height of a right circular cylinder are measured as 4 cm and 6 cm respectively, with a possible error of 0.1 cm. Find approximately the maximum possible error in the computed value of the volume and surface area.

Hint: $V = \pi r^2 h = \frac{\pi}{4} D^2 H$, $dV = \frac{\pi}{4} [2DHdD + D^2 dH]$
 $S = 2\pi r h = \pi DH$, $ds = \pi [HdD + DdH]$.

Ans. 1.6π cu. cm; π sq. cm

3.11 DIFFERENTIATION UNDER INTEGRAL SIGN: LEIBNITZ'S RULE

We know from the fundamental theorem on integral calculus that if $f(x)$ is a continuous function and $\phi(x) = \int_a^x f(t)dt$, then

$$\frac{d\phi}{dx} = \phi'(x) = \frac{d}{dx} \int_a^x f(t)dt = f(x) \quad (1)$$

i.e., the derivative of a definite integral w.r.t. the upper limit is equal to the integrand in which the variable of integration t' is replaced by the upper limit ' x '

Example 1: (i) $\frac{d}{dx} \int_0^x e^{-t^2} dt = e^{-x^2}$

(ii) $\frac{d}{dx} \int_1^x \frac{1}{t} dt = \frac{1}{x}$, $x > 0$

Now if $F(x)$ is some antiderivative of a continuous function $f(x)$, then the Newton-Leibnitz formula $\int_a^b f(x)dx = F(b) - F(a)$ yields a practical and convenient method of computing definite integrals in cases where the anti-derivative of the integrand is known. This general method has extended

3.32 — HIGHER ENGINEERING MATHEMATICS—II

the range of applications of definite integral to technology, mechanics, astronomy etc.

Differentiating integrals depend on a parameter:

Consider the definite integral

$$I(\alpha) = \int_a^b f(x, \alpha) dx \quad (2)$$

in which the integrand $f(x, \alpha)$ is dependent on a parameter α . The value of the definite integral (2) changes as the parameter α varies. It is difficult to integrate (2) in many cases.

Now to differentiate the integral (2) w.r.t. the parameter α , without having to first carry out integration and then differentiation, we use the Leibnitz's rule.

Book work 1. Leibnitz's formula (rule)

If $f(x, \alpha)$ and $\frac{\partial f}{\partial \alpha}$ are continuous functions when $c \leq \alpha \leq d$ and $a \leq x \leq b$, then

$$\frac{d}{d\alpha} \int_a^b f(x, \alpha) dx = \int_a^b \frac{\partial f(x, \alpha)}{\partial \alpha} dx \quad (3)$$

i.e., the order of differentiation and integration can be interchanged.

Proof: Consider

$$\begin{aligned} \frac{I(\alpha + \Delta\alpha) - I(\alpha)}{\Delta\alpha} &= \frac{1}{\Delta\alpha} \left[\int_a^b f(x, \alpha + \Delta\alpha) dx - \int_a^b f(x, \alpha) dx \right] \\ &= \int_a^b \frac{f(x, \alpha + \Delta\alpha) - f(x, \alpha)}{\Delta\alpha} dx \end{aligned}$$

By Lagrange's mean value theorem

$$\begin{aligned} \frac{f(x, \alpha + \Delta\alpha) - f(x, \alpha)}{\Delta\alpha} &= \frac{\partial f}{\partial \alpha}(x, \alpha + \theta \Delta\alpha) \\ &= \frac{\partial f}{\partial \alpha}(x, \alpha) + \varepsilon \end{aligned}$$

Here $0 < \theta < 1$ and ε which depends on $x, \alpha, \Delta\alpha$ tends to zero as $\Delta\alpha \rightarrow 0$.

As $\Delta\alpha \rightarrow 0$

$$\lim_{\Delta\alpha \rightarrow 0} \frac{I(\alpha + \Delta\alpha) - I(\alpha)}{\Delta\alpha} = \lim_{\Delta\alpha \rightarrow 0} \left[\int_a^b \frac{\partial f}{\partial \alpha}(x, \alpha) dx + \varepsilon \right]$$

$$+ \int_a^b \varepsilon dx \Big]$$

Thus

$$\frac{dI}{d\alpha} = \frac{d}{d\alpha} \int_a^b f(x, \alpha) dx = \int_a^b \frac{\partial f(x, \alpha)}{\partial \alpha} dx$$

General Leibnitz's rule

Book work 2. If $f(x, \alpha)$ and $f_\alpha(x, \alpha)$ are continuous and if the limits of integration a and b are functions of α then

$$\begin{aligned} \frac{d}{d\alpha} \int_{a(\alpha)}^{b(\alpha)} f(x, \alpha) dx &= \int_{a(\alpha)}^{b(\alpha)} \frac{\partial f(x, \alpha)}{\partial \alpha} dx \\ &+ f[b(\alpha), \alpha] \frac{db}{d\alpha} - f[a(\alpha), \alpha] \frac{da}{d\alpha} \end{aligned} \quad (4)$$

Proof: Consider the definite integral

$$I(\alpha) = \int_{a(\alpha)}^{b(\alpha)} f(x, \alpha) dx = \phi(\alpha, a(\alpha), b(\alpha))$$

which depends on the parameter α through the integrand and intermediate arguments $a(\alpha), b(\alpha)$, the limits of integration. From chain rule,

$$\frac{dI}{d\alpha} = \frac{\partial \phi}{\partial \alpha} + \frac{d\phi}{da} \frac{da}{d\alpha} + \frac{\partial \phi}{\partial b} \frac{db}{d\alpha} \quad (5)$$

Using (1), the fundamental theorem on integral calculus, we have

$$\frac{\partial \phi}{\partial b} = \frac{\partial}{\partial b} \int_a^b f(x, \alpha) dx = f(b(\alpha), \alpha) \quad (6)$$

$$\begin{aligned} \frac{\partial \phi}{\partial a} &= \frac{\partial}{\partial a} \int_a^b f(x, \alpha) dx = -\frac{\partial}{\partial a} \int_b^a f(x, \alpha) dx \\ &= -f(a(\alpha), \alpha) \end{aligned} \quad (7)$$

Now we know from (3) (in the above book work.

$$\frac{\partial \phi}{\partial \alpha} = \frac{\partial}{\partial \alpha} \int_a^b f(x, \alpha) dx = \int_a^b \frac{\partial f(x, \alpha)}{\partial \alpha} dx \quad (8)$$

Here the limits of integration a and b are treated as constants since the dependence of ϕ on α here is through the integrand $f(x, \alpha)$ substituting (6), (7), (8) in (5), we get the result.

Note: Leibnitz's rule is applicable even when one of the limits of integration is infinite.

WORKED OUT EXAMPLES

Example 1: Apply Leibnitz's rule $\frac{d}{d\alpha} \int_{-2\alpha^2}^{-\alpha} e^{\alpha x^3} dx$.

$$\begin{aligned} \text{Solution:} \quad \text{Here } I(\alpha) &= \int_{-2\alpha^2}^{-\alpha} e^{\alpha x^3} dx \\ &= \int_{a(\alpha)}^{b(\alpha)} f(x, \alpha) dx, \text{ so } b(\alpha) = -\alpha, a(\alpha) \\ &= -2\alpha^2 \cdot f(x, \alpha) = e^{\alpha x^3}. \text{ Applying Leibnitz's rule} \\ \frac{dI}{d\alpha} &= \frac{d}{d\alpha} \int_{-2\alpha^2}^{-\alpha} e^{\alpha x^3} dx = \int_{-2\alpha^2}^{-\alpha} x^3 \cdot e^{\alpha x^3} dx + \\ &\quad + (-1) \cdot e^{\alpha \cdot (-\alpha)^3} - (-4\alpha) e^{\alpha(-2\alpha^2)^3} \\ &= \int_{-2\alpha^2}^{-\alpha} x^3 e^{\alpha x^3} dx - e^{-\alpha^4} + 4\alpha e^{-8\alpha^7} \end{aligned}$$

Example 2: Using Leibnitz's rule, show that $\frac{d}{d\alpha} \int_0^{\alpha^2} \tan^{-1} \frac{x}{\alpha} dx = 2\alpha \tan^{-1} \alpha - \frac{1}{2} \log(\alpha^2 + 1)$. Verify this result by direct integration followed by differentiation.

Solution: Here $b(\alpha) = \alpha^2$, $a(\alpha) = 0$, $f(x, \alpha) = \tan^{-1} \frac{x}{\alpha}$. Using Leibnitz's rule

$$\begin{aligned} \frac{d}{d\alpha} \int_0^{\alpha^2} \tan^{-1} \frac{x}{\alpha} dx &= \int_0^{\alpha^2} \frac{1}{1 + \left(\frac{x}{\alpha}\right)^2} \cdot \left(\frac{-x}{\alpha^2}\right) dx \\ &\quad + 2\alpha \cdot \tan^{-1} \frac{\alpha^2}{\alpha} - 0 \\ &= - \int_0^{\alpha^2} \frac{1}{2} \frac{d(x^2 + \alpha^2)}{(x^2 + \alpha^2)} + 2\alpha \tan^{-1} \alpha \\ &= - \frac{1}{2} \ln(x^2 + \alpha^2) \Big|_{x=0}^{\alpha^2} + 2\alpha \tan^{-1} \alpha \\ &= - \frac{1}{2} \ln(\alpha^4 + \alpha^2) + \frac{1}{2} \ln \alpha^2 + 2\alpha \tan^{-1} \alpha \\ &= 2\alpha \tan^{-1} \alpha - \frac{1}{2} \ln(\alpha^2 + 1) \end{aligned}$$

Direct verification:

Integrating

$$\begin{aligned} \int_0^{\alpha^2} \tan^{-1} \frac{x}{\alpha} dx &= \alpha \left[\frac{x}{\alpha} \tan^{-1} \frac{x}{\alpha} - \log \sqrt{\frac{x^2}{\alpha^2} + 1} \right] \Big|_{x=0}^{\alpha^2} \\ &= \alpha^2 \tan^{-1} \frac{\alpha^2}{\alpha} - \alpha \log \sqrt{\alpha^2 + 1} \end{aligned}$$

Now differentiating w.r.t. ' α '

$$\begin{aligned} \frac{d}{d\alpha} \int_0^{\alpha^2} \tan^{-1} \frac{x}{\alpha} dx &= 2\alpha \cdot \tan^{-1} \alpha + \alpha^2 \cdot \frac{1}{1 + \alpha^2} \\ &\quad - \alpha \cdot \frac{1}{\sqrt{\alpha^2 + 1}} \cdot \frac{1}{2} \frac{1}{\sqrt{\alpha^2 + 1}} - \log \sqrt{\alpha^2 + 1} \\ &= 2\alpha \cdot \tan^{-1} \alpha + \frac{\alpha^2}{1 + \alpha^2} - \frac{\alpha^2}{\alpha^2 + 1} - \log \sqrt{\alpha^2 + 1} \\ &= 2\alpha \tan^{-1} \alpha - \frac{1}{2} \ln(\alpha^2 + 1) \end{aligned}$$

Example 3: Using Leibnitz rule evaluate the definite integral $\int_0^1 x^m (\log x)^n dx$.

Solution: Consider $I(m) = \int_0^1 x^m dx$. Using Leibnitz rule

$$\begin{aligned} \frac{dI}{dm} &= \frac{d}{dm} \int_0^1 x^m dx = \int_0^1 \frac{\partial}{\partial m} (x^m) dx \\ &= \int_0^1 x^m \cdot \log x dx \end{aligned}$$

Differentiating w.r.t. ' m ' again

$$\begin{aligned} \frac{d^2 I}{dm^2} &= \frac{d}{dm} \int_0^1 x^m \log x dx = \int_0^1 \frac{\partial}{\partial m} (x^m \log x) dx \\ &= \int_0^1 x^m \cdot \log x \cdot \log x dx = \int_0^1 x^m (\log x)^2 dx \end{aligned}$$

Thus differentiating ' n ' times w.r.t. m

$$\frac{d^n I}{dm^n} = \int_0^1 x^m (\log x)^n dx$$

From reduction formula we know that

$$\begin{aligned} \int_0^1 x^m (\log x)^n dx &= \frac{x^{m+1}}{m+1} \cdot (\log x)^n \Big|_{x=0}^1 \\ &\quad - \frac{n}{m+1} \cdot \int_0^1 x^m (\log x)^{n-1} dx \end{aligned}$$

3.34 — HIGHER ENGINEERING MATHEMATICS—II

$$= -\frac{n}{(m+1)} \cdot \int_0^1 x^m (\log x)^{n-1} dx$$

Applying reduction formula again

$$\begin{aligned} &= \frac{-n}{m+1} \left[\frac{x^{m+1}}{m+1} \cdot (\log x)^{n-1} \right. \\ &\quad \left. - \frac{n-1}{m+1} \int_0^1 x^m (\log x)^{n-2} dx \right] \\ &= (-1)^2 \frac{n(n-1)}{(m+1)^2} \left[\int_0^1 x^m (\log x)^{n-2} dx \right] \end{aligned}$$

By repeated application

$$\begin{aligned} &= \frac{(-1)^{(n-1)} \cdot n \cdot (n-1)(n-2) \cdots (n-(n-1))}{(m+1)^n} \times \\ &\quad \times \left[\int_0^1 x^m dx \right] \\ &= \frac{(-1)^{(n-1)} \cdot n!}{(m+1)^n} \cdot \frac{x^{m+1}}{m+1} \Big|_{x=0}^1 = \frac{(-1)^n \cdot n!}{(m+1)^{n+1}} \end{aligned}$$

Thus

$$\int_0^1 x^m (\log x)^n dx = \frac{(-1)^n n!}{(m+1)^{n+1}}$$

Example 4: Evaluate $\int_0^\infty x^n e^{-x} dx$

Solution: Consider $I(\alpha) = \int_0^\infty e^{-\alpha x} dx$.

Differentiating w.r.t. 'α' by Leibnitz's rule we get

$$\begin{aligned} \frac{dI}{d\alpha} &= \frac{d}{d\alpha} \int_0^\infty e^{-\alpha x} dx = \int_0^\infty \frac{\partial}{\partial \alpha} (e^{-\alpha x}) dx \\ &= - \int_0^\infty x e^{-\alpha x} dx \end{aligned}$$

Differentiating successively $(n-1)$ times,

$$\frac{d^n I}{d\alpha^n} = (-1)^n \int_0^\infty x^n \cdot e^{-\alpha x} dx \quad (1)$$

But we know that $I(\alpha) = \int_0^\infty e^{-\alpha x} dx$

$$I(\alpha) = \frac{e^{-\alpha x}}{-\alpha} \Big|_0^\infty = \frac{1}{\alpha} \quad (2)$$

So differentiating (2) n times and equating with (1) we get

$$\begin{aligned} (-1)^n \int_0^\infty x^n e^{-\alpha x} dx &= \frac{d^n I}{d\alpha^n} = \frac{d^n}{d\alpha^n} (\alpha^{-1}) \\ &= (-1)^n \cdot \frac{n!}{\alpha^{n+1}} \end{aligned}$$

Thus $\int_0^\infty x^n e^{-\alpha x} dx = \frac{n!}{\alpha^{n+1}}$ for $n = 0, 1, 2, \dots$
when $\alpha = 1$, $\int_0^\infty x^n e^{-x} dx = n!$; for $n = 0, 1, 2, \dots$

Example 5: If $\int_0^\infty \frac{x^\alpha}{1+x^3} dx = \frac{\pi}{3} \operatorname{cosec}\left(\frac{\alpha+1}{3}\pi\right)$, evaluate $\int_0^\infty \frac{(\ln x)^2}{(1+x^3)} dx$. Hence or otherwise evaluate $\int_0^\infty \frac{x \ln x}{(1+x^3)} dx$.

Solution: Consider $I(\alpha) = \int_0^\infty \frac{x^\alpha}{1+x^3} dx$. Differentiating w.r.t. 'α' by Leibnitz rule

$$\begin{aligned} \frac{dI}{d\alpha} &= \frac{d}{d\alpha} \int_0^\infty \frac{x^\alpha}{1+x^3} dx = \int_0^\infty \frac{\partial}{\partial \alpha} \left(\frac{x^\alpha}{1+x^3} \right) dx \\ \frac{dI}{d\alpha} &= \int_0^\infty \frac{x^\alpha}{(1+x^3)} (\log x) dx \quad (1) \quad \left(\because \frac{dx^\alpha}{d\alpha} = x^\alpha \log x \right) \end{aligned}$$

Differentiating once more with respect to 'α'

$$\begin{aligned} \frac{d^2 I}{d\alpha^2} &= \frac{d}{d\alpha} \int_0^\infty \frac{x^\alpha (\log x)}{(1+x^3)} dx = \int_0^\infty \frac{\partial}{\partial \alpha} \left(\frac{x^\alpha \log x}{1+x^3} \right) dx \\ \frac{d^2 I}{d\alpha^2} &= \int_0^\infty \frac{x^\alpha \cdot \log x}{1+x^3} \cdot \log x dx = \int_0^\infty \frac{x^\alpha (\log x)^2}{1+x^3} dx \quad (2) \end{aligned}$$

since

$$I(\alpha) = \int_0^\infty \frac{x^\alpha}{1+x^3} dx = \frac{\pi}{3} \operatorname{cosec}\left(\frac{\alpha+1}{3}\pi\right) \quad (3)$$

differentiating the RHS of (3) twice wrt α we have

$$\frac{dI}{d\alpha} = \frac{\pi}{3} [-\operatorname{cosec} y \pi \cdot \cot y \pi] \cdot \frac{\pi}{3} \quad (4)$$

$$\text{where } y = \left(\frac{\alpha+1}{3}\right)\pi$$

and

$$\begin{aligned} \frac{d^2 I}{d\alpha^2} &= -\frac{\pi^2}{9} [\cot y (-\operatorname{cosec} y) \cdot \cot y + (-\operatorname{cosec}^2 y) \cdot \operatorname{cosec} y] \frac{\pi}{3} \\ \frac{d^2 I}{d\alpha^2} &= \frac{\pi^3}{27} [\cot^2 y + \operatorname{cosec}^2 y] \cdot \operatorname{cosec} y \quad (5) \end{aligned}$$

Equating (2) and (5)

$$\int_0^\infty \frac{x^\alpha (\log x)^2}{1+x^3} dx = \frac{d^2 I}{d\alpha^2} =$$

$$\frac{\pi^3}{27} [\cot^2 y + \operatorname{cosec}^2 y] \operatorname{cosec} y \quad (6)$$

Put $\alpha = 0$ in (6) then $y = \frac{\pi}{3}$, so

$$\begin{aligned} \int_0^\infty \frac{(\log x)^2}{1+x^3} dx &= \frac{\pi^3}{27} \left[\cot^2 \frac{\pi}{3} + \operatorname{cosec}^2 \frac{\pi}{3} \right] \cdot \operatorname{cosec} \frac{\pi}{3} \\ &= \frac{\pi^3}{27} \left[\frac{1}{3} + \frac{4}{3} \right] \frac{2}{\sqrt{3}} = \frac{10\pi^3}{8\sqrt{3}} \end{aligned}$$

Put $\alpha = 1$ in (1) and (4)

$$\begin{aligned} \int_0^\infty \frac{x \log x}{1+x^3} dx &= \frac{dI}{d\alpha} \Big|_{\alpha=1} = \frac{-\pi^2}{9} \operatorname{cosec} \frac{2\pi}{3} \cdot \cot \frac{2\pi}{3} \\ &= \frac{-\pi^2}{9} \cdot \frac{2}{\sqrt{3}} \left(-\frac{1}{\sqrt{3}} \right) = \frac{2\pi^2}{27} \end{aligned}$$

Example 6: Show that $y(x)$ satisfies the initial value problem (IVP) where

(a) $y(x) = \frac{1}{6} \int_a^x (x-t)^3 f(t) dt$,
 IVP: $y''''(x) = f(x)$, $y(a) = y'(a) = y''(a) = y'''(a) = 0$

(b) $y(x) = e^x + \int_0^x t^2 \cosh(x-t) dt$,
 IVP: $y'' - y = 2x$; $y(0) = y'(0) = 1$

Solution: (a) Differentiating w.r.t. (the parameter) 'x' four times, we get

$$\begin{aligned} \frac{dy}{dx} &= \frac{1}{6} \frac{d}{dx} \int_a^x (x-t)^3 f(t) dt \\ &= \frac{1}{6} \int_a^x \frac{\partial}{\partial x} [(x-t)^3 f(t)] dt \\ \frac{dy}{dx} &= \frac{1}{6} \left[\int_a^x 3(x-t)^2 f(t) dt + 1 \cdot (x-x)^3 f(x) - 0 \right] \\ \frac{d^2 y}{dx^2} &= \frac{1}{6} \left[\int_a^x 3 \cdot 2 \cdot (x-t) f(t) dt + 3(x-x)^2 f(x) - 0 \right] \end{aligned}$$

$$\begin{aligned} \frac{d^3 y}{dx^3} &= \frac{d}{dx} \int_a^x (x-t) f(t) dt \\ \frac{d^3 y}{dx^3} &= \int_a^x 1 \cdot f(t) dt + 1 \cdot (x-x) f(x) - 0 \\ \frac{d^4 y}{dx^4} &= y'''' = \frac{d}{dx} \int_a^x f(t) dt = f(x) \end{aligned}$$

Thus y satisfies the D.E. $y'''' = f(x)$.

At $x = a$, from the above results, $y(a) = y'(a) = y''(a) = y'''(a) = 0$

(b) Differentiating w.r.t. x twice

$$\begin{aligned} \frac{dy}{dx} &= e^x + \int_0^x t^2 \cdot \sinh(x-t) dt \\ &\quad + 1 \cdot x^2 \cosh(x-x) - 0 \\ \frac{d^2 y}{dx^2} &= e^x + \int_0^x t^2 \cosh(x-t) dt \\ &\quad + 1 \cdot x^2 \cdot \sinh(x-x) - 0 + 2x = y(x) + 2x \end{aligned}$$

$\therefore y'' - y = 2x$, the DE is satisfied.

Note that at $x = 0$, $y(0) = y'(0) = 1$ from the above.

EXERCISE

Evaluate the following integrals $I(\alpha)$ using Leibnitz's rule

1. $\int_0^\infty x^2 e^{-x^2} dx$

Ans. $\frac{\sqrt{\pi}}{4}$

Hint: Differentiate w.r.t. ' α ' the well-known result

$$\int_0^\infty e^{-\alpha x^2} dx = \frac{1}{2} \sqrt{\frac{\pi}{\alpha}}$$

2. $I(\alpha) = \int_0^\infty e^{-x} \frac{\sin \alpha x}{x} dx$

Ans. $\tan^{-1} \alpha$

Hint: $I'(\alpha) = \int_0^\infty e^{-x} \cos \alpha x dx = \frac{1}{1+\alpha^2}$, integrating $I(\alpha) = \tan^{-1} \alpha + c$, use $I(0) = 0$

3. $I(\alpha) = \int_0^1 \frac{x^\alpha - 1}{\log x} dx$, $\alpha \geq 0$

Ans. $\log(1+\alpha)$

Hint: $I'(\alpha) = \int_0^1 x^\alpha dx = \frac{1}{1+\alpha}$, integrate and use $I(0) = 0$

4. $I(\alpha) = \int_0^\alpha \frac{\log(1+\alpha x)}{1+x^2} dx$ and deduce $\int_0^1 \frac{\log(1+x)}{1+x^2} dx$

Ans. $\frac{1}{2} \log(1+\alpha^2) \tan^{-1} \alpha$; with $\alpha = 1$, $\frac{\pi}{8} \log_e 2$

Hint: $I'(\alpha) = \int_0^\alpha \frac{x}{(1+\alpha x)(1+x^2)} dx + \frac{\log(1+\alpha^2)}{1+\alpha^2}$, use partial fraction $\frac{x}{(1+\alpha x)(1+x^2)} = -\frac{\alpha}{1+\alpha^2} \frac{1}{1+\alpha x} + \frac{1}{2(1+\alpha^2)} \cdot \frac{2x}{1+x^2} + \frac{\alpha}{1+\alpha^2} \frac{1}{1+x^2}$.

3.36 — HIGHER ENGINEERING MATHEMATICS—II

Integrating (R.H.S.), $I'(\alpha) = \frac{\log(1+\alpha^2)}{2(1+\alpha^2)} + \frac{\alpha \cdot \tan^{-1} \alpha}{1+\alpha^2}$.

Integrating both sides and use $I(0) = 0$.

5. If $I(\alpha) = \int_{-\alpha}^{\alpha^2} \cos(\alpha x^2) dx$. Find $I'(\alpha)$.

Ans. $I'(\alpha) = -\int_{-\alpha}^{\alpha^2} x^2 \sin(\alpha x^2) dx + 2\alpha \cos(\alpha^5) + \cos(\alpha^3)$

6. $\int_0^\infty \frac{\tan^{-1} \alpha x}{x(1+x^2)} dx$ where $\alpha \geq 0$.

Ans. $\frac{\pi}{2} \log(1+\alpha)$

Hint: $I'(\alpha) = \int_0^\infty \frac{1}{(1+x^2)(1+\alpha^2 x^2)} dx$

$$= \frac{1}{1-\alpha^2} \int_0^\infty \left(\frac{1}{1+x^2} - \frac{\alpha^2}{1+\alpha^2 x^2} \right) dx$$

$$= \frac{\pi}{2(1+\alpha)}, \text{ Integrate and use } I(0) = 0.$$

7. $\int_0^\infty e^{-x^2} \cos \alpha x dx$

Ans. $\frac{1}{2} \sqrt{\pi} e^{-\frac{1}{4}\alpha^2}$

Hint: $I'(\alpha) = -\frac{\alpha}{2}$, Integrating $I(\alpha) = ce^{-\frac{1}{4}\alpha^2}$, use $I(0) = \frac{\sqrt{\pi}}{2}$.

8. $\int_0^\pi \frac{\log(1 + \sin \alpha \cdot \cos x)}{\cos x} dx$

Ans. $\pi \alpha$

9. $\int_0^\infty x e^{-x^2} \sin \alpha x dx$

Ans. $\frac{\sqrt{\pi}}{4} \cdot \alpha e^{-\alpha^2/4}$

10. $\int_0^1 \frac{x^3 - 1}{\ln x} dx$

Ans. $\ln 4$

Hint: $I(\alpha) = \int_0^1 \frac{x^\alpha - 1}{\ln x} dx$, $I'(\alpha) = \frac{1}{\alpha+1}$, Integrate and use $I(0) = 0$

11. Show that $y(x) = \frac{1}{x} \int_a^x (x-t)f(t)dt$ satisfies the initial value problem $(xy)'' = f(x)$, $y(a) = y'(a) = 0$.

12. Show that $x(t) = \frac{1}{m\omega} \int_0^t \sin \omega(t-\tau)f(\tau)d\tau$ satisfies forced harmonic oscillator: $mx'' + kx = f(t)$, $x(0) = x'(0) = 0$; $\omega = \sqrt{\frac{k}{m}}$

Chapter 4

Maxima and Minima

INTRODUCTION

To optimize something means to maximize or minimize some aspects of it. An important application of multivariable differential calculus is finding the maximum and minimum values of functions of several variables and determining where they occur. In the study of stability of the equilibrium states of mechanical and physical systems, determination of extrema is of greatest importance. Lagrange multipliers method developed by Lagrange in 1755 is a powerful method for finding extreme values of constrained functions in economics, in designing multi-stage rockets in engineering, in geometry etc.

4.1 TAYLOR'S THEOREM FOR FUNCTION OF TWO VARIABLES

Functions of two or more variables often can be expanded in power series which generalize the familiar one-dimensional expansion. Let $f(x, y)$ be a function of two independent variables x and y . Let $P(x, y)$ and $Q(x + h, y + k)$ be two neighbouring points. Then, $f(x + h, y + k)$, the value of f at Q can be expressed in terms of f and its derivatives at P .

Keeping y temporarily constant, $f(x + h, y + k)$ is treated as a function of the single variable x and expanded as follows using Taylor's theorem.

$$f(x + h, y + k) = f(x, y + k) + \frac{h \partial f(x, y + k)}{\partial x}$$

$$+ \frac{h^2}{2!} \frac{\partial^2 f(x, y + k)}{\partial x^2} + \frac{h^3}{3!} \frac{\partial^3 f(x, y + k)}{\partial x^3} + \dots \quad (1)$$

Now the first term on the R.H.S. of (1) is expanded as function of y , treating x temporarily constant

$$f(x, y + k) = f(x, y) + \frac{k \partial f(x, y)}{\partial y} + \frac{k^2}{2!} \frac{\partial^2 f(x, y)}{\partial y^2} + \frac{k^3}{3!} \frac{\partial^3 f(x, y)}{\partial y^3} + \dots \quad (2)$$

To get the 2nd, 3rd, 4th terms on the R.H.S. of (1), differentiate (2) partially w.r.t. x , once, twice, thrice, etc., yielding

$$\frac{\partial f(x, y + k)}{\partial x} = \frac{\partial f(x, y)}{\partial x} + \frac{k \partial^2 f(x, y)}{\partial x \partial y} + \frac{k^2}{2!} \frac{\partial^3 f(x, y)}{\partial x \partial y^2} + \frac{k^3}{3!} \frac{\partial^4 f(x, y)}{\partial x \partial y^3} + \dots \quad (3)$$

$$\frac{\partial^2 f(x, y + k)}{\partial x^2} = \frac{\partial^2 f(x, y)}{\partial x^2} + \frac{k \partial^3 f(x, y)}{\partial x^2 \partial y} + \frac{k^2}{2!} \frac{\partial^4 f(x, y)}{\partial x^2 \partial y^2} + \frac{k^3}{3!} \frac{\partial^5 f(x, y)}{\partial x^2 \partial y^3} + \dots \quad (4)$$

$$\frac{\partial^3 f(x, y + k)}{\partial x^3} = \frac{\partial^3 f(x, y)}{\partial x^3} + \frac{k \partial^4 f(x, y)}{\partial x^3 \partial y} + \frac{k^2}{2!} \frac{\partial^5 f(x, y)}{\partial x^3 \partial y^2} + \frac{k^3}{3!} \frac{\partial^6 f(x, y)}{\partial x^3 \partial y^3} + \dots \quad (5)$$

4.2 — HIGHER ENGINEERING MATHEMATICS—II

Using (2), (3), (4), (5), Equation (1) becomes after rearrangement,

$$\begin{aligned} f(x+h, y+k) = & f(x, y) + \left(\frac{h \partial f(x, y)}{\partial x} + \frac{k \partial f(x, y)}{\partial y} \right) \\ & + \frac{1}{2!} \left[\frac{h^2 \partial^2 f(x, y)}{\partial x^2} + \frac{2hk \partial^2 f(x, y)}{\partial x \partial y} \right. \\ & \left. + \frac{k^2 \partial^2 f(x, y)}{\partial y^2} \right] + \frac{1}{3!} \left[\frac{h^3 \partial^3 f(x, y)}{\partial x^3} \right. \\ & + \frac{3h^2 k \partial^3 f(x, y)}{\partial x^2 \partial y} + \frac{3hk^2 \partial^3 f(x, y)}{\partial x \partial y^2} \\ & \left. + \frac{k^3 \partial^3 f(x, y)}{\partial y^3} \right] + \text{higher order terms.} \end{aligned} \quad (6)$$

In the suffix notation,

$$\begin{aligned} f(x+h, y+k) = & f(x, y) + [hf_x(x, y) + kf_y(x, y)] \\ & + \frac{1}{2!} [h^2 f_{xx}(x, y) + 2hk f_{xy}(x, y) \\ & + k^2 f_{yy}(x, y)] + \frac{1}{3!} [h^3 f_{xxx}(x, y) \\ & + 3h^2 k f_{xxy}(x, y) + 3hk^2 f_{xyy}(x, y) \\ & + k^3 f_{yyy}(x, y)] + \dots \end{aligned} \quad (7)$$

Equation (7) represents $f(x+h, y+k)$ in a power series of ascending powers of h and k .

For any specific point (a, b) replace (x, y) by (a, b) in (7) resulting in

$$\begin{aligned} f(a+h, b+k) = & f(a, b) + [hf_x(a, b) + kf_y(a, b)] \\ & + \frac{1}{2!} [h^2 f_{xx}(a, b) + 2hk f_{xy}(a, b) \\ & + k^2 f_{yy}(a, b)] + \frac{1}{3!} [h^3 f_{xxx}(a, b) \\ & + 3h^2 k f_{xxy}(a, b) + 3hk^2 f_{xyy}(a, b) \\ & + k^3 f_{yyy}(a, b)] + \dots \end{aligned} \quad (8)$$

Alternative Form

Equation (8) can be expressed in ascending powers of $(x-a)$ and $(y-b)$ by replacing h by $x-a$ and k by $y-b$ which gives

$$\begin{aligned} f(x, y) = & f(a, b) + [(x-a)f_x(a, b) \\ & + (y-b)f_y(a, b)] + \frac{1}{2!} [(x-a)^2 f_{xx}(a, b) \end{aligned}$$

$$\begin{aligned} & + 2(x-a)(y-b)f_{xy}(a, b) + (y-b)^2 f_{yy}(a, b)] \\ & + \frac{1}{3!} [(x-a)^3 f_{xxx}(a, b) + 3(x-a)^2(y-b) \times \\ & \times f_{xxy}(a, b) + 3(x-a)(y-b)^2 f_{xyy}(a, b) \\ & + (y-b)^3 f_{yyy}(a, b)] + \dots \end{aligned} \quad (9)$$

Equation (9) which expands $f(x, y)$ in infinite power series in powers (terms) of $(x-a)$ and $(y-b)$ is known as **Taylor's series** or **Taylor's expansion** or **Taylor's series expansion** of $f(x, y)$ about the point (a, b) .

Introducing the operator notation,

$$\Delta = h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y}$$

so that

$$\begin{aligned} \Delta^2 = & \left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y} \right)^2 = h^2 \frac{\partial^2}{\partial x^2} + 2hk \frac{\partial^2}{\partial x \partial y} + k^2 \frac{\partial^2}{\partial y^2} \\ \Delta^3 = & \left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y} \right)^3 = h^3 \frac{\partial^3}{\partial x^3} + 3h^2 k \frac{\partial^3}{\partial x^2 \partial y} + \\ & + 3hk^2 \frac{\partial^3}{\partial x \partial y^2} + k^3 \frac{\partial^3}{\partial y^3} \end{aligned}$$

Equation (6) can be rewritten now as

$$\begin{aligned} f(x+h, y+k) = & f(x, y) + \Delta f(x, y) + \frac{1}{2!} \Delta^2 f(x, y) \\ & + \frac{1}{3!} \Delta^3 f(x, y) + \dots \end{aligned}$$

$$\begin{aligned} \text{Alternatively } f(x, y) = & \sum_{n=0}^{\infty} \frac{1}{n!} \left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y} \right)^n f(a, b) \\ = & \sum_{n=0}^{\infty} \frac{\Delta^n}{n!} f(a, b). \end{aligned}$$

Maclaurin's series expansion is a special case of Taylor's series when the expansion is about the origin $(0, 0)$. Thus putting $a = 0, b = 0$ in (9), we get

$$\begin{aligned} f(x, y) = & f(0, 0) + [x \cdot f_x(0, 0) + y f_y(0, 0)] \\ & + \frac{1}{2!} [x^2 f_{xx}(0, 0) + 2xy f_{xy}(0, 0) \\ & + y^2 f_{yy}(0, 0)] + \frac{1}{3!} [x^3 f_{xxx}(0, 0) \\ & + 3x^2 y f_{xxy}(0, 0) + 3xy^2 f_{xyy}(0, 0) \end{aligned}$$

$$+ y^3 f_{yyy}(0, 0) \Big] + \dots \quad (10)$$

Thus the Maclaurin's series expansion of $f(x, y)$ given by (10) is a series of powers of x and y .

WORKED OUT EXAMPLES

Example 1: Use Taylor's theorem to expand $f(x, y) = x^2 + xy + y^2$ in powers of $(x - 1)$ and $(y - 2)$.

Solution: Differentiating $f(x, y) = x^2 + xy + y^2$ partially w.r.t. x and y , we get

$$f_x = 2x + y, \quad f_y = x + 2y, \quad f_{xy} = 1, \quad f_{xx} = 2, \quad f_{yy} = 2, \\ f_{xxx} = 0, \quad f_{xxy} = 0, \quad f_{yyx} = 0, \quad f_{yyy} = 0$$

The Taylor's series expansion of $f(x, y)$ in powers of $(x - 1)$ and $(y - 2)$ is

$$f(x, y) = f(1, 2) + [(x - 1)f_x(1, 2) \\ + (y - 2)f_y(1, 2)] + \frac{1}{2!} \left[(x - 1)^2 f_{xx}(1, 2) \right. \\ + 2(x - 1)(y - 2)f_{xy}(1, 2) + (y - 2)^2 f_{yy}(1, 2) \Big] \\ + \frac{1}{3!} \left[(x - 1)^3 f_{xxx}(1, 2) \right. \\ + 3(x - 1)^2(y - 2)f_{xxy}(1, 2) \\ + 3(x - 1)(y - 2)^2 f_{yyx}(1, 2) \\ + (y - 2)^3 f_{yyy}(1, 2) \Big] + \dots$$

Here, $f(1, 2) = 7$, $f_x(1, 2) = 4$, $f_y(1, 2) = 5$, $f_{xy}(1, 2) = 1$, $f_{xx} = f_{yy} = 2$, etc.
Substituting these values

$$f(x, y) = 7 + 4(x - 1) + 5(y - 2) + \frac{1}{2!} \left[2(x - 1)^2 \right. \\ + 2(x - 1)(y - 2) + 2(y - 2)^2 \Big] + 0 + \dots$$

Example 2: Expand $f(x, y) = e^{x+y}$ in Taylor's series up to terms of second degree in the form $a_0 + b_1x + b_2y + c_1x^2 + c_2xy + c_3y^2 + \dots$

- by direct use of Taylor's theorem
- by expanding e^{x+y} in a series of powers of $x + y$
- by multiplying together the separate expansions of e^x and e^y .

Solution:

- a. $f = e^{x+y}$, $f_x = e^{x+y}$, $f_y = e^{x+y}$, $f_{xx} = e^{x+y}$, $f_{yy} = e^{x+y}$, $f_{xy} = e^{x+y}$ etc. Since the series in powers of x and y , the expansion is about $(0, 0)$ (i.e., Maclaurin's series) so $f = f_x = f_y = f_{xx} = f_{yy} = f_{xy}$ at $(0, 0) = 1$.

By Taylor's theorem

$$e^{x+y} = 1 + x + y + \frac{x^2 + 2xy + y^2}{2!} + \dots$$

- b. Expanding in powers of $x + y$

$$e^{x+y} = \sum_{n=0}^{\infty} \frac{(x+y)^n}{n!} = 1 + (x+y) \\ + \frac{(x+y)^2}{2!} + \frac{(x+y)^3}{3!} + \dots$$

- c. Termwise series multiplication

$$e^{x+y} = e^x \cdot e^y = \left(\sum_{n=0}^{\infty} \frac{x^n}{n!} \right) \left(\sum_{n=0}^{\infty} \frac{y^n}{n!} \right) \\ = \left(1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots \right) \\ \left(1 + y + \frac{y^2}{2!} + \frac{y^3}{3!} + \dots \right) \\ = 1 + (x+y) + \frac{x^2}{2!} + xy + \frac{y^2}{2!} + \dots$$

Example 3: Expand $f(x, y) = e^y \ln(1+x)$ in powers of x and y and verify the result by direct expansion.

Solution: $f = e^y \ln(1+x)$

$$f_x = e^y \frac{1}{1+x}, \quad f_y = e^y \ln(1+x), \quad f_{xy} = \frac{e^y}{1+x} \\ f_{xx} = \frac{-e^y}{(1+x)^2}, \quad f_{yy} = e^y \ln(1+x), \\ f_{xxx} = \frac{2e^y}{(1+x)^3}, \quad f_{yyy} = e^y \ln(1+x), \\ f_{xxy} = \frac{-e^y}{(1+x)^2}, \quad f_{yyx} = \frac{e^y}{1+x}$$

Evaluating these derivations at $x = 0, y = 0$,

$$f(0, 0) = 0, \quad f_x(0, 0) = 1, \quad f_y(0, 0) = 0, \quad f_{xy} = 1 \\ f_{xx}(0, 0) = -1, \quad f_{yy}(0, 0) = 0, \quad f_{xxx}(0, 0) = 2$$

4.4 — HIGHER ENGINEERING MATHEMATICS—II

$$f_{yyy}(0, 0) = 0, \quad f_{xxy}(0, 0) = -1, \quad f_{yyx}(0, 0) = 1$$

The Taylor's series expansion up to 3rd degree terms is

$$\begin{aligned} e^y \ln(1+x) &= f(0, 0) + x f_x(0, 0) + y f_y(0, 0) \\ &\quad + \frac{1}{2!} [x^2 f_{xx}(0, 0) + 2xy f_{xy}(0, 0) \\ &\quad + y^2 f_{yy}(0, 0)] + \frac{1}{3!} [x^3 f_{xxx}(0, 0) \\ &\quad + 3x^2 y f_{xxy}(0, 0) + 3xy^2 f_{yyx}(0, 0) \\ &\quad + y^3 f_{yyy}(0, 0)] + \dots \\ &= 0 + x \cdot 1 + 0 + \frac{1}{2!} [-x^2 + 2.1 \cdot xy + 0] \\ &\quad + \frac{1}{3!} [2x^3 - 3x^2 y + 3xy^2 + 0] \\ &= x - \frac{x^2}{2} + xy + \frac{x^3}{3} - \frac{x^2 y}{2} + \frac{xy^2}{2} + \dots \end{aligned}$$

Verification by series multiplication:

we know that $e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!}$ and

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \dots$$

$$\begin{aligned} \text{so } e^y \ln(1+x) &= \left(1 + y + \frac{y^2}{2!} + \frac{y^3}{3!} + \dots\right) \\ &\quad \times \left(x - \frac{x^2}{2} + \frac{x^3}{3} - \dots\right) \end{aligned}$$

Multiplying term by term up to 3rd degree

$$e^y \ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} + xy - \frac{x^2 y}{2} + \frac{xy^2}{2} + \dots$$

Example 4: Find Taylor's expansion of $f(x, y) = \cot^{-1} xy$ in powers of $(x + 0.5)$ and $(y - 2)$ up to second degree terms. Hence compute $f(-0.4, 2.2)$ approximately.

Solution: Here $f(x, y) = \cot^{-1} xy$

$$\begin{aligned} f_x &= \frac{-y}{1+x^2 y^2}, \quad f_y = \frac{-x}{1+x^2 y^2}, \\ f_{xx} &= \frac{2xy^3}{(1+x^2 y^2)^2}, \quad f_{yy} = \frac{2x^3 y}{(1+x^2 y^2)^2}, \\ f_{xy} &= \frac{(x^2 y^2 - 1)}{(1+x^2 y^2)^2} \end{aligned}$$

Evaluating these derivatives at the point $x = -\frac{1}{2}$, $y = 2$

$$\begin{aligned} f(x, y) &= \cot^{-1}(x, y) \text{ at } x = -\frac{1}{2}, y = 2, \\ f\left(-\frac{1}{2}, 2\right) &= \cot^{-1}\left(-\frac{1}{2} \cdot 2\right) = \cot^{-1}(-1) = \frac{3\pi}{4} \\ f_x &= -1, f_y = \frac{1}{4}, f_{xy} = 0 \\ f_{xx} &= -2, f_{yy} = -\frac{1}{8} \end{aligned}$$

Expanding $\cot^{-1} xy$ in Taylor's series in powers of $(x + 0.5)$ and $(y - 2)$, we get

$$\begin{aligned} f(x, y) &= \cot^{-1} xy = f(-0.5, 2) + (x + 0.5)f_x(-0.5, 2) \\ &\quad + (y - 2)f_y(-0.5, 2) + \frac{1}{2!} [(x + 0.5)^2 \times \\ &\quad f_{xx}(-0.5, 2) + 2(x + 0.5)(y - 2) \times \\ &\quad f_{xy}(-0.5, 2) + (y - 2)^2 f_{yy}(-0.5, 2)] + \dots \\ &= \frac{3\pi}{4} - (x + 0.5) + \frac{y - 2}{4} + \frac{1}{2} [-2(x + 0.5)^2 \\ &\quad - \frac{1}{8}(y - 2)^2] + \dots \end{aligned}$$

Put $x = -0.4$ and $y = 2.2$ to compute

$$\begin{aligned} \cot^{-1}((-0.4), (2.2)) &= f(-0.4, 2.2) \\ &= \frac{3\pi}{4} - (0.1) + \frac{2}{4} \\ &\quad - (0.1)^2 - \frac{1}{16} (0.2)^2 \\ &= 2.29369. \end{aligned}$$

EXERCISE

1. Expand $f(x, y) = x^3 + y^3 + xy^2$ in powers of $(x - 1)$ and $(y - 2)$ using Taylor's series.
Ans. $13 + 7(x - 1) + 16(y - 2) + 3(x - 1)^2 + 4(x - 1)(y - 2) + 7(y - 2)^2 + (x - 1)^3 + (x - 1) \cdot (y - 2)^2 + (y - 2)^3$
2. Obtain Taylor's expansion of $(1 + x - y)^{-1}$ in powers of $(x - 1)$ and $(y - 1)$.
Ans. $1 - x + y + x^2 - 2xy + y^2 + \dots$
3. Expand $\cos x \cos y$ in powers of x and y up to fourth degree terms
Ans. $1 - \frac{1}{2}(x^2 + y^2) + \frac{1}{24}(x^4 + 6x^2 y^2 + y^4) + \dots$

4. Obtain the expansion of e^{xy} in powers of $(x-1)$ and $(y-1)$.

$$\text{Ans. } e \left[1 + (x-1) + (y-1) + \frac{(x-1)^2}{2!} + (x-1)(y-1) + \frac{(y-1)^2}{2!} + \dots \right]$$

5. Find the Taylor's expansion of $e^x \cos y$ about the point $x = 1, y = \frac{\pi}{4}$.

$$\text{Ans. } \frac{e}{\sqrt{2}} \left[1 + (x-1) - \left(y - \frac{\pi}{4}\right) + \frac{(x-1)^2}{2!} - (x-1)\left(y - \frac{\pi}{4}\right) - \frac{\left(y - \frac{\pi}{4}\right)^2}{2!} + \dots \right]$$

6. Find the Maclaurin's expansion of $e^x \ln(1+y)$ up to terms of 3rd degree.

$$\text{Ans. } y + xy - \frac{y^2}{2} + \frac{(x^2y - xy^2)}{2} + \frac{y^3}{3} + \dots$$

7. Expand $e^{ax} \sin by$ about origin up to 3rd degree terms

$$\text{Ans. } (by + abxy) + \frac{1}{6}(3a^2bx^2y - b^3y^3) + \dots$$

8. Find Taylor's expansion of x^y about $(1, 1)$.

$$\text{Ans. } 1 + (x-1) + (x-1)(y-1) + \frac{1}{2}(x-1)^2 + \dots$$

9. Expand $(xy + hk + hy + xk)/(x + y + h + k)$ in powers of h and k up to second degree terms.

Hint: Take $f(x, y) = \frac{xy}{x+y}$.

$$\text{Ans. } \frac{xy}{x+y} + \frac{y^2}{(x+y)^3}h + \frac{x^2}{(x+y)^3}k - \frac{y^2}{(x+y)^3}h^2 + \frac{2xy}{(x+y)^3}hk - \frac{x^2}{(x+y)^3}k^2 + \dots$$

10. Calculate $\ln \left[(1.03)^{\frac{1}{3}} + (0.98)^{\frac{1}{4}} - 1 \right]$ approximately by using Taylor's expansion up to first order terms.

Hint: Take $f(x, y) = \ln \left[x^{\frac{1}{3}} + y^{\frac{1}{4}} - 1 \right]$ and expand $f(x+h, y+k)$ in powers of h and k . Choose $x = 1, y = 1, h = 0.03, k = -0.02$.

$$\text{Ans. } 0.005$$

11. Compute $\tan^{-1}(0.9/1.1)$ approximately.

Hint: Take $f(x, y) = \tan^{-1}(y/x)$, expand in Taylor's series about $(1, 1)$ $\tan^{-1}(y/x) = \frac{\pi}{4} - \frac{1}{2}(x-1) + \frac{1}{2}(y-1) + \frac{1}{4}(x-1)^2 - \frac{1}{4}(y-1)^2$. Now put $x = 1.1$ and $y = 0.9$.

$$\text{Ans. } 0.6904$$

12. Find Taylor's expansion of $\sqrt{1+x+y^2}$ in powers of $(x-1)$ and $(y-0)$.

$$\text{Ans. } \sqrt{2} \left[1 + \frac{x-1}{4} - \frac{(x-1)^2}{32} + \frac{y^2}{4} + \dots \right]$$

4.2 MAXIMA AND MINIMA OF FUNCTIONS OF TWO VARIABLES: WITH AND WITHOUT CONSTRAINTS

Let $z = f(x, y)$ be a function of two independent variables x and y .

Relative maximum: $f(x, y)$ is said to have a relative maximum at a point (a, b) if

$$f(a, b) > f(a+h, b+k)$$

for small positive or negative values of h and k i.e., $f(a, b)$ the value of the function f at (a, b) is greater than the value of the function f at all points in some small neighbourhood of (a, b) .

Relative minimum is similarly defined. $f(x, y)$ has a relative minimum at (a, b) if

$$f(a, b) < f(a+h, b+k).$$

Denote $[f(a+h, b+k) - f(a, b)]$ by $\Delta f(a, b)$ or simply by Δ

$$\text{i.e., } \Delta = f(a+h, b+k) - f(a, b)$$

then f has a maximum at (a, b) if Δ has the same negative sign for all small values of h, k ; i.e., $\Delta < 0$ a minimum at (a, b) if Δ has the same positive sign

$$\text{i.e., } \Delta > 0.$$

Extremum is a point which is either a maximum or minimum. The value of the function f at an extremum (maximum or minimum) point is known as the extremum (maximum or minimum) value of the function f .

Geometrically, $z = f(x, y)$ represents a surface. The maximum is a point on the surface (hill top) from which the surface descends (comes down) in every direction towards the xy -plane (see Fig. 4.1). The minimum is the bottom of depression from which the surface ascends (climbs up) in every direction (refer Fig. 4.1). In either case, the tangent planes to the surface at a maximum or minimum point is horizontal (parallel to xy -plane) and perpendicular to z -axis.

Fig. 4.1

Saddle point or minimax is a point where function is neither maximum nor minimum. At such point f is maximum in one direction while minimum in another direction.

Geometrically such a surface (looks like the leather seat on back of a horse) (Fig. 4.2) forms a ridge rising in one direction and falling in another direction.

Fig. 4.2

Example: $z = xy$, hyperbolic paraboloid has a saddle point at the origin.

Necessary and Sufficient Conditions for Extrema of a Function f of Two Variables

By Taylor's theorem,

$$f(a + h, b + k) = f(a, b) + [hf_x(a, b) + kf_y(a, b)]$$

$$+ \frac{1}{2!} [h^2 f_{xx}(a, b) + 2hk f_{xy}(a, b) + k^2 f_{yy}(a, b)] + \dots \quad (1)$$

Neglecting higher order terms of h^2 , hk , k^2 , etc. since h, k are small, the above expansion reduces to

$$\Delta = [f(a + h, b + k) - f(a, b)] = hf_x(a, b) + kf_y(a, b) \quad (2)$$

The necessary condition that Δ has the same positive or same negative sign is when $f_x(a, b) = 0$ and $f_y(a, b) = 0$ (even though h and k can take both positive and negative values).

With $f_x(a, b) = 0$ and $f_y(a, b) = 0$, expansion (1), neglecting higher order terms h^3 , k^3 , h^2k etc. reduces to

$$\Delta = \frac{1}{2!} [h^2 f_{xx}(a, b) + 2hk f_{xy}(a, b) + k^2 f_{yy}(a, b)] \quad (3)$$

Denote $f_{xx}(a, b) = r$, $f_{yy}(a, b) = t$, $f_{xy}(a, b) = s$.

From (3) we observe that the nature of sign of Δ depends on the nature of sign of $h^2r + 2hks + k^2t$.

Rewriting

sign of $\Delta = \text{sign of } (h^2r + 2hks + k^2t)$

$$= \text{sign of } \left(\frac{h^2r^2 + 2hkr s + k^2tr}{r} \right) = \text{sign of } \left\{ \frac{(hr + ks)^2 + k^2(rt - s^2)}{r} \right\} \quad (4)$$

If $rt - s^2 > 0$ then the numerator in R.H.S. of (4) is positive. In that case sign of $\Delta = \text{sign of } r$.

Thus $\Delta < 0$ if $rt - s^2 > 0$ and $r < 0$

and $\Delta > 0$ if $rt - s^2 > 0$ and $r > 0$.

Therefore the sufficient (Lagrange's) conditions for extrema are:

- I. f attains (has) a **maximum** at (a, b) if $rt - s^2 > 0$ and $r < 0$.
- II. f attains a **minimum** at (a, b) if $rt - s^2 > 0$ and $r > 0$.
- III. **Saddle point:** If $rt - s^2 < 0$ then $\Delta > 0$ or < 0 depending on h and k . Therefore f has a saddle point (minimax) at (a, b) if

$$rt - s^2 < 0$$

IV. Failure case: If $rt - s^2 = 0$, further investigation is needed to determine the nature of function f .

Method of Finding Extrema of $f(x, y)$

1. Solving $f_x = 0$ and $f_y = 0$ yields **critical or stationary point** P of f .
2. Calculate $r = f_{xx}$, $s = f_{xy}$, $t = f_{yy}$ at the critical point P.
3. **a.** Maximum: If $rt - s^2 > 0$ and $r < 0$ then f has a maximum at P.
b. Minimum: If $rt - s^2 > 0$ and $r > 0$ then f has a minimum at P.
c. Saddle point: If $rt - s^2 < 0$ then f has neither maximum nor minimum.
d. Failure case: If $rt - s^2 = 0$, further investigation needed.

Note: Extrema occur only at stationary points. However stationary points need not be extrema.

Examples

- a.** $f = 1 - x^2 - y^2$, $f_x = -2x$, $f_y = -2y$
 $\therefore$ Stationary point $(0, 0)$, $r = r_{xx} = -2$, $t = f_{yy} = -2$, $s = 0$ so $rt - s^2 = (-2)(-2) - 0 = 4 > 0$ and $r = -2 < 0$. $(0, 0)$ is maximum point of f and the maximum value of f is 1.
- b.** $f = x^2 + y^2$, $f_x = 2x$, $f_y = 2y$, $f_{xx} = 2$, $f_{yy} = 2$, $f_{xy} = 0$ $\therefore$ stationary point $(0, 0)$.
 $rt - s^2 = 2 \cdot 2 - 0 = 4 > 0$ and $r = 2 > 0$. $(0, 0)$ is a minimum point of f and the minimum value of f is 0.
- c.** $f = xy$; $f_x = y$, $f_y = x$, $f_{xx} = 0$, $f_{yy} = 0$, $f_{xy} = 1$ $\therefore$ stationary point $(0, 0)$.

$$rt - s^2 = 0 \cdot 0 - 1 = -1 < 0$$

So $(0, 0)$ is a saddle point of f

- d. i.** $f = 1 - x^2y^2$,
 $f_x = -2xy^2$, $f_y = -2x^2y$
 $\therefore$ stationary point $(0, 0)$
 $f_{xx} = -2y^2$, $f_{yy} = -2x^2$, $f_{xy} = -4xy$
 At stationary point $(0, 0)$, $f_{xx} = f_{yy} = f_{xy} = 0$

By inspection f has a maximum at $(0, 0)$.

- ii.** $f = x^2y^2$, $f_x = 2xy^2$, $f_y = 2x^2y$,
 $\therefore$ stationary point $(0, 0)$, $f_{xx} = 2y^2$, $f_{yy} = 2x^2$, $f_{xy} = 4xy$
 At stationary point $(0, 0)$, $f_{xx} = f_{yy} = f_{xy} = 0$
 However observe that f has a minimum at $(0, 0)$.
- iii.** $f = x^3y^2$, $f_x = 3x^2y^2$, $f_y = 2x^3y$
 $\therefore$ stationary point $(0, 0)$
 $f_{xx} = 6xy^2$, $f_{yy} = 2x^3$, $f_{xy} = 6x^2y$
 At stationary point $(0, 0)$, $f_{xx} = f_{yy} = f_{xy} = 0$.
 Note that $(0, 0)$ is a saddle point.

WORKED OUT EXAMPLES

Example 1: Find the maximum and minimum values of $f(x, y) = x^3 + 3xy^2 - 15x^2 - 15y^2 + 72x$.

Solution: Differentiating f partially w.r.t. x and y ,

$$f_x = \frac{\partial f}{\partial x} = 3x^2 + 3y^2 - 30x + 72$$

$$f_y = \frac{\partial f}{\partial y} = 6xy - 30y$$

The stationary (critical) points are given by $f_x = 0$ and $f_y = 0$
 From

$$f_y = 6xy - 30y = 0$$

$$\text{so } 6y(x - 5) = 0$$

Thus either $y = 0$ or $x = 5$

Since $f_x = 3x^2 + 3y^2 - 30x + 72 = 0$,

$$\text{for } y = 0, 3x^2 - 30x + 72 = 0$$

$$\text{so } x = 6 \text{ or } 4$$

$$\text{for } x = 5, 75 + 3y^2 - 150 + 72 = 0$$

$$\text{so } y = \pm 1$$

Thus the four stationary points are given by

$$(6, 0), (4, 0), (5, 1), (5, -1)$$

To determine the nature of these points, calculate

4.8 — HIGHER ENGINEERING MATHEMATICS—II

f_{xx} , f_{yy} and f_{xy}

$f_{xx} = A = 6x - 30$, $f_{xy} = B = 6y$, $C = f_{yy} = 6x - 30$
so $AC - B^2 = (6x - 30)^2 - 36y^2 = 36\{(x - 5)^2 - y^2\}$

- i. At the stationary point (6, 0), we have $A = 36 - 30 = 6 > 0$ and $AC - B^2 = 36 > 0$. So (6, 0) is a minimum point of the given function f and the minimum value of f at (6, 0) is $6^3 + 0 - 15.36 + 72.6 = 108$.
- ii. At (4, 0) : $A = 24 - 30 = -6 < 0$ and $AC - B^2 = 36 > 0$. So a maximum occurs at the point (4, 0) and the maximum value of f at (4, 0) is 112.
- iii. At (5, 1), $A = 0$, $AC - B^2 = -36 < 0$. (5, 1) is a saddle point (it is neither maximum nor minimum).
- iv. At (5, -1), $A = 0$, $AC = B^2 = -36 < 0$. So (5, -1) is neither a maximum nor a minimum (it is a saddle point).

Example 2: Find the shortest distance from origin to the surface $xyz^2 = 2$.

Solution: Let d be the distance from origin (0, 0, 0) to any point (x, y, z) of the given surface then

$$d = \sqrt{(x - 0)^2 + (y - 0)^2 + (z - 0)^2}$$

or $d^2 = x^2 + y^2 + z^2$

Eliminate z^2 using the equation of the surface $xyz^2 = 2$. So replace z^2 by $\frac{2}{xy}$

$$\therefore d^2 = x^2 + y^2 + \frac{2}{xy} = f(x, y)$$

$$f_x = 2x - \frac{2}{x^2y}, f_y = 2y - \frac{2}{xy^2}.$$

Solving $f_x = 0$ and $f_y = 0$, we get

$$\frac{x^3y - 1}{x^2y} = 0 \text{ and } \frac{xy^3 - 1}{xy^2} = 0$$

$$x^3y = 1 = xy^3 \text{ or } xy(x^2 - y^2) = 0$$

since $x \neq 0$, $y \neq 0$, so $x = \pm y = 1$

Thus the two stationary points are (1, 1) and (-1, -1)

$$f_{xx} = 2 + \frac{4}{x^3y}, f_{yy} = 2 + \frac{4}{xy^3}, f_{xy} = \frac{2}{x^2y^2}$$

At (1, 1) : $f_{xx} = 6 > 0$, $f_{xx} \cdot f_{yy} - f_{xy}^2 = 6 \cdot 6 - 4 = 32 > 0$

At (-1, -1), $f_{xx} = +6$, $f_{xx}f_{yy} - f_{xy}^2 = 32$

So minimum occurs at (1, 1, $\sqrt{2}$) and (-1, -1, $\sqrt{2}$). The shortest distance is $\sqrt{1^2 + 1^2 + (\sqrt{2})^2} = \sqrt{4} = 2$.

Example 3: The temperature T at any point (x, y, z) in space is $T(x, y, z) = kxyz^2$ where k is a constant. Find the highest temperature on the surface of the sphere

$$x^2 + y^2 + z^2 = a^2.$$

Solution: Eliminating the variable z , using $z^2 = a^2 - x^2 - y^2$, we get

$$T(x, y, z) = kxyz^2 = kxy(a^2 - x^2 - y^2) = F(x, y)$$

$$F_x = ky(a^2 - 3x^2 - y^2), F_y = kx(a^2 - x^2 - 3y^2)$$

The stationary points are given by $(x = 0, y = 0)$ or solution of

$$3x^2 + y^2 = a^2$$

$$x^2 + 3y^2 = a^2$$

Solving $x = y = \pm \frac{a}{2}$

$$F_{xx} = -6kxy, F_{yy} = -6kxy, F_{xy} = k(a^2 - 3x^2 - 3y^2)$$

$$\text{At } (0, 0), F_{xx} = 0 = F_{yy}, F_{xy} = ka^2$$

$\therefore 0 \cdot 0 - ka^2 < 0$ so (0, 0) is a saddle point.

At both the points $(\frac{a}{2}, \frac{a}{2})$ and $(-\frac{a}{2}, -\frac{a}{2})$, $F_{xx} = -6\frac{ka^2}{4} < 0$ and

$$F_{xx} \cdot F_{yy} - F_{xy}^2 = \frac{9}{4}k^2a^4 - \frac{a^4k^2}{4} = 2k^2a^4 > 0$$

$\therefore T$ attains a maximum value at both these points $(\frac{a}{2}, \frac{a}{2})$ and $(-\frac{a}{2}, -\frac{a}{2})$. The maximum value of T is $k \cdot \frac{a^2}{4} \left(\frac{a^2}{2}\right) = \frac{ka^4}{8}$.

Example 4: Find the shortest distance between the lines

$$\frac{x - 3}{1} = \frac{y - 5}{-2} = \frac{z - 7}{1} \quad (1)$$

$$\text{and } \frac{x + 1}{7} = \frac{y + 1}{-6} = \frac{z + 1}{1} \quad (2)$$

Solution: Equating each of the fractions of (1) to λ , we get $x = 3 + \lambda$, $y = 5 - 2\lambda$, $z = 7 + \lambda$. Thus

any point P on the first line (1) is given by

$$(3 + \lambda, 5 - 2\lambda, 7 + \lambda).$$

Similarly any point Q on the second line (2) is $(-1 + 7\mu, -1 - 6\mu, -1 + \mu)$.

The distance between the given two lines is

$$PQ = \sqrt{(3+\lambda+1-7\mu)^2 + (5-2\lambda+1+6\mu)^2 + (7+\lambda+1-\mu)^2}$$

Consider $f(\lambda, \mu) = (PQ)^2 = 6\lambda^2 + 86\mu^2 - 40\lambda\mu + 105$. The problem is to find minimum value of f as a function of the two variables λ, μ .

$$f_\lambda = 12\lambda - 40\mu, f_\mu = 172\mu - 40\lambda.$$

Solving $12\lambda - 40\mu = 0$ and $172\mu - 40\lambda = 0$, we get, $\lambda = 0, \mu = 0$ as the only stationary point

$$f_{\lambda\lambda} = 12, f_{\mu\mu} = 172, f_{\lambda\mu} = -40$$

$$\text{Now } f_{\lambda\lambda} \cdot f_{\mu\mu} - f_{\lambda\mu}^2 = (12) \cdot (172) - (-40)^2 > 0$$

Since $f_{\lambda\lambda} = 12 > 0$ and $f_{\lambda\lambda}f_{\mu\mu} - f_{\lambda\mu}^2 > 0$, a minimum occurs at $\lambda = 0, \mu = 0$. The minimum, (shortest) distance is given by

$$PQ = \sqrt{4^2 + 6^2 + 8^2} = \sqrt{116} = 2\sqrt{29}$$

EXERCISE

- Test the functions for maxima, minima and saddle points:

a. $x^4 + y^4 - x^2 - y^2 + 1$

b. $x^2 + 2y^2 + 3z^2 - 2xy - 2yz - 2$

Ans. a. maximum at (0,0)

maximum value is 1.

minima at four points $(\pm 1/\sqrt{2}, \pm 1/\sqrt{2})$

minimum value at these 4 points is $\frac{1}{2}$.

Saddle points at four points $(0, \pm 1/\sqrt{2})$, $(\pm 1/\sqrt{2}, 0)$

b. maximum at (1,1), minimum at (-1, -1)

- Find the extrema of $f(x, y)$:

$$(x^2 + y^2)e^{6x+2x^2}$$

Ans. minima at (0,0) (minimum value 0) and at $(-1, 0)$ (minimum value e^{-4}).

Saddle point at $(-\frac{1}{2}, 0)$

- Examine the following function $f(x, y)$ for extrema:

$$\sin x + \sin y + \sin(x + y)$$

Ans. Maximum at $(\pi/3, \pi/3)$, maximum value $\frac{3\sqrt{3}}{2}$.

- Find the shortest distance from the origin to the plane $x - 2y - 2z = 3$.

Ans. Shortest distance is 1 (from (0,0,0)) to the point $(\frac{1}{3}, -\frac{2}{3}, -\frac{2}{3})$ on the plane.

- Given $ax + by + cz = p$ find the minimum value of $x^2 + y^2 + z^2$.

Ans. $p^2/(a^2 + b^2 + c^2)$

- Find the shortest distance between the lines

$$\frac{x-2}{3} = \frac{y-6}{-2} = \frac{z-5}{-2}$$

$$\text{and } \frac{x-5}{2} = \frac{y-3}{1} = \frac{z-8}{6}.$$

Ans. Shortest distance is 3 between the points (5, 4, 3) and (3, 2, 2).

- If the perimeter of a triangle is constant, prove that the area of this triangle is maximum when the triangle is equilateral.

Hint: $2s = a + b + c$ where a, b, c are sides

$$\text{Area of } \Delta = \sqrt{s(s-a)(s-b)(s-c)}$$

Maximum when $a = b = c = \frac{2s}{3}$.

- Find the volume of the largest rectangular parallelepiped with edges parallel to the axes, that can be inscribed in the:

a. ellipsoid $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$

b. sphere

c. equation of ellipsoid is $4x^2 + 4y^2 + 9z^2 = 36$.

Ans. a. volume $\frac{8abc}{3\sqrt{3}}$, parallelepiped has dimensions

$$x = \frac{a}{\sqrt{3}}, y = \frac{b}{\sqrt{3}}, z = \frac{c}{\sqrt{3}}$$

b. special case $a = b = c$

$$\text{volume} : \frac{8a^3}{3\sqrt{3}}, x = y = z = \frac{a}{\sqrt{3}}$$

c. volume: $16\sqrt{3}$ (with $a = 3, b = 3, c = 2$)

- Show that the rectangular solid of maximum volume that can be inscribed in a sphere is a cube.

4.10 — HIGHER ENGINEERING MATHEMATICS—II

Hint: V be the volume of the rectangular solid with length, breadth and height x, y, z

$$V = xyz$$

diagonal of solid $= \sqrt{x^2 + y^2 + z^2} = d =$
diameter of sphere. Eliminate $z =$
 $\sqrt{d^2 - x^2 - y^2}$ so

$$v = xy\sqrt{d^2 - x^2 - y^2} = f(x, y).$$

10. Find the dimensions of a rectangular box, with open top, so that the total surface area of the box is a minimum, given that the volume of the box is constant say V .

Hint: $S = xy + 2xz + 2yz$, eliminate $z = \frac{V}{xy}$
where V is a given constant so that

$$S = xy + \frac{2V}{y} + \frac{2V}{x} = f(x, y).$$

Ans. $x = y = 2z = (2V)^{1/3}$

11. Find the dimensions of the rectangular box, with open top, of maximum capacity whose surface area is 432 sq. cm.

Ans. 12, 12, 6

12. If the total surface area of a closed rectangular box is 108 sq. cm, find the dimensions of the box having maximum capacity.

Ans. $\sqrt{18}, \sqrt{18}, \sqrt{18}$

13. An aquarium with rectangular sides and bottom (and no top) is to hold 32 litres. Find its dimensions so that it will use the least amount of material.

Hint: Work as Example 10 with $V = 32$.

Ans. 4, 4, 2.

4.3 LAGRANGE'S* METHOD OF UNDETERMINED MULTIPLIERS

In many practical and theoretical problems, it is required to find the maximum or minimum of a function of several variables, where the variables are connected by some given relation or condition

known as a constraint. Thus if $f(x, y, z)$ is a function of 3 independent variables, where x, y, z are related by a known constraint $g(x, y, z) = 0$, then the problem of constrained extrema consists of finding the

$$\text{Extrema of } u = f(x, y, z) \quad (1)$$

$$\text{subject to } g(x, y, z) = 0 \quad (2)$$

This problem can be solved by (a) elimination method (b) Implicit differentiation method (c) Lagrange's multiplier's method.

- a. In elimination method, the constraint (2) is solved for say one variable z in terms of the other variables x and y . Then z is eliminated from $f(x, y, z)$ resulting in a function of two variables x and y only. The disadvantage of this method is that many times, (2) may not be solvable and in case of solution also the amount of algebra will be generally enormous.

- b. In implicit differentiation method, no elimination of variables is done but derivatives are eliminated by calculating them through implicit differentiation. This method also suffers due to more labour involved.

- c. The very useful Lagrange's method of undetermined multiplier's introduces an additional unknown constant λ known as Lagrange multiplier. Since the stationary values occur when $f_x = f_y = f_z = 0$, so the total differential

$$df = f_x dx + f_y dy + f_z dz = 0 \quad (3)$$

Differential of the constraint (2) is

$$dg = g_x dx + g_y dy + g_z dz = 0 \quad (4)$$

Multiplying (4) by λ and adding to (3), we get

$$(f_x + \lambda g_x)dx + (f_y + \lambda g_y)dy + (f_z + \lambda g_z)dz = 0 \quad (5)$$

Since x, y, z are independent variables (5) implies that

$$f_x + \lambda g_x = 0 \quad (6)$$

$$f_y + \lambda g_y = 0 \quad (7)$$

$$f_z + \lambda g_z = 0 \quad (8)$$

Solving the four Equations (2), (6), (7), (8) for the four unknowns x, y, z, λ , we get the required stationary points of $f(x, y, z)$ subject to the

*Joseph Louis Lagrange (1736–1813).

constraint (2). Thus the method of Lagrange's multipliers consists of:

Step I. From the auxiliary equation

$$F(x, y, z) = f(x, y, z) + \lambda \phi(x, y, z) \quad (9)$$

Step II. Partially differentiate F in (9) w.r.t. x, y, z respectively

Step III. Solve the four equations

$$F_x = 0, F_y = 0, F_z = 0$$

and the constraint (2) for the Lagrange multiplier λ and stationary values x, y, z .

Advantages

1. The stationary value $f(x, y, z)$ can be determined from (2), (6), (7), (8) even without determining x, y, z explicitly.
2. This method can be extended to a function of several ' n ' variables $x_1, x_2, x_3, \dots, x_n$ and subject to many (more than one) ' m ' constraints by forming the auxiliary equation

$$F(x_1, x_2, \dots, x_n) = f(x_1, x_2, \dots, x_n) + \sum_{i=1}^m \lambda_i \phi_i(x_1, x_2, \dots, x_n).$$

The stationary values are obtained by solving the $n + m$ equations consisting of n equations $\frac{\partial F}{\partial x_i} = 0$, for $i = 1, 2, 3, \dots, n$ and the m constraint, $\phi_i = 0$ for $i = 1, 2, 3, \dots, m$.

Disadvantages

1. Nature of the stationary points can not be determined. Further investigation needed.
2. Equations (6), (7), (8) are only necessary conditions but not sufficient.

WORKED OUT EXAMPLES

Example 1: Find the maximum value of $x^m y^n z^p$ when $x + y + z = a$.

Solution: This is a constrained maximum problem where the function $f(x, y, z) = x^m y^n z^p$, subjected

to the constraint $x + y + z = a$. So consider the auxiliary function

$$F(x, y, z) = x^m y^n z^p + \lambda(x + y + z - a) \quad (1)$$

Differentiating (1) partially w.r.t. x, y, z and equating to zero we get

$$F_x = \frac{\partial F}{\partial x} = mx^{m-1} y^n z^p + \lambda = 0 \quad (2)$$

$$F_y = \frac{\partial F}{\partial y} = nx^m y^{n-1} z^p + \lambda = 0 \quad (3)$$

$$F_z = \frac{\partial F}{\partial z} = px^m y^n z^{p-1} + \lambda = 0 \quad (4)$$

Solving for x, y, z , $\frac{m}{x} f + \lambda = 0$ so $x = -\frac{mf}{\lambda}$.

Similarly $y = -\frac{nf}{\lambda}$ and $z = -\frac{pf}{\lambda}$.

Substituting these values of x, y, z in the given constraint, we have

$$x + y + z = -\left(\frac{m}{\lambda} + \frac{n}{\lambda} + \frac{p}{\lambda}\right) f = a$$

Solving, we get the value of λ as

$$\lambda = -\frac{(m + n + p)}{a} f.$$

Using this λ , we get

$$x = -\frac{mf}{\lambda} = -\frac{mf \cdot (-a)}{f(m + n + p)} = \frac{am}{m + n + p}$$

$$\text{Similarly } y = -\frac{nf}{\lambda} = \frac{an}{m + n + p}$$

$$\text{and } z = -\frac{pf}{\lambda} = \frac{ap}{m + n + p}$$

Thus the maximum value is

$$\begin{aligned} x^m y^n z^p &= \left(\frac{am}{m + n + p}\right)^m \left(\frac{an}{m + n + p}\right)^n \left(\frac{ap}{m + n + p}\right)^p \\ &= \frac{a^{m+n+p} \cdot m^m \cdot n^n \cdot p^p}{(m + n + p)^{m+n+p}}. \end{aligned}$$

Example 2: Find the maximum and minimum distances from the origin to the curve

$$3x^2 + 4xy + 6y^2 = 140.$$

Solution: The distance d from the origin $(0, 0)$ to any point (x, y) is given by

$$d^2 = x^2 + y^2 = f(x, y)$$

To find extrema of $f(x, y)$ subject to the condition that the point (x, y) lies on the curve $3x^2 + 4xy + 6y^2 = 140$.

4.12 — HIGHER ENGINEERING MATHEMATICS—II

So the auxiliary function is

$$F(x, y) = (x^2 + y^2) + \lambda(3x^2 + 4xy + 6y^2 - 140)$$

$$F_x = 2x + \lambda(6x + 4y) = 0,$$

$$F_y = 2y + \lambda(12y + 4x) = 0$$

Solving for $\lambda = -\frac{x}{(3x+2y)} = -\frac{y}{6y+2x}$

$$-\lambda = \frac{x^2}{3x^2 + 2xy} = \frac{y^2}{6y^2 + 2xy} = \frac{x^2 + y^2}{3x^2 + 4xy + 6y^2}$$

$$\therefore -\lambda = \frac{f}{140}$$

Substituting λ in $F_x = 0$ and $F_y = 0$, we get

$$(140 - 3f)x - 2fy = 0$$

$$-2fx + (140 - 6f)y = 0$$

This system has non-trivial solution if

$$\begin{vmatrix} 140 - 3f & -2f \\ -2f & (140 - 6f) \end{vmatrix} = 0$$

$$\text{i.e., } (140 - 3f)(140 - 6f) - 4f^2 = 0$$

$$14f^2 - 1260f + 140^2 = 0$$

$$f^2 - 90f - 1400 = 0$$

$$(f - 70)(f - 20) = 0$$

$$\therefore f = 70, 20$$

Thus the maximum and minimum distances are $\sqrt{70}, \sqrt{20}$.

Example 3: A wire of length b is cut into two parts which are bent in the form of a square and circle respectively. Find the least value of the sum of the areas so found.

Solution: Let x and y be two parts into which the given wire is cut so that $x + y = b$. Suppose the piece of wire of length x is bent into a square so that each side is $\frac{x}{4}$ and thus the area of the square is $\frac{x}{4} \cdot \frac{x}{4} = \frac{x^2}{16}$.

Suppose the wire of length y is bent into a circle with the perimeter y . So the area of this circle so formed is

$$\pi(\text{radius})^2 = \pi \left(\frac{y}{2\pi} \right)^2 = \frac{\pi y^2}{4\pi^2} = \frac{y^2}{4\pi}$$

Thus to find the minimum of the sum of the two areas subject to the constraint that sum is b . So the

auxiliary equation is

$$F(x, y) = \left(\frac{x^2}{16} + \frac{y^2}{4\pi} \right) + \lambda(x + y - b)$$

$$F_x = \frac{x}{8} + \lambda = 0, F_y = \frac{y}{2\pi} + \lambda = 0$$

Solving $x = -8\lambda, y = -2\pi\lambda$.

Substituting these values in the constraint $x + y = b$

$$\therefore -8\lambda - 2\pi\lambda = b$$

$$\text{Thus } x^* = -8\lambda = \frac{8b}{8+2\pi}, y^* = -2\pi\lambda = \frac{2\pi b}{8+2\pi}$$

The least value of the sum of the areas of the square and circle is

$$\begin{aligned} f(x, y) &= \frac{x^2}{16} + \frac{y^2}{4\pi} \Big|_{x^*, y^*} = \frac{64b^2}{16(8+2\pi)^2} + \frac{4\pi^2 b^2}{(8+2\pi)^2} \\ &= \frac{b^2(\pi+4)}{4(\pi+4)^2} = \frac{b^2}{4(\pi+4)}. \end{aligned}$$

Example 4: Find the dimensions of a rectangular box of maximum capacity whose surface area is given when (a) box is open at the top (b) box is closed.

Solution: Let x, y, z be the dimensions of the rectangular box so that its volume V is

$$V = xyz \quad (1)$$

The total surface area of the box is

$$nxy + 2yz + 2zx = S = \text{given constant} \quad (2)$$

Here $n = 1$, the box is open at the top

$n = 2$, the box is closed (on all sides)

The constrained maximum problem is to maximize V subject to constraint (2).

So the auxiliary function is

$$F(x, y, z) = xyz + \lambda(nxy + 2yz + 2zx - S) \quad (3)$$

$$F_x = yz + \lambda(ny + 2z) = 0 \quad (4)$$

$$F_y = xz + \lambda(nx + 2z) = 0 \quad (5)$$

$$F_z = xy + \lambda(2y + 2x) = 0 \quad (6)$$

Multiplying (4), (5), (6) by x, y, z respectively and adding, we get

$$3xyz + \lambda[2(nxy + 2yz + 2zx)] = 0$$

or $3 \cdot V + 2\lambda \cdot S = 0$ using (1) and (2)

$$\text{solving, } \lambda = -\frac{3V}{2S} \quad (7)$$

Substituting value of λ from (7) in (4), (5), (6)

$$yz - \frac{3V}{2S}(ny + 2z) = 0 \text{ or } yz - \frac{3xyz}{2S}(ny + 2z) = 0$$

$$nxy + 2xz = \frac{2S}{3} \quad (8)$$

$$\text{Similarly } nxy + 2yz = \frac{2S}{3} \quad (9)$$

$$2yz + 2zx = \frac{2S}{3} \quad (10)$$

$$\text{From (8) - (9), } x = y \quad (11)$$

$$\text{From (9) - (10), } ny = 2z \quad (12)$$

Substituting (11) and (12) in the given constraint (2)

$$n \cdot x \cdot x + 4x \frac{nx}{2} = S \quad \therefore 3nx^2 = S$$

$$\therefore x^2 = \frac{S}{3n}$$

a. When box is open at the top $n = 1$

$$\therefore x^2 = \frac{S}{3} \text{ or } x = \sqrt{\frac{S}{3}}$$

The dimensions of the open top box are

$$x = y = \sqrt{\frac{S}{3}}, \quad z = \frac{1}{2}\sqrt{\frac{S}{3}}$$

b. When the box is closed: $n = 2$

$$x^2 = \frac{S}{6} \text{ or } x = \sqrt{\frac{S}{6}}, \quad x = y = z$$

The dimensions are

$$x = y = z = \sqrt{\frac{S}{6}}$$

Example 5: Suppose a closed rectangular box has length twice its breadth and has constant volume V . Determine the dimensions of the box requiring least surface area (sheet metal).

Solution: Let x be the breadth so that the length is $2x$ and y be the height of the closed rectangular box. Its volume is $x \cdot 2x \cdot y = 2x^2y = V$ (given). The surface area (6 faces) S is given by

$$S = 2(2x \cdot x) + 2(2x \cdot y) + 2(x \cdot y) = 4x^2 + 6xy$$

Thus the problem is to minimize

$$f(x, y) = 4x^2 + 6xy \quad (1)$$

Subject to the condition that

$$x^2y = \frac{V}{2} \text{ (known)} \quad (2)$$

The auxiliary function is

$$F(x, y) = 4x^2 + 6xy + \lambda \left(x^2y - \frac{V}{2} \right) \quad (3)$$

Differentiating (3) w.r.t. x and y and equating to zero, we get

$$F_x = 8x + 6y + 2\lambda xy = 0 \quad (4)$$

$$F_y = 6x + \lambda x^2 = 0 \quad (5)$$

$$\text{Solving (5), } \lambda = -\frac{6}{x} \text{ or } x = -\frac{6}{\lambda} \quad (6)$$

Substituting x from (6) in (4), we get

$$\frac{-48}{\lambda} + 6y - 12y = 0 \text{ or } y = -\frac{8}{\lambda} \quad (7)$$

Substituting (6) and (7) in (2), we have

$$\lambda^3 = -\frac{576}{V} \text{ or } \lambda = -\left(\frac{576}{V}\right)^{\frac{1}{3}} \quad (8)$$

using (8); from (6) and (7), we get

$$x = \frac{-6}{\lambda} = 6 \cdot \left(\frac{V}{576}\right)^{\frac{1}{3}} = \left(\frac{3V}{8}\right)^{\frac{1}{3}} \quad (9)$$

$$y = \frac{-8}{\lambda} = 8 \left(\frac{V}{576}\right)^{\frac{1}{3}} = \left(\frac{8V}{9}\right)^{\frac{1}{3}} \quad (10)$$

The least surface area with these dimensions (9) (10) is

$$S = 4x^2 + 6xy = 4 \cdot \left(\frac{3V}{8}\right)^{\frac{2}{3}} + 6 \cdot \left(\frac{3V}{8}\right)^{\frac{1}{3}} \left(\frac{8V}{9}\right)^{\frac{1}{3}}$$

On simplification

$$S = (3^5 V^2)^{\frac{1}{3}} = (243 V^2)^{\frac{1}{3}}$$

EXERCISE

- Find the extremum values of $\sqrt{x^2 + y^2}$ when $13x^2 - 10xy + 13y^2 = 72$.

Ans. maximum 3, minimum 2

4.14 — HIGHER ENGINEERING MATHEMATICS—II

2. Find the minimum value of $x^2 + y^2 + z^2$ subject to the condition $\frac{1}{x} + \frac{1}{y} + \frac{1}{z}$.

Ans. minimum is 27

3. Divide 24 into three parts such that the continued product of the first, square of the second and the cube of the third may be maximum.

Ans. 4, 8, 12, maximum value: $4 \cdot 8^2 \cdot 12^3$

4. Determine the perpendicular distance of the point (a, b, c) from the plane $lx + my + nz = 0$ by the Lagrange's method.

Ans. minimum distance = $\frac{la+mb+nc}{\sqrt{l^2+m^2+n^2}}$

5. Determine the point in the plane $3x - 4y + 5z = 50$ nearest to the origin.

Ans. (3, -4, 5)

6. Find the maximum and minimum distances of the point (3, 4, 12) from the unit sphere with centre at origin.

Hint:

$$F = (x - 3)^2 + (y - 4)^2 + (z - 12)^2 + \lambda(x^2 + y^2 + z^2 - 1),$$

$$x = \frac{3}{1 \pm \sqrt{f}}, y = \frac{4}{1 \pm \sqrt{f}}, z = \frac{12}{1 \pm \sqrt{f}}$$

$$\text{where } f = (x - 3)^2 + (y - 4)^2 + (z - 12)^2.$$

Ans. maximum 14 and minimum 12

7. Determine the point on the paraboloid $z = x^2 + y^2$ which is closest to the point (3, -6, 4).

Ans. (1, -2, 6)

8. a. Find the dimensions of the rectangular box, without top, of maximum capacity whose surface is 108 sq. cm.

- b. What are the dimensions when the box is closed (on all sides).

Ans. a. 6, 6, 3 maximum capacity (volume) = $6 \cdot 6 \cdot 3 = 108$

b. $\sqrt{18}, \sqrt{18}, \sqrt{18}$

9. a. If the surface of a rectangular box, with open top, is 432 sq. cm, find the dimensions of the box having maximum capacity (volume).

- b. If the box is closed (on all sides) what are the dimensions.

Ans. a. 12, 12, 6 for open top box

b. $\sqrt{72}, \sqrt{72}, \sqrt{72}$ for closed box

10. Find the length and breadth of a rectangle of maximum area that can be inscribed in the ellipse $4x^2 + 9y^2 = 36$.

Ans. length = $3\sqrt{2}/2$, breadth: $\sqrt{2}$, maximum area of the rectangle is 12

11. Find the volume of the largest rectangular parallelepiped that can be inscribed in the ellipsoid of revolution $4x^2 + 4y^2 + 9z^2 = 36$.

Ans. maximum volume of rectangular parallelepiped $16\sqrt{3}$

12. Find the dimensions of a rectangular box, with open top, of given capacity (volume) such that the sheet metal (surface area) required is least.

Hint: Auxiliary function.

$$F(x, y, z) = xy + 2xz + 2yz + \lambda(xyz - V).$$

Ans. $x = y = 2z = (2V)^{\frac{1}{3}}$ where V = Volume of the box (given).

Chapter 5

Curve Tracing

INTRODUCTION

Curve tracing is an analytical method of drawing an approximate shape of a curve by the study of some of its important characteristics such as symmetry, intercepts, asymptotes, tangents, multiple points, region of existence, sign of the first and second derivatives. Knowledge of curve tracing is useful in application of integration in finding length, area, volume etc. In this chapter, we study tracing of standard and other curves in the (a) cartesian (b) polar and (c) parametric form.

5.1 CURVE TRACING : CURVES IN CARTESIAN FORM

Plane algebraic curve of n th degree is represented by

$$f(x, y) = ay^n + (bx + c)y^{n-1} + (dx^2 + ex + f)y^{n-2} + \dots + u_n(x) = 0 \quad (1)$$

where $a, b, c, d, e, f \dots$ are all constants and $u_n(x)$ is a polynomial in x of degree n .

General procedure for tracing the algebraic curve (1) consists of the study of the following characteristics of the curve.

Symmetry

A plane algebraic curve (1) is

- a. **Symmetric about x -axis:** if only even powers of y occur in (1) i.e., if y is replaced by $-y$ in (1), the Equation (1) remains unaltered or in other words

$$f(x, -y) = f(x, y).$$

Example: $y^2 = 4ax$ (see Fig. 5.1).

Fig. 5.1

- b. **Symmetric about y -axis:** if only even powers of x appear in (1) i.e., $f(-x, y) = f(x, y)$.

Example: $x^2 = 4ay$ (refer Fig. 5.2).

Fig. 5.2

- c. **Symmetric about both x - and y -axes:** if only even powers of x and y appear in (1) i.e., $f(-x, -y) = f(x, y)$.

Example: $x^2 + y^2 = a^2$ (see Fig. 5.3).

Fig. 5.3

5.2 — HIGHER ENGINEERING MATHEMATICS—II

- d. Symmetric about origin:** if equation remains unaltered when x and y are replaced by $-x$ and $-y$ i.e., $f(-x, -y) = f(x, y)$

Example: $x^5 + y^5 = 5a^2x^2y$ (Fig. 5.4).

Fig. 5.4

Note: Curve symmetric about both x - and y -axes is also symmetric about origin but not the converse (because of the presence of odd powers)

- e. Symmetric about the line $y = x$:** if the equation remains unaltered if x and y are replaced by y and x i.e., x, y are interchanged or

$$f(x, y) = f(y, x)$$

Example: $x^3 + y^3 = 3axy$ (Fig. 5.5).

Fig. 5.5

- f. Symmetric about the line $y = -x$:** if

$$f(x, y) = f(-y, -x)$$

i.e., x is replaced by $-y$ and y is replaced by $-x$.

Example: $x^3 - y^3 = 3axy$ (Fig. 5.6).

Fig. 5.6

Region or Extent

is obtained by solving y in terms of x or vice versa. Real horizontal extent is defined by values of x for which y is defined. Real vertical extent is defined by values of y for which x is defined.

Imaginary region: is the region in which the curve does not exist. In such region y becomes imaginary (undefined) for values of x or vice versa.

Asymptotes

- Parallel to x -axis: are obtained by equating to zero the coefficients of the highest powers of x in (1).
- Parallel to y -axis: are obtained by equating to zero the coefficients of the highest powers of y in (1).

Example: $x^2y - y - x = 0$ is of 3rd degree has maximum number of 3 asymptotes.

y is the coefficient of highest power of x i.e., of x^2 . Thus asymptote parallel to x -axis is $y = 0$. $(x^2 - 1)$ is the coefficient of highest power of y i.e., of y . Thus asymptotes parallel to y -axis are $x^2 - 1 = 0$ or $x = \pm 1$ are two asymptotes parallel to y -axis.

- No vertical or horizontal asymptotes: In cases (a) and (b) if the coefficients are constants or has imaginary (no real) factors, then curve has no asymptotes.

Example: $x^3 + y^3 = 3axy$, no asymptotes parallel to x - and y -axes because coefficients of x^3 and y^3 are constant one.

- Oblique asymptotes (not parallel to x -axes and y -axes): are given by $y = mx + c$ where $m = \lim_{x \rightarrow \infty} \left(\frac{y}{x} \right)$ and $c = \lim_{x \rightarrow \infty} (y - mx)$

Example:

$$\begin{aligned} y &= \frac{x^2 + 2x - 1}{x}, m = \lim_{x \rightarrow \infty} \left(\frac{y}{x} \right) \\ &= \lim_{x \rightarrow \infty} \left(\frac{x^2 + 2x - 1}{x^2} \right) = 1 \end{aligned}$$

$$c = \lim_{x \rightarrow \infty} (y - mx) = \lim_{x \rightarrow \infty} \left(\frac{x^2 + 2x - 1}{x} - x \right) = 2$$

So $y = x + 2$ is an oblique (inclined) asymptote.

- e. Oblique asymptotes (when curve is represented by implicit equation $f(x, y) = 0$): are given by $y = mx + c$ where

m is solution of $\phi_n(m) = 0$ and

c is solution of $c\phi'_n(m) + \phi_{(n-1)}(m) = 0$ or

$$c = \frac{-\phi_{n-1}(m)}{\phi'_n(m)}$$

Here $\phi_n(m)$ and $\phi_{n-1}(m)$ are obtained by putting $x = 1$ and $y = m$ in the collection of highest degree terms of degree n and in the collection of the next highest degree terms of degree $(n - 1)$.

Example: $x^3 + y^3 = 3axy$, highest degree $n = 3$.

$\phi_3(m) = 1 + m^3$ (obtained by putting $x = 1$ and $y = m$ in $x^3 + y^3$). Real solution $m = -1$.
 $\phi_2(m) = -3am$ (obtained by putting $x = 1$ and $y = m$ in the next highest degree 2 term $-3axy$)

$$c = -\frac{(-3am)}{(3m^2)} = \frac{a}{m}, \quad \text{At } m = -1, c = -a$$

Thus,

$$y = mx + c = -x - a \quad \text{or} \quad y + x + a = 0$$

is the oblique asymptote.

Origin

If origin $(0, 0)$ lies on the curve then there will be no constant term in equation (1).

Tangents to the Curve at the Origin

When the curve passes through origin, then the tangents to the curve at this origin are obtained by equating to zero the group (or collection) of the lowest degree terms in (1).

Example: $y^2 = 4ax$, lowest degree term $4ax$ equated to zero gives $x = 0$ (y -axis) as tangent to curve at origin.

Example: $x^3 + y^3 = 3axy$, lowest degree term $3axy$ equated to zero gives $xy = 0$ or $x = 0$ and $y = 0$ are the two tangents to the curve at origin.

Example: $a^2y^2 = a^2x^2 - x^4$, lowest degree term $(y^2 - x^2)$ equating to zero gives $y = \pm x$ as the two tangents at origin.

Intercepts

- The x -intercept (i.e., the point where the curve meets the x -axis) is obtained by putting $y = 0$ in (1) and solving for x . Similarly y -intercept (where curve crosses y -axis) is obtained by putting $x = 0$ in (1) and solving for y .
- Points of intersection: when curve is symmetric about the line $y = \pm x$, the points of intersection are obtained by putting $y = \pm x$ in Equation (1).
- Tangents to the curve at other points (h, k) can be obtained by shifting the origin to these points (h, k) by the substitution $x = X + h$, $y = Y + k$ and calculating the tangents at origin in the new XY -plane.

Note: At point where $\frac{dy}{dx} = 0$, the tangent is parallel to x -axis i.e., horizontal. At point where $\frac{dy}{dx} = \infty$, the tangent is vertical i.e., parallel to y -axis.

Sign of First Derivative $\frac{dy}{dx}$

In an interval $a \leq x \leq b$ if

- $\frac{dy}{dx} > 0$ then curve is increasing in $[a, b]$
- $\frac{dy}{dx} < 0$ then curve is decreasing in $[a, b]$
- If at $x = x_0$, $\frac{dy}{dx} = 0$ then (x_0, y_0) is a stationary point where maxima and minima can occur.

Sign of Second Derivative $\frac{d^2y}{dx^2}$

In an interval $a \leq x \leq b$ if

- $\frac{d^2y}{dx^2} > 0$ then curve is convex or concave upward (holds water)
- $\frac{d^2y}{dx^2} < 0$ then curve is concave downward (spills water)
- A point at which $\frac{d^2y}{dx^2} = 0$ is known as an inflection point where the curve changes the direction of concavity from downward to upward or vice versa.

Multiple Point (or Singular Point)

A point through which r branches of a curve pass is called a multiple point of the r th order and has r

5.4 — HIGHER ENGINEERING MATHEMATICS—II

tangents. Thus at a double point two branches of the curve pass.

Double point is classified as a node, a cusp or an isolated (or conjugate) point according as the two tangents are real distinct, coincident or imaginary.

Multiple points are obtained by solving for (x, y) the three equations

$$f_x(x, y) = 0, f_y(x, y) = 0, f(x, y) = 0$$

The slopes of the tangents at a double point are the roots of

$$f_{yy} \left(\frac{dy}{dx} \right)^2 + 2f_{xy} \frac{dy}{dx} + f_{xx} = 0$$

Thus the point (x, y) will be a double point and will be a node, cusp or conjugate according as values of $\left(\frac{dy}{dx} \right)$ are real/distinct, equal or imaginary i.e., according as $(f_{xy})^2 - f_{xx}f_{yy} > 0, = 0, < 0$.

Example: $y^2 = x^2(x - 1)$. So $f(x, y) = y^2 - x^3 + x^2 = 0$, $f_x = -3x^2 + 2x = 0$, $f_y = 2y = 0$.

$\therefore (0, 0)$ is a double point. Equating to zero lowest degree terms $x^2 + y^2$, we get imaginary tangents. So $(0, 0)$ is a conjugate point.

Example: $y^2(a - x) = x^3$. So $f(x, y) = x^3 - ay^2 + xy^2 = 0$, $f_x = 3x^2 + y^2 = 0$, $f_y = 2y(x - a) = 0$, $(0, 0)$ is a double point. Tangents at origin are given by equating to zero the lowest degree terms i.e., $y^2 = 0$.

$\therefore x$ -axis is coincident tangent: $(0, 0)$ is a cusp.

Example: $f(x, y) = x^3 - y^2 - 7x^2 + 4y + 15x - 13 = 0$, $f_x = 3x^2 - 14x + 15 = 0$, $f_y = -2y + 4 = 0$, out of $(3, 2), (5/3, 2)$ only $(3, 2)$ lies on curve. $f_{xy} = 0$, $f_{xx} = 6x$, $f_{yy} = -2$. At $(3, 2)$, $f_{xx} = 18$, $f_{xy} = 0$, $f_{yy} = -2$ so $(f_{xy})^2 - f_{xx}f_{yy} > 0$. $\therefore (3, 2)$ is a node.

WORKED OUT EXAMPLES

Example 1: Trace the curve $y = (x^2 - x - 6)(x - 7)$.

Solution: Equation is $y = (x + 2)(x - 3)(x - 7)$

1. No symmetry.

2. Origin does not lie on curve.

3. No asymptotes.

4. **Intercepts:** x -intercepts: $x = -2, 3, 7$. Curve crosses x -axis at A(-2, 0), B(3, 0) and C(7, 0)
 y -intercepts: $y = 42$.

Curve crosses y -axis at D(0, 42).

5. **Maxima and Minima:**

$$\frac{dy}{dx} = 3x^2 - 16x + 1 = 3(x - x_1)(x - x_2)$$

where

$$x_1 = \frac{8 - \sqrt{61}}{3} = 0.063, \quad x_2 = \frac{8 + \sqrt{61}}{3} = 5.27$$

Thus the stationary points where $y' = 0$ are x_1 and x_2 .

$$\frac{d^2y}{dx^2} = 6x - 16 = 2(3x - 8)$$

At $x_1 = .063$, $y'' < 0$, so y attains maximum value 42.0314 at $x_1 = 0.063$ i.e., at B(0.063, 42.0314). At $x_2 = 5.27$, $y'' > 0$, so y attains minimum value -28.152 at $x_2 = 5.27$ i.e., E(5.27, -28.152).

6. **Inflection point:** is at $x = \frac{8}{3} = 2.66$ since $y'' = 0$ at $x = \frac{8}{3}$.

7. **Extent:** $-\infty < x < \infty$ since y is defined for all x .

8. **Sign of first derivative:**

Fig. 5.7

Interval	Sign of y	Quad-rant	Sign of y'	Nature of curve
	$y = (x+2)(x-3)(x-7)$		$y' = 3(x-x_1)(x-x_2)$	
$-\infty < x < -2$	$y < 0$	III	$y' > 0$	increasing
$-2 < x < 0$	$y > 0$	II	$y' > 0$	increasing
$0 < x < .063$	$y > 0$	I	$y' > 0$	increasing
$.063 < x < 3$	$y > 0$	I	$y' < 0$	decreasing
$3 < x < 5.27$	$y < 0$	IV	$y' < 0$	decreasing
$5.27 < x < 7$	$y < 0$	IV	$y' > 0$	increasing
$7 < x < \infty$	$y > 0$	I	$y' > 0$	increasing

$A(-2, 0), B(0.063, 42.0314), C(2.66, 6.74), D(3, 0), E(5.27, -28.152), F(7, 0), x_1 = 0.063, x_2 = 5.27$

Using the above knowledge the graph of the given curve is as shown above (in Fig. 5.7).

Example 2: Trace the curve $y = \frac{x^2-3x}{(x-1)}$.

Solution:

1. Curve is not symmetric
2. Origin lies on the curve
3. Tangent at origin is $y = 3x$ obtained by equating the lowest degree term $y - 3x$ to zero.
4. Intercepts: x -intercept: put $y = 0$, then

$$x(x-3) = 0.$$

$\therefore$ Curve crosses x -axis at $x = 0$ and $x = 3$
 y -intercepts: put $x = 0$, then $y = 0$,

Fig. 5.8

Thus curve meets the x -axis at $O(0, 0), A(3, 0)$ (see Fig. 5.8)

5. *Extent or Region:* y is defined for all x , except at $x = 1$ where it is discontinuous. Thus the region of definition is $\{-\infty < x < \infty\} - \{1\}$ or $R - \{1\}$.

6. *Asymptotes*

a. No horizontal asymptote because co-efficient of x^2 is constant.

b. $x = 1$ is the vertical asymptote which is obtained by equating to zero the coefficient of the highest power in y i.e., $(x-1) = 0$.

c. *Oblique asymptote:* $m = \lim_{x \rightarrow \infty} \frac{y}{x} = \lim_{x \rightarrow \infty} \frac{x(x-3)}{(x-1)} \cdot \frac{1}{x} = 1$

$$c = \lim_{x \rightarrow \infty} (y - mx) = \lim_{x \rightarrow \infty} \left(\frac{-2x}{x-1} \right) = -2.$$

Oblique asymptote is $y = mx + c = x - 2$.

7. *Maxima and Minima:* $\frac{dy}{dx} = \frac{x^2-2x+3}{(x-1)^2}$, $y' > 0$ for any x except $x = 1$. $y' = 0$ when $x^2 - 2x + 3 = 0$ whose roots are imaginary. So no stationary points and therefore no maximum and no minimum.

8. *Inflection point:*

$$\frac{d^2y}{dx^2} = -\frac{4}{(x-1)^3}$$

No inflection points since $y'' \neq 0$.

9. *Sign of derivative:*

Interval	Sign of y	Quad-rant	Sign of y'	Nature of curve
$-\infty < x < 0$	$y < 0$	III	$y' > 0$	increasing
$0 < x < 1$	$y > 0$	I	$y' > 0$	increasing
$1 < x < 3$	$y < 0$	IV	$y' > 0$	increasing
$3 < x < \infty$	$y > 0$	I	$y' > 0$	increasing

Example 3: Trace the curve

$$a^2 y^2 = x^2(2a-x)(x-a)$$

Solution: Equation is $a^2 y^2 = -x^4 + 3ax^3 - 2a^2 x^2$.

1. Curve is symmetric about x -axis only.
2. Origin lies on the curve.
3. *Intercepts:* y -intercept: $(0, 0)$.
 x -intercepts: $(0, 0), (a, 0), (2a, 0)$.

5.6 — HIGHER ENGINEERING MATHEMATICS—II

4. *Region:* Solving for y , we get

$$y = \pm \frac{1}{a} \sqrt{x^2(2a-x)(x-a)}$$

y is not imaginary if both $x-a > 0$ and

$$(2a-x) > 0 \text{ i.e., } a < x < 2a$$

Thus curve exists only between $x = a$ and $x = 2a$. Curve has two branches one above and other below x -axis.

5. *Multiple point:*

Tangents at origin are obtained by equating to zero terms of lowest degree i.e., $a^2y^2 + 2a^2x^2 = 0$ which has imaginary values. Thus tangents at origin are imaginary. Therefore origin O is an isolated point.

6. *Asymptotes:* No horizontal and no vertical asymptotes because coefficients of x^4 and y^2 are constants. No oblique asymptotes because $m = \lim_{x \rightarrow \infty} \frac{y}{x} = \lim_{x \rightarrow \infty} \sqrt{(2a-x)(x-a)} = \infty$ (Fig. 5.9).

Fig. 5.9

7. *Loop:* curve crosses at $A(a, 0)$ and $B(2a, 0)$ and is symmetric about x -axis. Therefore curve has a loop between A and B .

8. *Maxima and Minima:* Derivative $\frac{dy}{dx} = \pm \frac{2x^2 - \frac{9}{2}ax + 2a^2}{a(x-a)^{1/2}(2a-x)^{1/2}}$ stationary points where $y' = 0$ are given by $2x^2 - \frac{9}{2}ax + 2a^2 = 0$ or $x = \frac{a(9 \pm \sqrt{17})}{8} = \frac{a}{8}(9 \pm 4.1231)$. Out of these $x_1 = \frac{a}{8}(9 - 4.1231) = 0.6096a$ does not lie in the region of interest $a < x < 2a$. The other value $x_2 = \frac{a}{8}(9 + 4.1231) = 1.64a$ is the required value where a maximum value $M = 0.7872a$ occurs on the upper branch of the curve. Similarly the minimum value $m = -0.7872a$

occurs on the lower branch at $x_2 = 1.64a$ (because of symmetry). $C(1.64a, \pm 0.7872a)$.

9. Tangents at A and B are vertical because $\frac{dy}{dx} = \infty$ at $x = a$ and $x = 2a$. Thus $x = a$ and $x = 2a$ are the tangents to the curve at the points A and B .

10. *Sign of derivative:*

$$\text{For } y = + \frac{1}{a} \sqrt{x^2(2a-x)(x-a)}$$

$$\text{the derivative is } y' = \frac{-2(x-x_1)(x-x_2)}{a(x-a)^{\frac{1}{2}}(2a-x)^{\frac{1}{2}}}$$

For $x_1 = .6a < a < x < x_2 = 1.64a$, then $y > 0$, $y' > 0$, increasing.

For $x_2 = 1.64a < x < 2a$, then $y > 0$, $y' < 0$, decreasing.

Similar arguments for the other branch of the curve below the x -axis i.e., $y < 0$.

EXERCISE

Trace the following curves giving the salient points:

1. $y = x^3 - 12x - 16$.

Ans. Not symmetric, does not pass through origin, $(-2, 0)$, $(0, -16)$, $(4, 0)$ are intercepts, maximum at $x = -2$ and minimum at $x = 2$, inflection point at $(0, -16)$, y is increasing in $(-\infty, -2]$, and $[2, \infty)$ and decreasing in $(-2, 2)$, no asymptotes (Fig. 5.10).

Fig. 5.10

2. $y = c \cosh \frac{x}{c} = \frac{c}{2} [e^{\frac{x}{c}} + e^{-\frac{x}{c}}]$.

Ans. Symmetric about y -axis, origin does not lie on the curve, $(0, c)$ is the intercept, no asymptotes, $y' = \sinh \frac{x}{c} > 0$ for $x > 0$, < 0 for $x < 0$. Curve increasing in $(0, \infty)$ and decreasing in $(-\infty, 0)$, tangent at origin $y = c$ is horizontal (Fig. 5.11).

Fig. 5.11

3. $y = (x^2 + 1)/(x^2 - 1)$.

Ans. Symmetric about y-axis, origin not on curve, $(0, -1)$ intercept point, $x = \pm 1$ vertical asymptotes, $y=1$ horizontal asymptote, no inclined asymptote, maximum value -1 at $x = 0$, curve does not exist between the lines $y = -1$ and $y = 1$, no inflection points (Fig. 5.12).

Fig. 5.12

4. $y^2x^2 = x^2 - a^2$.

Ans. Symmetric about both axes, origin not on curve, $(-a, 0)$, $(a, 0)$ are intercepts and $x = a$, $x = -a$ are tangents at these points, $y = \pm 1$ are asymptotes, curve is defined only when $x \geq a$ or $x \leq -a$, no curve between $x = -a$ and $x = a$, $y' = \pm a^2/(x^2\sqrt{x^2 - a^2}) \neq 0$, for $y' > 0$ in $(-\infty, -a)$ and (a, ∞) curve is increasing in these intervals (Fig. 5.13).

Fig. 5.13

5. $y^2(x^2 - 1) = 2x - 1$.

Ans. Symmetric about x-axis, not through origin, $(0, 1)$, $(0, -1)$, $(\frac{1}{2}, 0)$ are intercepts, $x = \frac{1}{2}$ is tangent at $(\frac{1}{2}, 0)$, $x = \pm 1$, $y = 0$ are asymptotes; curve exists in the region $-1 < x < \frac{1}{2}$ and $x > 1$, $y = \pm \sqrt{\frac{2x-1}{x^2-1}}$, $y' = \pm(-x^2 + x + 1)/[(2x - 1)^{1/2}(x^2 - 1)^{3/2}]$ (Fig. 5.14).

Fig. 5.14

6. $x^3 + y^3 = 3axy^2$, $a > 0$.

Ans. Not symmetric, origin is cusp; $x = 0$ is tangent thereat, $(0, 0)$, $(3a, 0)$ are intercepts; $x = 3a$ is tangent at $(3a, 0)$; $y + x = a$ is asymptote, meets curve at $(\frac{a}{3}, \frac{2a}{3})$; curve does not exist in 3rd quadrant because both x and y cannot be negative, $y' = x(2a - x)/y^2$ (Fig. 5.15).

Fig. 5.15

7. $9ay^2 = x(x - 3a)^2$.

Ans. Symmetric about x-axis, origin on curve; $x = 0$ is tangent at origin 0; $(3a, 0)$ is intercept; tangents at $(3a, 0)$ are $y = \pm(x - 3a)/\sqrt{3}$; curve exists only for $x > 0$ (in Ist and IV quadrants), no asymptotes; $y = \sqrt{x(x - 3a)}/(3\sqrt{a})$; $y' = (x - a)/(2\sqrt{ax})$ (Fig. 5.16).

Fig. 5.16

8. Hypocycloid or Astroid

$$\left(\frac{x}{a}\right)^{2/3} + \left(\frac{y}{b}\right)^{2/3} = 1.$$

Ans. Symmetric about both axes. Origin not on curve; Intercepts are $(\pm a, 0)$, $(0, \pm b)$ tangents at $(\pm a, 0)$ are parallel to x -axis, tangents at $(0, \pm b)$ are parallel to y -axis; curve exists when $-a < x < a$ and $-b < y < b$; no asymptotes (Fig. 5.17).

Fig. 5.17

9. $(x^2 - a^2)(y^2 - b^2) = a^2b^2$.

Ans. Symmetric about both x and y axes, and about the lines $y = \pm x$; origin lies on curve, has imaginary tangents at origin, origin is isolated point; curve does not exist when $-a \leq x \leq a$, and $-b \leq y \leq b$; $x = \pm a$, $y = \pm b$ are asymptotes (Fig. 5.18).

Fig. 5.18

10. $y^3 = a^2x - x^3$ or $y^3 = x(a^2 - x^2)$

Ans. $f(-x, -y) = f(x, y)$, symmetry in opposite quadrants, $(0, 0)(\pm a, 0)$ are intercepts, y -axis tangent at origin, $y = -x$ asymptote. For $0 < x < a$, $y > 0$. For $x > a$, $y < 0$. When $-a < x < 0$ then $y < 0$, also $-a > x$ then $y > 0$; $y' = \frac{a^2 - 3x^2}{3y^2}$ Max at $x = \frac{a}{\sqrt{3}}$, min at $x = \frac{-a}{\sqrt{3}}$. Also $y' < 0$ when $(-\infty, \frac{-a}{\sqrt{3}}]$ and $(\frac{a}{\sqrt{3}}, \infty)$ so curve is decreasing. Finally $y' > 0$ in $(\frac{-a}{\sqrt{3}}, \frac{a}{\sqrt{3}})$ so curve is increasing (Fig. 5.19).

Fig. 5.19

5.2 CURVE TRACING: STANDARD CURVES IN CARTESIAN FORM

WORKED OUT EXAMPLES

Example 1: Folium of Descartes: $x^3 + y^3 = 3axy$.

Solution:

- Symmetry:** Curve is symmetric about the line $y = x$ because $f(x, y) = f(y, x)$.
- Asymptotes:** Since the coefficients of the highest powers of x and y are constants, there are no asymptotes parallel to the coordinate axis.

To obtain oblique asymptote, put $y = mx + c$ in the equation $x^3 + (mx + c)^3 = 3ax(mx + c)$ or $(1 + m^3)x^3 + 3x^2(m^2c - am) + 3x(cm - ca) + c^3 = 0$ This equation will give

$$1 + m^3 = 0 \text{ and } m^2c - am = 0.$$

Solving $m = -1$ and $c = -a$. Oblique asymptote is $y = -x - a$ or $y + x + a = 0$.

3. **Origin:** $O(0, 0)$ is a point on the curve. Tangents at origin: Equating to zero the lowest degree term xy i.e., $xy = 0$, observe that $x = 0$ and $y = 0$ are tangents to the curve at the origin.

4. **Intercepts:** there are no x -intercepts and no y intercepts except the origin $(0, 0)$ (Fig. 5.20) because by putting $x = 0$ in equation $0 + y^3 = 0$ so $y = 0$ (similarly by putting $y = 0$, $x^3 + 0 = 0$ so $x = 0$).

Fig. 5.20

5. **Intersection of curve with the line $y = x$:** put $y = x$ in equation: $x^3 + x^3 = 3a \cdot x \cdot x$ or $x^2(2x - 3a) = 0$ so $x = 0$ or $x = \frac{3a}{2} = y$. Thus line $y = x$ meets the curve in two points $(0, 0)$ and $(\frac{3a}{2}, \frac{3a}{2})$.

$$\text{Derivative : } \frac{dy}{dx} = \frac{ay - x^2}{y^2 - ax}$$

$$\text{At } \left(\frac{3a}{2}, \frac{3a}{2}\right), \frac{dy}{dx} = -1.$$

Equation of tangent to the curve at the point $(\frac{3a}{2}, \frac{3a}{2})$ is

$$\left(y - \frac{3a}{2}\right) = -\left(x - \frac{3a}{2}\right) \text{ or } x + y - 3a = 0$$

Thus this tangent is parallel to the asymptote $x + y + a = 0$

6. **Region:**

- a. When both x and y are negative simultaneously equation of the curve is not satisfied

$$(-x)^3 + (-y)^3 = 3a(-x)(-y)$$

$$-(x^3 + y^3) = 3axy$$

(R.H.S. is positive while L.H.S. is negative). Thus no part of the curve exists in the 3rd quadrant.

- b. To study the variation of y with x , put $x = r \cos \theta$, $y = r \sin \theta$ in the equation. $r^3(\cos^3 \theta + \sin^3 \theta) = 3ar^2 \sin \theta \cos \theta$

$$r = \frac{3a \sin \theta \cos \theta}{\cos^3 \theta + \sin^3 \theta}$$

$\theta = 0$	$\pi/4$	$\pi/3$	$\pi/2$	$2\pi/3$	$3\pi/4$	π
$r = 0$	$\frac{3\sqrt{2}a}{2} = 2.12a$	$\frac{6\sqrt{3}a}{1+3\sqrt{3}} = 1.51a$	0	$\frac{-6\sqrt{3}a}{3\sqrt{3}-1} = -2.46a$	∞	0

$$\frac{dr}{d\theta} = \frac{3a(\cos \theta - \sin \theta)[1 + \sin \theta \cos \theta + \sin^2 \theta \cos^2 \theta]}{(\cos^3 \theta + \sin^3 \theta)}$$

$$\frac{dr}{d\theta} = 0 \text{ when } \cos \theta = \sin \theta \text{ i.e., at } \theta = \frac{\pi}{4}.$$

$$\frac{dr}{d\theta} > 0 \text{ in } (0, \pi/4) \text{ and } < 0 \text{ in } (\pi/4, \pi/2).$$

Thus the curve has a loop between $\theta = 0$ to $\frac{\pi}{2}$ since r increases first as θ increases from 0 to $\pi/2$ from 0 to $3\sqrt{2}a/2$ as θ increases from 0 to $\pi/4$, then r decreases from $3\sqrt{2}a/2$ to 0 as θ varies from $\pi/4$ to $\pi/2$.

Example 2: Cissoid: $y^2(a - x) = x^3$, $a > 0$.

Solution:

- Curve is symmetric about x -axis since y^2 is present in the equation.
- Origin lies on the curve.
- Tangents at origin: Equating to zero the lowest degree terms i.e., $y^2 = 0$. Thus x -axis is a coincidental tangent to the curve at the origin. Hence origin is a cusp.
- Intercepts:** only intercept point is $x = 0$, $y = 0$. i.e., origin is the only point where curve meets the coordinate axes.

5.10 — HIGHER ENGINEERING MATHEMATICS—II

5. **Asymptotes:** Asymptotes parallel to y -axis are given by equating to zero, the coefficient of the highest degree terms in y i.e., $a - x = 0$. Thus $x = a$ is the asymptote. For $a > 0$ the asymptote $x = a$ is parallel to y -axis and lies to the right ($y > 0$).

Since coefficient of x^3 is constant, no asymptotes parallel to x -axis.

6. **Extent:** solving $y = \pm x \left(\frac{x}{a-x} \right)^{\frac{1}{2}}$.

y is imaginary when $x < 0$.

y is imaginary when $x > a$.

Thus curve does not exist for $x < 0$ and $x > a$.

Hence curve exists only for $0 \leq x < a$.

7. **Sign of derivative**

$$\frac{dy}{dx} = \pm \frac{\sqrt{x}(\frac{3}{2}a - x)}{(a-x)(a-x)^{1/2}}$$

In the first quadrant for $0 < x < a$, $\frac{dy}{dx} > 0$ curve increases in the first quadrant (Fig. 5.21).

Fig. 5.21

Example 3: $y = 8a^3/(x^2 + 4a^2)$

Solution:

1. Curve is symmetric about y -axis.
2. Curve does not pass through origin.
3. **y -intercept:** curve meets y -axis at $(0, 2a)$.
 x -intercept: curve does not cross x -axis.
4. **Tangent at $(0, 2a)$:** $\frac{dy}{dx} = \frac{-16a^3x}{(x^2+4a^2)^2}$

So $\frac{dy}{dx} = 0$ when $x = 0$. (then $y = 2a$).

Thus at $(0, 2a)$, the tangent is parallel to x -axis i.e., the horizontal line $y = 2a$ is tangent at $(0, 2a)$.

5. **Region:** y is always positive for any value of x (because of the presence of x^2 term). Thus curve lies above the x -axis ($y > 0$). Also solving the equation $x = 2a \left(\frac{2a-y}{y} \right)^{\frac{1}{2}}$, x is imaginary when $y < 0$ or $y > 2a$.

Curve does not exist below the x -axis (i.e., $y < 0$) and above the horizontal line $y = 2a$ (i.e., $y > 2a$). So region is $0 < y < 2a$, $-\infty < x < \infty$.

6. **Asymptotes:** Asymptote parallel to x -axis is obtained by equating the coefficient of highest power of x i.e., coefficient of x^2 namely y to zero. Thus $y = 0$ (x -axis) is the asymptote.

No asymptote parallel to y -axis because the coefficient of y namely $x^2 + 4a^2$ has no real factors.

7. **Sign of derivative:** $\frac{dy}{dx} = -\frac{16a^3x}{(x^2+4a^2)^2}$.

For $x > 0$, $\frac{dy}{dx} < 0$ curve is decreasing.

For $x < 0$, $\frac{dy}{dx} > 0$ so curve is increasing.

For $x = 0$, $\frac{dy}{dx} = 0$ is stationary point which is a maximum point (since $\frac{d^2y}{dx^2} = \frac{16a^3(3x^2-4a^2)}{(x^2+4a^2)^3} < 0$ at $x = 0$).

8. **Inflection points** occur at $3x^2 - 4a^2 = 0$ where

$$\frac{d^2y}{dx^2} = 0 \text{ i.e., at } x_{1,2} = \pm 2a/\sqrt{3}$$

9. **Variation of y w.r.t. x** (Fig. 5.22)

Fig. 5.22

$x = -\infty$	$-2a$	$-a$	0	a	$2a$	∞
$y = 0$	a	$1.6a$	$2a$	$1.6a$	a	0

Example 4: Lemniscate of Bernoulli

$$y^2(a^2 + x^2) = x^2(a^2 - x^2)$$

or $x^2(x^2 + y^2) = a^2(x^2 - y^2)$.

Solution:

1. Curve is symmetric about both x -axis and y -axis since it contains even powers of x and y .
2. Origin lies on the curve.
3. Tangents at origin are obtained by equating the lowest degree term $(y^2 - x^2)a^2$ to zero. Thus $y = \pm x$ are the two tangents to the curve at origin. Hence origin is a node because there two real distinct tangents.
4. *Asymptotes:* no asymptotes parallel to x -axis because the coefficient of x^4 is constant. No asymptotes parallel to y -axis because the coefficient of y^2 has no real factors.
5. *Intercepts:* x -intercept is $(0, 0)$.
 y -intercept is $x^2(a^2 - x^2) = 0$ or $x = 0$ or $x \pm a$.

Fig. 5.23

Thus curve meets the x -axis at $A(-a, 0)$ and $B(a, 0)$. To find the tangents at A and B , shift the origin to $(\pm a, 0)$. So put $X = x + a$, $Y = y + 0$ in the equation of the curve.

Then $Y^2[a^2 + (X + a)^2] = (X + a)^2[a^2 - (X \pm a)^2]$
 or $Y^2[2a^2 + 2aX + X^2] = (X + a^2)^2[-2aX - X^2]$

Equating to zero the lowest degree terms the tangent at the next origin i.e., $-2aX^3 = 0$ i.e., new y -axis. Thus $X = x \pm a = 0$ or $x = \pm a$ are the tangents to the curve at B and A .

6. Region: Solving the equation for y , we get

$$y = \pm x \sqrt{\frac{a^2 - x^2}{a^2 + x^2}}$$

y is defined only when $a^2 - x^2 \geq 0$ or $-a \leq x \leq a$. Thus curve exists only when $-a \leq x \leq a$ i.e., curve lies between the lines $x = -a$ and $x = a$.

Sign of derivative: $\frac{dy}{dx} = \frac{\pm[a^4 - 2a^2x^2 - x^4]}{(a^2 + x^2)^{3/2}(a^2 - x^2)^{1/2}}$.

Stationary points: $\frac{dy}{dx} = 0$ when $x^4 + 2a^2x^2 - a^4 = 0$

or at $x = \pm a\sqrt{2} - 1$, $x_1 = \sqrt{-1 + \sqrt{2}a}$,
 and $x_2 = -\sqrt{-1 + \sqrt{2}a}$
 or $x_1 = .64a$ and $x_2 = -.64a$

Also $\frac{dy}{dx} \rightarrow \infty$ when $x \rightarrow +a$ and $x \rightarrow -a$.

Thus tangents are parallel to x -axis at x_1 and x_2 while parallel to y -axis at $x = a$ and $x = -a$.

Suppose $y > 0$ then y is considered with + sign. Then for $-a < x < x_2$ and $0 < x < x_1$, $y' > 0$ curve is increasing in these two intervals.

For $x_2 < x < 0$ and $x_1 < x < a$, $y' < 0$ curve is decreasing in these two intervals. Similarly for $y < 0$ take y' with $-ve$ sign. Then for $-a < x < x_2$ and $0 < x < x_1$, $y' < 0$, curve decreasing.

For $x_2 < x < 0$ and $x_1 < x < a$, $y' > 0$, curve increasing. M_1, M_2, m_1, m_2 are the extrema at x_1, x_2 (Fig. 5.23).

Example 5: $y = x + \frac{1}{x}$

Solution:

1. Curve is symmetric about the origin since $f(-x, -y) = f(x, y)$ (but is not symmetric about both x - and y -axis because of the odd powers of x and y).
2. Origin does not lie on the curve.
3. *No intercepts:* Rewriting the equation we get $x^2 - xy + 1 = 0$. This has no solutions when $x = 0$ ($1 = 0$) and $y = 0$, ($x^2 + 1 = 0$).

5.12 — HIGHER ENGINEERING MATHEMATICS—II

4. *Region:* y is defined for any value of x except $x = 0$ where it is discontinuous. Thus Region is $\{-\infty < x < \infty\} - \{0\}$ i.e., $R - \{0\}$.

5. *Asymptotes:* As $x \rightarrow 0$, $y \rightarrow \pm\infty$ so y -axis is an asymptote. No horizontal asymptote because coefficient of x^2 is constant 1.

Oblique asymptote: $y = mx + c$

$$m = \lim_{x \rightarrow \infty} \frac{y}{x}$$

$$m = \lim_{x \rightarrow \infty} 1 + \frac{1}{x^2} = 1$$

$$c = \lim_{x \rightarrow \infty} (y - mx) = \lim_{x \rightarrow \infty} \frac{1}{x} = 0$$

Thus the oblique asymptote is the line $y = x$.

6. *No multiple points:* $f(x, y) = x^2 - xy + 1 = 0$.
 $f_x(x, y) = 2x - y = 0$, $f_y(x, y) = -x = 0$ has no solution.

7. *Sign of derivative:* $\frac{dy}{dx} = \frac{x^2-1}{x^2} = \frac{(x-1)(x+1)}{x^2}$
 (Fig. 5.24)

Fig. 5.24

a. *Stationary points:* $x^2 - 1 = 0$ or $x = \pm 1$

$\frac{d^2y}{dx^2} = \frac{2}{x^3}$, so at $x = 1$, $y'' > 0$, attains minimum. At $x = -1$, $y'' < 0$, attains maximum. Thus $A(1, 2)$ is minimum, while $B(-1, -2)$ is maximum.

b. Tangents to curve at A, B are parallel to x -axis.

c. For $0 < x < 1$, $y' < 0$, curve is decreasing.

For $1 < x < \infty$, $y' > 0$, curve is increasing.

Similarly (also by symmetry about origin).

For $-\infty < x < -1$, $y' > 0$, curve is increasing.

$-1 < x < 0$, $y' < 0$, curve is decreasing.

8. *No inflection points:* since $y'' \neq 0$.

Example 6: $y^2(x - a) = x^2(x + a)$, $a > 0$

Solution:

1. Curve is symmetric about x -axis only.

2. Curve passes through origin.

3. *Tangents at origin:* Equating to zero group of terms with lowest degree i.e., $a(x^2 + y^2) = 0$. The two tangents $y = \pm ix$ are imaginary.

4. Therefore origin is an isolated point.

5. *Intercepts:* y -intercept: $x = 0$ then $y = 0$ so origin $(0, 0)$ is the y -intercept point.

x -intercept: $y = 0$ then $x = 0$ or $x = -a$. Thus $A(-a, 0)$ is x -intercept.

The tangent at A is $x = a$ which is obtained by putting $x = X - a$ and $Y = y = 0$ in the equation resulting in $y^2X = (X + a)^2(X + 2a)$ and equating to zero the lowest term i.e., $X = 0$ or $x + a = 0$ i.e., $x = -a$ (Fig. 5.25).

Fig. 5.25

6. Equation of curve is of third degree. The maximum number of asymptotes is three. Asymptote parallel to y -axis: equating to zero coefficient of y^2 i.e., $x - a = 0$ or $x = a$ is the vertical asymptote.

Asymptotes parallel to x-axis: no horizontal asymptote since coefficient of x^3 is constant. Oblique asymptotes: $\phi_3(m) = m^2 - 1$ (obtained by putting $x = 1$ and $y = m$ in 3rd degree terms $xy^2 - x^3$). So $m = \pm 1$ are solution of $\phi_3(m) = 0$. $\phi_2(m) = -a(x^2 + y^2) = -a(1 + m^2)$, (put $x = 1, y = m$).

$c = -\frac{(-a)(1+m^2)}{2m}$. At $m = \pm 1, c = \pm a$.

Thus the two oblique asymptotes are

$$y = x + a \quad \text{and} \quad y = -x - a.$$

7. *Region:* Solving for y , we get two branches of the curve as

$$y = \pm x \sqrt{\frac{x+a}{x-a}}$$

y is imaginary when $-a < x < a$. Curve does not exist between the lines $x = -a$ and $x = a$ (except the isolated point 0).

8. *Sign of derivative:* $\frac{dy}{dx} = \pm \frac{(x^2 - ax - a^2)}{(x-a)^{\frac{3}{2}}(x+a)^{\frac{1}{2}}}$

a. *Stationary points:* $\frac{dy}{dx} = 0$ when $x^2 - ax - a^2 = 0$. Out of the two stationary points $x = \frac{1}{2}(1 \pm \sqrt{5})a$ only $x^* = \frac{1}{2}(1 + \sqrt{5})a = 1.62a$ is considered, because for $x = \frac{1}{2}(1 - \sqrt{5})a, y$ becomes imaginary.

Maximum and minimum occur at x^* .

b. For the branch of curve $y = +x \sqrt{\frac{x+a}{x-a}}$, the derivative $\frac{dy}{dx} = + \frac{x^2 - ax - x^2}{(x-a)^{3/2}(x+a)^{1/2}}$.

Then for $-\infty < x < -a, \frac{dy}{dx} < 0$, curve is decreasing, for $a < x < \infty, \frac{dy}{dx} > 0$, curve is increasing.

c. $x = a$ and $x = -a$ are vertical tangents to the curve because $\frac{dy}{dx} = \infty$ when $x = a$ or $x = -a$.

Example 7: Strophoid: $y^2(a + x) = x^2(b - x)$.

Solution:

1. Curve is symmetric about x -axis.
2. It passes through origin $O(0, 0)$.
3. *Tangents at origin:* are $y = \pm \sqrt{\frac{b}{a}}x$ which are obtained by equating the lowest degree terms $bx^2 - ay^2$ to zero.

4. Origin is a node since there are two real distinct tangents.

5. *Intercepts:* x -intercept: Put $y = 0$

$$x^2(b - x) = 0 \quad \text{or} \quad x = 0 \quad \text{or} \quad b.$$

The curve meets x -axis at $(0, 0)$ and $A(b, 0)$. y -intercept: put $x = 0$ then $y = 0$, so $O(0, 0)$ is the y -intercept (Fig. 5.26).

Fig. 5.26

6. *Asymptotes:* No horizontal asymptote since coefficient of x^3 is constant.

$x = -a$ is the vertical asymptote obtained by equating the coefficient of y^2 namely $a + x$ to zero.

7. *Loop:* since curve crosses the x -axis (x -intercepts) at $O(0, 0)$ and $A(b, 0)$ and is symmetric about x -axis, a loop exists between O and A .

8. *Region:* solving for y , we get

$$y = \pm x \left(\frac{b-x}{a+x} \right)^{\frac{1}{2}}$$

y becomes imaginary when $x > b$ and when $x < -a$. Thus the curve exists only between $x = -a$ and $x = b$ i.e., for $-a < x < b$.

9. *Derivative:*

$$\frac{dy}{dx} = \frac{(-2x^2 - 3ax + bx + 2ab)}{2(a+x)^{\frac{3}{2}}(b-x)^{\frac{1}{2}}}$$

5.14 — HIGHER ENGINEERING MATHEMATICS—II

$\frac{dy}{dx} = \infty$ at $x = b$. So the tangent to the curve at $(b, 0)$ is vertical (parallel to y -axis). Therefore curve cuts the x -axis at right angle at $(b, 0)$.

Case 1: $b = a$ (Fig. 5.27) equation is $y^2(a + x) = x^2(a - x)$.

Fig. 5.27

Case 2: $b = a$ and x is replaced by $-x$, then equation is $y^2(a - x) = x^2(a + x)$ (Fig. 5.28).

Fig. 5.28

Example 8: $y^2 = (x - a)(x - b)(x - c)$ with a, b, c all positive.

Solution: **Case 1:** Let $a < b < c$.

1. Curve is symmetric about x -axis only.
2. Does not pass through origin.
3. **Intercepts:** x -intercept: put $y = 0$. Then $(x - a)(x - b)(x - c) = 0$.
Curve crosses the x -axis at $A(a, 0)$, $B(b, 0)$ and $D(c, 0)$.

y -intercept: put $x = 0$.

$$y^2 = -abc$$

no solution, no y -intercepts. Curve does not cut the y -axis (Fig. 5.29).

Fig. 5.29

4. **Tangents at points A, B, D:** are obtained by shifting the origin to these points. For example put $x = X + a$, equation becomes $Y^2 = X(X + (a - b))(X + (a - c))$. Terms of least degree in x are $(a - b)(a - c)X$. The tangent at A is $X = 0$ or $x - a = 0$ or $x = a$. Similarly $x = b$ and $x = c$ are the tangents to the curve at B and D.

5. **Region:** Solving for y , we get

$$y = \pm \sqrt{(x - a)(x - b)(x - c)}$$

when $x < a$, y is imaginary when $b < x < c$, y is imaginary. Thus curve exists when

- i. $a < x < b$
- ii. $x > c$.

6. No horizontal or vertical asymptotes since coefficients of x^3 and y^2 are constants.
7. **Loop:** Curve crosses the x -axis between A and B and is symmetric about x -axis. Therefore curve has a loop between A and B.
8. y^2 increases and tends to infinity as x takes values bigger than c and tends to infinity.

9. **Derivative:** $\frac{dy}{dx} = \frac{(x-b)(x-c) + (x-c)(x-a) + (x-a)(x-b)}{2\sqrt{(x-a)(x-b)(x-c)}}$

$$\frac{dy}{dx} \rightarrow \infty \text{ at } x = a, b, c$$

Thus the tangents at A, B, D are vertical as proved already in 4.

Case 2: Let $b = c$ and $a < b$. Then the equation reduces to $y^2 = (x - a)(x - b)^2$.

1. Curve is symmetric about x -axis.
2. Origin does not lie on the curve.
3. *Intercepts:* no y -intercepts x -intercepts: put $y = 0$, $(x - a)(x - b)^2 = 0$. Curve meets x -axis at $x = a$ and $x = b$. i.e., at $A(a, 0)$ and $B(b, 0)$.
4. *Region:* solving for y ,

$$y = \pm(x - a)^{\frac{1}{2}}(x - b)$$

y is imaginary when $x < a$.
Curve exists only when $x \geq a$.

5. *Loop:* curve has a loop between A and B as curve crosses x -axis at A and B and is symmetric about x -axis (see Fig. 5.30).

Fig. 5.30

6. For $x > b$ and x tends to ∞ , y^2 also tends to ∞ .
7. *Derivative:* $\frac{dy}{dx} = \pm \frac{[3x - 2a - b]}{2(x - a)^{\frac{1}{2}}}$
8. Tangents at A and B . At $A(a, 0)$, $\frac{dy}{dx} = \infty$, so tangent at A , $x = a$ is vertical. At $B(b, 0)$, $\frac{dy}{dx} = \pm(b - a)^{\frac{1}{2}}$. So there are two distinct tangents at B given by

$$y = \pm m(x - b) = \pm(b - a)^{\frac{1}{2}}(x - b)$$

9. B is a node because there are two real distinct tangents to the curve.

Case 3: Let $a = b = c$. Then the equation is

$$y^2 = (x - a)^3$$

1. Curve is symmetric about x -axis.
2. Origin does not lie on the curve.
3. No y -intercepts. $x = a$ is the x -intercept.
4. *Region:* For $x < a$, y is imaginary. So curve exists only when $x \geq a$.
5. No asymptotes because coefficients of y^2 and x^3 are constants.
6. *Derivative:* $\frac{dy}{dx} = \pm \frac{3}{2}(x - a)^{\frac{1}{2}}$.
At $x = a$, $\frac{dy}{dx} = 0$ twice.

So x -axis is common tangent to the two branches of the curve at the point $A(a, 0)$. Thus A is cusp (Fig. 5.31).

Fig. 5.31

7. As $x > b$ and x tends to infinity, y also tends to infinity.

5.3 CURVE TRACING: POLAR CURVES

The general equation of a curve in polar coordinates (r, θ) in the explicit form is $r = f(\theta)$ or $\theta = f(r)$ and in the implicit form is $F(r, \theta) = 0$.

Salient points to trace polar curves.

Symmetry

- a. Curve is symmetric about the initial line $\theta = 0$ (usually the positive x -axis in the cartesian form) if the equation remains unaltered when θ is replaced by $-\theta$ i.e., $f(r, -\theta) = f(r, \theta)$.

5.16 — HIGHER ENGINEERING MATHEMATICS—II

Example: $r = a(1 \pm \cos \theta)$.

- b. Curve is symmetric about the line $\theta = \frac{\pi}{2}$ (passing through the pole and perpendicular to the initial line) which is usually the positive y -axis in the cartesian form if the equation does not change when θ is replaced by $\pi - \theta$ i.e., $f(r, \theta) = f(r, \pi - \theta)$.

Example: $r = a(1 \pm \sin \theta)$.

- c. Curve is symmetric about the pole (usually the origin) if equation remains unchanged when r is replaced by $-r$ i.e., $f(r, \theta) = f(-r, \theta)$. Equation contains only even powers of r .

Example: $r^2 = a \cos 2\theta$.

- d. Curve is symmetric about pole if

$$f(r, \theta) = f(r, \theta + \pi)$$

Example: $r = 4 \tan \theta$, kappa curve.

- e. Symmetric about the line $\theta = \frac{\pi}{4}$ (the line $y = x$ in the cartesian form) if

$$f(r, \theta) = f(r, \frac{\pi}{2} - \theta)$$

- f. Symmetric about the line $\theta = \frac{3\pi}{4}$ (the line $y = -x$ in cartesian form) if

$$f(r, \theta) = f(r, \frac{3\pi}{2} - \theta)$$

Pole

If $r = f(\theta_1) = 0$ for some $\theta = \theta_1 = \text{constant}$ then curve passes through the pole and the tangent at the pole is $\theta = \theta_1$

Example: At $\theta = \pi$, $r = a(1 + \cos \theta) = 0$

Asymptote

If $\lim_{\theta \rightarrow \theta_1} r = \infty$ then an asymptote to the curve exists and is given by the equation

$$r \sin(\theta - \theta_1) = f^1(\theta_1)$$

where θ_1 is the solution of $\frac{1}{f(\theta)} = 0$.

Points of Intersection

Points of intersection of the curve with the initial line and line $\theta = \pi/2$ are obtained by putting $\theta = 0$ and $\theta = \pi/2$ respectively in the polar equation.

Region or Extent

- a. If a and b are the least and greatest values of r such that $a < r < b$ then curve lies in the annulus region between the two circles of radii a and b .

Example: $r = a \sin 2\theta$; since $\max \sin 2\theta = 1$, curve lies in the circle $r = a$.

- b. Curve does not exist for values of θ for which r is imaginary.

Example: $r^2 = a^2 \cos 2\theta$; for $\frac{\pi}{4} < \theta < \frac{3\pi}{4}$, $\cos 2\theta$ is $-ve$ so r is imaginary, hence no curve exists in this region.

- c. For equations involving periodic functions generally θ varies from 0 to 2π .

Direction of Tangent

At any point (r, θ) : Tangent at a point on the curve is determined from

$$\tan \phi = r \frac{d\theta}{dr}$$

where ϕ is the angle between radius vector and the tangent.

The tangents at $\phi = 0$ and $\phi = \frac{\pi}{2}$ are parallel and perpendicular to the initial line respectively.

Derivative

If $\frac{dr}{d\theta} > 0$, then r increases while,

if $\frac{dr}{d\theta} < 0$, then r decreases.

Loop

If curve meets the initial line at points A and B and the curve is symmetric about the initial line, then a loop of the curve exists between A and B .

Curves of the type $r = a \sin n\theta$ and $r = a \cos n\theta$ (are called roses) consist of either n or $2n$ equal (similar) loops (leaves) according as n is odd or even. Divide each quadrant into n equal parts and plot r for θ .

$n = 1$ corresponds to a circle.

Some times it may be advantageous to convert polar curves to cartesian curves by the transormation $x = r \cos \theta$, $y = r \sin \theta$.

Result:

$\theta =$	0	$\pi/6$	$\pi/4$	$\pi/3$	$\pi/2$	$2\pi/3$	$3\pi/4$	$5\pi/6$	π	$7\pi/6$	$4\pi/3$	$3\pi/2$	2π

	Max				Min				Max			Min	Max

WORKED OUT EXAMPLES

Example 1: Lemniscate $r^2 = a^2 \sin 2\theta$ (Fig. 5.32).

Solution:

- Symmetry:** a. Curve is symmetric about the pole since equation contains even power of r i.e., $f(-r, \theta) = f(r, \theta)$.

Fig. 5.32

- Curve is symmetric about the line $\theta = \frac{\pi}{4}$ since

$$f(r, \frac{\pi}{2} - \theta) = r^2 - a^2 \sin 2\left(\frac{\pi}{2} - \theta\right)$$

$$= r^2 - a^2 \sin (\pi - 2\theta)$$

$$= r^2 - a^2 \sin 2\theta = f(r, \theta)$$

- Pole:** Curve passes through the pole (origin 0) since at $\theta = 0$ and $\theta = \frac{\pi}{2}$, the value of

$r^2 = a^2 \sin 2 \cdot 0 = 0$. Thus the two tangents to the curve at the pole are given by $\theta = 0$ and $\theta = \frac{\pi}{2}$ (i.e., x and y -axis). Thus pole is a node.

- No asymptote since r is finite for any value of θ .
- Intersection:** Curve meets the lines $\theta = \frac{\pi}{4}$ and $\theta = \frac{5\pi}{4}$ at $A(a, \frac{\pi}{4})$ and $B(-a, \frac{5\pi}{4})$ respectively since $r^2 = a^2 \sin 2(\frac{\pi}{4}) = a^2 \sin \frac{\pi}{2} = a^2$ i.e., $r = \pm a$
- Region:**

- Curve lies completely within a circle of radius 'a' since the maximum value of $\sin 2\theta$ is 1.
- Imaginary:** $\sin \theta$ curve is negative when θ is between π and 2π , then $\sin 2\theta$ is negative between $\frac{\pi}{2}$ to π . Thus r^2 is negative and therefore r is imaginary for $\frac{\pi}{2} < \theta < \pi$. Similarly r is imaginary for $\frac{3\pi}{2} < \theta < 2\pi$. Hence curve does not exist in the 3rd and 4th quadrants.

6. Loop:	$\theta :$	0	$\frac{\pi}{8}$	$\frac{\pi}{4}$	$\frac{3\pi}{8}$	$\frac{\pi}{2}$
	$2\theta :$	0	$\frac{\pi}{4}$	$\frac{\pi}{2}$	$\frac{3\pi}{4}$	π
	$r :$	0	$\cdot 7a$	a	$\cdot 7a$	0
	Point:	0	C	A	D	0

Since curve is symmetric about the line $\theta = \frac{\pi}{4}$ ($y = x$ in the cartesian form), the arc OCA gets reflected about the line $\theta = \frac{\pi}{4}$ and thus forms the loop $OCADO$ in the first quadrant.

Due to symmetry about the pole (origin) this loop $OCADO$ in the first quadrant gets reflected to a loop $OFBEO$ in the third quadrant.

- Tangent:** $\tan \phi = r \frac{d\theta}{dr} = \frac{a\sqrt{\sin 2\theta} \cdot \sqrt{\sin 2\theta}}{a \cos 2\theta} = \tan 2\theta$.

5.18 — HIGHER ENGINEERING MATHEMATICS—II

Then $\phi = 2\theta$. So when $\theta = \frac{\pi}{4}$, $\phi = \frac{\pi}{2}$, $\tan \phi = \infty$. Thus the tangent to curve at $A(a, \frac{\pi}{4})$ is perpendicular to the initial line. On a similar argument, tangent to curve at $B(-a, \frac{3\pi}{4})$ is perpendicular to initial line.

Example 2: Three leaved rose $r = a \cos 3\theta$.

Solution:

Fig. 5.33

1. **Symmetry:** Curve is symmetric about the initial line, since $r(-\theta) = a \cos 3(-\theta) = a \cos 3\theta = r(\theta)$

2. **Pole:** Curve passes through the pole O when $r = a \cos 3\theta = 0$ i.e., when $\cos 3\theta = 0$ or for

$$3\theta = \frac{\pi}{2}, \frac{3\pi}{2}, \frac{5\pi}{2}, \frac{7\pi}{2}, \frac{9\pi}{2}, \frac{11\pi}{2}$$

Thus the curve passes through the pole when

$$\theta = \frac{\pi}{6}, \frac{3\pi}{6} = \frac{\pi}{2}, \frac{5\pi}{6}, \frac{7\pi}{6}, \frac{9\pi}{6} = \frac{3\pi}{2}, \frac{11\pi}{6}$$

The tangents to the curve at pole O are given by the 6 lines I: $\theta = \frac{\pi}{6}$; II: $\theta = \frac{\pi}{2}$; III: $\theta = \frac{5\pi}{6}$; IV: $\theta = \frac{7\pi}{6}$; V: $\theta = \frac{3\pi}{2}$; VI: $\theta = \frac{11\pi}{6}$.

Hence pole is a node.

3. **Asymptote:** No asymptote since r is finite for any θ

4. Curve intersects the initial line $\theta = 0$ at $A(a, 0)$ only (Fig. 5.33).

5. **Region:** curve lies completely within a circle $r = a$ since maximum value of $\cos 3\theta$ is one.

6. **Tangent:** $\tan \phi = r \frac{d\theta}{dr} = \frac{\cos 3\theta}{-3 \sin 3\theta}$. At $\theta = 0$, $\tan \phi = \infty$. So the tangent at the point $A(a, 0)$ is perpendicular to the initial line.

7. For $n = 3$, the curve has 3 loops.

8. **Variation of r :**

θ :	0	$\frac{\pi}{12}$	$\frac{\pi}{6}$	$\frac{3\pi}{12}$	$\frac{4\pi}{12}$	$\frac{5\pi}{12}$	$\frac{6\pi}{12}$
3θ :	0	$\frac{\pi}{4}$	$\frac{\pi}{2}$	$\frac{3\pi}{4}$	π	$\frac{5\pi}{4}$	$\frac{3\pi}{2}$
r :	a	$\cdot 7a$	0	$\cdot 7a$	$-a$	$\cdot 7a$	0
point :	A	B	O	C	D	E	O.

9. **Loop:** As θ varies from $\frac{\pi}{6}$ to $\frac{\pi}{2}$, r varies from 0 to $-a$ thus forming a loop $OCDEO$. Due to symmetry about initial line, this loop $OCDEO$ gets reflected to the loop in the second quadrant. Similarly the arc ABO gets reflected as OFA thus forming the loop $ABOFA$. Hence the three loops (or leaves).

Example 3: Limacon $r = 2(1 - 2 \sin \theta)$.

Solution:

1. Curve is symmetric about the line $\theta = \frac{\pi}{2}$ through pole and perpendicular to the initial line because $\sin(\pi - \theta) = \sin \theta$ i.e., $f(r, \pi - \theta) = f(r, \theta)$ (Fig. 5.34).

Fig. 5.34

2. **Pole:** Curve passes through the pole (origin O) since $r = 2(1 - 2 \sin \theta) = 0$ when $\theta = \frac{\pi}{6}$ and $\frac{5\pi}{6}$ ($\therefore \sin \frac{\pi}{6} = \sin \frac{5\pi}{6} = \frac{1}{2}$). The tangents to the curve at pole are given by two lines $\theta = \frac{\pi}{6}$ and $\theta = \frac{5\pi}{6}$. Thus pole is a node.

3. Curve meets the initial line $\theta = 0$ at the two points $A(2, 0)$ and $H(2, \pi)$. Curve meets the line $\theta = \frac{\pi}{2}$ at the two points $E(-2, \frac{\pi}{2})$ and $K(6, \frac{3\pi}{2})$.
4. *Asymptote*: No asymptote since r is finite for any θ .
5. *Region*: Since $|\sin \theta| \leq 1$, the entire curve lies within a circle $r = 6$ (of radius 6).
6. *Variation of r* :

$\theta =$	0	$\frac{\pi}{12}$	$\frac{\pi}{6}$	$\frac{\pi}{4}$	$\frac{\pi}{3}$	$\frac{\pi}{2}$
$\sin \theta =$	0	.26	0.5	$\frac{1}{\sqrt{2}}$	$\frac{\sqrt{3}}{2}$	1
$r =$	2	.965	0	-.83	-1.46	-2
Point:	A	B	O	C	D	E

As θ varies from $\frac{3\pi}{2}$ to $\frac{\pi}{2}$, r varies from 6 to -2, traversing the curve $KABOCDE$ which due to symmetry about $\theta = \frac{\pi}{2}$ gives a limaçon with an inner loop.

EXERCISE

Trace the following curves stating the salient points:

1. $r = a \sin 2\theta$.

Ans. Symmetric about the lines $\theta = \frac{\pi}{4}$, and $\theta = \frac{3\pi}{4}$ and about the line $\theta = \frac{\pi}{2}$; pole lies on curve, pole is node, four tangents at pole are $\theta = 0, \frac{\pi}{2}, \pi, \frac{3\pi}{2}$; $r \leq a$; $\theta = \frac{\pi}{4}$ meets curve at $A(a, \frac{\pi}{4})$; for $0 \leq \theta \leq \frac{\pi}{2}$, $0 \leq r \leq a$, first loop in first quadrant; other 3 loops by symmetry: for $n = 2$ there are 4 similar loops (refer Fig. 5.35).

Fig. 5.35

2. $r^2 = a^2 \sec 2\theta$ or $r^2 \cos 2\theta = a^2$.

Ans. Symmetric about $\theta = 0, \theta = \frac{\pi}{2}$, and $\theta = \frac{3\pi}{4}$. Curve exists for $r > a$; $\theta = \pm \frac{\pi}{4}$ are asymptotes ($r \rightarrow \infty$ as $\theta \rightarrow \pm \frac{\pi}{4}$); meets $\theta = 0$ line at $A(a, 0)$ (Fig. 5.36).

Fig. 5.36

$\frac{2\pi}{3}$	$\frac{3\pi}{4}$	$\frac{5\pi}{6}$	π	$\frac{7\pi}{6}$	$\frac{4\pi}{3}$	$\frac{3\pi}{2}$	2π
$\frac{\sqrt{3}}{2}$	$\frac{1}{\sqrt{2}}$	$\frac{1}{2}$	0	$-\frac{1}{2}$	$-\frac{\sqrt{3}}{2}$	-1	0
-1.46	-.83	0	2	4	5.464	6	2
F	G	O	H	I	J	K	A

3. $r = a(1 + \sin \theta)$.

Ans. Symmetric about $\theta = \frac{\pi}{2}$, pole O lies on curve, $\theta = \frac{-\pi}{2}$ is tangent at O; curve meets $A(a, 0)$, and $B(0, 2a)$; $\phi = \frac{\pi}{4} + \frac{\theta}{2}$; tangent $\theta = \frac{\pi}{2}$ is $\perp r$ to initial line; $r \leq 2a$ (Fig. 5.37).

Fig. 5.37

4. $r = a(1 - \cos \theta)$.

Ans. Symmetric about $\theta = 0$, pole lies on curve, $\theta = 0$ is tangent at pole, intersection points $(a, \frac{\pi}{2})$, $(a, \frac{3\pi}{2})$, $(2a, \pi)$; tangent at $\theta = \pi$, vertical, curve lies within $r = 2a$ (Fig. 5.38).

Fig. 5.38

5. $r = 1 + \sqrt{2} \cos \theta$.

Ans. Symmetric about $\theta = 0$, pole lies on the curve when $\theta = \frac{2\pi}{3}, \frac{7\pi}{6}$; lies within $r = 2.414$ (Fig. 5.39).

Fig. 5.39

6. Cissoid: $r = a \sin^2 \theta / \cos \theta$

Ans. Cartesian form $r = a \frac{(y/r)^2}{(x/r)}$ or $(x^2 + y^2)x = ay^2$ or $y^2(a - x) = x^3$. Symmetric about x -axis, passes through origin, origin is a cusp, $x = a$ is asymptote. Curve exists for $0 < x < a$ (refer Fig. 5.40).

Fig. 5.40

5.4 CURVE TRACING: STANDARD POLAR CURVES

Example: Lemniscate of Bernoulli,

$$r^2 = a^2 \cos 2\theta.$$

Solution:

I. Symmetry:

- Curve is symmetric about the initial line because $f(r, -\theta) = f(r, \theta)$.
- Curve is symmetric about the line $\theta = \pi/2$ because $f(r, \pi - \theta) = f(r, \theta)$.
- Curve is symmetric about the pole because $f(-r, \theta) = f(r, \theta)$.

II. Pole: Pole lies on the curve because $r = 0$ when $\cos 2\theta = 0$ or $2\theta = \pm \frac{\pi}{2}$ or $\theta = \pm \frac{\pi}{4}$. Thus there two distinct real tangents $\theta = \pm \frac{\pi}{4}$ to the curve at the pole. Hence pole is a node.

III. Asymptote: No asymptote because r is finite for any value of θ .

IV. Points of intersection of the curve with the initial line are $A(a, 0)$, $B(-a, 0)$ which are obtained by putting $\theta = 0$ in the equation. (i.e., $r^2 = a^2 \cos 2 \cdot 0 = a^2 \therefore r = \pm a$ and $\theta = 0$).

V. Region: Cosine curve is positive between $-\frac{\pi}{2}$ and $\frac{\pi}{2}$. Thus $\cos 2\theta \geq 0$ when $-\frac{\pi}{2} \leq 2\theta \leq \frac{\pi}{2}$ or $-\frac{\pi}{4} \leq \theta \leq \frac{\pi}{4}$.

Similarly, cosine curve is negative between $\frac{\pi}{2}$ to $\frac{3\pi}{2}$. Thus $\cos 2\theta < 0$ when $\frac{\pi}{2} < 2\theta < \frac{3\pi}{2}$ or $\frac{\pi}{4} < \theta < \frac{3\pi}{4}$. Thus $r^2 = a^2 \cos 2\theta < 0$ when $\frac{\pi}{4} < \theta < \frac{3\pi}{4}$. Hence curve does not exist between the lines $\theta = \frac{\pi}{4}$ and $\theta = \frac{3\pi}{4}$ (Fig. 5.41).

Fig. 5.41

VI. Direction of tangent: Differentiating the given equation

$$r^2 = a^2 \cos 2\theta$$

w.r.t. θ , we get $\frac{dr}{d\theta} = \frac{-2a^2 \sin 2\theta}{r} = \frac{-a \sin 2\theta}{\sqrt{\cos 2\theta}}$.

$$\text{We know that } \tan \phi = r \frac{d\theta}{dr} = r \cdot \frac{(-r)}{a^2 \sin 2\theta}.$$

$$\tan \phi = -\frac{a^2 \cos 2\theta}{a^2 \sin 2\theta} = -\cot 2\theta = \tan \left(2\theta + \frac{\pi}{2}\right).$$

$$\text{Thus } \phi = \frac{\pi}{2} + 2\theta.$$

When $\theta = 0$, $\phi = \frac{\pi}{2}$ or $\tan \theta = \infty$. Thus the tangents when $\theta = 0$ i.e., at $r = \pm a$ are perpendicular to the initial line.

When $\theta = \frac{\pi}{4}$, $\phi = \frac{\pi}{2} + 2 \cdot \frac{\pi}{4} = \pi$ so the radius vector itself is the tangent to curve at pole (corresponding to $\theta = \pi/4$).

VII. Derivative: $\frac{dr}{d\theta} = -\frac{a \sin 2\theta}{\sqrt{\cos 2\theta}}$.

Variation of θ	Variation of r	Sign of derivative	Nature of curve	Curve traced
$0 \leq \theta \leq \frac{\pi}{4}$	$a, 0.70a, 0$	Negative	Decreasing	ACO
$\frac{\pi}{4} < \theta < \frac{3\pi}{4}$	r is imaginary		Does not exist	
$\frac{3\pi}{4} < \theta < \pi$	$0, -0.70a, -a$	Positive	Increasing	ODB

VIII. Loop: Since curve crosses the initial line at A and O and is symmetric about the initial line, a loop of the curve ACOEA exists between O and A. Since curve is symmetric about the line $\theta = \frac{\pi}{2}$, this loop ACOEA is reflected as another loop ODBFO.

Example: Four leaved Rose: $r = a \cos 2\theta, a > 0$.

Solution: Since $n = 2$ the curve consists of $2n = 2 \cdot 2 = 4$ equal (similar) loops. Divide each quadrant into $(n = 2)$ equal parts (Fig. 5.42).

Fig. 5.42

1. **Symmetry:**

a. Curve is symmetric about the initial line since

$$r(-\theta) = a \cos (2(-\theta)) = a \cos 2\theta = r(\theta)$$

b. Curve is symmetric about the line $\theta = \frac{\pi}{2}$ which is perpendicular to the initial line since $r(\pi - \theta) = a \cos 2(\pi - \theta) = a \cos 2\pi \cdot \cos 2\theta = a \cos 2\theta = r(\theta)$.

2. **Pole:** Curve passes through the pole when

$$r = a \cos 2\theta = 0 \text{ i.e., } \cos 2\theta = 0 \text{ so when}$$

$$2\theta = \frac{\pi}{2}, \frac{3\pi}{2}, \frac{5\pi}{2}, \frac{7\pi}{2}.$$

Thus curve passes through the pole when $\theta = \frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}, \frac{7\pi}{4}$.

The tangents to the curve at pole are given by the lines $\theta = \frac{\pi}{4}, \theta = \frac{3\pi}{4}, \theta = \frac{5\pi}{4}$ and $\theta = \frac{7\pi}{4}$.

3. **Asymptote:** No asymptote since r is finite for any θ . In fact $r \leq a$ since maximum value of $\cos 2\theta = 1$. Thus the entire θ curve lies within the circle $r = a$.

4. **Value of r :** The following table gives values of $r = a \cos 2\theta$ for different values of θ . (Note: $\frac{1}{\sqrt{2}} = 0.70$).

$\theta = 0$	$\frac{\pi}{8}$	$\frac{\pi}{4}$	$\frac{3\pi}{8}$	$\frac{\pi}{2}$	$\frac{5\pi}{8}$	$\frac{3\pi}{4}$	$\frac{7\pi}{8}$	π
$2\theta = 0$	$\frac{\pi}{4}$	$\frac{\pi}{2}$	$\frac{3\pi}{4}$	π	$\frac{5\pi}{4}$	$\frac{3\pi}{2}$	$\frac{7\pi}{4}$	2π
$r = a$	$.7a$	0	$-.7a$	$-a$	$-.7a$	0	$.7a$	a
$\theta = \frac{9\pi}{8}$	$\frac{5\pi}{4}$	$\frac{11\pi}{8}$	$\frac{3\pi}{2}$	$\frac{13\pi}{8}$	$\frac{7\pi}{4}$	$\frac{15\pi}{8}$	2π	
$2\theta = \frac{9\pi}{4}$	$\frac{5\pi}{2}$	$\frac{11\pi}{4}$	3π	$\frac{13\pi}{4}$	$\frac{7\pi}{2}$	$\frac{15\pi}{4}$	4π	
$r = .7a$	0	$-.7a$	$-a$	$-.7a$	0	$.7a$	a	

As θ varies from 0 to $\frac{\pi}{4}$, r varies from a to 0 thus traversing the curve ABO. Due to symmetry about initial line ABO gets reflected as OCA. The loop ABOCA gets reflected as OEDFO due to symmetry about line $\theta = \frac{\pi}{2}$. Similarly OGH forms loop OGHIO due to symmetry about the line $\theta = \frac{\pi}{2}$. This loop gets reflected as another loop OLJKO due to symmetry about the initial line.

Example: Three leaved Rose; $r = a \sin 3\theta$.

Solution: For $n = 3$ odd, the curve consists of three loops (Fig. 5.43).

Fig. 5.43

5.22 — HIGHER ENGINEERING MATHEMATICS—II

1. **Symmetry:** Curve is symmetric about the line $\theta = \frac{\pi}{2}$ passing through the pole 0 and perpendicular to the initial line, since

$$\begin{aligned} r(\pi - \theta) &= a \sin(3(\pi - \theta)) \\ &= a \sin 3\theta = r(\theta) \end{aligned}$$

2. **Pole:** Curve passes through the pole 0 when $r = a \sin 3\theta = 0$ i.e., when $3\theta = 0, \pi, 2\pi, 3\pi, 4\pi, 5\pi$. Thus for $\theta = 0, \frac{\pi}{3}, \frac{2\pi}{3}, \pi, \frac{4\pi}{3}, \frac{5\pi}{3}$, curve passes through the pole. The tangents to the curve at the pole are given by the lines $\theta = 0, \theta = \frac{\pi}{3}, \theta = \frac{2\pi}{3}, \theta = \pi, \theta = \frac{4\pi}{3}$ and $\theta = \frac{5\pi}{3}$. Pole is a node since $\theta = \frac{\pi}{3}$ and $\theta = \frac{2\pi}{3}$ are two real distinct tangents at 0.

3. **Asymptote:** No asymptote since r is always finite for any θ . In fact maximum value of r is a since maximum value of $\sin 3\theta$ is 1. Thus the entire curve lies within the region of the circle $r = a$.

4. **Intersection:** Curve meets the line $\theta = \frac{\pi}{2}$ at $r = a \sin 3(\frac{\pi}{2}) = -a$.

5. **Variation of r :** Variation of r as θ varies from 0 to $\frac{\pi}{3}$.

θ :	0	$\frac{\pi}{12}$	$\frac{\pi}{6}$	$\frac{\pi}{4}$	$\frac{\pi}{3}$
3θ :	0	$\frac{\pi}{4}$	$\frac{\pi}{2}$	$\frac{3\pi}{4}$	π
r :	a	$\cdot 7a$	a	$\cdot 7a$	0

6. **Loops:** As θ varies from 0 to $\frac{\pi}{3}$, r varies from 0 to a to 0. So the curve traverses the loop OAO in the first quadrant. This loop OAO is reflected as the second loop OBO in the second quadrant because curve is symmetric about the line $\theta = \frac{\pi}{2}$. Thus the second loop OBO is obtained as θ varies from $2\pi/3$ to π .

7. **Third loop:**

θ :	$\frac{\pi}{3}$	$\frac{5\pi}{12}$	$\frac{\pi}{2}$	$\frac{7\pi}{12}$	$\frac{2\pi}{3}$
3θ :	π	$\frac{5\pi}{4}$	$\frac{3\pi}{2}$	$\frac{7\pi}{4}$	2π
r :	0	$\cdot 7a$	$-a$	$\cdot 7a$	0

As θ varies from 0 to $\frac{\pi}{2}$ the arc OC is traversed which gets reflected to form the third loop OCO in the third quadrant because the curve is symmetric about the line $\theta = \frac{\pi}{2}$.

Solution: Limacons are polar curves whose equations are of the form

$$r = a + b \sin \theta, r = a - b \sin \theta,$$

$$r = a + b \cos \theta, r = a - b \cos \theta$$

with $a > 0$ and $b > 0$. We get a

Limacon with inner loop when $a/b < 1$ or $a < b$; a cardioid when $a = b$; dimpled Limacon when $1 < a/b < 2$ and convex Limacon when $\frac{a}{b} \geq 2$.

For the curve $r = a + b \cos \theta$ consider three cases $a < b$, $a = b$ and $a > b$

Case 1: $a < b$: Limacon with inner loop:

$$r = 1 + 2 \cos \theta; \quad a = 1 < 2 = b$$

Solution:

1. **Symmetry:** Curve is symmetric about the initial line since $r(-\theta) = 1 + 2 \cos(-\theta) = 1 + 2 \cos \theta = r(\theta)$.

2. **Pole:** Curve passes through the pole when $\theta = \frac{2\pi}{3}$ and $\theta = \frac{4\pi}{3}$ because $r = 1 + 2 \cos \frac{2\pi}{3} = 1 - 1 = 0$ and $r = 1 + 2 \cos \frac{4\pi}{3} = 1 - 1 = 0$.

3. **Tangents:** The lines $\theta = \frac{2\pi}{3}$ and $\theta = \frac{4\pi}{3}$ are the tangents to the curve at pole 0.

4. **Pole (origin)** is a node point since there are two real distinct tangents at pole.

5. **Intercepts:** Curve meets the initial line $\theta = 0$ at the points $A(3, 0)$ and $f(\pi, 1)$.

Curve meets the line $\theta = \frac{\pi}{2}$ (perpendicular to the initial line) at $D(\frac{\pi}{2}, 1)$ and $H(\frac{3\pi}{2}, 1)$ (Fig. 5.44).

Fig. 5.44

Example: Limacon of pascal $r = a + b \cos \theta$.

6. *Asymptote*: No asymptote since r is finite for any θ .
7. *Region*: Since maximum value of $\cos \theta$ is 1, $r \leq 3$. Thus the entire curve lies inside the circle $r = 3$.
8. *Derivative*: $\tan \phi = r \frac{d\theta}{dr} = \frac{1+2\cos\theta}{-2\sin\theta}$. For $\theta = 0$ and $\frac{\pi}{2}$, $\tan \phi = \infty$ i.e., $\phi = \frac{\pi}{2}$. Thus the tangents to the curve at $\theta = 0$ and $\theta = \frac{\pi}{2}$ are perpendicular to the initial line.
9. Value of r :

$\theta =$	0	$\frac{\pi}{6}$	$\frac{\pi}{3}$	$\frac{\pi}{2}$	$\frac{2\pi}{3}$	$\frac{5\pi}{6}$	π
$r =$	3	$1 + \sqrt{3}$	2	1	0	$1 - \sqrt{3}$	-1
Point:	A	B	C	D	O	E	F

Note: $\sqrt{3} = 1.732$.

10. *Loops*: **Inner loop**: As the curve crosses the initial line at O and F and is symmetric about the initial line, a loop exists between O and F . Similarly another loop exists between O and A . The curve is traced as shown in the figure.

Case 2: $a = b$: **Cardioid**: $r = a(1 + \cos \theta)$.

Solution:

- Symmetric**: Curve is symmetric about the initial line.
- Pole**: Curve passes through pole O since $r = a(1 + \cos(\pi)) = a(1 - 1) = 0$ when $\theta = \pi$. The tangent to the curve at the pole is $\theta = \pi$.
- Asymptote**: No asymptote since r is finite for any θ .
- Region**: Curve lies within the circle $r = 2a$ since maximum value of $\cos \theta$ is 1.
- Intersection**: Curve meets the initial line at $A(2a, 0)$ and $O(0, \pi)$ curve intersects the line $\theta = \frac{\pi}{2}$ at $C(a, \frac{\pi}{2})$ and $F(a, \frac{3\pi}{2})$.
- Value of r :

θ :	0	$\frac{\pi}{3}$	$\frac{\pi}{2}$	$\frac{2\pi}{3}$	π	$\frac{4\pi}{3}$	$\frac{3\pi}{2}$	$\frac{11\pi}{6}$	2π
r :	$2a$	$\frac{3a}{2}$	a	$\frac{a}{2}$	0	$\frac{a}{2}$	a	$\frac{3a}{2}$	$2a$
Point:	A	B	C	D	O	E	F	G	A

(Fig. 5.45)

Fig. 5.45

$\frac{7\pi}{6}$	$\frac{4\pi}{3}$	$\frac{3\pi}{2}$	$\frac{5\pi}{3}$	$\frac{11\pi}{6}$	2π
$1 - \sqrt{3}$	0	1	2	$1 + \sqrt{3}$	3
G	O	H	I	J	A

7. *Tangent*:

$$\begin{aligned}\tan \phi &= r \frac{d\theta}{dr} = \frac{a(1 + \cos \theta)}{-a \sin \theta} \\ &= -\cot \frac{\theta}{2} \\ &= \tan\left(\frac{\theta}{2} + \frac{\pi}{2}\right).\end{aligned}$$

So $\phi = \frac{\theta}{2} + \frac{\pi}{2}$. When $\theta = 0$, $\phi = \frac{\pi}{2}$, $\tan \phi = \infty$. Then tangent at $A(2a, 0)$ is perpendicular to the initial line.

Case 3: $a > b$: **Dimpled limaçon** $r = 3 + 2 \cos \theta$

- Curve is symmetric about the initial line.
- Curve does not pass through pole because for any θ , $r = 3 + 2 \cos \theta \neq 0$ (otherwise $|\cos \theta| = |\frac{-3}{2}| > 1$ which is not true for any θ).
- Curve meets the initial line at $A(5, 0)$ and at $E(1, \pi)$.
Curve meets the line $\theta = \frac{\pi}{2}$ at $C(3, \frac{\pi}{2})$ and $F(3, \frac{3\pi}{2})$.
- No asymptote since r is finite.
- Region**: Curve lies within a circle of radius 5 since $\cos \theta$ maximum value is 1.
- Tangent**: $\tan \phi = r \frac{d\theta}{dr} = \frac{3+2\cos\theta}{-2\sin\theta}$.

No tangent to the curve is parallel to the initial line since $\tan \phi \neq 0$ for any θ . The tangent at $A(5, 0)$

5.24 — HIGHER ENGINEERING MATHEMATICS—II

is perpendicular to the initial line since $\tan \theta = \infty$ when $\theta = 0$

7. Value of r :

$\theta =$	0	$\frac{\pi}{3}$	$\frac{\pi}{2}$	$\frac{2\pi}{3}$	π
$r =$	5	4	3	2	1
Point:	A	B	C	D	E

Since the curve is symmetric about the initial line EFCA is obtained as a reflection of ABCDE (see Fig. 5.46).

Fig. 5.46

5.5 CURVE TRACING: PARAMETRIC CURVES

Let $x = f(t)$ and $y = g(t)$ be the parametric equations of a curve with t as parameter.

Case 1: If t can be eliminated between $x = f(t)$ and $y = g(t)$ we may obtain a cartesian equation in x and y .

Example: $x = a \cos t$, $y = b \sin t$, Eliminating t , $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ is the cartesian equation.

Example: $x = a \sin^2 t$, $y = a \frac{\sin^2 t}{\cos t}$, Eliminating t , $y^2(a - x) = x^3$ is cartesian equation, of cissoid.

Case 2: Suppose t can not be eliminated.

1. **Symmetry:** Symmetric about x -axis if $x = f(t)$ is even and $y = g(t)$ is odd function of t . Symmetric

about y -axis if $x = f(t)$ is odd and $y = g(t)$ is an even function of t .

2. **Origin:** Determine t for which $x = 0$ and $y = 0$.

3. **Intercept:** y -intercept obtained for values of t for which $x = 0$, x -intercept for values of t for which $y = 0$.

4. Find the least and greatest values of x and y .

5. **Asymptotes:** $\lim_{t \rightarrow t_1} x = \infty$, $\lim_{t \rightarrow t_1} y = \infty$. Then $t = t_1$ is an asymptote.

6. **Tangents:** Vertical and horizontal tangents exist at points where $\frac{dy}{dx} = \frac{(dy/dt)}{(dx/dt)}$ is ∞ or 0.

7. Curve does not exist when x or y is imaginary.

8. If $x = f(t)$ and $y = g(t)$ are periodic functions of t having a common period, it is enough to trace the curve for one period.

WORKED OUT EXAMPLES

Example 1: Cycloid

$$x = a(t - \sin t); y = a(1 - \cos t)$$

Solution: $y = 0$ when $\cos t = 1$ i.e., when $t = 0, 2\pi, 4\pi$, etc. Curve meets x -axis when $t = 0, 2\pi, 4\pi, 6\pi$, etc.

Since $|\cos t| \leq 1$, $0 \leq y \leq 2a$, curve lies above the x -axis and below the horizontal line $y = 2a$. At $t = 0$, $x = 0$, $y = 0$. Thus origin O lies on the curve. Curve is symmetric about y -axis since x is an odd function and y is an even function of t . For any t , x and y are finite, no asymptote.

$$\frac{dx}{dt} = a(1 - \cos t)$$

$$\frac{dy}{dt} = a \sin t$$

$$\frac{dy}{dx} = \frac{(dx/dt)}{(dy/dt)} = \frac{a \sin t}{a(1 - \cos t)}$$

$$= \frac{2 \cdot \sin \frac{t}{2} \cdot \cos \frac{t}{2}}{2 \cdot \sin^2 \frac{t}{2}} = \frac{\cos \frac{t}{2}}{\sin \frac{t}{2}} = \cot \frac{t}{2}$$

t :	0	$\frac{\pi}{2}$	π	$\frac{3\pi}{2}$	2π
x :	0	$a(\frac{\pi}{2} - 1)$ (0.57a)	$a\pi$	$a(\frac{3\pi}{2} + 1)$ (5.71a)	$2\pi a$ (6.28a)
y :	0	a	$2a$	a	0
$\frac{dy}{dx}$:	∞	1	0	-1	∞
point:	O	A	B	C	D

x and y are defined for all t .

Tangents at the points O and D are vertical while tangent at B is horizontal ($y = 2a$) and tangents at A and C are of slope 1 and -1 . B is known as vertex and x -axis as base. Curve is periodic of period 2π in the interval $[0, 2\pi]$ with t as the parameter. Curve repeats over intervals of $[0, 2a\pi]$ (refer Fig. 5.47).

Fig. 5.47

EXERCISE

Trace the following curves:

1. Cycloid $x = a(t + \sin t)$, $y = a(1 - \cos t)$.

Ans. $t = 0$, then $x = 0$, $y = 0$, origin lies. Symmetric about y -axis since x is odd and y is even function of t . Curve lies between $y = 0$ and $y = 2a$. Periodic of period 2π . Tangent at O horizontal, tangents at $t = \pm\pi$ are vertical. No asymptote, $dy/dx = \tan(t/2)$ (Fig. 5.48).

Fig. 5.48

2. Tractrix: $x = a[\cos t + \frac{1}{2} \ln \tan^2(\frac{t}{2})]$; $y = a \sin t$.

Ans. Symmetric about x -axis since x is even and y odd function of t (Fig. 5.49). Symmetric about

y -axis, origin does not on curve, y lies between $\pm a$, x -axis is asymptote $(0, \pm a)$ are intersection with y -axis at $t = \pm\frac{\pi}{2}$, at which tangents are parallel to y -axis since $\frac{dy}{dx} = \tan t$.

Fig. 5.49

3. $x = a(t + \sin t)$, $y = a(1 + \cos t)$.

Ans. Symmetric about y -axis, since x is odd and y is even function of t . Origin does not lie on curve. $(0, 2a)$ is y -intercept.

Curve lies between $y = 0$ and $y = 2a$. No asymptote, $\frac{dy}{dx} = -\tan \frac{\theta}{2}$. Tangent at $(0, 2a)$ is horizontal. Tangent, at $\theta = \pm\pi$ i.e., $(\pm a\pi, 0)$ are vertical (refer Fig. 5.50).

Fig. 5.50

4. $x = a \sin 2t(1 + \cos 2t)$, $y = a \cos 2t(1 - \cos 2t)$ (see Fig. 5.51).

Fig. 5.51

Ans. x and y are periodic of period π . Origin lies on curve. y -intercept $B(0, 2a)$; $\frac{dx}{dt} = 4a \cos 3t \cos t$, $\frac{dy}{dt} = 4a \cos 3t \sin t$, $\frac{dy}{dx} = \tan t$, $A(\frac{3\sqrt{3}a}{4}, \frac{a}{4})$, $C(\frac{-3\sqrt{3}a}{4}, \frac{a}{4})$.

5.26 — HIGHER ENGINEERING MATHEMATICS—II

Range of t	Range of x	Range of y	Quadrant	Sign of y'	Nature of curve $y = h(x)$	Sign of y''	Type of curve
$0 < t < \frac{\pi}{2}$	$0 < x < a$	$0 < y < a$	I	–ve	Decreases	> 0	Concave
$\frac{\pi}{2} < t < \pi$	$-a < x < 0$	$0 < y < a$	II	+ve	Increases	> 0	Concave
$\pi < t < \frac{3\pi}{2}$	$-a < x < 0$	$-a < y < 0$	III	–ve	Decreases	< 0	Convex
$\frac{3\pi}{2} < t < 2\pi$	$0 < x < a$	$-a < y < 0$	IV	+ve	Increases	< 0	Convex

5.6 CURVE TRACING: STANDARD PARAMETRIC CURVES

Example: Four Cusped Hypocycloid or Astroid. $x = a \cos^3 t$, $y = a \sin^3 t$, with $a > 0$ (Fig. 5.52).

Fig. 5.52

$$\frac{dy}{dx} = \frac{3a \sin^2 t \cos t}{-3a \cos^2 t \sin t} = -\tan t.$$

$\frac{dy}{dx}$ at $t = \pi/2, 3\pi/2$ is ∞ . Therefore the tangents at $t = \pi/2$ and $t = 3\pi/2$ are vertical. Similarly horizontal tangents occur at $t = 0, \pi, 2\pi$ where $\frac{dy}{dx} = 0$.

$$\frac{d^2y}{dx^2} = 1/(3a \cos^4 t \sin t).$$

Example: Folium of Descartes: $x = 3at/(1+t^3)$; $y = 3at^2/(1+t^3)$, $a > 0$.

Solution: x and y are defined for all values of t except at $t = -1$.

$x = 0, y = 0$ when $t = 0$. As $t \rightarrow \pm\infty$, $x \rightarrow 0$ and $y \rightarrow 0$

$$\frac{dx}{dt} = 6a\left(\frac{1}{2} - t^3\right)/(1+t^3)^2$$

Range of t	Range of x	Range of y	Sign of y'	Nature of curve	Quadrant
$-\infty < t < -1$	$0 < x < \infty$	$-\infty < y < 0$	–ve	Decreases	IV
$-1 < t < 0$	$-\infty < x < 0$	$0 < y < \infty$	–ve	Decreases	II
$0 < t < \frac{1}{\sqrt[3]{2}}$	$0 < x < a\sqrt[3]{4}$	$0 < y < a\sqrt[3]{2}$	+ve	Increases	I
$\frac{1}{\sqrt[3]{2}} < t < \sqrt[3]{2}$	$a\sqrt[3]{4} > x > a\sqrt[3]{2}$	$a\sqrt[3]{2} < y < a\sqrt[3]{4}$	–ve	Decreases	I
$\sqrt[3]{2} < t < \infty$	$a\sqrt[3]{2} > x > 0$	$a\sqrt[3]{4} < y < 0$	+ve	Increases	I

Solution: x and y are defined for all values of t . It is enough to consider t in $[0, 2\pi]$ since $\cos^3 t$ and $\sin^3 t$ are periodic functions of period 2π . As x and y vary in $[-a, a]$ curve has no asymptotes.

$$\frac{dx}{dt} = -3a \cos^2 t \sin t,$$

$$\frac{dy}{dt} = 3a \sin^2 t \cos t$$

$$\frac{dy}{dx} = 3at(2-t^3)/(1+t^3)^2$$

$$\frac{dy}{dx} = t(2-t^3)/[2(\frac{1}{2}-t^3)].$$

Tangents at $(x = a\sqrt[3]{2}, y = a\sqrt[3]{4})$ is horizontal since $\frac{dy}{dx} = 0$ at this point $t = \sqrt[3]{2}$. Tangent at $(x = a\sqrt[3]{4}, y = a\sqrt[3]{2})$ is vertical since $\frac{dy}{dx} = \infty$ at this point $t = \sqrt[3]{2}$.

$$\text{Asymptote: } m = \lim_{x \rightarrow \infty} \frac{y}{x} = \lim_{t \rightarrow -1} \frac{3at^2(1+t^3)}{3at(1+t^3)} = -1$$

$$c = \lim_{x \rightarrow \infty} (y - mx) = \lim_{t \rightarrow -1} \left[\frac{3at^2}{1+t^3} - (-1) \cdot \frac{3at}{1+t^3} \right] = -a.$$

So $y = -x - a$ or $y + x + a = 0$ is the asymptote (Fig. 5.53).

Fig. 5.20

Chapter 6

Integral Calculus

INTRODUCTION

Integral calculus is the study of finding a function from information about its rate of change. Application of integral calculus includes finding areas of irregular plane regions, length of curves, volume, surface area of solid of revolution, mass, moment of inertia, centre of gravity. Successive application of a reduction formula, which connects an integral with another integral of lower order, enables to evaluate the given integral. Sine-integral function (useful in optics), gamma, beta, functions are some important improper integrals.

6.1 REDUCTION FORMULAE

Reduction formulae reduces a given integral to a known integration form by the repeated application of integration by parts. Here reduction formulae of only trigonometric functions $\sin^n x$, $\cos^n x$, $\tan^n x$, $\cot^n x$, $\sec^n x$, $\operatorname{cosec}^n x$, $\sin^n x \cdot \cos^n x$ are considered.

Reduction Formula for $\int \sin^n x \, dx$; $n > 0$

Consider

$$\begin{aligned} I &= \int \sin^n x \, dx = \int \sin^{n-1} x \cdot \sin x \, dx \\ &= - \int \sin^{n-1} x \cdot d(\cos x) \end{aligned}$$

Integrating by parts. $\int u \, dv = uv - \int v \, du$

$$\begin{aligned} I &= \sin^{n-1} x (-\cos x) - \\ &\quad - \int (-\cos x) \cdot (n-1) \sin^{n-2} x \cdot \cos x \, dx \end{aligned}$$

$$\begin{aligned} &= -\cos x \cdot \sin^{n-1} x + (n-1) \int \sin^{n-2} x \cdot \cos^2 x \, dx \\ &= -\cos x \cdot \sin^{n-1} x + (n-1) \int \sin^{n-2} x (1 - \sin^2 x) \, dx \\ I &= -\cos x \cdot \sin^{n-1} x - (n-1) \int \sin^n x \, dx + \\ &\quad + (n-1) \cdot \int \sin^{n-2} x \, dx \quad \text{or} \\ (1+n-1)I &= -\cos x \cdot \sin^{n-1} x + (n-1) \int \sin^{n-2} x \, dx \\ \int \sin^n x \, dx &= -\frac{1}{n} \cos x \cdot \sin^{n-1} x + \frac{n-1}{n} \int \sin^{n-2} x \, dx \quad (1) \end{aligned}$$

Reduction Formula for $\int \cos^n x \, dx$; $n > 0$

Put $x = \frac{\pi}{2} - y$, $dx = -dy$ in (1) then

$$\int \cos^n y \, dy = \frac{1}{n} \sin y \cos^{n-1} y + \frac{n-1}{n} \int \cos^{n-2} y \, dy \quad (2)$$

Note 1: In the reduction formulae (1) and (2), the powers of $\sin x$ and $\cos x$ are reduced by 2.

Note 2: Instead of reduction formulae, alternatively the following substitution methods can also be used, to evaluate (1) and (2).

- Put $\cos x = t$ in $\int \sin^n x \, dx$ when the power (index) n is odd and integrate the integral in t . Then replace t by $\cos x$.
- Put $\sin x = t$ in $\int \cos^n x \, dx$ when the power (index) n is odd.
- When the index n is an even positive integer and n is small, then express powers of $\sin x$ and $\cos x$ in terms of multiple

6.2 — HIGHER ENGINEERING MATHEMATICS—II

angles using $\sin^2 x = \frac{1-\cos 2x}{2}$, $\cos^2 x = \frac{1+\cos 2x}{2}$,
 $\sin x \cdot \cos x = \frac{\sin 2x}{2}$

- d. When n is large positive integer, use DeMoivre's theorem to express $\sin^n x$ and $\cos^n x$ in terms of multiple angles as follows: put $z = \cos x + i \sin x$, then $\frac{1}{z} = \cos x - i \sin x$, $2 \cos x = z + \frac{1}{z}$, and $2i \sin x = z - \frac{1}{z}$ so that $2 \cos nx = z^n + \frac{1}{z^n}$ and $2i \sin nx = z^n - \frac{1}{z^n}$. Now $(2 \cos x)^n = 2^n \cos^n x = (z + \frac{1}{z})^n = z^n + nc_1 z^{n-2} + \dots + nc_{n-1} \frac{1}{z^{n-2}} + \frac{1}{z^n}$.

Using $nc_1 = nc_{n-1}$, $nc_2 = nc_{n-2}$ etc.

$$2^n \cos^n x = (z^n + \frac{1}{z^n}) + nc_1(z^{n-2} + \frac{1}{z^{n-2}}) + \dots$$

$$= 2 \cos nx + nc_1 \cdot 2 \cdot \cos(n-2)x + \dots$$

$$2^n \int \cos^n x dx = 2 \left[\frac{\sin nx}{n} + \frac{nc_1}{(n-2)} \cdot \sin(n-2)x + \dots \right]$$

Similarly, $(2i \sin x)^n = (y - \frac{1}{y})^n$.

Wallis' Formula*

Prove that

$$I_n = \int_0^{\pi/2} \sin^n x dx = \int_0^{\pi/2} \cos^n x dx$$

$$= \begin{cases} \frac{n-1}{n} \cdot \frac{n-3}{n-2} \cdot \frac{n-5}{n-4} \dots \frac{2}{3} \cdot I_1 & \text{when } n \text{ is odd} \\ \frac{n-1}{n} \cdot \frac{n-3}{n-2} \cdot \frac{n-5}{n-4} \dots \frac{1}{2} \cdot I_0 & \text{when } n \text{ is even.} \end{cases} \quad (3)$$

Here

$$I_1 = \int_0^{\pi/2} \sin x dx = \int_0^{\pi/2} \cos x dx = 1$$

$$\text{and } I_0 = \int_0^{\pi/2} dx = \frac{\pi}{2}.$$

Solution: Taking the limits 0 to $\frac{\pi}{2}$ in the reduction formula (1), we have

$$I_n = \int_0^{\pi/2} \sin^n x dx = -\frac{\cos x \cdot \sin^{n-1} x}{n} \Big|_0^{\pi/2} +$$

$$+ \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x dx$$

$$I_n = 0 + \frac{n-1}{n} \cdot I_{n-2}$$

Using this recurrence relation

$$I_{n-2} = \frac{n-3}{n-2} I_{n-4}$$

$$I_{n-4} = \frac{n-5}{n-4} I_{n-6}$$

$$\begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \end{array}$$

$$I_3 = \frac{2}{3} I_1 \quad \text{when } n \text{ is odd}$$

$$I_2 = \frac{1}{2} I_0 \quad \text{when } n \text{ is even}$$

Substituting these values and using $I_1 = 1$, $I_0 = \frac{1}{2}$

$$I_n = \frac{n-1}{n} \cdot \frac{n-3}{n-2} \cdot \frac{n-5}{n-4} \dots \frac{2}{3} \cdot \frac{1}{2} \cdot \frac{\pi}{2} \quad \text{when } n \text{ is odd} \quad (3)$$

$$I_n = \frac{n-1}{n} \cdot \frac{n-3}{n-2} \cdot \frac{n-5}{n-4} \dots \frac{1}{2} \cdot \frac{\pi}{2} \quad \text{when } n \text{ is even.}$$

By the substitution $x = \frac{\pi}{2} - y$, we have

$$I_n = \int_0^{\pi/2} \sin^n x dx = \int_0^{\pi/2} \cos^n x dx$$

Note: The numerator of I_n consists of products of numbers starting from $(n-1)$ and decreasing by 2. The denominator of I_n consists of products of numbers starting from n and decreasing by 2. In either case the process terminates with the last quotient as $\frac{2}{3}$ or $\frac{1}{2}$ according as n is odd or even. In the event when n is even the last factor $\frac{1}{2}$ is multiplied by $\frac{\pi}{2}$.

Corollary 1: Certain definite integrals can be reduced to Wallis's formula (3) by simple trigonometric substitution. Let n be a positive integer. Then

a. Putting $x = a \sin \theta$,

$$\int_0^a \frac{x^n dx}{\sqrt{a^2 - x^2}} = \int_0^{\pi/2} \frac{a^n \cdot \sin^n \theta \cdot a \cos \theta d\theta}{\cos \theta}$$

$$= a^n \int_0^{\pi/2} \sin^n \theta d\theta$$

b. Putting $x = a \tan \theta$,

$$\int_0^\infty \frac{dx}{(a^2 + x^2)^n} = \int_0^{\pi/2} \frac{a \sec^2 \theta d\theta}{a^{2n} (\sec^2 \theta)^n}$$

$$= \frac{1}{a^{2n-1}} \int_0^{\pi/2} \cos^{2n-2} \theta d\theta$$

c. Putting $x = a \tan \theta$

$$\int_0^\infty \frac{dx}{(a^2 + x^2)^{n+\frac{1}{2}}} = \frac{1}{a^{2n+1}} \int_0^{\pi/2} \frac{a \sec^2 \theta d\theta}{\sec^{2n+1} \theta}$$

$$= \frac{1}{a^{2n}} \int_0^{\pi/2} \cos^{2n-1} \theta d\theta$$

*John Wallis (1616–1703), English mathematician.

Reduction Formula for $\int \tan^n x \, dx$

$$\begin{aligned}
 \int \tan^n x \, dx &= \int \tan^{n-2} x \cdot \tan^2 x \, dx \\
 &= \int \tan^{n-2} x \cdot (\sec^2 x - 1) \, dx \\
 &= \int \tan^{n-2} x \cdot \sec^2 x \, dx - \int \tan^{n-2} x \, dx \\
 &= \int \tan^{n-2} x \cdot d(\tan x) - \int \tan^{n-2} x \, dx \\
 \int \tan^n x \, dx &= \frac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x \, dx \quad (4)
 \end{aligned}$$

This formula reduces power of $\tan x$ by 2. After repeated application, the integral on R.H.S. reduces to $I_1 = \int \tan x \, dx = \log \sec x$ if n is odd or reduces to $I_2 = \int \tan^2 x \, dx = \tan x - x$ if n is even. Similarly,

Reduction Formula for $\int \cot^n x \, dx$

$$\begin{aligned}
 \int \cot^n x \, dx &= \int \cot^{n-2} x (\operatorname{cosec}^2 x - 1) \, dx \\
 &= -\frac{\cot^{n-1} x}{n-1} - \int \cot^{n-2} x \, dx \quad (5)
 \end{aligned}$$

If n is odd, $I_1 = \int \cot x \, dx = \ln \sin x$ or
 If n is even, $I_2 = \int \cot^2 x \, dx = -\cot x - x$

Reduction Formula for $\int \sec^n x \, dx$

$$\int \sec^n x \, dx = \int \sec^{n-2} x \cdot \sec^2 x \, dx = \int \sec^{n-2} x \cdot d(\tan x).$$

Integrating by parts

$$\begin{aligned}
 &= \tan x \cdot \sec^{n-2} x - \int \tan x \cdot (n-2) \cdot \sec^{n-3} x \cdot \sec x \cdot \tan x \, dx \\
 &= \tan x \cdot \sec^{n-2} x - (n-2) \int \tan^2 x \cdot \sec^{n-2} x \, dx \\
 &= \tan x \cdot \sec^{n-2} x - (n-2) \int \sec^{n-2} x \cdot (\sec^2 x - 1) \, dx \\
 &= \tan x \cdot \sec^{n-2} x - (n-2) \left[\int \sec^n x \, dx - \int \sec^{n-2} x \, dx \right] \\
 [1+(n-2)] \int \sec^n x \, dx &= \tan x \cdot \sec^{n-2} x + \\
 &\quad + (n-2) \int \sec^{n-2} x \, dx
 \end{aligned}$$

$$\begin{aligned}
 \int \sec^n x \, dx &= \frac{\tan x \cdot \sec^{n-2} x}{n-1} + \\
 &\quad + \frac{n-2}{n-1} \int \sec^{n-2} x \, dx \quad (6)
 \end{aligned}$$

The powers of $\sec x$ are reduced by 2.

If n is odd, $I_1 = \int \sec x \, dx = \ln (\sec x + \tan x)$ or
 If n is even, $I_2 = \int \sec^2 x \, dx = \tan x$

Reduction Formula for $\int \operatorname{cosec}^n x \, dx$

Similarly, we get

$$\begin{aligned}
 \int \operatorname{cosec}^n x \, dx &= -\frac{\cot x \cdot \operatorname{cosec}^{n-2} x}{n-1} + \\
 &\quad + \frac{n-2}{n-1} \int \operatorname{cosec}^{n-2} x \, dx \quad (7)
 \end{aligned}$$

If n is odd, $I_1 = \int \operatorname{cosec} x \, dx = \ln \tan \frac{x}{2}$ or
 If n is even, $I_2 = \int \operatorname{cosec}^2 x \, dx = -\cot x$.

Reduction Formula for $\int \sin^m x \cdot \cos^n x \, dx$; $m, n > 0$

Consider

$$\begin{aligned}
 \int \sin^m x \cdot \cos^n x \, dx &= \int \sin^{m-1} x \cdot \sin x \cdot \cos^n x \, dx \\
 &= \int \sin^{m-1} x \cdot d\left(-\frac{\cos^{n+1} x}{n+1}\right)
 \end{aligned}$$

Integrating by parts

$$\begin{aligned}
 &= -\frac{\sin^{m-1} x \cdot \cos^{n+1} x}{(n+1)} + \int \frac{\cos^{n+1} x}{n+1} \cdot (m-1) \times \\
 &\quad \times \sin^{m-2} x \cdot \cos x \, dx \\
 &= -\frac{\sin^{m-1} x \cdot \cos^{n+1} x}{(n+1)} + \frac{m-1}{n+1} \int \cos^n x \cdot \sin^{m-2} x \times \\
 &\quad \times (1 - \sin^2 x) \, dx \\
 &= -\frac{\sin^{m-1} x \cdot \cos^{n+1} x}{(n+1)} + \\
 &\quad + \frac{m-1}{n+1} \left[\int \cos^n x \cdot \sin^{m-2} x \, dx - \int \cos^n x \cdot \sin^m x \, dx \right] \\
 &\quad \left(1 + \frac{m-1}{n+1} \right) \int \sin^m x \cdot \cos^n x \, dx \\
 &= -\frac{\sin^{m-1} x \cdot \cos^{n+1} x}{(n+1)} + \frac{m-1}{n+1} \int \cos^n x \cdot \sin^{m-2} x \, dx
 \end{aligned}$$

6.4 — HIGHER ENGINEERING MATHEMATICS—II

Therefore the reduction formula is

$$\begin{aligned} \int \sin^m x \cdot \cos^n x \, dx &= -\frac{\sin^{m-1} x \cdot \cos^{n+1} x}{m+n} + \\ &+ \frac{m-1}{m+n} \int \sin^{m-2} x \cdot \cos^n x \, dx \end{aligned} \quad (8)$$

Similarly considering

$$\begin{aligned} \int \sin^m x \cos^n x \, dx &= \int \cos^{n-1} x \cdot \cos x \cdot \sin^m x \, dx \\ &= \int \cos^{n-1} x \cdot d\left(\frac{\sin^{m+1} x}{m+1}\right) \end{aligned}$$

and integrating by parts as above we get another form of the reduction formula as

$$\begin{aligned} \int \sin^m x \cdot \cos^n x \, dx &= \frac{\sin^{m+1} x \cdot \cos^{n-1} x}{m+n} + \\ &+ \frac{n-1}{m+n} \int \sin^m x \cdot \cos^{n-2} x \, dx \end{aligned} \quad (9)$$

In addition to (8) and (9), we can obtain the following other four reduction formulae.

$$\begin{aligned} \int \sin^m x \cdot \cos^n x \, dx &= \frac{\sin^{m+1} x \cos^{n-1} x}{m+1} + \\ &+ \frac{n-1}{m+1} \int \sin^{m+2} x \cdot \cos^{n-2} x \, dx \end{aligned} \quad (10)$$

Note 1: (10) is useful when m is negative integer and n is positive integer

$$\begin{aligned} \int \sin^m x \cdot \cos^n x \, dx &= -\frac{\sin^{m+1} x \cdot \cos^{n+1} x}{n+1} + \\ &+ \frac{m+n+2}{n+1} \int \sin^m x \cdot \cos^{n+2} x \, dx \end{aligned} \quad (11)$$

Note 2: (11) is useful when n is a negative integer. See WE 16 on Page 6.11.

$$\begin{aligned} \int \sin^m x \cdot \cos^n x \, dx &= \frac{\sin^{m+1} x \cdot \cos^{n+1} x}{m+1} + \\ &+ \frac{m+n+2}{m+1} \int \sin^{m+2} x \cdot \cos^n x \, dx \end{aligned} \quad (12)$$

Note 3: (12) is useful when n is a negative integer

$$\begin{aligned} \int \sin^m x \cdot \cos^n x \, dx &= -\frac{\sin^{m-1} x \cdot \cos^{n+1} x}{n+1} + \\ &+ \frac{m-1}{n+1} \int \sin^{m-2} x \cdot \cos^{n+2} x \, dx \end{aligned} \quad (13)$$

Note 4: (13) is useful when m is positive and n is negative integer.

Evaluation of Definite Integral $\int_0^{\frac{\pi}{2}} \sin^m x \cdot \cos^n x \, dx$ when both m and n are Positive Integers

Introduce the notation

$$I_{m,n} = \int_0^{\frac{\pi}{2}} \sin^m x \cdot \cos^n x \, dx \quad (14)$$

and using the reduction formula (8), we obtain

$$\begin{aligned} I_{m,n} &= \int_0^{\frac{\pi}{2}} \sin^m x \cdot \cos^n x \, dx \\ &= -\frac{\sin^{m-1} x \cdot \cos^{n+1} x}{m+n} \Big|_0^{\frac{\pi}{2}} + \\ &+ \frac{m-1}{m+n} \int_0^{\frac{\pi}{2}} \sin^{m-2} x \cdot \cos^n x \, dx \end{aligned}$$

Since the first term on R.H.S. is zero at both the limits, we get

$$I_{m,n} = \frac{m-1}{m+n} \cdot I_{m-2,n} \quad (15)$$

Using this recurrence relation, we obtain

$$I_{m-2,n} = \frac{m-3}{m+n-2} I_{m-4,n}$$

$$I_{m-4,n} = \frac{m-5}{m+n-4} I_{m-6,n}$$

$$I_{3,n} = \frac{2}{3+n} I_{1,n} \quad \text{when } m \text{ is odd.}$$

$$I_{2,n} = \frac{1}{2+n} I_{0,n} \quad \text{when } m \text{ is even.}$$

Observe that

$$I_{1,n} = \int_0^{\frac{\pi}{2}} \sin x \cdot \cos^n x \, dx = -\frac{\cos^{n+1} x}{n+1} \Big|_0^{\frac{\pi}{2}} = \frac{1}{n+1} \quad (16)$$

and

$$I_{0,n} = \int_0^{\frac{\pi}{2}} \cos^n x \, dx \quad (17)$$

Substituting these values, we have

(a) When m is odd and n may be odd or even

$$I_{m,n} = \frac{(m-1)}{(m+n)} \cdot \frac{(m-3)}{(m+n-2)} \times \\ \times \frac{(m-5)}{(m+n-4)} \cdots \frac{2}{3+n} \cdot \frac{1}{1+n}$$

Rewriting

$$I_{m,n} = \frac{(m-1)(m-3)(m-5) \cdots 2 \cdot 1}{(m+n)(m+n-2)(m+n-4) \cdots (n+3)(n+1)} \times \\ \times \left[\frac{(n-1)(n-3)(n-5) \cdots}{(n-1)(n-3)(n-5) \cdots} \right]$$

(b) When m is even and n is odd

$$I_{m,n} = \frac{(m-1)(m-3)(m-5) \cdots}{(m+n)(m+n-2) \cdots} \times \\ \times \frac{1}{2+n} \left(\frac{n-1}{n} \cdot \frac{n-3}{n-2} \cdots \frac{2}{3} \right)$$

(c) When m is even and n is even

$$I_{m,n} = \frac{(m-1)(m-3) \cdots 1}{(m+n)(m+n-2) \cdots (n+2)} \times \\ \times \left(\frac{n-1}{n} \cdot \frac{n-3}{n-2} \cdots \frac{1}{2} \cdot \frac{\pi}{2} \right)$$

General result

$$I_{m,n} = \int_0^{\frac{\pi}{2}} \sin^m x \cdot \cos^n x \, dx = \frac{NR}{DR} \cdot e$$

where NR = product of two sets of factors each commencing from $(m-1)$ and $(n-1)$ and decreasing by 2 at a time, while DR = product of factors starting from $(m+n)$ and decreasing by 2 at a time, descending ultimately to 1 or 2 according as the first factor of the set is odd or even. Here $e = \frac{\pi}{2}$ only when **both** m and n are even. In all other cases $e = 1$.

Corollary 1: Certain definite (proper and improper) integrals reduce to the $I_{m,n}$ form by simple substitutions. Let n and m be positive integers.

a. Putting $x = 2a \sin^2 \theta$

$$\int_0^{2a} x^m \sqrt{2ax - x^2} \, dx \\ = \int_0^{2a} x^{m+\frac{1}{2}} \sqrt{2a-x} \, dx = \int_0^{\frac{\pi}{2}} (2a)^{m+\frac{1}{2}} \sin^{2m+1} \theta \times \\ \times \sqrt{2a} \cdot \cos \theta \cdot 4a \cdot \sin \theta \cdot \cos \theta \, d\theta \\ = (2a)^{m+2} \cdot 2 \int_0^{\frac{\pi}{2}} \sin^{2m+2} \theta \cdot \cos^2 \theta \, d\theta$$

b. Putting $x = a \tan \theta$

$$\int_0^{\infty} \frac{x^n \, dx}{(a^2 + x^2)^m} = \frac{a^{2n}}{a^{2m}} \int_0^{\pi/2} \frac{\tan^n \theta \cdot a \cdot \sec^2 \theta}{\sec^{2m} \theta} \, d\theta \\ = a^{2n-2m+1} \int_0^{\pi/2} \sin^n \theta \cdot \cos^{2m-n-2} \theta \, d\theta$$

c. Putting $x = a \tan \theta$

$$\int_0^{\infty} \frac{x^n \, dx}{(a^2 + x^2)^{m+\frac{1}{2}}} \\ = \int_0^{\pi/2} \frac{a^n \sin^n \theta}{\cos^n \theta} \cdot \frac{1}{a^{2m+1} \cdot (\sec^2 \theta)^{\frac{2m+1}{2}}} \cdot a \cdot \sec^2 \theta \, d\theta \\ = a^{n-2m} \int_0^{\pi/2} \sin^n \theta \cdot \cos^{2m-n-1} \theta \, d\theta$$

Note: Instead of the six reduction formulae (8), (9), (10), (11), (12), (13), the integral $\int \sin^m x \cdot \cos^n x \, dx$ can be evaluated using certain substitutions as follows.

a. If the power (index) m of $\sin x$ is odd, then put $\cos x = t$.

b. If the power n of $\cos x$ is odd, then put $\sin x = t$.

c. If $m+n$ is negative even integer, then put $\tan x = t$.

In all the three above cases, integrand becomes a function of t and is easily integrated.

d. If both m and n are even integers and

i. m, n are small, then convert $\cos x$ and $\sin x$ into cosine and sines of multiple angles using $\cos^2 x = \frac{1+\cos 2x}{2}$, $\sin^2 x = \frac{1-\cos 2x}{2}$, $\sin x \cdot \cos x = \frac{\sin 2x}{2}$.

ii. m, n are large, use DeMoivre's theorem and use $z = \cos x + i \sin x$, $(2 \cos x) = (z + \frac{1}{z})$ and $(2i \sin x) = z - \frac{1}{z}$ etc.

WORKED OUT EXAMPLES

Reduction formulae for
 $\int \sin^n x \, dx$, $\int \cos^n x \, dx$

Example 1: Evaluate $\int \sin^5 x \, dx$

a. by reduction formula

b. by substitution

c. Hence find $\int_0^{\pi/2} \sin^5 x \, dx$.

Solution:

a. From reduction formula (1) on page 6.1

$$\int \sin^n x \, dx = -\frac{\sin^{n-1} x}{n} \cdot \cos x + \frac{n-1}{n} \int \sin^{n-2} x \, dx$$

Put $n = 5$

$$\int \sin^5 x \, dx = -\frac{1}{5} \sin^4 x \cdot \cos x + \frac{4}{5} \int \sin^3 x \, dx$$

Put $n = 3$

$$\int \sin^3 x \, dx = -\frac{\sin^2 x}{3} \cdot \cos x + \frac{2}{3} \int \sin x \, dx$$

$$\begin{aligned} \int \sin^5 x \, dx &= -\frac{1}{5} \sin^4 x \cdot \cos x \\ &\quad + \frac{4}{5} \left[\frac{-\sin^2 x \cdot \cos x}{3} + \frac{2}{3} (-\cos x) \right] \\ &= -\frac{1}{5} \sin^4 x \cdot \cos x \\ &\quad - \frac{4}{15} \sin^2 x \cdot \cos x - \frac{8}{15} \cos x \end{aligned}$$

b. Since the index $n = 5$ is odd, put $\cos x = t$

$$\begin{aligned} \int \sin^5 x \, dx &= \int \sin^4 x \cdot \frac{dt}{-\sin x} = -\int \sin^4 x \, dt \\ &= -\int (1 - \cos^2 x)^2 dt = -\int (1 - t^2)^2 dt \\ &= -\int (1 + t^4 - 2t^2) dt = -\left[t + \frac{t^5}{5} - \frac{2t^3}{3} \right] \\ &= -\left[\cos x + \frac{1}{5} \cos^5 x - \frac{2}{3} \cos^3 x \right] \end{aligned}$$

This result can be rewritten as in (a).

$$\begin{aligned} &= -\left[\cos x + \frac{1}{5} \cdot \cos x (1 - \sin^2 x)^2 - \right. \\ &\quad \left. - \frac{2}{3} \cdot \cos x (1 - \sin^2 x) \right] \\ &= -\frac{8}{15} \cos x - \frac{4}{15} \sin^2 x \cdot \cos x - \frac{1}{5} \sin^4 x \cdot \cos x. \end{aligned}$$

$$\begin{aligned} \text{c. } \int_0^{\pi/2} \sin^5 x \, dx &= \left[-\frac{8}{15} \cos x - \frac{4}{15} \sin^2 x \cdot \cos x \right. \\ &\quad \left. - \frac{1}{5} \sin^4 x \cdot \cos x \right]_0^{\pi/2} \\ &= 0 + 0 + 0 - \left(-\frac{8}{15} \right) = \frac{8}{15} \end{aligned}$$

Example 2: Without using reduction formula, evaluate $\int \sin^6 x \, dx$ and hence find $\int_0^{\pi/2} \sin^6 x \, dx$. Verify by Wallis's formula.

Solution: Since power $n = 6$ is even, use $\sin^2 x = \frac{1 - \cos 2x}{2}$ to rewrite

$$\begin{aligned} \int \sin^6 x \, dx &= \int (\sin^2 x)^3 dx \\ &= \int \left(\frac{1 - \cos 2x}{2} \right)^3 dx \\ &= \frac{1}{8} \int (1 - 3 \cos 2x + 3 \cos^2 2x - \cos^3 2x) dx \end{aligned}$$

Using $\cos^2 x = \frac{1 + \cos 2x}{2}$, we have

$$\begin{aligned} &= \frac{1}{8} \int \left[1 - 3 \cos 2x + 3 \left(\frac{1 + \cos 4x}{2} \right) \right. \\ &\quad \left. - \cos 2x \left(\frac{1 + \cos 4x}{2} \right) \right] dx \\ &= \frac{1}{8} \int \left(\frac{5}{2} - \frac{7}{2} \cos 2x + \frac{3}{2} \cos 4x - \frac{1}{2} \cos 2x \cdot \cos 4x \right) dx \\ &= \frac{1}{8} \int \left(\frac{5}{2} - \frac{7}{2} \cos 2x + \frac{3}{2} \cos 4x \right. \\ &\quad \left. - \frac{1}{2} \cdot \frac{1}{2} [\cos 6x + \cos 2x] \right) dx \\ &= \frac{1}{8} \int \left(\frac{5}{2} - \frac{15}{4} \cos 2x + \frac{3}{2} \cos 4x - \frac{1}{4} \cos 6x \right) dx \\ &= \frac{1}{8} \left[\frac{5}{2} x - \frac{15}{8} \sin 2x + \frac{3}{8} \sin 4x - \frac{1}{24} \sin 6x \right] \end{aligned}$$

So

$$\begin{aligned}\int_0^{\pi/2} \sin^6 x \, dx &= \frac{1}{8} \left[\frac{5}{2}x - \frac{15}{8} \sin 2x + \frac{3}{8} \sin 4x - \frac{1}{24} \sin 6x \right]_0^{\pi/2} \\ &= \frac{1}{8} \cdot \frac{5}{2} \cdot \frac{\pi}{2} = \frac{5\pi}{32}\end{aligned}$$

Verification:

$$\begin{aligned}\int_0^{\pi/2} \sin^6 x \, dx &= \frac{(6-1)(6-3)(6-5)}{6 \cdot (6-2)(6-4)} \cdot \frac{\pi}{2} \\ &= \frac{5 \cdot 3 \cdot 1}{6 \cdot 4 \cdot 2} \cdot \frac{\pi}{2} = \frac{5\pi}{32}\end{aligned}$$

Example 3: Evaluate $\int \cos^3 x \, dx$ (i) by reduction formula (ii) by substitution (iii) hence find $\int_0^{\pi/2} \cos^3 x \, dx$.

Solution:

i. Use the reduction formula (2) on page 6.1

$$\int \cos^n x \, dx = \frac{1}{n} \sin x \cdot \cos^{n-1} x + \frac{n-1}{n} \int \cos^{n-2} x \, dx$$

Put $n = 3$

$$\begin{aligned}\int \cos^3 x \, dx &= \frac{1}{3} \sin x \cdot \cos^2 x + \frac{2}{3} \int \cos x \, dx \\ &= \frac{1}{3} \sin x \cdot \cos^2 x + \frac{2}{3} \cdot \sin x\end{aligned}$$

ii. Since the power of $\cos$ is $n = 3$ is odd, use the substitution $\sin x = t$, $\cos x \, dx = dt$

$$\begin{aligned}\int \cos^3 x \, dx &= \int \cos^2 x \cdot \cos x \cdot dx \\ &= \int (1 - \sin^2 x) \cos x \cdot dx \\ &= \int (1 - t^2) dt = t - \frac{t^3}{3} = \sin x - \frac{1}{3} \sin^3 x\end{aligned}$$

Rewriting

$$\begin{aligned}&= \sin x - \frac{1}{3} \cdot \sin x \cdot (1 - \cos^2 x) \\ &= \frac{2}{3} \sin x + \frac{1}{3} \sin x \cdot \cos^2 x\end{aligned}$$

iii. $\int_0^{\pi/2} \cos^3 x \, dx = \frac{(3-1)}{3} = \frac{2}{3}$ from Wallis's formula

From above integral (ii) also

$$\begin{aligned}\int_0^{\pi/2} \cos^3 x \, dx &= \frac{2}{3} \sin x + \frac{1}{3} \sin x \cdot \cos^2 x \Big|_0^{\pi/2} \\ &= \frac{2}{3} + 0 - 0 - 0 = \frac{2}{3}\end{aligned}$$

Example 4: Evaluate $\int_0^5 \frac{x^6 \cdot dx}{\sqrt{25-x^2}}$.

Solution: Put $x = 5 \sin \theta$, $x = 0$ then $\theta = 0$, $x = 5$, then $\theta = \frac{\pi}{2}$.

$$\begin{aligned}\int_0^5 \frac{x^6 \, dx}{\sqrt{25-x^2}} &= \int_0^{\pi/2} \frac{5^6 \sin^6 \theta}{5 \cos \theta} \cdot 5 \cdot \cos \theta \, d\theta \\ &= 5^6 \cdot \frac{5}{6} \cdot \frac{3}{4} \cdot \frac{1}{2} \cdot \frac{\pi}{2} = \frac{5^7}{32} \pi = \frac{78125}{32} \pi\end{aligned}$$

(by Wallis's formula, with $n = 6$, even).

Example 5:

$$\int_0^\infty \frac{dx}{(a^2 + x^2)^7}$$

Solution: Put $x = a \tan \theta$, $dx = a \sec^2 \theta \, d\theta$, when $x = 0$, then $\theta = 0$; when $x = \infty$, then $\theta = \frac{\pi}{2}$.

$$\begin{aligned}\int_0^\infty \frac{dx}{(a^2 + x^2)^7} &= \int_0^{\pi/2} \frac{a \cdot \sec^2 \theta \cdot d\theta}{a^{14} \sec^{14} \theta} = \frac{1}{a^{13}} \int_0^{\pi/2} \cos^{12} \theta \, d\theta \\ &= \frac{1}{a^{13}} \cdot \frac{11}{12} \cdot \frac{9}{10} \cdot \frac{7}{8} \cdot \frac{5}{6} \cdot \frac{3}{4} \cdot \frac{1}{2} \cdot \frac{\pi}{2} = \frac{1}{a^{13}} \cdot \frac{231}{2048}\end{aligned}$$

Example 6: Evaluate $\int_0^\infty \frac{dx}{(16+x^2)^{\frac{9}{2}}}$

Solution: Put $x = 4 \tan \theta$, limits: $\theta : 0$ to $\frac{\pi}{2}$, $dx = 4 \cdot \sec^2 \theta \, d\theta$

$$\begin{aligned}\int_0^\infty \frac{dx}{(16+x^2)^{\frac{9}{2}}} &= \int_0^{\pi/2} \frac{4 \cdot \sec^2 \theta \cdot d\theta}{4^9 \sec^9 \theta} \\ &= \frac{1}{4^8} \int_0^{\pi/2} \cos^7 \theta \, d\theta = \frac{1}{4^8} \cdot \frac{6}{7} \cdot \frac{4}{5} \cdot \frac{2}{3} \\ &= \frac{1}{4^6 \cdot 7.5} = \frac{1}{143360}\end{aligned}$$

6.8 — HIGHER ENGINEERING MATHEMATICS—II

Reduction formula for $\int \tan^n x \, dx$,
 $\int \cot^n x \, dx$, $\int \sec^n x \, dx$, $\int \operatorname{cosec}^n x \, dx$

Example 7: Evaluate $\int_0^{\pi/4} \tan^6 x \, dx$.

Solution: Use the reduction formula (4) on page 6.3

$$\int \tan^n x \, dx = \frac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x \, dx$$

Put $n = 6$, $\int \tan^6 x \, dx = \frac{\tan^5 x}{5} - \int \tan^4 x \, dx$

Put $n = 4$, $\int \tan^4 x \, dx = \frac{\tan^3 x}{3} - \int \tan^2 x \, dx$

Put $n = 2$, $\int \tan^2 x \, dx = \frac{\tan x}{1} - \int dx$

Substituting, $\int \tan^6 x \, dx = \frac{\tan^5 x}{5} - \frac{\tan^3 x}{3} + \tan x - x$

Now,

$$\begin{aligned} \int_0^{\pi/4} \tan^6 x \, dx &= \left. \frac{\tan^5 x}{5} - \frac{\tan^3 x}{3} + \tan x - x \right|_0^{\pi/4} \\ &= \left(\frac{1}{5} - \frac{1}{3} + 1 - \frac{\pi}{4} \right) - 0 = \frac{13}{15} - \frac{\pi}{4} \end{aligned}$$

Example 8: Find $\int_{\pi/4}^{\pi/2} \cot^4 x \, dx$.

Solution: Use the reduction formula (5) on page 6.3

$$\int \cot^n x \, dx = -\frac{\cot^{n-1} x}{(n-1)} - \int \cot^{n-2} x \, dx$$

Put $n = 4$, $\int \cot^4 x \, dx = -\frac{\cot^3 x}{3} - \int \cot^2 x \, dx$

Put $n = 2$, $\int \cot^2 x \, dx = -\frac{\cot x}{1} - \int dx$

Substituting,

$$\begin{aligned} \int \cot^4 x \, dx &= -\frac{\cot^3 x}{3} + \cot x + x \\ \int_{\pi/4}^{\pi} \cot^4 x \, dx &= \left(-\frac{\cot^3 x}{3} + \cot x + x \right) \Big|_{\pi/4}^{\pi} \\ &= \left(0 + 0 + \frac{\pi}{2} \right) - \left(-\frac{1}{3} + 1 + \frac{\pi}{4} \right) \\ &= \frac{\pi}{4} - \frac{2}{3} = \frac{3\pi - 8}{12} \end{aligned}$$

Example 9: If $I_n = \int_0^{\pi/4} \tan^n x \, dx$, prove that

i. $(n-1)(I_n + I_{n-2}) = 1$

ii. $(n-1)(I_{n+1} + I_{n-1}) = 1$

iii. Evaluate I_5

iv. Hence find $\int_0^a x^5(2a^2 - x^2)^{-3} \, dx$.

Solution: From the reduction formula (4) on page 6.3

i. $I_n = \frac{\tan^{n-1} x}{n-1} \Big|_0^{\pi/4} - I_{n-2} = \frac{1}{n-1} - I_{n-2}$

So $(n-1)(I_n + I_{n-2}) = 1$

ii. Put $n = n+1$

$$n(I_{n+1} + I_{n-1}) = 1$$

iii. Put $n = 5$ in (i): $4(I_5 + I_3) = 1$

Put $n = 3$ in (i): $2(I_3 + I_1) = 1$

$$I_5 = -\frac{1}{4} \cdot -I_3 = \frac{1}{4} - \left(\frac{1}{2} - I_1 \right) = -\frac{1}{4} + I_1$$

But $I_1 = \int_0^{\pi/4} \tan x \, dx = \ln \sec x \Big|_0^{\pi/4} = \ln \sqrt{2}$

Thus $I_5 = -\frac{1}{4} + \ln \sqrt{2}$

iv. Put $x = \sqrt{2}a \sin \theta$, $dx = \sqrt{2}a \cdot \cos \theta \, d\theta$

Limits: $x = 0$ then $\theta = 0$, $x = a$ then $\theta = \frac{\pi}{4}$

$$\begin{aligned} \int_0^a x^5(2a^2 - x^2)^{-3} \, dx &= \int_0^{\pi/4} (\sqrt{2}a)^5 \sin^5 \theta (2a^2)^{-3} \cos^{-6} \theta \cdot \sqrt{2}a \cdot \cos \theta \, d\theta \\ &= (\sqrt{2}a)^6 (\sqrt{2}a)^{-6} \int_0^{\pi/4} \frac{\sin^5 \theta}{\cos^5 \theta} \, d\theta = I_5 \\ &= \ln \sqrt{2} - \frac{\pi}{4} \quad \text{[from (iii)]} \end{aligned}$$

Example 10: Determine (i) $\int_0^{\pi/4} \sec^5 x \, dx$

(ii) $\int_{\pi/4}^{\pi/2} \operatorname{cosec}^3 x \, dx$

Solution: i. Use reduction formula (6) on page 6.3

$$\int \sec^n x \, dx = \frac{\tan x \cdot \sec^{n-2} x}{n-1} + \frac{n-2}{n-1} \int \sec^{n-2} x \, dx$$

Putting $n = 5, 3, 1$ and substituting

$$\begin{aligned} \int_0^{\pi/4} \sec^5 x \, dx &= \frac{1}{4} \left[\sec^3 x \cdot \tan x \right. \\ &\quad \left. + \frac{3}{2} \left\{ \sec x \cdot \tan x + \ln (\tan x + \sec x) \right\} \right] \Big|_0^{\pi/4} \\ &= \frac{1}{4} \left[(\sqrt{2})^3 \cdot 1 + \frac{3}{2} \left\{ \sqrt{2} \cdot 1 + \ln (1 + \sqrt{2}) \right\} \right] \end{aligned}$$

ii. Use reduction formula (7) on page 6.3

$$(n-1) \int \operatorname{cosec}^n x \, dx = -\cot x \cdot \operatorname{cosec}^{n-2} x + (n-2) \int \operatorname{cosec}^{n-2} x \, dx$$

Putting $n = 3, 1$ and substituting

$$\begin{aligned} \int_{\pi/4}^{\pi/2} \operatorname{cosec}^3 x \, dx &= \frac{-1}{2} [\operatorname{cosec} x \cdot \cot x + \ln(\operatorname{cosec} x + \cot x)]_{\pi/4}^{\pi/2} \\ &= -\frac{1}{2} [(0 - \sqrt{2}) + \ln(1) - \ln(\sqrt{2} + 1)] \end{aligned}$$

iii. Put $x = a \tan \theta$, $dx = a \sec^2 \theta d\theta$, limits: $\theta: 0$ to $\frac{\pi}{2}$

$$\begin{aligned} \int_0^\infty \frac{x^4}{(a^2 + x^2)^5} dx &= \int_0^{\pi/2} \frac{\tan^4 \theta}{a^{10}} \cdot \frac{\sec^2 \theta}{\sec^{10} \theta} d\theta \\ &= \frac{1}{a^{10}} \int_0^{\pi/2} \sin^4 \theta \cdot \cos^4 \theta d\theta \\ &= \frac{1}{a^{10}} \cdot \frac{3 \cdot 3}{8 \cdot 6 \cdot 4 \cdot 2} \cdot \frac{\pi}{2} = \frac{3\pi}{256} \end{aligned}$$

Reduction formulae for $\int \sin^m x \cdot \cos^n x \, dx$

Example 11: Evaluate

- $\int_0^{\pi/2} \sin^4 x \cdot \cos^5 x \, dx$
- $\int_0^{\pi/2} \sin^8 x \cdot \cos^{12} x \, dx$
- $\int_0^\infty \frac{x^4 dx}{(a^2 + x^2)^5}$

Solution:

i. Here $m = 4 = \text{even}$, $n = 5 = \text{odd}$

$$\int_0^{\pi/2} \sin^4 x \cdot \cos^5 x \, dx = \frac{3 \cdot 1 \cdot 4 \cdot 2}{9 \cdot 7 \cdot 5 \cdot 3 \cdot 1} = \frac{8}{315}$$

ii. Here $m = 8, n = 12$ are both even.

$$\begin{aligned} \int_0^{\pi/2} \sin^8 x \cdot \cos^{12} x \, dx &= \frac{7 \cdot 5 \cdot 3 \cdot 11 \cdot 9 \cdot 7 \cdot 5 \cdot 3}{20 \cdot 18 \cdot 16 \cdot 14 \cdot 12 \cdot 10 \cdot 8 \cdot 6 \cdot 4 \cdot 2} \cdot \frac{\pi}{2} \\ &= \frac{539\pi}{3670016} \end{aligned}$$

Example 12: Find $\int \sin^5 x \cdot \cos^{\frac{3}{4}} x \, dx$.

Solution: Since $m = 5$ is odd, put $\cos x = t$, so $-\sin x \, dx = dt$.

$$\begin{aligned} \int \sin^5 x \cdot \cos^{\frac{3}{4}} x \, dx &= \int \sin^4 x \cdot \sin x \cdot \cos^{\frac{3}{4}} x \, dx \\ &= \int (1 - \cos^2 x)^2 \sin x \cdot \cos^{\frac{3}{4}} x \, dx \\ &= \int (1 - t^2)^2 \cdot t^{\frac{3}{4}} (-dt) \\ &= - \int t^{\frac{3}{4}} (1 + t^4 - 2t^2) dt \\ &= - \left[\frac{4}{7} t^{\frac{7}{4}} + \frac{4}{23} t^{\frac{23}{4}} - \frac{8}{15} t^{\frac{15}{4}} \right] \\ &= -\frac{4}{7} \cos^{\frac{7}{4}} x - \frac{4}{23} \cos^{\frac{23}{4}} x + \frac{8}{15} \cos^{\frac{15}{4}} x \end{aligned}$$

Example 13: Evaluate $\int \operatorname{cosec} x \cdot \cot^5 x \, dx$.

Solution:

$$\begin{aligned} \int \operatorname{cosec} x \cdot \cot^5 x \, dx &= \int \frac{1}{\sin x} \cdot \frac{\cos^5 x}{\sin^5 x} dx \\ &= \int \sin^{-6} x \cdot \cos^5 x \, dx \end{aligned}$$

Here $n = 5$ is odd, so put $\sin x = t$, $\cos x \, dx = dt$

$$\begin{aligned} &= \int \sin^{-6} x \cdot (1 - \sin^2 x)^2 \cdot \cos x \, dx = \int \frac{1}{t^6} (1 - t^2)^2 dt \\ &= \int \frac{1 + t^4 - 2t^2}{t^6} dt = -\frac{1}{5} \frac{1}{t^5} - \frac{1}{t} - \frac{2}{3} \frac{1}{t^3} \\ &= -\operatorname{cosec} x - \frac{2}{3} \operatorname{cosec}^3 x - \frac{1}{5} \operatorname{cosec}^5 x \end{aligned}$$

Example 14: Calculate $\int \frac{dx}{\sin^3 x \cdot \cos^5 x}$.

Solution: Here $m = -3$, $n = -5$, so $m + n = -3 - 5 = -8$ is a negative even integer. Put $\tan x = t$, $\sec^2 x \, dx = dt$, then $\sin x = \frac{t}{\sqrt{1+t^2}}$, and

$$\cos x = \frac{1}{\sqrt{1+t^2}} \quad (\text{Fig. 6.1}).$$

$$\int \frac{dx}{\sin^3 x \cdot \cos^5 x}$$

Fig. 6.1

$$\begin{aligned}
 &= \int \left(\frac{t}{\sqrt{1+t^2}} \right)^{-3} \left(\frac{1}{\sqrt{1+t^2}} \right)^{-5} \frac{1}{(1+t^2)} dt \\
 &= \int \frac{(1+t^2)^3}{t^3} dt = \int \frac{1+3t^2+3t^4+t^6}{t^3} dt \\
 &= -\frac{1}{2} \frac{1}{t^2} + 3 \ln t + 3 \frac{t^2}{2} + \frac{t^4}{4} \\
 &= 3 \ln \tan x + \frac{3}{2} \tan^2 x - \frac{1}{2} \cot^2 x + \frac{1}{4} \tan^4 x
 \end{aligned}$$

Example 15: Evaluate $\int_0^{\pi/4} \sin^2 x \cdot \cos^4 x \, dx$ by (i) substitution method (ii) using DeMoivre's theorem.

Solution: Since $m = 2$, $n = 4$ are both even integers

i. Replace $\sin^2 x$ by $\frac{1-\cos 2x}{2}$ and $\cos^2 x$ by $\frac{1+\cos 2x}{2}$

$$\begin{aligned}
 &\int_0^{\pi/4} \sin^2 x \cdot \cos^4 x \, dx \\
 &= \int_0^{\pi/4} \frac{(1-\cos 2x)}{2} \left(\frac{1+\cos 2x}{2} \right)^2 dx \\
 &= \frac{1}{8} \int_0^{\pi/4} (1 + \cos 2x - \cos^2 2x - \cos^3 2x) dx
 \end{aligned}$$

Put $2x = t$, $dx = \frac{1}{2} dt$, limits: t : 0 to $\frac{\pi}{2}$

$$\begin{aligned}
 &= \frac{1}{16} \int_0^{\pi/2} (1 + \cos t - \cos^2 t - \cos^3 t) dt \\
 &= \frac{1}{16} \left[\frac{\pi}{2} + 1 - \frac{1}{2} \cdot \frac{\pi}{2} - \frac{2}{3} \right] = \frac{1}{8} \left(\frac{\pi}{8} + \frac{1}{6} \right)
 \end{aligned}$$

ii. Put $z = \cos x + i \sin x$, then $\frac{1}{z} = \cos x - i \sin x$,
 $z + \frac{1}{z} = 2 \cos x$, $z - \frac{1}{z} = 2i \sin x$.

Consider

$$\begin{aligned}
 (2i \sin x)^2 (2 \cos x)^4 &= \left(z - \frac{1}{z} \right)^2 \left(z + \frac{1}{z} \right)^4 \\
 &= \left(z^2 - \frac{1}{z^2} \right)^2 \left(z + \frac{1}{z} \right)^2 \\
 &= \left(z^4 + \frac{1}{z^4} - 2 \right) \left(z^2 + \frac{1}{z^2} + 2 \right) \\
 &= \left(z^4 + \frac{1}{z^4} \right) \left(z^2 + \frac{1}{z^2} \right) \\
 &\quad + 2 \left(z^4 + \frac{1}{z^4} \right) - 2 \left(z^2 + \frac{1}{z^2} \right) - 4 \quad (*)
 \end{aligned}$$

Now,

$$z^n = (\cos x + i \sin x)^n = \cos nx + i \sin nx$$

$$\frac{1}{z^n} = (\cos x + i \sin x)^{-n} = \cos nx - i \sin nx$$

$$z^n + \frac{1}{z^n} = 2 \cos nx \quad \text{and} \quad z^n - \frac{1}{z^n} = 2i \sin nx$$

$$\begin{aligned}
 (2i \sin x)^2 (2 \cos x)^4 &= -2^2 \sin^2 x \cdot 2^4 \cdot \cos^4 x = -2^6 \sin^2 x \cdot \cos^4 x
 \end{aligned}$$

using (*)

$$= (2 \cos 4x)(2 \cos 2x) + 2 \cdot 2 \cdot \cos 4x - 2 \cdot 2 \cos 2x - 4$$

$$\begin{aligned}
 \sin^2 x \cdot \cos^4 x &= -\frac{1}{2^6} \left[4 \cdot \frac{1}{2} (\cos 6x + \cos 2x) \right. \\
 &\quad \left. + 4 \cos 4x - 4 \cos 2x - 4 \right] \\
 &= -\frac{1}{2^4} \left[\frac{1}{2} \cos 6x + \cos 4x - \frac{1}{2} \cos 2x - 1 \right]
 \end{aligned}$$

Integrating both sides w.r.t. x ,

$$\begin{aligned}
 &\int_0^{\pi/4} \sin^2 x \cdot \cos^4 x \, dx \\
 &= -\frac{1}{16} \left[\frac{1}{2} \cdot \frac{\sin 6x}{6} + \frac{\sin 4x}{4} - \frac{1}{2} \cdot \frac{\sin 2x}{2} - x \right]_0^{\pi/4} \\
 &= -\frac{1}{16} \left[\left(\frac{1}{12} \sin \frac{3\pi}{2} + \frac{1}{4} \sin \pi - \frac{1}{4} \sin \frac{\pi}{2} - \frac{\pi}{4} \right) - 0 \right] \\
 &= -\frac{1}{16} \left[-\frac{1}{12} + 0 - \frac{1}{4} - \frac{\pi}{4} \right] = \frac{1}{8} \left[\frac{\pi}{8} + \frac{1}{6} \right]
 \end{aligned}$$

Example 16: Find $\int_0^{\pi/4} \frac{\sin^2 x}{\cos^3 x} dx$.

Solution: Use the reduction formula (11) on page 6.4

$$\int \sin^m x \cdot \cos^n x dx = -\frac{\sin^{m+1} x \cdot \cos^{n+1} x}{n+1} + \frac{m+n+2}{n+1} \int \sin^m x \cdot \cos^{n+2} x dx$$

Here $m = 2, n = -3$

$$\begin{aligned} \int_0^{\pi/4} \sin^2 x \cos^{-3} x dx &= -\frac{\sin^3 x \cdot \cos^{-2} x}{-2} + \left(\frac{1}{-2}\right) \int \sin^2 x \cos^{-1} x dx \\ &= \frac{1}{2} \frac{\sin^3 x}{\cos^2 x} - \frac{1}{2} \int \frac{1 - \cos^2 x}{\cos x} dx \\ &= \frac{1}{2} \frac{\sin^3 x}{\cos^2 x} - \frac{1}{2} \int (\sec x - \cos x) dx \\ &= \frac{1}{2} \frac{\sin^3 x}{\cos^2 x} - \frac{1}{2} \ln (\sec x + \tan x) + \frac{1}{2} \sin x \\ &= \frac{1}{2} \sin x \left(\frac{\sin^2 x}{\cos^2 x} + 1 \right) - \frac{1}{2} \ln (\sec x + \tan x) \\ &= \frac{1}{2} \sec x \cdot \tan x - \frac{1}{2} \ln (\sec x + \tan x) \Big|_0^{\pi/4} \\ &= \frac{1}{2} \left[\sqrt{2} - \frac{1}{2} \ln (\sqrt{2} + 1) - \ln \sqrt{2} \right] \end{aligned}$$

EXERCISE

1. Evaluate

- (a) $\int \sin^4 x dx$; (b) $\int_0^{\pi/2} \sin^7 x dx$;
(c) $\int_0^{\pi/4} \cos^6 2t dt$; (d) $\int_0^{\pi/2} \cos^9 x dx$

Hint: a. Put $n = 4, 2$

c. Put $2t = x$, limits: 0 to $\frac{\pi}{2}$

Ans. a. $-\frac{\cos x \sin^2 x}{4} - \frac{3}{8} \cos x \cdot \sin x + \frac{3}{8} x$

b. $\frac{6}{7} \cdot \frac{4}{5} \cdot \frac{2}{3} = \frac{16}{35}$

c. $\frac{1}{2} \left[\frac{5}{6} \cdot \frac{3}{4} \cdot \frac{1}{2} \cdot \frac{\pi}{2} \right] = \frac{5\pi}{64}$

d. $\frac{8}{9} \cdot \frac{6}{7} \cdot \frac{4}{5} \cdot \frac{2}{3} \cdot 1 = \frac{128}{315}$, Note: $n = 9$ is odd

2. Solve Example 1 without using reduction formulae

Hint:

a. Express $\sin^4 x = (\sin^2 x)^2 = \left(\frac{1 - \cos 2x}{2}\right)^2 = \frac{1}{8}(3 - 4 \cos 2x + \cos 4x)$

b. Since $n = 7$ is odd, put $\cos x = t, -\sin x dx = dt, \sin^7 x dx = \sin^6 x \cdot \sin x dx = (1 - \cos^2 x)^3 \sin x dx = -(1 - t^2)^3 dt$

c. Express $\cos^6 x = (\cos^2 x)^3 = \left(\frac{1 + \cos 2x}{2}\right)^3$

d. Since $n=9$ is odd, put $\sin x = t, \cos x dx = dt, \cos^9 x dx = (1 - \sin^2 x)^4 \cdot \cos x dx = (1 - t^2)^4 dt$

Ans. Same as in Example 1

3. Use Wallis's formula to evaluate

(i) $\int_0^{\pi/2} \sin^8 x \cdot \cos^4 x dx$; (ii) $\int_0^{\pi/2} \sin^2 x \times \cos^6 x dx$; (iii) $\int_0^{\pi/4} 8 \cos^4 x \cdot \sin^4 x dx$

Hint:

i. $\sin^8 x \cdot \cos^4 x = \sin^8 x (1 - \sin^2 x)^2 = \sin^8 x - 2 \sin^{10} x + \sin^{12} x, I_8 - 2I_{10} + I_{12}$

ii. $\sin^2 x \cos^6 x = (1 - \cos^2 x)(\cos^6 x), I_6 - I_8$

iii. $(\cos x \cdot \sin x)^4 = \left(\frac{\sin 2x}{2}\right)^4, \text{ put } 2x = t, \frac{1}{4} \int_0^{\pi/2} \sin^4 t dt$

Ans. i. $\frac{7\pi}{2048}$ ii. $\frac{5\pi}{256}$ iii. $\frac{3\pi}{64}$

4. Evaluate the integrals

(i) $\int_0^a \frac{x^7 dx}{\sqrt{a^2 - x^2}}$; (ii) $\int_0^\infty \frac{dx}{(a^2 + x^2)^{7/2}}$;

(iii) $\int_0^{2a} \frac{x^3 dx}{\sqrt{2ax - x^2}}$; (iv) $\int_0^1 x^{\frac{3}{2}} (1 - x)^{\frac{1}{2}} dx$

Hint:

i. Put $x = a \sin \theta, \theta; 0 \text{ to } \frac{\pi}{2}$

ii. Put $x = a \tan \theta, \theta; 0 \text{ to } \frac{\pi}{2}$

iii. $\frac{x^3}{\sqrt{2ax - x^2}} = \frac{x^3 \cdot x^{-1/2}}{\sqrt{2a - x}}, \text{ put } x = 2a \sin^2 \theta,$

limits: $\theta: 0 \text{ to } \frac{\pi}{2}, \int_0^{\pi/2} 16a^3 \sin^6 \theta d\theta$

iv. Put $x = \sin^2 \theta, dx = 2 \sin \theta \cdot \cos \theta d\theta$

6.12 — HIGHER ENGINEERING MATHEMATICS—II

Limits: $\theta: 0$ to $\frac{\pi}{2}$, $2[\int_0^{\pi/2} \sin^4 \theta d\theta - \int_0^{\pi/2} \sin^6 \theta d\theta]$

Ans. (i) $\frac{16}{35}a^7$ (ii) $\frac{8}{15a^6}$ (iii) $\frac{5\pi a^3}{2}$ (iv) $\frac{\pi}{16}$

5. Evaluate

(i) $\int_0^{\pi/4} \tan^4 x dx$; (ii) $\int_0^{\pi/4} \tan^5 x dx$

(iii) $\int_{\pi/4}^{\pi/2} \operatorname{cosec}^5 x dx$; (iv) $\int \sec^4 x dx$

(v) $\int_{\pi/6}^{\pi/2} \operatorname{cosec}^5 x dx$; (vi) $\int_0^a (a^2 + x^2)^{5/2} dx$

Hint: Put $x = a \tan \theta$,

Limits: $\theta: 0$ to $\frac{\pi}{4}$, $a^6 \int_0^{\pi/4} \sec^7 \theta d\theta$ for (vi)

Ans. i $-\frac{2}{3} + \frac{\pi}{4}$

ii. $-\frac{1}{4} + \frac{1}{2} \ln 2$

iii. $\frac{7}{4\sqrt{2}} + \frac{3}{8} \ln(\sqrt{2} + 1)$

iv. $\frac{1}{3} \sec^2 x \tan x + \frac{2}{3} \tan x$

v. $\frac{11\sqrt{3}}{4} + \frac{3}{8} \ln(2 + \sqrt{3})$

vi. $a^6 \left\{ \frac{67\sqrt{2}}{48} + \frac{5}{16} \ln(1 + \sqrt{2}) \right\}$

6. Evaluate

(i) $\int \sec x \cdot \tan^5 x dx$; (ii) $\int \sec^{\frac{4}{3}} x \operatorname{cosec}^{\frac{8}{3}} x dx$

Hint:

i. Put $\cos x = t$, $\int \frac{\sin^4 x \cdot \sin x dx}{\cos^6 x} = \int \frac{(1-t^2)(-dt)}{t^6}$

ii. $\int \frac{dx}{\cos^{\frac{4}{3}} x \cdot \sin^{\frac{8}{3}} x} = \int \frac{dx}{\cos^{\frac{4}{3}} x \cdot \cos^{\frac{8}{3}} x \cdot \tan^{\frac{8}{3}} x} =$

$\int \frac{\sec^4 x dx}{\tan^{\frac{8}{3}} x}$, put $\tan x = t$, $\int \frac{(1+t^2)}{t^{\frac{8}{3}}} dt$

Ans. i. $\frac{1}{5} \sec^5 x - \frac{2}{3} \sec^3 x + \sec x$

ii. $-\frac{3}{5} \cot^{\frac{5}{3}} x + 3 \tan^{\frac{1}{3}} x$

7. Evaluate

i. $\int_0^{\pi/2} \sin^9 x \cdot \cos^3 x dx$

ii. $\int_0^{\pi/2} \sin^8 x \cdot \cos^4 x dx$

iii. $\int_0^{\pi/2} \sin^5 x \cdot \cos^6 x dx$

iv. $\int_0^{\pi/2} \sin^6 x \cdot \cos^8 x dx$

v. $\int_0^{\pi/6} \sin^3 6\theta \cdot \cos^4 3\theta d\theta$

Hint: $\cos^4 3\theta (2 \sin 3\theta \cos 3\theta)^3$, put $3\theta = t$ for (v)

Ans. i $\frac{8 \cdot 6 \cdot 4 \cdot 2 \cdot 2}{12 \cdot 10 \cdot 8 \cdot 6 \cdot 4 \cdot 2} = \frac{1}{60}$

ii. $\frac{7 \cdot 5 \cdot 3 \cdot 3}{12 \cdot 10 \cdot 8 \cdot 6 \cdot 4 \cdot 2} \cdot \frac{\pi}{2} = \frac{7\pi}{2048}$

iii. $\frac{4 \cdot 2 \cdot 5 \cdot 3}{11 \cdot 9 \cdot 7 \cdot 5 \cdot 3} = \frac{8}{693}$

iv. $\frac{5 \cdot 3 \cdot 7 \cdot 5 \cdot 3}{14 \cdot 12 \cdot 10 \cdot 8 \cdot 6 \cdot 4 \cdot 2} \cdot \frac{\pi}{2} = \frac{5\pi}{4096}$

v. $\frac{1}{15}$

8. Evaluate the integrals in Example 7 without using reduction formulae.

Hint:

i. Put $\cos x = t \sin \theta m = 9$ is odd or put $\sin x = t$ since $n = 3$ is odd

ii. Since $m = 8$, $n = 4$ are both even integers,

$$\sin^8 x \cdot \cos^4 x = \left(\frac{1 - \cos 2x}{2} \right)^4 \cdot \left(\frac{1 + \cos 2x}{2} \right)^2$$

iii. Since $m = 5$ is odd put $\cos x = t$

iv. Since $m = 6$, $n = 8$ are both even integers

$$\sin^6 x \cdot \cos^8 x = \left(\frac{1 - \cos 2x}{2} \right)^3 \left(\frac{1 + \cos 2x}{2} \right)^4$$

Ans. Same as in Example 7

Note: (ii) and (iv) can also be solved using demoveis theorem: see WOE 15 (ii) on Page 6.10.

9. Evaluate

(i) $\int \sin^3 x \cdot \sec^7 x dx$; (ii) $\int \frac{\cos^3 x}{\operatorname{cosec}^{3/4} x} dx$

Hint:

i. Put $\tan x = t$ since $m + n = 3 - 7 = -4$

ii. put $\sin x = t$ since $n = 3$ is odd

Ans. i. $\frac{1}{4} \tan^4 x + \frac{1}{6} \tan^6 x$

ii. $\frac{4}{7} \sin^{7/4} x - \frac{4}{15} \sin^{15/4} x$

10. Evaluate the following integral

(i) $\int_0^{2a} x \sqrt{2ax - x^2} dx$; (ii) $\int_0^\infty \frac{x^2}{(1+x^2)^4} dx$;

(iii) $\int_0^1 x^4 (1 - x^2)^{3/2} dx$

Hint:

i. Put $x = 2a \sin^2 \theta$

ii. Put $x = \tan \theta$

iii. Put $x = \sin t$

Ans. i. $\frac{\pi a^3}{2}$

ii. $\frac{\pi}{32}$

iii. $\frac{3\pi}{256}$

11. Evaluate

(i) $\int \cos^3 x \cdot \operatorname{cosec}^4 x \, dx$

(ii) $\int \sin^2 x \cdot \sec^6 x \, dx$

Hint:

i. Put $\sin x = t$

ii. Put $\tan x = t$

Ans. i. $-\frac{1}{3} \operatorname{cosec}^3 x + \operatorname{cosec} x$

ii. $\frac{\tan^3 x}{3} + \frac{\tan^5 x}{5}$

6.2 AREA OF A PLANE REGION: QUADRATURE

Quadrature is the process of determining the plane area bounded by a given set of plane curves.

Area of a Curvilinear Trapezoid

Suppose $y = f(x)$ be a function defined on the interval $[a, b]$ and assume that $f(x) \geq 0$.

Fig. 6.2

Then the area A of the curvilinear trapezoid $MLQN$ bounded by the given curve (graph of) $y = f(x)$, the x -axis and the two ordinates (straight lines) $x = a$ and $x = b$ is numerically equal to the definite integral:

$$A = \int_a^b f(x) dx \quad (1)$$

Similarly, if the curve is defined by the function $x = f(y)$ on the interval $[c, d]$, then

$$\text{Area} = \int_c^d f(y) dy$$

If $f(x) \leq 0$ on $[a, b]$, then $\int_a^b f(x) dx \leq 0$. Then

$$A = \left| \int_a^b f(x) dx \right|$$

Fig. 6.3

Thus if $f(x)$ changes sign on the interval $[a, b]$ a finite number of times i.e., if the graph (curve) of $y = f(x)$ crosses the x -axis several times, then the total area bounded by the curve is the sum of the areas above and below the x -axis, with absolute value taken for the areas when $f(x) \leq 0$ i.e., below the x -axis or equivalently

$$A = \int_a^b |f(x)| dx$$

Example: For the curve shown in the figure

$$\begin{aligned} A &= \left| \int_a^{a_1} f(x) dx \right| + \left| \int_{a_1}^{b_1} f(x) dx \right| + \left| \int_{b_1}^b f(x) dx \right| \\ &= \int_a^b |f(x)| dx \end{aligned}$$

Area between Two Curves

The area bounded by the curves $y = f_2(x)$, $y = f_1(x)$, and the ordinates $x = a$, $x = b$ is given by

$$\begin{aligned} A &= \int_a^b f_2(x) dx - \int_a^b f_1(x) dx \\ &= \int_a^b [f_2(x) - f_1(x)] dx \end{aligned} \quad (2)$$

Provided $f_2(x) \geq f_1(x)$.

Fig. 6.4

Area Bounded by a Parametric Curve

Suppose the curve is represented by the parametric equations

$$x = x(t), \quad y = y(t)$$

with $\alpha \leq t \leq \beta$ and $x(\alpha) = a$, $x(\beta) = b$. Then

$$A = \int_a^b f(x) dx = \int_a^b y dx = \int_\alpha^\beta y(t) \frac{dx}{dt} dt \quad (3)$$

Area Bounded by a Polar Curve

Suppose the equation of the given curve in polar coordinates (r, θ) be

$$r = f(\theta)$$

where $\alpha \leq \theta \leq \beta$. Let r_i be the length of the radius vector corresponding to some angle θ_i between θ_{i-1} and θ_i . Divide the given area OAB into n parts by radius vectors $\theta_0 = \alpha$, $\theta = \theta_1, \dots, \theta_n = \beta$. Then the area of the sector OAB bounded by the polar curve $r = f(\theta)$ and the radius vectors $\theta = \alpha$ and $\theta = \beta$ is

$$A = \lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{1}{2} r_i^2 \Delta \theta_i = \frac{1}{2} \int_\alpha^\beta r^2 d\theta = \frac{1}{2} \int_\alpha^\beta [f(\theta)]^2 d\theta$$

Fig. 6.5

since the area of any typical circular sector with radius r_i and central angle $\Delta \theta_i$ is given by

$$\Delta A_i = \frac{1}{2} r_i^2 \Delta \theta_i$$

Thus area of sector OAB is

$$A = \frac{1}{2} \int_\alpha^\beta [f(\theta)]^2 d\theta \quad (4)$$

WORKED OUT EXAMPLES

Example 1: Find the area bounded by the parabolic arc $\sqrt{x} + \sqrt{y} = \sqrt{a}$ and the coordinate axes.

Solution: Curve intersects x -axis at $(a, 0)$ and y -axis at $(0, a)$ (Fig. 6.6). So area is

Fig. 6.6

$$\begin{aligned} A &= \int_{x=0}^a y dx = \int_0^a (\sqrt{a} - \sqrt{x})^2 dx \\ &= \int_0^a (a + x - 2\sqrt{a}\sqrt{x}) dx \end{aligned}$$

$$= ax + \frac{x^2}{2} - 2\sqrt{a} \frac{2}{3} x^{\frac{3}{2}} \cdot \Big|_0^a = a^2 + \frac{a^2}{2} - \frac{4}{3} a^2 = \frac{1}{6} a^2$$

Example 2: Find the total area between the cubic $y = 2x^3 - 3x^2 - 12x$, x -axis and its maximum and minimum ordinates.

Solution: $y' = 6x^2 - 6x - 12$, $y'' = 12x - 6$

Stationary points: $y' = 6x^2 - 6x - 12 = 0$

$\therefore x = -1, 2$

$$y'' \Big|_{x=-1} = -18 < 0 \quad \text{and} \quad y'' \Big|_{x=2} = 18 > 0$$

Thus y attains maximum at $x = -1$ and minimum at $x = 2$ (Fig. 6.7).

Fig. 6.7

The cubic crosses the x -axis when

$$0 = y = 2x^3 - 3x^2 - 12x \quad \text{or when } x = 0, \frac{3 \pm \sqrt{104}}{4}.$$

Here only $x = 0$ lies between -1 and 2 .

Further $y \Big|_{x=-\frac{1}{2}} = 5 > 0$ and

$$y \Big|_{x=1} = -13 < 0$$

Thus $f(x) \geq 0$ in $[-1, 0]$ and $f(x) \leq 0$ in $[0, 2]$

$$\begin{aligned} A &= \int_{-1}^2 f(x) dx = \int_{-1}^0 f(x) dx + \left| \int_0^2 f(x) dx \right| \\ &= -\left[\frac{1}{2} + 1 - 6 \right] + \left| (8 - 8 - 24) \right| = \frac{9}{2} + 24 = \frac{57}{2} \end{aligned}$$

Example 3: Determine the area between the cubic $y = x^3$ and the parabola $y = 4x^2$.

Solution: The points of intersection of the two curves are

$$\begin{aligned} 4x^2 &= y = x^3 \\ x^2(x - 4) &= 0 \end{aligned}$$

i.e., $x = 0$ and $x = 4$.

Since at $x = 1, y \Big|_{x=1} = 4x^2 \Big|_{x=1} = 4,$

while $y \Big|_{x=1} = x^3 \Big|_{x=1} = 1$

so $y = 4x^2$ is the upper curve and $y = x^3$ is the lower curve (Fig. 6.8). The area bounded between the two curves is

Fig. 6.8

$$A = \int_{x=0}^4 (4x^2 - x^3) dx = \left[\frac{4x^3}{3} - \frac{x^4}{4} \right]_{x=0}^4 = \frac{64}{3}$$

Example 4: Show that the area bounded by the three straight lines $x + 2y = 2$, $y - x = 1$ and $2x + y = 7$ is 6.

Solution: The points of intersection of the two lines

$$x + 2y = 2 \quad \text{(I)} \quad \text{and} \quad -x + y = 1 \quad \text{(II)}$$

is $B(0, 1)$ and of (I) and $2x + y = 7$ (III) is $C(4, -1)$

Fig. 6.9

6.16 — HIGHER ENGINEERING MATHEMATICS—II

and of II and III is $A(2, 3)$ (refer Fig. 6.9).

$$\text{Area } ABC = \text{Area } ABD + \text{Area } BDC$$

$$\begin{aligned} &= \int_{y=-1}^1 \left[\left(\frac{7-y}{2} \right) - (2-2y) \right] dy \\ &\quad + \int_{y=1}^3 \left[\left(\frac{7-y}{2} \right) - (y-1) \right] dy \\ &= 3 + 3 = 6 \end{aligned}$$

Aliter: $\text{Area } ABC = \text{Area } ABE + \text{Area } AEC$

$$\begin{aligned} &= \int_{x=0}^2 \left[(x+1) - \left(\frac{2-x}{2} \right) \right] dx \\ &\quad + \int_{x=2}^4 \left[(7-2x) - \left(\frac{2-x}{2} \right) \right] dx = 6 \end{aligned}$$

Example 5: Calculate the area between the curve $y^2(a+x) = (a-x)^3$ and its asymptotes.

Solution: $x = -a$ is the only asymptote to the given curve. Since the curve is symmetric about the x -axis, area bounded by the given curve and the asymptote MN is twice the area BAN (Fig. 6.10).

Fig. 6.10

$$\begin{aligned} A &= 2 \int_{x=-a}^a y \, dx = 2 \int_{-a}^a \sqrt{\frac{(a-x)^3}{(a+x)}} \, dx \\ &= 2 \int_{-a}^a (a-x) \sqrt{\frac{a-x}{a+x}} \, dx = 2 \int_{-a}^a \frac{(a-x)^2}{a^2-x^2} \, dx. \end{aligned}$$

Put $x = a \sin \theta$, $dx = a \cos \theta \, d\theta$, limits: $-\frac{\pi}{2}$ to $\frac{\pi}{2}$.

$$A = 2 \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \frac{a^2(1-\sin^2 \theta)}{a \cdot \cos \theta} \cdot a \cos \theta \, d\theta$$

$$\begin{aligned} &= 2a^2 \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} (1 + \sin^2 \theta) \, d\theta - 2a^2 \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} 2 \sin \theta \, d\theta \\ &= 4a^2 \int_0^{\frac{\pi}{2}} (1 + \sin^2 \theta) \, d\theta = 4a^2 \left[\frac{\pi}{2} + \frac{1}{2} \cdot \frac{\pi}{2} \right] = 3\pi a^2 \end{aligned}$$

Example 6: Find the whole area bounded by the four infinite branches of the tractrix.

$$x = a \cos t + \frac{1}{2} a \ln \tan^2 \frac{t}{2}, \quad y = a \sin t.$$

Solution: Variation of x , y w.r.t. t ,

t :	0	$\frac{\pi}{2}$	π	$-\frac{\pi}{2}$
x :	$-\infty$	0	∞	0
y :	0	a	0	$-a$

The whole area bounded by the four infinite branches of the tractrix, by symmetry, equals 4 times the area under one infinite branch say AD for which x varies from $-\infty$ to 0 while t varies from 0 to $\frac{\pi}{2}$ (Fig. 6.11).

Fig. 6.11

$$\text{Required area } A = 4 \int_0^{\frac{\pi}{2}} y(t) \frac{dx}{dt} \, dt \quad (1)$$

$$\begin{aligned} \text{Now } \frac{dx}{dt} &= -a \sin t + \frac{1}{2} a \cdot \frac{2}{\tan \frac{t}{2}} \cdot \frac{1}{2} \cdot \sec^2 \frac{t}{2} \\ &= -a \sin t + \frac{a}{2 \sin \frac{t}{2} \cdot \cos \frac{t}{2}} \\ &= -a \sin t + \frac{a}{\sin t} = \frac{a}{\sin t} (1 - \sin^2 t) \\ &= \frac{a}{\sin t} \cdot \cos^2 t \quad (2) \end{aligned}$$

Substituting (2) in (1), we have

$$A = 4 \int_0^{\frac{\pi}{2}} (a \sin t) \left(\frac{a}{\sin t} \cdot \cos^2 t \right) dt$$

$$= 4a^2 \int_0^{\frac{\pi}{2}} \cos^2 t dt = 4a^2 \cdot \frac{1}{2} \cdot \frac{\pi}{2} = \pi a^2.$$

Example 7: Find the common area included between the parabolas $y^2 = 4a(x + a)$, and $y^2 = 4b(b - x)$.

Solution: The points of intersection of the two parabolas are $4a(x + a) = y^2 = 4b(b - x)$ or $x = \frac{b^2 - a^2}{b + a}$ i.e., $x = (b - a)$ or in B and D (Fig. 6.12).

Fig. 6.12

The parabola I: $y^2 = 4b(b - x)$ meets the x -axis in $A(b, 0)$, meets the parabola II: $y^2 = 4a(x + a)$ in $B(b - a, 2\sqrt{ab})$ and in $D(b - a, -2\sqrt{ab})$. Here $E(b - a, 0)$. Also parabola II meets x -axis in $C(-a, 0)$. Since both the parabolas I and II are symmetric about the x -axis, the required common area A between the two parabolas I and II is twice the area $ABCEA$.

$$A = 2 \text{ Area of } ABCEA = 2[\text{Area of } ABE + \text{Area of } BCE]$$

$$= 2 \left[\int_E^A y_I dx + \int_C^E y_{II} dx \right]$$

where suffix I, II indicate the respective parabolas.

$$\begin{aligned} A &= 2 \int_{b-a}^b 2\sqrt{b}\sqrt{(b-x)} dx + 2 \int_{-a}^{b-a} 2\sqrt{a}\sqrt{(x+a)} dx \\ &= 4\sqrt{b} \cdot (b-x)^{\frac{3}{2}} \cdot \frac{2}{3}(-1) \Big|_{x=b-a}^b + \\ &\quad + 4\sqrt{a} \cdot (x+a)^{\frac{3}{2}} \cdot \frac{2}{3} \Big|_{-a}^{b-a} \\ &= \frac{8}{3}\sqrt{b} \left[0 + (b-(b-a))^{3/2} \right] + \frac{8}{3}\sqrt{a} \left[(b-a+a)^{3/2} + 0 \right] \end{aligned}$$

$$= \frac{8}{3}\sqrt{b}a^{3/2} + \frac{8}{3}\sqrt{a}b^{3/2} = \frac{8}{3}\sqrt{ab} \cdot (a + b).$$

Example 8: Find the whole area of the curve

- (i) $r = a \cos n\theta$ (ii) $r = a \sin n\theta$ (iii) $r = a \sin 3\theta$
(iv) $r = a \cos 4\theta$ (v) $r = a \cos 3\theta + b \sin 3\theta$

Solution: The curves of the type $r = a \sin n\theta$ or $r = a \cos n\theta$ consists of either n or $2n$ equal loops respectively based on whether n is odd or even (Fig. 6.13).

Fig. 6.13

i. Consider the curve $r = a \cos n\theta$

$$\text{Area of one loop} = \text{twice the area of } OBC \\ = 2 \int_0^{\frac{\pi}{2n}} \frac{1}{2} r^2 d\theta = a^2 \int_0^{\frac{\pi}{2n}} \cos^2 n\theta d\theta$$

$$\text{Put } n\theta = t, \text{ so } d\theta = \frac{1}{n} dt \text{ and limits are } \theta = 0, \text{ then } t = 0, \theta = \frac{\pi}{2n} \text{ then } t = \frac{\pi}{2}. \text{ So area of one loop} \\ = \frac{a^2}{n} \int_0^{\frac{\pi}{2}} \cos^2 t \cdot dt = \frac{a^2}{n} \cdot \frac{1}{2} \cdot \frac{\pi}{2} = \frac{\pi a^2}{4n}.$$

Then the whole area of the curve = (number of loops) $\times$ (area of one loop)

$$= n \cdot \frac{\pi a^2}{4n} = \frac{\pi a^2}{4} \quad \text{when } n \text{ is odd}$$

$$= 2n \cdot \frac{\pi a^2}{4n} = \frac{\pi a^2}{2} \quad \text{when } n \text{ is even}$$

ii. When $r = a \sin n\theta$,

$$\text{Area of one loop} = \frac{a^2}{n} \int_0^{\frac{\pi}{2}} \sin^2 t dt = \frac{a^2}{n} \cdot \frac{1}{2} \cdot \frac{\pi}{2} = \frac{\pi a^2}{4n}.$$

So whole area = $\frac{\pi a^2}{4}$ or $\frac{\pi a^2}{2}$ according as n is odd or even.

iii. When $r = a \sin 3\theta$, take $n = 3$ (odd). Then the entire area = $\frac{\pi a^2}{4}$.

iv. When $r = a \cos 4\theta$, take $n = 4$ (even). Then the entire area = $\frac{\pi a^2}{2}$.

v. When $r = a \cos 3\theta + b \sin 3\theta$, introduce

$$\sin 3\alpha = \frac{a}{\sqrt{a^2 + b^2}}, \cos 3\alpha = \frac{b}{\sqrt{a^2 + b^2}}. \quad \text{Then}$$

6.18 — HIGHER ENGINEERING MATHEMATICS—II

$$r = \sqrt{a^2 + b^2} [\sin 3\alpha \cdot \cos 3\theta + \cos 3\alpha \cdot \sin 3\theta]$$

$$r = \sqrt{a^2 + b^2} \cdot \sin \{3(\theta + \alpha)\}$$

This curve is obtained by the rotation of the curve $r = \sqrt{a^2 + b^2} \sin 3\theta$ through an angle α . Then entire area of the loops of the two curves is same. Thus entire area of the curve $r = a \cos 3\theta + b \sin 3\theta$ is the same as the entire area of the curve $r = \sqrt{a^2 + b^2} \sin 3\theta$.

$$\text{Required area} = \frac{\pi(\sqrt{a^2+b^2})^2}{4} = \frac{\pi(a^2+b^2)}{4}$$

since $n = 3$ is odd.

Example 9: Determine the common area between the circle $r = \frac{3}{2}a$ and the cardioid $r = a(1 + \cos \theta)$. Deduce the area which is external to the circle but inside the cardioid.

Solution: The points of intersection of the two curves are $\frac{3}{2}a = a(1 + \cos \theta)$ i.e., $\theta = \pm \frac{\pi}{3}$ or $B(\frac{3}{2}a, \frac{\pi}{3})$, $C(\frac{3}{2}a, -\frac{\pi}{3})$. Here $D(\frac{3}{2}a, 0)$ and $A(2a, 0)$, $E(a, \frac{\pi}{2})$. Common area included between the circle and the cardioid is twice the area of the shaded region $ODBEO$ because both the curves circle and cardioid are symmetric about the initial line (x -axis) (Fig. 6.14). Again area of $ODBEO$ = Area of ODB + Area of $OBEO$ common area

Fig. 6.14

$$= 2 \left[\int_0^{\pi/3} \frac{1}{2} r^2 d\theta + \int_{\pi/3}^{\pi} \frac{1}{2} r^2 d\theta \right]$$

$$= \int_0^{\pi/3} \frac{9}{4} a^2 d\theta + \int_{\pi/3}^{\pi} a^2 (1 + \cos \theta)^2 d\theta$$

$$= \frac{9}{4} a^2 \theta \Big|_0^{\pi/3} + a^2 \int_{\pi/3}^{\pi} \left[1 + 2 \cos \theta + \frac{1 + \cos 2\theta}{2} \right] d\theta$$

$$= \frac{3\pi a^2}{4} + a^2 \left[\frac{3}{2} \theta + 2 \sin \theta + \frac{\sin 2\theta}{4} \right]_{\pi/3}^{\pi}$$

$$= \frac{3\pi a^2}{4} + a^2 \left[\frac{3}{2} \cdot \frac{2\pi}{3} + 2 \left(0 - \frac{\sqrt{3}}{2} \right) + \frac{1}{4} \left(0 - \frac{\sqrt{3}}{2} \right) \right]$$

$$A = \frac{7\pi a^2}{4} - \frac{9}{8} \sqrt{3} a^2 = \left(\frac{7\pi}{4} - \frac{9\sqrt{3}}{8} \right) a^2$$

Now area of the cardioid = twice of area of $OABEO$

$$= 2 \cdot \frac{1}{2} \int_0^{\pi} r^2 d\theta = \frac{1}{2} \int_0^{\pi} a^2 (1 + \cos \theta)^2 d\theta$$

$$= a^2 \int_0^{\pi} \left[1 + 2 \cos \theta + \frac{1 + \cos 2\theta}{2} \right] d\theta$$

$$= a^2 \left[\frac{3}{2} \theta + 2 \sin \theta + \frac{\sin 2\theta}{4} \right]_0^{\pi} = a^2 \left[\frac{3}{2} \pi + 0 + 0 \right] = \frac{3\pi a^2}{2}$$

Now area outside the circle but inside the cardioid is

$$= \frac{3\pi a^2}{2} - \left(\frac{7\pi}{4} - \frac{9\sqrt{3}}{8} \right) a^2$$

EXERCISE

Find the area bounded by the following curve (1 to 7).

1. $y = 2x + x^2 - x^3$, x -axis, $x = -1$, $x = 1$

Hint: Curve crosses x -axis at -1 , 0 , 2 . So

$$\text{Area} = \left| \int_{-1}^0 \right| + \int_0^1 = \left| -\frac{5}{12} \right| + \frac{13}{12} = \frac{3}{2}$$

Ans. $\frac{3}{2}$

2. $y = 2x^4 - x^2$, x -axis, its two minimum ordinates.

Hint: $x = \pm \frac{1}{2}$ minimum ordinates

Ans. $\frac{7}{120}$

3. Parabola $y = x^2$ and the line $y = x$.

Hint: $= \int_0^1 (x - x^2) dx$

Ans. $\frac{1}{6}$

4. $x^2 = 2ay, y = 2a$.

Hint: $\int_0^{2a} [\sqrt{2ay} - (-\sqrt{2ay})] \cdot dy$

Ans. $\frac{16}{3}a^2$

5. $y = \sin x, x\text{-axis}, 0 \leq x \leq 2\pi$.

Hint: $\int_0^\pi \sin x \, dx + \left| \int_\pi^{2\pi} \sin x \, dx \right|$

Ans. 4

6. $y^2 = x, y = x^2$.

Hint: $\int_0^1 (\sqrt{x} - x^2) dx$

Ans. $\frac{1}{3}$

7. Ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ or $x = a \cos t, y = b \sin t$.

Hint: $\int_0^a \frac{b}{a} \sqrt{a^2 - x^2} dx$ or $2 \int_\pi^0 (b \sin t)(-a \sin t) dt$

Ans. πab

8. Find the area of the loop of the curve

$a^4 y^2 = x^5(2a - x)$

Hint: Loop between $x = 0, x = 2a$, curve is symmetric about x -axis,

$$A = 2 \int_0^{2a} \frac{1}{2} x^{\frac{5}{2}} \sqrt{2a - x} dx$$

Ans. $\frac{5\pi a^2}{4}$

9. Show that the area of the loop of the curve $ay^2 = x^2(a - x)$ is $\frac{8a^2}{15}$.

Hint: $A = 2 \int_0^a x \sqrt{\frac{a-x}{a}} dx$

10. Find the area included between the curve

$y^2(2a - x) = x^3$ and its asymptote.

Hint: $x=2a$ is asymptote. $A=2 \int_0^{2a} \sqrt{\frac{x^3}{2a-x}} dx$

Ans. $3\pi a^2$

11. Determine the area enclosed by the curve

$a^2 x^2 = y^3(2a - y)$

Hint: Loop between $y = 0$ to $y = 2a$. Curve is symmetric about y -axis

$$A = 2 \int_0^{2a} \frac{1}{a} y \sqrt{y(2a - y)} dy$$

Ans. πa^2

12. Obtain the area enclosed between one arch of the cycloid $x = a(\theta \mp \sin \theta), y = a(1 - \cos \theta)$ and its base.

Hint: $\int_{x=0}^{2\pi a} y \, dx = \int_0^{\frac{\pi}{2}} y(t) \frac{dx}{d\theta} d\theta, d\theta = \int_0^{\pi/2} a(1 - \cos \theta) \cdot a(1 - \cos \theta) d\theta$ or $2a^2 \int_0^\pi (\theta + \sin \theta)(\sin \theta) d\theta$

Ans. $3\pi a^2$

13. Find the area of the loop and area between the curve $x(x^2 + y^2) = a(x^2 - y^2)$ and its asymptote.

Ans. $\frac{4-\pi}{2}a^2, \frac{4+\pi}{2}a^2; x = -a$ is the asymptote. Loop is between $x = 0$ to $x = a$, symmetry about x -axis.

14. Find the area of the hypocycloid. Deduce the area of the astroid.

Hint: Eq. $\frac{x^{\frac{2}{3}}}{a^{\frac{2}{3}}} + \frac{y^{\frac{2}{3}}}{b^{\frac{2}{3}}} = 1$, parametric

$$x = a \cos^3 t, y = b \sin^3 t$$

$$A = 4 \int_{\pi/2}^0 (b \sin^3 t)(-3a \cos^2 t \cdot \sin t) dt$$

Ans. $\frac{3}{8}\pi ab, \frac{3}{8}\pi a^2$ (Put $a = b$)

15. Find the area common to the parabola $y^2 = ax$ and the circle $x^2 + y^2 = 4ax$.

Hint: $A = 2 \int_0^{3a} \sqrt{ax} dx + 2 \int_{3a}^{4a} \sqrt{4ax - x^2} dx$

Ans. $\left(3\sqrt{3} + \frac{4}{3}\pi\right)a^2$

16. Compute the area bounded by the lemniscate

$$r^2 = a^2 \cos 2\theta.$$

Hint: $A = 4 \cdot \int_0^{\frac{\pi}{4}} \frac{1}{2} \cdot a^2 \cdot \cos 2\theta d\theta$

Ans. a^2

6.20 — HIGHER ENGINEERING MATHEMATICS—II

17. Find the area of the limaçon $r = a + b \cos \theta$ (with $a > b$). Deduce the area of the cardioids $r = a(1 + \cos \theta)$, and $r = a(1 - \cos \theta)$. When $a < b$ find the sum of the areas of the loops of the curve $r = a + b \cos \theta$.

Ans. $\pi \left(a^2 + \frac{b^2}{2} \right), \frac{3\pi a^2}{2}$ (with $b = a$), $\frac{3\pi a^2}{2}$
(with $b = -a$), $\pi \left(a^2 + \frac{b^2}{2} \right)$

18. Find the area common to the circles $r = a\sqrt{2}$ and $r = 2a \cos \theta$.

Hint:

$$A = 2 \left[\frac{1}{2} \int_0^{\frac{\pi}{4}} (a\sqrt{2})^2 d\theta + \int_{\frac{\pi}{4}}^{\frac{\pi}{2}} (2a \cos \theta)^2 d\theta \right]$$

Ans. $a^2(\pi - 1)$

19. Find the common area between the cardioids

$$r = a(1 + \cos \theta) \text{ and } r = a(1 - \cos \theta)$$

Hint: $A = 4 \int_0^{\frac{\pi}{2}} \frac{1}{2} a^2 (1 - \cos \theta)^2 d\theta$

Ans. $\frac{a^2}{2} \cdot (3\pi - 8)$

20. Let PQ be the common tangent to the two loops of the lemniscate $r^2 = a^2 \cos 2\theta$ with pole at O . Then find the area bounded by the line PQ and the arcs OP and OQ of the curve (Fig. 6.15).

Fig. 6.15

Hint: $\phi = \pi = \theta + \phi, \cot \phi = -\tan 2\theta, \pi = \phi = \theta + \frac{\pi}{2} + 2\theta \therefore \theta = 30^\circ, OP = \frac{a}{\sqrt{2}} = OQ, A = \Delta OPQ - 2 \int_{\frac{\pi}{6}}^{\frac{\pi}{4}} \frac{1}{2} a^2 \cos 2\theta d\theta.$

Ans. $\frac{a^2}{8}(3\sqrt{3} - 4)$

6.3 LENGTH OF PLANE CURVE: RECTIFICATION

Rectification is the process of determining the length of arc of a plane curve whose equation may be given in cartesian, parametric cartesian or polar form.

Cartesian Form

Let S be the length of the arc of the plane curve c included between two points A and B whose abscissa are a and b . Let $y = f(x)$ be the equation of the curve c in the cartesian form, with $a \leq x \leq b$. Divide the curve into n segments by n points $P_k(x_k, y_k)$. Then the length $S =$ limit of the sum of the lengths of the n line segments $= AP_1 + P_1P_2 + \dots + P_{n-1}B$. By mean value theorem the length of the k th line segment is (refer Fig. 6.16)

Fig. 6.16

$$\begin{aligned} P_{k-1}P_k &= \sqrt{(x_k - x_{k-1})^2 + (y_k - y_{k-1})^2} \\ &= \sqrt{(x_k - x_{k-1})^2 + \{f'(x_k^*)(x_k - x_{k-1})\}^2} \\ &= \sqrt{1 + (f'(x_k^*))^2} \cdot \Delta x_k \text{ where } \Delta x_k = x_k - x_{k-1} \end{aligned}$$

Therefore,

$$S = \lim_{n \rightarrow \infty} \sum_{k=1}^n \left\{ 1 + [f'(x_k^*)]^2 \right\}^{\frac{1}{2}} \Delta x_k$$

$$S = \int_a^b \sqrt{1 + [f'(x)]^2} dx$$

$$= \int_a^b \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx.$$

Corollary 1: If the equation of the curve is $x = f(y)$ then the length of the arc of the plane curve included between two points whose ordinates are c, d is

$$S = \int_c^d \sqrt{1 + \left(\frac{dx}{dy}\right)^2} dy$$

Parametric Form

When the equation of the curve is in the parametric form $x = x(t), y = y(t)$ with the parameter t varying from t_1 to t_2 , then

$$\begin{aligned} S &= \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\ &= \int_{t_1}^{t_2} \sqrt{\dot{x}^2 + \dot{y}^2} dt \end{aligned}$$

since $\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{\dot{y}}{\dot{x}}$ Here dot ($\dot{}$) denotes differentiation w.r.t. the parameter t .

Polar Form

The length of the arc of the curve $r = f(\theta)$ included between two points whose vectorial angles are $\theta = \theta_1$, and $\theta = \theta_2$ is

$$S = \int_{\theta_1}^{\theta_2} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta$$

Corollary 1: When the equation of the curve is $\theta = g(r)$ then the length included between two points whose radii vectors are r_1 and r_2 is

$$S = \int_{r_1}^{r_2} \sqrt{1 + r^2 \left(\frac{d\theta}{dr}\right)^2} dr$$

WORKED OUT EXAMPLES

Example 1: Find the length of the curve

$$y = \ln(e^x + 1) - \ln(e^x - 1) \quad \text{from } x = 1 \text{ to } x = 2$$

Solution: Differentiating y w.r.t. x

$$\frac{dy}{dx} = \frac{e^x}{e^x + 1} - \frac{e^x}{e^x - 1} = -\frac{2e^x}{e^{2x} - 1}$$

$$\begin{aligned} 1 + \left(\frac{dy}{dx}\right)^2 &= 1 + \frac{4e^{2x}}{(e^{2x} - 1)^2} = \frac{e^{4x} + 1 - 2e^{2x} + 4e^{2x}}{(e^{2x} - 1)^2} \\ &= \left(\frac{e^{2x} + 1}{e^{2x} - 1}\right)^2 \end{aligned}$$

Length of the curve:

$$\begin{aligned} S &= \int_1^2 \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx = \int_1^2 \frac{e^{2x} + 1}{e^{2x} - 1} dx \\ S &= \int_1^2 \frac{(e^{2x} - 1) + 1 + 1}{e^{2x} - 1} dx \\ &= \int_1^2 dx + 2 \int_1^2 \frac{1}{e^{2x} - 1} dx \\ &= 1 + 2 \int_1^2 \frac{dx}{(e^x)^2 - 1} \end{aligned}$$

Put $e^x = \sec t, dx = \tan t dt, \cos t = \frac{1}{e^x}$

$$\begin{aligned} \text{Consider } \int_1^2 \frac{dx}{(e^x)^2 - 1} &= \int \frac{\tan t dt}{\tan^2 t} = \int \cot t dt = \ln \sin t \\ &= \ln \left(\frac{\sqrt{e^{2x} - 1}}{e^x} \right) \Bigg|_1^2 = \ln \frac{e^4 - 1}{e^2} - \ln \frac{e^2 - 1}{e} \\ &= \ln \frac{e^2 + 1}{e} \end{aligned}$$

Fig. 6.17

Thus the length of the curve $S = 1 + 2 \ln \frac{e^2 + 1}{e}$.

Example 2: Find the length of the curve

$$8x = y^4 + 2y^{-2} \quad \text{from } y = 1 \text{ to } y = 2$$

Solution: Here y is the independent variable. Differentiating w.r.t. y , we get

$$\frac{dx}{dy} = \frac{4y^3 - 4y^{-3}}{8} = \frac{1}{2} \left(y^3 - \frac{1}{y^3} \right)$$

Length of the curve:

$$S = \int_{y_1}^{y_2} \sqrt{1 + \left(\frac{dx}{dy}\right)^2} dy$$

6.22 — HIGHER ENGINEERING MATHEMATICS—II

$$= \int_1^2 \sqrt{1 + \frac{1}{4} \left(y^3 - \frac{1}{y^3} \right)^2} dy = \int_1^2 \frac{y^6 + 1}{2y^3} dy$$

$$S = \frac{1}{2} \left[\frac{y^4}{4} - \frac{y^{-2}}{2} \right]_1^2 = \frac{33}{16}$$

Example 3: Determine the length of the curve whose parametric equation is

$$x = e^{-t} \cos t, y = e^{-t} \sin t, 0 \leq t \leq \frac{\pi}{2}$$

Solution: Differentiating x and y w.r.t. ' t '

$$\frac{dx}{dt} = -e^{-t} \cos t - e^{-t} \sin t,$$

$$\frac{dy}{dt} = -e^{-t} \sin t + e^{-t} \cos t$$

$$\begin{aligned} \left(\frac{dx}{dt} \right)^2 + \left(\frac{dy}{dt} \right)^2 &= e^{-2t} \cos^2 t + e^{-2t} \sin^2 t \\ &\quad + 2e^{-2t} \sin t \cos t + e^{-2t} \sin^2 t \\ &\quad + e^{-2t} \cos^2 t - 2e^{-2t} \sin t \cos t \\ &= 2e^{-2t} \end{aligned}$$

Length of the curve

$$\begin{aligned} S &= \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt} \right)^2 + \left(\frac{dy}{dt} \right)^2} dt \\ &= \int_0^{\frac{\pi}{2}} \sqrt{2e^{-2t}} dt = \sqrt{2} \cdot \left. \frac{e^{-t}}{-1} \right|_0^{\frac{\pi}{2}} = \sqrt{2}(1 - e^{-\frac{\pi}{2}}) \end{aligned}$$

Example 4: Calculate the distance travelled by the particle $P(x, y)$ after 4 minutes if the position at any time is given by

$$x = \frac{t^2}{2}, \quad y = \frac{1}{3}(2t + 1)^{\frac{3}{2}}.$$

Solution: The distance travelled by the particle $P(x, y)$ is the length of the curve whose parametric equation is given above when t varies from 0 to 4. So differentiating x, y w.r.t. t

$$\frac{dx}{dt} = t; \quad \frac{dy}{dt} = (2t + 1)^{\frac{1}{2}}$$

$$\left(\frac{dx}{dt} \right)^2 + \left(\frac{dy}{dt} \right)^2 = t^2 + 2t + 1 = (t + 1)^2$$

distance travelled by P = Length of the curve

$$= \int_0^4 \sqrt{(t + 1)^2} dt = \left. \frac{t^2}{2} + t \right|_0^4 = 12$$

Example 5: Determine the length (perimeter) of one loop of the curve $6ay^2 = x(x - 2a)^2$.

Solution: The curve is symmetric about the x -axis and crosses the x -axis at the points $x = 0$ and $x = 2a$. The length of the loop of the curve is twice the length of OBA (see Fig. 6.18).

Fig. 6.18

$$\text{Length of curve } OBA = \int_0^{2a} \sqrt{1 + y'^2} dx$$

Differentiating y w.r.t. x

$$\frac{dy}{dx} = \frac{3x - 2a}{\sqrt{2} \cdot 4ax}, \quad \text{so } 1 + y'^2 = \frac{(3x + 2a)^2}{24ax}$$

Length of the loop

$$\begin{aligned} &= 2 \int_0^{2a} \frac{3x + 2a}{\sqrt{24ax}} dx \\ &= \frac{2}{\sqrt{24a}} \left[3 \cdot \frac{x^{\frac{3}{2}}}{\frac{3}{2}} + 2a \cdot \frac{x^{\frac{1}{2}}}{\frac{1}{2}} \right]_0^{2a} \\ &= \frac{4}{\sqrt{24a}} \left[(2a)^{\frac{3}{2}} + 2a \cdot (2a)^{\frac{1}{2}} \right] = \frac{8a}{\sqrt{3}} \end{aligned}$$

Example 6: Find the perimeter of the curve

$$r = a(\cos \theta + \sin \theta); \quad 0 \leq \theta \leq \pi$$

Solution: Differentiating r w.r.t. θ

$$\frac{dr}{d\theta} = a(-\sin \theta + \cos \theta)$$

$$\begin{aligned} r^2 + \left(\frac{dr}{d\theta} \right)^2 &= a^2(\cos \theta + \sin \theta)^2 \\ &\quad + a^2(-\sin \theta + \cos \theta)^2 \\ &= 2a^2 \end{aligned}$$

$$\begin{aligned} \text{Length of the curve} &= \int_0^\pi \sqrt{r^2 + \left(\frac{dr}{d\theta} \right)^2} d\theta \\ &= \int_0^\pi \sqrt{2}a \cdot \theta^{\frac{1}{2}} d\theta = \sqrt{2}a\pi \end{aligned}$$

Example 7: Find the length of the spiral $r = e^{\alpha\theta}$ from the pole to the point (r, θ) .

Solution: $\frac{dr}{d\theta} = \alpha e^{\alpha\theta}$

$$\sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} = \sqrt{e^{2\alpha\theta} + \alpha^2 e^{2\alpha\theta}}$$

$$\begin{aligned} \text{Length of the spiral} &= \int_0^\theta \sqrt{[e^{2\alpha\theta} + \alpha^2 e^{2\alpha\theta}]} d\theta \\ &= \sqrt{1 + \alpha^2} \int_0^\theta e^{\alpha\theta} d\theta \\ &= \sqrt{1 + \alpha^2} \left. \frac{e^{\alpha\theta}}{\alpha} \right|_0^\theta \\ &= \frac{\sqrt{1 + \alpha^2}}{\alpha} (e^{\alpha\theta} - 1) = \frac{\sqrt{1 + \alpha^2}}{\alpha} (r - 1) \end{aligned}$$

Example 8: What is the length of the loop of the curve $x = t^2$, $y = t - \frac{t^3}{3}$.

Solution: $t = \sqrt{x}$, $y = \sqrt{x} - \frac{x^{\frac{3}{2}}}{3}$ so the equation in cartesian form is

$$3y = 3\sqrt{x} - x^{\frac{3}{2}} = \sqrt{x}(3 - x)$$

So loop of the curve lies between $x = 0$ and $x = 3$. Differentiating x and y w.r.t. t

$$\begin{aligned} \frac{dx}{dt} &= 2t, \quad \frac{dy}{dt} = 1 - t^2 \\ \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} &= \sqrt{(2t)^2 + (1 - t^2)^2} \\ &= \sqrt{(1 + t^2)^2} = 1 + t^2 \end{aligned}$$

$$\begin{aligned} \text{Length of the loop} &= \int_{-\sqrt{3}}^{\sqrt{3}} (1 + t^2) dt \\ &= 2 \left(\frac{t^3}{3} + t \right) \Big|_0^{\sqrt{3}} = 4\sqrt{3} \end{aligned}$$

Example 9: Determine the length of the loop of the curve $r = a(\theta^2 - 1)$.

Solution: As θ varies from $-1, 0, 1$, r takes the values $0, -a, 0$. Thus travelling the loop of the given

curve. Differentiating r w.r.t. θ , we get

$$\begin{aligned} \frac{dr}{d\theta} &= 2a\theta, \text{ so } r^2 + \left(\frac{dr}{d\theta}\right)^2 = a^2(\theta^2 - 1)^2 + (2a\theta)^2 \\ \therefore \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} &= \sqrt{a^2(\theta^2 + 1)^2} = a(\theta^2 + 1) \end{aligned}$$

Length of the loop of the curve is

$$= \int_{-1}^1 a(\theta^2 + 1) d\theta = a \left(\frac{\theta^3}{3} + \theta \right) \Big|_{-1}^1 = \frac{8a}{3}$$

Example 10: Show that the curve

$$x = a(\theta - \sin \theta), y = a(1 - \cos \theta)$$

is divided in the ratio 1:3 at $\theta = 2\pi/3$.

Solution: $\frac{dx}{d\theta} = a(1 - \cos \theta)$, $\frac{dy}{d\theta} = a \sin \theta$

$$\begin{aligned} \left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2 &= a^2(1 - \cos \theta)^2 + a^2 \sin^2 \theta \\ &= 2a^2(1 - \cos \theta) = 4a^2 \sin^2 \frac{\theta}{2} \end{aligned}$$

Length of the curve as θ varies from 0 to 2π is

$$\begin{aligned} L &= \int_0^{2\pi} \sqrt{4a^2 \sin^2 \frac{\theta}{2}} d\theta = 2a \int_0^{2\pi} \sin \frac{\theta}{2} d\theta \\ &= -2a \cdot 2 \cos \frac{\theta}{2} = -4a \cos \frac{\theta}{2} \Big|_0^{2\pi} \\ &= -4a [-1 - 1] = 8a \end{aligned}$$

Length of the curve as θ varies from 0 to $\frac{2\pi}{3}$ is M

$$\begin{aligned} M &= \int_0^{\frac{2\pi}{3}} 2a \sin \frac{\theta}{2} d\theta = -4a \cos \frac{\theta}{2} \Big|_0^{\frac{2\pi}{3}} \\ &= -4a \left[\frac{1}{2} - 1 \right] = 2a \end{aligned}$$

Thus L is divided in the ratio 1:3 when $\theta = \frac{2\pi}{3}$.

EXERCISE

Cartesian form

Find the length of the curve

$$1. y = x\sqrt{x} \text{ from } x = 0 \text{ to } x = 4/3$$

$$\text{Ans. } \frac{56}{27}$$

6.24 — HIGHER ENGINEERING MATHEMATICS—II

2. $3y = 2(x^2 + 1)^{\frac{3}{2}}$ from $x = 0$ to $x = 3$

Ans. 21

3. $x = \ln y$, between the points whose ordinates are $\frac{3}{4}$ and $\frac{4}{3}$

Hint: Treat y as the independent variable.

Ans. $\ln \frac{3}{2} + \frac{5}{12}$

4. Find the perimeter of a circle of radius b .

Hint: Take equation of circle as $x^2 + y^2 = a^2$,

$$S = 2 \int_{-a}^a \sqrt{1 + y'^2} dx$$

Ans. $2\pi b$

5. Calculate the length of the arc of parabola $y^2 = 4ax$ cut-off by the latus rectum.

Ans. $2a \left[\sqrt{2} + \ln(1 + \sqrt{2}) \right]$

6. What is the length of the catenary (hanging chain; hyperbolic cosine curve) $y = \frac{1}{2}a(e^{\frac{x}{a}} + e^{-\frac{x}{a}})$ from $x = -a$ to $x = a$.

Hint: $y = a \cosh\left(\frac{x}{a}\right)$

Ans. $a(e - e^{-1})$

7. Show that the length of the arc of the curve

$$y = \ln \tanh(x/2)$$

from $x = 1$ to $x = 2$ is $\ln[(e^2 + 1)/e]$.

8. Determine the distance a particle which moves along a curve $20x = 3(4t^2 - 20t + 9)$ is 4 minutes starting at $t = \frac{1}{2}$.

Ans. $\frac{5}{6} \left[\frac{156}{25} + \ln 5 \right]$

9. Find the length of the curve $y^2 = x(1 - \frac{x}{3})^2$ from origin to the ordinate when $x = a$.

Ans. $\frac{(3+a)}{3} \sqrt{a}$

10. Find the perimeter of the loop of the curve

$$3ay^2 = x(x - a)^2$$

Hint: Perimeter $= 2 \int_0^a \sqrt{1 + y'^2} dx$ since curve is symmetric about x -axis and lies between 0 to 9.

Ans. $\frac{4a}{\sqrt{3}}$

11. Calculate the perimeter of the loop of the curve

$$9ay^2 = (x - 2a)(x - 5a)^2.$$

Hint: Curve lies between $x = 2a$ and $x = 5a$ and is symmetric about y -axis. Perimeter is $2 \int_{2a}^{5a} \sqrt{1 + y'^2} dx$.

Ans. $4\sqrt{3}a$

12. Determine the total length of the curve

$$x^2(a^2 - x^2) = 8a^2y^2$$

Hint: Curve is symmetric about both x -axis and y -axis and lies between $x = -a$ to $x = a$.

$$\text{Total length} = 4 \times \int_0^a \sqrt{1 + y'^2} dx$$

Ans. $\pi a \sqrt{2}$

13. What is the length of the arc of the parabola $y^2 = 12x$ cut-off by its latus rectum.

Hint: Length is twice that from $(0, 0)$ to $(3, 6)$.

Ans. $6 \left[\sqrt{2} + \ln(1 + \sqrt{2}) \right]$

14. Find the length of an arc of the curve

$$x^2 = a^2(1 - e^{\frac{y}{a}})$$

measured from $(0, 0)$ to any point (x, y) .

Ans. $a \ln \left(\frac{a+x}{a-x} \right) - x$

15. Determine the length of the parabola $y^2 = 4ax$ cut-off by the line $3y = 8x$.

Ans. $\left(\frac{15}{16} + \ln 2 \right) a$

16. Find the length of the loop of the curve $9ay^2 = x(x - 3a)^2$.

Hint: Curve is symmetric about x -axis and meets x -axis at $x = 0$, and $x = 3a$

$$S = \frac{1}{2\sqrt{a}} \int_0^{3a} \frac{x+a}{\sqrt{x}} dx$$

Ans. $2a\sqrt{3}$

Parametric form

Find the length of the curve whose equation is given in the parametric form:

1. $x = t^3 - 3t$; $y = 3t^2$; t : from 0 to 1

Ans. 4

2. $x = a(t + \sin t); y = a(1 - \cos t), t : -\pi$ to π

Ans. 8a

3. $x = e^t \sin t, y = e^t \cos t, t : 0$ to $\frac{\pi}{2}$

Ans. $\sqrt{2}(e^{\frac{\pi}{2}} - 1)$

4. $x = a(\cos t + t \sin t), y = a(\sin t - t \cos t)$
from $t = 0$ to $t = \pi/2$

Ans. $\frac{a\pi^2}{8}$

5. Find the distance travelled by a particle $P(x, y)$ whose position at any time t is given by

$$x = \frac{1}{3}(2t + 3)^{\frac{3}{2}}, y = \frac{t^2}{2} + t$$

in 3 minutes commencing from $t = 0$.

Ans. $\frac{21}{2}$

6. (a) Determine the total length of the four-cusped hypocycloid given by

$$x = a \cos^3 \theta, y = b \sin^3 \theta$$

or

$$\left(\frac{x}{a}\right)^{\frac{2}{3}} + \left(\frac{y}{b}\right)^{\frac{2}{3}} = a^{\frac{2}{3}}.$$

Hint: (a) Curve is symmetric about both x -axis and y -axis. For one cusp: θ varies from 0 to $\pi/2$

$$\text{Total length} = 4 \int_0^{\frac{\pi}{2}} \sqrt{\left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2} d\theta$$

Ans. $4(a^2 + ab + b^2)/(a + b)$.

6. (b) Deduce whole length of the astroid given by

$$x = a \cos^3 \theta, y = a \sin^3 \theta$$

Hint: take $a = b$

Ans. 6a

7. Calculate the length of the arc of the cycloid $x = a(t - \sin t), y = a(1 - \cos t)$ between two cusps.

Hint: Between two cusps t varies from 0 to 2π .

Ans. 8a

8. Determine the length of the curve given by

$$x = a \sin 2t(1 + \cos 2t); y = a \cos 2t(1 - \cos 2t)$$

measured from origin to any point (x, y) .

Ans. $\frac{4a}{3} \sin 3t$

Polar coordinates

1. Find the perimeters of the curves:

a. $r = a \cos \theta$ (circle with centre at origin and radius a)

b. $r = a \sin \theta$

c. $r = 2a \cos \theta$ (circle with centre at $r = a$ and radius a).

Ans. (a) πa (b) πa (c) $2a\pi$

2. Show that the arc of the upper half of the curve

$$r = a(1 - \cos \theta)$$

is bisected at $\theta = 2\pi/3$.

3. Calculate the length of the curve

$$r = a \sin \theta + b \cos \theta, 0 \leq \theta \leq 2\pi$$

Ans. $\pi\sqrt{a^2 + b^2}$

4. a. Find the perimeter of the cardioid

$$r = (1 + \cos \theta).$$

b. Show that the arc of the upper half is bisected at $\theta = \pi/3$.

c. Also show that the length of the part of the curve which lies on the side of the line $4r = 3a \sec \theta$ remote from the pole is equal to $4a$.

Hint: (b) Curve is symmetrical about initial line $\theta = 0$ and for the upper half of the curve, θ varies from 0 to π . The length of the curve as θ varies from 0 to $\frac{\pi}{3}$ is $2a$ i.e., half of $4a$, therefore, bisected at $\theta = \pi/3$.

Hint: (c) Line meets cardioid at $\theta = \frac{\pi}{3}$;
length = twice $\int_0^{\frac{\pi}{3}} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta$.

Ans. (a) 8a

5. Determine the perimeter of the curve

$$r = a \sin^3 \left(\frac{\theta}{3}\right)$$

Hint: As θ varies from 0, $\frac{3\pi}{2}, 3\pi, r$ takes c, a, c , perimeter = 2 length from $\theta = 0$ to $\frac{3\pi}{2}$

Ans. $\frac{3a\pi}{2}$

6.26 — HIGHER ENGINEERING MATHEMATICS—II

6. Find the length of the arc of the parabola

$$r = 2a/(1 + \cos \theta)$$

cut-off but its latus rectum.

Ans. $\left[\sqrt{2} + \ln(1 + \sqrt{2}) \right] \cdot 2a$

7. Prove that the length of the curve

$$r = a \cos^3 \left(\frac{\theta}{3} \right) \text{ is } 8a\pi/2$$

8. Determine the whole length of the lemniscate

$$r^2 = a^2 \cos 2\theta$$

Hint: 4 times the length as θ varies from 0 to $\frac{\pi}{4}$ since curve is symmetric about both x -axis and y -axis (i.e., $\theta = 0$ line and $\theta = \frac{\pi}{2}$ line).

Ans. $\sqrt{2}\pi a \left\{ 1 + \left(\frac{1}{2}\right)^2 + \left(\frac{1.3}{2.4}\right)^2 \cdot \left(\frac{1}{2}\right)^2 + \left(\frac{1.3.5}{2.4.6}\right)^2 \left(\frac{1}{2}\right)^2 + \dots \right\}$

9. Find the length of the arc of the equiangular spiral $r = a e^{\theta \cot \alpha}$ between the points for which the radii vectors are r_1 and r_2 .

Hint: $\frac{dr}{d\theta} = r \cot \alpha$, $\frac{d\theta}{dr} = \frac{1}{r} \tan \alpha$

$$\begin{aligned} \text{length} &= \int_{r_1}^{r_2} \sqrt{1 + r^2 \left(\frac{d\theta}{dr} \right)^2} dr \\ &= \int_{r_1}^{r_2} \sqrt{1 + \tan^2 \alpha} dr = \int_{r_1}^{r_2} \sec \alpha dr \end{aligned}$$

Ans. $(r_2 - r_1) \sec \alpha$

10. Calculate the length of the arc of the hyperbolic spiral $r = a/\theta$ between $r = a$ and $r = 2a$.

Ans. $a \left[\sqrt{5} - \sqrt{2} + \ln \left(\frac{2+\sqrt{8}}{1+\sqrt{5}} \right) \right]$

11. Determine the whole length of a loop of the curve

$$r = a(1 + \cos 2\theta)$$

Ans. $\frac{2}{3}\sqrt{3} \left[2\sqrt{3} + \ln(\sqrt{3} + 2) \right] a$

6.4 VOLUME OF SOLID OF REVOLUTION

A solid of revolution is generated by revolving a plane area R about a line L in the plane. Line L

is known as the axis of revolution. Line L does not intersect the plane area R but may touch the boundary of R .

Examples:

1. Sphere is a solid of revolution generated by revolving the semicircular region R about its diameter L (Fig. 6.19).

Fig. 6.19

2. Right circular cylinder is a solid of revolution obtained by revolving a rectangle R about its edge L (Fig. 6.20).

Fig. 6.20

3. Parabola about x -axis generates paraboloid (Fig. 6.21).

Fig. 6.21

4. Circular region R about L not touching it, produces a torus (see Fig. 6.22).

The volume of solid of revolution may be obtained by (a) *cylindrical disc (C.D.) method* (b) *cylindrical shell (C.S.) method*.

Fig. 6.22

Cartesian Form

Cylindrical disc method

- I. Axis of revolution L is a part of the boundary of the plane area. Consider the plane area $ABCD$ bounded by the curve $y = f(x)$, x -axis, ordinates $x = a$ and $x = b$ as shown in Fig. 6.23. When the plane area $ABCD$ is revolved about x -axis, a solid of revolution is obtained, one quarter of which is shown in Fig. 6.23. The volume of an element circular disk of radius y

Fig. 6.23

and thickness dx is $\pi y^2 dx$. Integrating these elements, the volume V of solid of revolution obtained by revolving about the x -axis the plane area bounded by $y = f(x)$, $x = a$, $x = b$, x -axis is

$$V = \int_a^b \pi y^2 dx$$

Similarly, when plane area bounded by the curve $x = g(y)$, $y = c$, $y = d$, y -axis, is revolved about y -axis,

$$V = \int_c^d \pi x^2 dy$$

- II. Any axis of revolution:

$$V = \int_a^b \pi r^2 dh$$

where r = perpendicular distance from the curve to the axis of revolution AB (Fig. 6.24).

Fig. 6.24

- III. The plane area is bounded by two curves: Let the plane area bounded by two curves $y = y_1(x)$ lower curve, $y = y_2(x)$ upper curve, the ordinates $x = a$, $x = b$ is revolved about x -axis, then volume of solid of revolution generated is the difference between the volume generated by the upper curve and lower curve. Thus

$$V = \int_a^b \pi y_2^2 dx - \int_a^b \pi y_1^2 dx = \int_a^b \pi (y_2^2 - y_1^2) dx$$

where y_2 and y_1 are the ordinates of the upper and lower curves.

Cylindrical shell method

Axis of rotation AB is not part of the boundary of the plane area $DEFG$, volume element generated by revolving a rectangular strip about an axis AB (Fig. 6.25).

Fig. 6.25

$$dV = (\text{mean circumference}) \times (\text{height}) \times (\text{thickness})$$

$$dV = (2\pi r)(h)(dr)$$

$$\text{So } V = \int_{r=a}^{r=b} 2\pi r h dr$$

6.28 — HIGHER ENGINEERING MATHEMATICS—II

If area $DEFG$ is rotated about y -axis (AB) thus

$$V = \int_{x=a}^{x=b} (2\pi x)(y)dx$$

Similarly, about x -axis,

$$V = \int_{y=c}^{y=d} (2\pi y)(x)dy$$

Parametric Form

If the equation of the curve binding the plane area is given in parametric form

$$x = f(t), y = g(t)$$

with the parameter t varying between t_1 and t_2 , then the volume about x -axis

$$V = \int_{t_1}^{t_2} \pi y^2 \frac{dx}{dt} dt = \int_{t_1}^{t_2} \pi g^2(t) \frac{df(t)}{dt} dt$$

Similarly, about y -axis

$$V = \int_{t_1}^{t_2} \pi x^2 \frac{dy}{dt} dt = \int_{t_1}^{t_2} \pi f^2(t) \frac{dg(t)}{dt} dt$$

Polar Form

The volume of the solid of revolution generated by revolving the plane area R , bounded by the curve c whose equation is given in polar form $r = f(\theta)$, and radii vectors $\theta = \theta_1, \theta = \theta_2$ (Fig. 6.26).

Fig. 6.26

I. About the initial line $OX(\theta = 0)$

$$V = \int_{\theta_1}^{\theta_2} \frac{2\pi}{3} r^3 \sin \theta \, d\theta$$

II. About the line through the pole and perpendicular to the initial line i.e., $OY (\theta = \frac{\pi}{2})$

$$V = \int_{\theta_1}^{\theta_2} \frac{2\pi}{3} r^3 \cos \theta \, d\theta$$

WORKED OUT EXAMPLES

Cartesian Form

Example 1: The equation of the curve OP is $y = x^2$. Find the volume of solid of revolution generated when the area OAP , bounded by $y = x^2$, $x = 3$ and x -axis, is revolved about (a) x -axis (b) y -axis (c) line AP (d) Line BP (Fig. 6.27).

Fig. 6.27

Solution:

a. About x -axis: (cylindrical disk method) (Fig. 6.28).

Fig. 6.28

A rectangle of height y and thickness Δx revolved about x -axis (Line OA), generates a solid of revolution, a circular disk, of volume $\pi y^2 \Delta x$. Since x varies from 0 to 3, the volume V of solid of revolution obtained by revolving the area OAP about x -axis is

$$V = \int_{x=0}^3 \pi y^2 \, dx = \pi \int_0^3 (x^2)^2 \, dx = \frac{243\pi}{5}$$

- b. About y -axis: (cylindrical shell method) (Fig. 6.29) when a rectangle of height y and thickness Δx is revolved about y -axis (line

Fig. 6.29

OB), it generates a cylindrical shell whose circumference is $2\pi x$, height y and thickness Δx so that its volume is

$$2\pi x \cdot y \cdot \Delta x$$

Thus the volume of solid of revolution generated by revolving the area OAP about y -axis is

$$\begin{aligned} V &= \int_0^3 (2\pi x)(y) dx = \int_0^3 2\pi x \cdot x^2 dx \\ &= 2\pi \left[\frac{x^4}{4} \right]_0^3 = \frac{81\pi}{2} \end{aligned}$$

- c. About the line AP (Fig. 6.30).

Fig. 6.30

- i. By cylindrical disk method: When a horizontal rectangle of length $(3 - x)$ and thickness Δy is revolved about the line AP , it generates a circular disk of volume $\pi(3 - x)^2$, so the volume generated by revolving OAP about AP is

$$\begin{aligned} V &= \int_0^9 \pi(3 - x)^2 dy = \int_0^9 \pi(3 - \sqrt{y})^2 dy \\ &= \pi \left(9y + \frac{y^2}{2} - 12y^{\frac{3}{2}} \right) \Big|_0^9 = \frac{27\pi}{2} \end{aligned}$$

- ii. **Aliter:** By cylindrical shell method: (Fig. 6.31): By revolving a vertical rectangle of height y and thickness Δx about the

Fig. 6.31

line AP , a cylindrical shell of circumference $2\pi(3 - x)$, height y and thickness Δx is generated. Its volume is

$$2\pi(3 - x) \cdot y \cdot \Delta x$$

So the volume required is

$$\begin{aligned} V &= \int_0^3 2\pi(3 - x) \cdot y dx = \int_0^3 2\pi(3 - x)(x^2) dx \\ &= 2\pi \left[x^3 - \frac{x^4}{4} \right]_0^3 = \frac{27\pi}{2} \end{aligned}$$

- d. About the line BP (Fig. 6.32). A horizontal strip of length $(3 - x)$ and width Δy , revolved about the line BP generates a cylindrical shell of circumference $2\pi(9 - y)$, height $(3 - x)$ and width Δy . Thus the required volume

$$\begin{aligned} V &= \int_0^9 2\pi(9 - y) \cdot (3 - x) dy \\ &= 2\pi \int_0^9 (9 - y)(3 - \sqrt{y}) dy = \frac{567\pi}{5} \end{aligned}$$

Fig. 6.32

Example 2: Determine the volume of solid generated by revolving the plane area bounded by $y^2 = 4x$ and $x = 4$ about the line $x = 4$.

6.30 — HIGHER ENGINEERING MATHEMATICS—II

Solution: $OACB$ is the plane region bounded by $y^2 = 4x$ and $x = 4$ (Fig. 6.33). A typical horizontal element of length $(4 - x)$ and width dy rotated about the line $x = 4$ generates a circular disk of

Fig. 6.33

volume $\pi(4 - x)^2 dy$. Here y varies from -4 to 4 . Thus the required volume generated by rotating $OACB$ about $x = 4$ is

$$\begin{aligned} V &= \int_{-4}^4 \pi(4 - x)^2 \cdot dy = \int_{-4}^4 \pi \left(4 - \frac{y^2}{4} \right)^2 dy \\ &= 2\pi \int_0^4 \left(16 + \frac{y^4}{16} - 2y^2 \right) dy \\ &= 2\pi \left[16y + \frac{y^5}{80} - \frac{2}{3}y^3 \right]_0^4 = \frac{1024}{15}\pi \end{aligned}$$

Example 3: Calculate the volume of the solid of revolution generated by revolving about y -axis the plane area bounded by the straight lines $y = x + 2$, $y = 2x - 1$ and outside of the parabola $y = x^2$.

Solution: The plane area which is outside of the parabola and included between the two straight lines is $ACDB$ shown shaded in Fig. 6.34.

Fig. 6.34

[The points of intersection are:

$A(1, 1)$ between parabola $y = x^2$ and the st line $2x - 1 = y$
 $B(2, 4)$ between parabola $y = x^2$ and the line $y = x + 2$
 $D(3, 5)$ between the lines $y = 2x - 1$ and $y = x + 2]$

Since $ACBD$ is revolved about y -axis, apply cylindrical shell method. Divide the plane arc $ACBD$ into two parts ACB and CDB since the variation y is different in these two parts. Thus volume V generated by revolving $ACDB$ about y -axis is sum of the volumes V_1 and V_2 generated by revolving ACB and CDB about y -axis respectively. These volumes V_1 and V_2 are obtained by cylindrical shell method.

For the plane area ACB , the height of a vertical element is $(x^2) - (2x - 1)$. So the volume V_1 of the solid of revolution generated by revolving ACB about y -axis is

$$\begin{aligned} V_1 &= \int_1^2 (2\pi x)[(x^2) - (2x + 1)]dx \\ &= 2\pi \left[\frac{x^4}{4} - \frac{2x^3}{3} + \frac{x^2}{2} \right]_1^2 = \frac{7\pi}{6} \end{aligned}$$

Similarly, for CDB , we have

$$\begin{aligned} V_2 &= \int_2^3 (2\pi x)[(x + 2) - (2x - 1)]dx \\ &= \int_2^3 2\pi(-x^2 + 3x)dx = \frac{7\pi}{3} \end{aligned}$$

Thus the required volume of solid generated by revolving $ACDB$ about y -axis is

$$V = V_1 + V_2 = \frac{7\pi}{6} + \frac{7\pi}{3} = \frac{7\pi}{2}$$

Example 4: Find the volume generated when the plane area bounded by the parabola $y + x^2 + 3x - 6 = 0$ and the line $x + y = 3$ is revolved about the line.

Solution: For the representative rectangle of the Fig. 6.35, the height is $\frac{x+y-3}{\sqrt{2}}$ and the width is $\sqrt{(\Delta x)^2 + (\Delta y)^2} = \sqrt{2}\Delta x$. By circular disc method, the volume of the solid of revolution generated by revolving the plane area $ACBD$ about the line BDA is

$$V = \int_{-3}^1 \pi \left(\frac{x + y - 3}{\sqrt{2}} \right)^2 \cdot (\sqrt{2}dx)$$

Fig. 6.35

$$\begin{aligned}
 &= \frac{\sqrt{2}\pi}{2} \int_{-3}^1 [x + (-x^2 - 3x + 6) - 3]^2 dx \\
 &= \frac{\pi}{\sqrt{2}} \int_{-3}^1 (-x^2 - 2x + 3)^2 dx = \frac{256}{15} \sqrt{2}\pi
 \end{aligned}$$

Example 5: Find the volume of the solid generated by revolving about the x -axis, the smaller area bounded by the circle $x^2 + y^2 = 2$ and the semicircular parabola $y^3 = x^2$.

Solution: The smaller area $OACB$ bounded by the circle and parabola is shaded in the Fig. 6.36. Consider a typical vertical element whose length is $y_2 - y_1$ where y_2 and y_1 are the ordinates of the outer curve circle and the inner curve parabola respectively.

Fig. 6.36

This vertical element revolved about x -axis generates a circular ring whose outer and inner radii are the respective ordinates of the outer and inner curves. Thus the volume generated by $OACB$ by revolving about x -axis is

$$\begin{aligned}
 V &= \left(\int \pi y_2^2 dy \right) - \left(\int \pi y_1^2 dy \right) \\
 &= \pi \int (y_2^2 - y_1^2) dy
 \end{aligned}$$

$$\begin{aligned}
 V &= \pi \int_{-1}^1 [(2 - x^2) - (x^{\frac{4}{3}})] dx \\
 &= \pi \left[2x - \frac{x^3}{3} - \frac{3}{7} x^{\frac{7}{3}} \right]_{-1}^1 = \frac{52}{21} \pi
 \end{aligned}$$

Example 6: What is the volume generated by revolving the area enclosed by the loop of the curve $y^4 = x(4 - x)$ about x -axis.

Solution: Curve meets the x axis at $x = 0$ and $x = 4$ and is symmetric about the x -axis. The area OAO enclosed by the loop of the curve is shaded in Fig. 6.37. By circular disc method

Fig. 6.37

$$V = \int \pi y^2 dx = \pi \int_0^4 \sqrt{x(4-x)} dx$$

Put $\sqrt{x} = 2 \cos t$

$$V = \pi \int_{-\frac{\pi}{2}}^0 2 \cos t \cdot 2 \sin t \cdot (-4) 2 \cos t \cdot \sin t dt$$

$$V = 32\pi \int_0^{\frac{\pi}{2}} \cos^2 t \sin^2 t dt = 32\pi \cdot \frac{1}{4} \cdot \frac{1}{2} \cdot \frac{\pi}{2} = 2\pi^2$$

Example 7: Determine the volume of the solid of revolution generated by revolving the loop of the curve $ay^2 = x^2(a - x)$ about the straight line $y = b$.

Solution: The loop lies between the points $O(0, 0)$ and $A(a, 0)$. Solving the given equation for y ,

Fig. 6.38

6.32 — HIGHER ENGINEERING MATHEMATICS—II

$$y = \pm x \sqrt{\frac{a-x}{a}}$$

So the lower part of the loop below (x -axis) (see Fig. 6.38)

OBA is $y = -x \sqrt{\frac{a-x}{a}}$ and

the upper part of the loop above (x -axis)

OCA is $y = x \sqrt{\frac{a-x}{a}}$

The volume V obtained by revolving the loop about the line $y = b$ is the difference of the two volumes V_{OBA} and V_{OCA} obtained by revolving the arcs OBA and OCA about $y = b$. Volume obtained by revolving the arc OBA about $y = b$ is

$$V_{OBA} = \int_0^a \pi y^2 dx = \pi \int_0^a \left[b - \left(-x \sqrt{\frac{a-x}{a}} \right) \right]^2 dx$$

Similarly,

$$V_{OCA} = \int_0^a \pi y^2 dx = \pi \int_0^a \left[b - \frac{x \sqrt{a-x}}{\sqrt{a}} \right]^2 dx$$

$$V = V_{OBA} - V_{OCA} = \pi \int_0^a \frac{4bx(a-x)^{\frac{1}{2}}}{\sqrt{a}} dx$$

Put $x = a \cos^2 t$. As x varies from 0 to a , t varies from $\frac{\pi}{2}$ to 0

$$V = \frac{4\pi b}{\sqrt{a}} \int_{\frac{\pi}{2}}^0 a \cos^2 t \sqrt{a} \sin t \cdot 2a \cdot \cos t (-\sin t) dt$$

$$= 8\pi a^2 b \int_0^{\frac{\pi}{2}} \sin^2 t \cdot \cos^3 t dt = 8\pi a^2 b \cdot \frac{2}{5} \cdot \frac{1}{3}$$

$$V = \frac{16\pi a^2 b}{15}$$

Example 8: Find the volume of the solid of revolution obtained by the revolution of the curve $yx = a(x-b)$ about its asymptote (Fig. 6.39).

Solution: $y = a$ is the asymptote of the curve. The perpendicular distance PM from any point $P(x, y)$ on the curve to the asymptote is

$$PM = a - y$$

x varies from b to ∞ .

Fig. 6.39

The volume of solid of revolution obtained

$$\begin{aligned} V &= \int_b^\infty \pi (PM)^2 dx = \int_b^\infty \pi (a-y)^2 dx \\ &= \int_b^\infty \pi \left(a - \frac{a(x-b)}{x} \right)^2 dx = \pi a^2 \int_b^\infty \frac{b^2}{x^2} dx \\ &= \pi a^2 b^2 \left(-\frac{1}{x} \right)_b^\infty = \pi a^2 b \end{aligned}$$

Parametric Form

Example 1: Calculate the volume of the solid of revolution generated by revolving the hypocycloid

$$\left(\frac{x}{a} \right)^{\frac{2}{3}} + \left(\frac{y}{b} \right)^{\frac{2}{3}} = 1$$

a. about x -axis

b. about y -axis

Deduce the results when Astroid

$$x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}}$$

is revolved.

c. about x -axis

d. about y -axis

Solution: The parametric equations of hypocycloid are

$$x = a \cos^3 t, y = b \sin^3 t \quad (1)$$

The curve is symmetric about both x -axis and y -axis and meets them at the points $ABCD$ (Fig. 6.40).

Fig. 6.40

- a. Revolution about x-axis:** The solid of revolution obtained by revolving the plane area $BACOB$ enclosed by the arc BAC is the same as the solid obtained by revolving the plane area $ABOA$ contained by the arc BA in the first quadrant. Also due to symmetry about y-axis, the required volume V is twice the volume obtained by revolving arc BA in the first quadrant. Thus

$$V = 2 \int_0^a \pi y^2 dx = 2 \int_0^a \pi y^2 \frac{dx}{dt} dt \quad (2)$$

Using the parametric Equation (1)

$$\frac{dx}{dt} = 3a \cdot \cos^2 t (-\sin t)$$

and t varies from $\frac{\pi}{2}$ to 0 as x varies from 0 to a .

With this (2) becomes

$$\begin{aligned} V &= 2 \int_{\frac{\pi}{2}}^0 \pi (b^2 \sin^6 t) \cdot (-3a \cos^2 t \cdot \sin t) dt \\ &= 6\pi ab^2 \int_0^{\frac{\pi}{2}} \sin^7 t \cdot \cos^2 t dt \\ &= 6\pi ab^2 \frac{6 \cdot 4 \cdot 2 \cdot 1}{9 \cdot 7 \cdot 5 \cdot 3} = \frac{32}{105} \pi ab^2 \end{aligned}$$

- b. Revolution about y-axis:** By similar arguments, volume generated by revolving hypocycloid about y-axis is

$$\begin{aligned} V &= 2 \cdot \int_0^b \pi x^2 dy = 2\pi \int_0^b x^2 \frac{dy}{dt} dt \\ &= 2\pi \int_0^{\frac{\pi}{2}} a^2 \cos^6 t \cdot 3b \cdot \sin^2 t \cdot \cos t dt \\ &= 6\pi a^2 b \int_0^{\frac{\pi}{2}} \sin^2 t \cos^7 t dt = 6\pi a^2 b \frac{1 \cdot 6 \cdot 4 \cdot 2}{9 \cdot 7 \cdot 5 \cdot 3} \\ &= \frac{32\pi a^2 b}{105} \end{aligned}$$

- c. Astroid** is special case of hypocycloid for $b = a$ volume generated by revolving astroid about

$$x\text{-axis is } V = \frac{32}{105} a^3$$

- d. Due to symmetry about both x and y-axis** volume generated by revolving astroid about y-axis is also $V = \frac{32}{105} a^3$.

Example 2: Determine the volume of solid of revolution generated by revolving the curve whose parametric equation are

$$x = 2t + 3, y = 4t^2 - 9$$

about x-axis for $t_1 = -\frac{3}{2}$ to $t_2 = \frac{3}{2}$.

Solution: Required volume V is

$$V = \int \pi y^2 dx = \int \pi y^2 \frac{dx}{dt} dt$$

using the parametric equations

$$= \int_{-\frac{3}{2}}^{\frac{3}{2}} \pi (4t^2 - 9)^2 (2) dt = 4\pi \int_0^{\frac{3}{2}} (16t^4 + 81 - 72t^2) dt$$

$$V = 1296\pi$$

Aliter: Eliminating t , the equation of the curve in the cartesian form is $y = x^2 - 6x$ which meet x-axis at $x = 0$ and $x = 6$ and is shown in the Fig. 6.41. Revolving the arc OBA about x-axis

$$\begin{aligned} V &= \pi \int_0^6 y^2 dx = \pi \int_0^6 (x^2 - 6x)^2 dx \\ &= 1296\pi. \end{aligned}$$

Fig. 6.41

Polar Form

Example 1: Find the volume generated by the revolution of the curve $r = 2a \cos \theta$ about the initial line.

6.34 — HIGHER ENGINEERING MATHEMATICS—II

Solution: Volume generated by revolution about initial line is given by

$$\begin{aligned} V &= \int_{\theta_1}^{\theta_2} \frac{2}{3} \pi r^3 \sin \theta \, d\theta \\ &= \frac{2}{3} \pi \int_0^{\frac{\pi}{2}} (2a \cos \theta)^3 \sin \theta \, d\theta \\ &= \frac{16\pi a^3}{3} \int_0^{\frac{\pi}{2}} \cos^3 \theta \cdot \sin \theta \, d\theta \\ &= \frac{16\pi a^3}{3} \cdot \frac{2}{4} \cdot \frac{1}{2} = \frac{4\pi a^3}{3} \end{aligned}$$

Example 2: The arc of the cardioid:

$r = a(1 + \cos \theta)$ included between $\theta = -\pi/2$ and $\theta = \pi/2$ is rotated about the line $\theta = \pi/2$. Find the volume of the solid of revolution.

Solution: Volume of solid generated by revolution about the line $\theta = \pi/2$ is

$$\begin{aligned} V &= \int_{\theta_1}^{\theta_2} \frac{2}{3} \pi r^3 \cos \theta \, d\theta \\ &= \frac{2}{3} \pi \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} a^3 (1 + \cos \theta)^3 \cdot \cos \theta \, d\theta \\ &= \frac{2\pi a^3}{3} \cdot 2 \int_0^{\frac{\pi}{2}} (\cos^4 \theta + 3 \cos^3 \theta + 3 \cos^2 \theta + \cos \theta) d\theta \\ &= \frac{4\pi a^3}{3} \left[1 + \frac{3}{4} \cdot \frac{1}{2} \cdot \frac{\pi}{2} + 3 \cdot \frac{2}{3} + 3 \cdot \frac{1}{2} \cdot \frac{\pi}{2} \right] \\ &= \frac{\pi a^3}{4} [16 + 5\pi] \end{aligned}$$

EXERCISE

Cartesian Form

Find the volume of the solid of revolution generated by revolving the plane area bounded by the given curves about the indicated line.

1. $y = x^3$, $y = 0$, $x = 2$ about x -axis

Ans. $\frac{128\pi}{7}$

2. $y = 2x + 1$, $y = 0$, $x = 1$, $x = 2$ about x -axis

Ans. $\frac{49\pi}{3}$

3. $y = x^3$, $y = 8$, $x = 0$ about y -axis

Ans. $\frac{96\pi}{5}$

4. $y^2 = 4ax$, cut off by its latus rectum, about y -axis

Ans. $\frac{4\pi a^3}{5}$

5. $y = e^x \sin x$, x -axis about x -axis

Ans. $\frac{\pi}{8}(e^{2\pi} - 1)$

6. Parabola $y^2 = 8x$, latus rectum $x = 2$

a. About x -axis

Hint: $V = \int_0^2 \pi y^2 dx = \int_0^2 8x dx$

Ans. 16π

b. About its latus rectum $x = 2$

Hint 1: $V = \int_{-4}^4 \pi (2 - x)^2 dy$ by cylindrical disc method.

Ans. $\frac{256}{15}\pi$

Hint 2: By cylindrical shell method

$$V = \int_0^2 (2\pi(2 - x)) \cdot (4\sqrt{2x}) \cdot dx$$

Ans. $\frac{256}{15}\pi$

7. $y = 1 - x^2$, $y = 0$ about $x = 1$

Ans. $\frac{8\pi}{3}$

8. Circle $x^2 + y^2 = a^2$ about a diameter

Ans. $\frac{4}{3}\pi a^3$

9. $2x + y = 2$, $x = 0$, $y = 0$ about y -axis

Ans. $\frac{2\pi}{3}$

10. Parabola $y^2 = 4ax$, $x = 0$, $x = ah$ about x -axis

Ans. $2\pi ah^2$

11. a. Ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ about x -axis

Ans. $\frac{4}{3}\pi ab^2$

b. About y -axis

Ans. $\frac{4}{3}\pi a^2 b$

12. $y = x \sin mx$, $x = 0$, $x = \frac{2\pi}{m}$ about x -axis

Ans. $\frac{\pi^2}{6} \frac{(8\pi^2 - 3)}{m^3}$

13. $\sqrt{x} + \sqrt{y} = \sqrt{a}$, $x = 0$, $y = 0$ about x -axis

Ans. $\frac{\pi a^3}{12}$

14. $y^2 = x(2x - 1)^2$ about x -axis

Ans. $\frac{\pi}{48}$

15. $y = 2x, y = x, x + y = 6$ about x -axis

Hint: The plane region $OBAC$ where $O(0, 0), B(3, 3), A(2, 4), C(\frac{3}{2}, 3)$; is to be divided into two parts OBC and CBA and each volume to be calculated by shell method.

$$V_{OBC} = \int_0^3 (2\pi y) \cdot \left(y - \frac{y}{2}\right) dy$$

$$V_{ABC} = \int_3^4 (2\pi y) \cdot \left[(6 - y) - \frac{y}{2}\right] dy$$

Ans. 14π

Bounded by two curves: $\int_a^b \pi(y_2^2 - y_1^2) dx$:

16. $y = x^2, y = 2x$ about x -axis

Hint: $V = \int_0^2 \pi [(2x)^2 - (x^2)^2] dx$

Element of volume generated by a vertical element of area is a circular ring with outer radius $y_2 = 2x$ and inner radius $y_1 = x^2$.

Ans. $\frac{64\pi}{15}$

17. $y = x^2, y = x$ about y -axis

Hint: $V = \int_0^1 \pi [(\sqrt{y})^2 - (y)^2] dy$

As above outer radius $x_2 = \sqrt{y}$ and inner radius $x_1 = y$.

Ans. $\frac{\pi}{6}$

18. $y^2 = ax^3, x^2 = ay^3$ about x -axis

Hint: $V = \int_0^{1/a} \pi \left[\left(\frac{x^{\frac{2}{3}}}{a^{\frac{1}{3}}}\right)^2 - \left(\sqrt{ax^{\frac{3}{2}}}\right)^2 \right] dx$

since points of intersection of the two curves are $(0, 0), (1/a, 1/a)$.

Ans. $\frac{5\pi}{28a^3}$

19. $y^2 = 4ax, x = 2$, about y -axis

Hint: $V = \int_{-4}^4 \pi (2)^2 dy - \int_{-4}^4 \pi (x)^2 dy$

y varies from -4 to 4 since $y^2 = 4ax$ and $x = 2$ intersects at $(2, 4)$ and $(2, -4)$.

Ans. $\frac{128}{5}\pi$

20. $y = 4x - x^2, x$ -axis, about the line $y = 6$

Hint: $V = \pi \int_0^4 [(6)^2 - (6 - y)^2] dx =$

$$\pi \int_0^4 (48x - 28x^2 + 8x^3 - x^4) dx.$$

Ans. $1408\pi/15$

21. $y^2 = 4ax, 27ay^2 = 4(x - 2a)^3$, about x -axis

Hint: Points of intersection of the two curves are $B(8a, 4a\sqrt{2}), C(8a, -4a\sqrt{2})$

second curve meets the x -axis when $x = 2a$ (i.e., $A(2a, 0)$ is point on the 2nd curve).

volume = volume generated by the area under arc OB
 - volume generated by the area under arc AB

$$= \int_0^{8a} \pi(4ax) dx - \int_{2a}^{8a} \pi \frac{4(x - 2a)^3}{27a} dx$$

Ans. $80\pi a^3$

Loop Volumes

Find the volume of the solid of revolution generated by revolving the plane area enclosed by the loop of the following curve about the indicated line

22. $y^2(a - x) = x^2(a + x)$, about the x -axis

Hint: $V = \int_{-a}^0 \pi y^2 dx = \pi \int_{-a}^0 \frac{x^2(a+x)}{(a-x)} dx$
 $= \pi \int_{-a}^0 \left[-x^2 - 2ax - 2a^2 + \frac{2a^3}{(a-x)} \right] dx$

Ans. $2\pi a^3 \left[\ln 2 - \frac{2}{3} \right]$

23. $y^2(a + x) = x^2(3a - x), 0 \leq x \leq 3a$, about x -axis

Hint: $V = \int_0^{3a} \pi y^2 dx = \pi \int_0^{3a} \frac{x^2(3a-x)}{(a+x)} dx$
 $= \pi \int_0^{3a} \left(-x^2 + 4ax - 4a^2 + \frac{4a^3}{x+a} \right) dx$

Ans. $\pi a^3 (4 \ln 4 - 3)$

24. $2ay^2 = x(x - a)^2$, about x -axis

Ans. $\frac{\pi a^3}{24}$

25. $y^2 = x^2(1 - x^2)$, about x -axis

Ans. $\frac{2\pi}{15}$

26. $a^2x^2 = y^3(2a - y)$, about y -axis

Ans. $\frac{8}{5}\pi a^3$

27. $a^2y^2 = x^2(2a - x)(x - a)$, about x -axis

Ans. $\frac{23\pi a^3}{60}$

6.36 — HIGHER ENGINEERING MATHEMATICS—II

28. $2ay^2 = x(x - a)^2$, about the line $y = a$

Hint: Loop lies between $O(0, 0)$ and $A(a, 0)$

$$\text{Since, } y = \pm \frac{\sqrt{x}(x - a)}{\sqrt{2a}}$$

lower part of the loop (below x -axis)

$$\text{be } OBA : y = \frac{-\sqrt{x}(a - x)}{\sqrt{2a}}$$

$$\text{upper part } OCA : y = \frac{\sqrt{x}(a - x)}{\sqrt{2a}}$$

volume = volume_{OBA} - volume_{OCA}

$$\begin{aligned} &= \pi \int_0^a \left[a - \left(-\frac{\sqrt{x}(a - x)}{\sqrt{2a}} \right) \right]^2 dx \\ &\quad - \pi \int_0^a \left[a - \frac{\sqrt{x}(a - x)}{\sqrt{2a}} \right]^2 dx \end{aligned}$$

Ans. $\frac{8\sqrt{2}\pi a^3}{15}$

29. $ay^2 = x^2(a - x)$, about x -axis

Ans. $\pi a^3/12$

30. $y^2 = x^2(1 - x^2)$ about y -axis

Hint: Use shell method: $V = \int_0^1 (2\pi x) \cdot (2y) \cdot dx$

Ans. $\pi^2/4$.

Any Axis of Revolution: Asymptote

Find the volume of the solid obtained by the revolution of the area enclosed by the curve about its asymptote (or any axis)

31. Cissoid $y^2(2a - x) = x^3$

Hint: $x = 2a$ is the asymptote to the given curve.

MP = perpendicular distance between curve and asymptote = $(2a - x)$

$$\begin{aligned} V &= 2\pi \int_0^\infty (2a - x)^2 dy \\ &= 2\pi \int_0^{2a} (3a - x)\sqrt{(2a - x)}\sqrt{x} dx \end{aligned}$$

Ans. $2\pi^2 a^3$

32. $xy^2 = a^2(a - x)$

Hint: y -axis is the asymptote.

Curve is symmetric above x -axis

$$V = \text{twice} \int_0^\infty \pi x^2 dy = 2\pi a^6 \int_0^\infty (y^2 + a^2)^{-2} dy$$

Ans. $\pi^2 a^3/2$

33. $(a^2 + x^2)y = a^3$

Hint: x -axis is the asymptote, curve symmetric about y -axis

$$V = \text{twice} \int_0^\infty \pi y^2 dx = 2\pi a^6 \int_0^\infty (a^2 + x^2)^{-2} dx$$

Ans. $\pi^2 a^3/2$

34. $y^2(2a - x) = x^3$, $a > 0$

Hint: $x = 2a$ is the asymptote.

Curve is symmetric about x -axis

$$V = \text{twice} \int_0^\infty \pi (2a - x)^2 dy. \text{ Put } x = 2a \cos^2 t$$

Ans. $2\pi^2 a^3$

35. Witch of Agnesi: $xy^2 = 4a^2(2a - x)$, $a > 0$

Hint: y -axis is the asymptote.

Curve is symmetric about x -axis

$$V = \text{twice} \int_0^\infty \pi x^2 dy = 128\pi a^6 \int_0^\infty \frac{dy}{(y^2 + 4a^2)^2}$$

Ans. $4\pi^2 a^3$

36. Cissoid $y^2(a - x) = a^2x$

Hint: $x = a$ is the asymptote. Curve is symmetric about x -axis

$$V = \text{twice} \int_0^\infty \pi (a - x)^2 dy = 2\pi a^2 \int_0^\infty \frac{dy}{(y^2 + a^2)^2}$$

Ans. $\pi^2 a^3/2$

37. Parabola $y^2 = 4ax$, cut-off by its latus rectum, revolved about its directrix.

Hint: Curve is symmetric about x -axis. Latus rectum meets parabola at $x = 2a$ and $x = -2a$

PM = perpendicular distance from parabola to directrix = $a + x$

$$\begin{aligned} V &= \text{twice} \int_0^{2a} \pi (ax)^2 dy \\ &= 2\pi \int_0^{2a} \left(a + \frac{y^2}{4a} \right)^2 dy \end{aligned}$$

Ans. $128\pi a^3/15$.

Parametric Form

38. Find the volume of the solid obtained by revolving about x -axis, the plane area enclosed by one arch of the cycloid

$$x = a(t + \sin t)$$

$$y = a(1 + \cos t)$$

and the x -axis.

Hint: t varies from 0 to π .

Ans. $5\pi a^3$

39. Determine the volume the (reel shaped) solid formed by the revolution of the cycloid

$$x = a(t + \sin t)$$

$$y = a(1 - \cos t)$$

about x -axis.

Hint: t varies from 0 to π .

Ans. $\pi^2 a^3$

40. The cycloid $x = a(t - \sin t)$, $y = a(1 - \cos t)$ rotates about its base. Calculate the volume of the solid generated.

Hint: t varies from 0 to 2π .

Ans. $5\pi^2 a^3$

41. Find the volume of solid generated by revolving the loop of the curve

$$x = t^2, y = t - \frac{t^3}{3}$$

Hint: t varies from 0 to $\sqrt{3}$ (since $y = \frac{t^3-3t}{3} = 0$)

Ans. $3\pi/4$

42. The tractrix $x = a \cos t + a \ln \tan \frac{t}{2}$, $y = a \sin t$ is revolved about its asymptote. Find the volume of the solid so generated.

Hint: x -axis is the asymptote. Curve is symmetric about both x -axis and y -axis. t varies from 0 to $\pi/2$ for one arc

$$\begin{aligned} \text{Volume} &= \text{twice} \int_0^{\pi/2} \pi y^2 \frac{dx}{dt} dt \\ &= 2 \int_0^{\pi/2} \pi a^3 \cos^2 t \sin t dt \end{aligned}$$

Ans. $2\pi a^3/3$

43. Prove that the volume of solid generated by revolving the cissoid

$$x = 2a \sin^2 t, \quad y = 2a \frac{\sin^3 t}{\cos t}$$

(with $-\pi/2 < t < \pi/2$) about its asymptote, is $2\pi a^3$.

44. If the ellipse $x = a \cos t$, $y = b \sin t$ is revolved about the line $x = 2a$, show that the volume of the solid generated is $4\pi^2 a^2 b$.

45. If one arch of the cycloid

$$x = a(t + \sin t), \quad y = a(1 - \cos t)$$

(with $-\pi < t < \pi$) is revolved about y -axis, prove that the volume of the solid generated is $\frac{\pi^3}{6}(9a^3 - 16)$.

Polar Form

Find the volume of the solid generated by revolving the given curve in polar form about the indicated line:

46. Cardioid $r = a(1 + \cos \theta)$ about the initial line

Hint: θ varies from 0 to π .

Ans. $8\pi a^3/3$

47. Cardioid $r = a(1 - \cos \theta)$ about the initial line

Hint: θ varies from 0 to π .

Ans. $8\pi a^3/3$

48. $r^2 = a^2 \cos 2\theta$ about the initial line

Hint: Curve is symmetric about both x -axis and y -axis. θ varies from 0 to $\frac{\pi}{4}$.

volume = twice volume generated by one arch in the 1st quadrant

$$= 2 \int_0^{\pi/4} \frac{2}{3} \pi r^3 \sin \theta d\theta$$

$$\begin{aligned} V &= 2\pi a^3 \int_0^{\pi/4} \sin^2 \theta (3 \sin \theta - 4 \sin^3 \theta) \\ &\quad \times \sqrt{\cos 2\theta} d\theta \end{aligned}$$

Ans. $\frac{\pi a^3}{2} \left[\frac{1}{\sqrt{2}} \ln (\sqrt{2} + 1) - \frac{1}{3} \right]$

6.38 — HIGHER ENGINEERING MATHEMATICS—II

49. $r^2 = a^2 \cos 2\theta$, about the line $\theta = \frac{\pi}{2}$

Hint:

$$\begin{aligned} V &= \text{twice} \int_0^{\frac{\pi}{4}} \frac{2}{3} \pi r^3 \cos \theta \, d\theta, \text{ put } \sqrt{2} \sin \theta = \sin \phi \\ &= \frac{4\pi a^3}{3\sqrt{2}} \int_0^{\frac{\pi}{2}} \cos^4 \phi \, d\phi \\ &= \frac{4\pi a^3}{3\sqrt{2}} \cdot \frac{3 \cdot 1}{4 \cdot 2} \cdot \frac{\pi}{2} \end{aligned}$$

Ans. $\frac{\pi^2 a^3}{4\sqrt{2}}$

50. $r^2 = a^2 \cos 2\theta$ about a tangent at the pole

Ans. $\frac{\pi a^3}{12} \left[\frac{3}{\sqrt{2}} \ln(1 + \sqrt{2}) - 1 \right]$

51. $r^2 = a^2 \cos \theta$ about initial line

Ans. $\frac{8\pi a^3}{15}$

52. Loop of the curve $r = a \cos 3\theta$ lying between $\theta = -\pi/6$ and $\theta = \pi/6$ about the initial line.

Ans. $19\pi a^3/960$

53. Area lying within the cardioid

$$r = 2a(1 + \cos \theta)$$

and outside the parabola.

$$r = \frac{2a}{1 + \cos \theta}$$

about the initial line (Fig. 6.42).

Fig. 6.42

Hint: Points of intersection are $\theta = \frac{-\pi}{2}$ and $\frac{\pi}{2}$. Both curves are symmetric about x-axis.

volume = volume generated by area under the cardioid $ODAO$

– volume generated by area under the parabola $OBAO$

$$= \int_0^{\frac{\pi}{2}} \frac{2}{3} \pi r_2^3 \sin \theta \, d\theta - \int_0^{\frac{\pi}{2}} \frac{2}{3} \pi r_1^3 \sin \theta \, d\theta$$

where r_2 is r of cardioid, r_1 is r of parabola.

Ans. $18\pi a^3$

54. $r = a + b \cos \theta$ with $a < b$ about the initial line.

Hint: θ varies from 0 to π , curve symmetric about the initial line

$$\begin{aligned} V &= \frac{2\pi}{3} \int_0^\pi r^3 \sin \theta \, d\theta \\ &= \frac{2\pi}{3} \int_0^\pi (a + b \cos \theta)^3 \sin \theta \, d\theta \end{aligned}$$

$$V = \frac{2\pi}{3} \int_{a+b}^{a-b} t^3 \frac{dt}{b} \quad \text{with } a + b \cos \theta = t$$

Ans. $4\pi a(a^2 + b^2)/3$

6.5 AREA OF THE SURFACE OF A SOLID OF REVOLUTION

Let $y = f(x)$ be a plane curve c in the xy -plane included between the ordinates $x = a$ and $x = b$. Let $P(x, y)$ be any point on c (Fig. 6.43). When the chord $PQ = \Delta S$ is revolved about the x -axis, a solid of revolution is generated which is the frustum of cone of slant height $PQ = \Delta S$ and radii y and $y + \Delta y$. Hence the area (of the surface of solid of revolution of) of this elementary belt is $2\pi y \Delta S$. Dividing the curve c into n parts and summing up the areas, of these elementary belts from $x = a$ to $x = b$, we get the surface area of solid of revolution.

Fig. 6.43

Cartesian Form

- a. Area of the surface of the solid of revolution generated by revolving the arc AB of the curve $y = f(x)$ about the x -axis is given by

$$S = \int_{AB} 2\pi y \, ds = \int_{x=a}^{x=b} 2\pi y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx$$

$$\left[\text{Note that } \frac{ds}{dx} = \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \right]$$

- b. Area of the surface generated by revolving an arc AB of the curve $x = g(y)$ about y -axis is

$$S = \int_{AB} 2\pi x \, ds = \int_{y=c}^{y=d} 2\pi x \sqrt{1 + \left(\frac{dx}{dy}\right)^2} dy$$

$$\left[\text{Note that } \frac{ds}{dy} = \sqrt{1 + \left(\frac{dx}{dy}\right)^2} \right]$$

Parametric Form: $x = x(t)$, $y = y(t)$

- a. About x -axis:

$$S = \int_{t=t_1}^{t_2} 2\pi y(t) \cdot \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt$$

- b. About y -axis

$$S = \int_{t=t_1}^{t_2} 2\pi x(t) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt$$

Polar Form: $r = f(\theta)$

- a. About the x -axis: initial line $\theta = 0$

$$S = \int_{\theta=\theta_1}^{\theta_2} 2\pi y \frac{ds}{d\theta} d\theta$$

$$= \int_{\theta=\theta_1}^{\theta_2} 2\pi(r \sin \theta) \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta$$

Here replace r by $f(\theta)$.

- b. About the y -axis perpendicular line through the pole $\theta = \pi/2$

$$S = \int_{\theta=\theta_1}^{\theta_2} 2\pi x \frac{ds}{d\theta} d\theta$$

$$= \int_{\theta=\theta_1}^{\theta_2} 2\pi(r \cos \theta) \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta$$

Here replace r by $f(\theta)$.

About Any (axis) Line L

$$S = \int 2\pi(PM)ds$$

where PM is the perpendicular distance from a point P of the given curve to the axis of revolution (Line L) (Fig. 6.44)

Fig. 6.44

- a. *Limits for x* : If limits for x are given as $x = a$ to $x = b$ then

$$S = \int_{x=a}^{x=b} 2\pi(PM) \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx$$

Here PM is expressed in terms of x .

- b. *Limits for y* : If limits for y are given as $y = c$ to $y = d$ then

$$S = \int_{y=c}^{y=d} 2\pi(PM) \sqrt{1 + \left(\frac{dx}{dy}\right)^2} dy$$

Here PM is expressed in terms of y .

WORKED OUT EXAMPLES

Example 1: Find the area of the surface of the solid of revolution generated by revolving the parabola $y^2 = 4ax$, $0 \leq x \leq 3a$ about the x -axis.

Solution: $2yy' = 4a$, $y' = \frac{2a}{y}$, $1 + y'^2 = 1 + \left(\frac{2a}{y}\right)^2$
 $= \frac{y^2 + 4a^2}{y^2}$.

$$\sqrt{1 + y'^2} = \frac{4ax + 4a^2}{y^2} = \frac{2\sqrt{a}}{y} \sqrt{a + x}$$

The area S of the curved surface of the solid generated by revolving the arc of the parabola $y^2 = 4ax$

6.40 — HIGHER ENGINEERING MATHEMATICS—II

included between the ordinates $x = 0$ and $x = 3a$, about the x -axis is given by

$$\begin{aligned} S &= \int 2\pi y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx \\ &= 2\pi \int_0^{3a} y \left(\frac{2\sqrt{a}}{y} \cdot \sqrt{a+x} \right) dx \\ &= 4\pi \sqrt{a} \int_0^{3a} \sqrt{a+x} dx \end{aligned}$$

put $x = a \tan^2 t$, $dx = 2a \cdot \tan t \cdot \sec^2 t dt$

$$\begin{aligned} S &= 4\pi \sqrt{a} \int (\sqrt{a} \sec t)(2a \tan t \sec^2 t dt) \\ &= 8\pi a^2 \int \sec^2 t d(\sec t) \end{aligned}$$

$$S = 8\pi a^2 \cdot \frac{\sec^3 t}{3} = \frac{8\pi a^2}{3} \cdot \left(1 + \frac{x}{a}\right)^{\frac{3}{2}} \Big|_{x=0}^{3a} = \frac{56\pi a^2}{3}.$$

Example 2: Determine the surface area of the paraboloid generated by revolving the curve $y = x^2$ included between $x = 0$ and $x = \frac{6}{5}$ about y -axis.

Solution: $y' = 2x$, $\sqrt{1 + y'^2} = \sqrt{1 + 4x^2}$

$$\text{Surface area} = S = \int_0^{\frac{6}{5}} 2\pi x \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \cdot dx$$

$$S = \int_0^{\frac{6}{5}} 2\pi x \sqrt{1 + 4x^2} dx$$

$$\text{put } 1 + 4x^2 = t$$

$$= \frac{2\pi}{8} \int t^{\frac{1}{2}} dt = \frac{\pi}{6} t^{\frac{3}{2}}$$

$$= \frac{\pi}{6} (1 + 4x^2)^{\frac{3}{2}} \Big|_0^{\frac{6}{5}}$$

$$S = \frac{1036\pi}{375}$$

Example 3: Show that the area of the surface generated when the loop of the curve

$$9ay^2 = x(3a - x)^2$$

revolves about the x -axis is $3\pi a^2$.

Solution: Curve is symmetric about x -axis. The loop of the curve lies between $x = 0$ and $x = 3a$ (Fig. 6.45).

Differentiating the equation of the curve

$$18ay y' = (3a - x)^2 - 2x(3a - x)$$

Fig. 6.45

$$1 + y'^2 = \frac{1}{18^2 a^2 y^2} \left[(3a - x)^2 - 2x(3a - x) + 18^2 a^2 y^2 \right]$$

$$\begin{aligned} \sqrt{1 + y'^2} &= \frac{1}{18ay} \left[(3a - x)^2 - 2x(3a - x) + 36ax(3a - x) \right]^{\frac{1}{2}} \\ &= \frac{3}{18ay} (3a - x)(a + x) \end{aligned}$$

Surface area obtained by revolution about x -axis is

$$S = \int 2\pi y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx$$

$$= \int_0^{3a} 2\pi y \cdot \frac{3}{18ay} (3a - x)(a + x) dx$$

$$S = \frac{\pi}{3a} \left[3a^2 x + 2a \frac{x^2}{2} - \frac{x^3}{3} \right]_0^{3a} = 3\pi a^2$$

Example 4: Calculate the area of the surface of revolution generated by revolving the cardioid $x = 2 \cos \theta - \cos 2\theta$; $y = 2 \sin \theta - \sin 2\theta$ about the x -axis.

Fig. 6.46

Solution: The required surface is generated by revolving the arc of the curve from $\theta = 0$ to $\theta = \pi$ (Fig. 6.46).

$$\begin{aligned}\frac{dx}{d\theta} &= -2 \sin \theta + 2 \sin 2\theta, \\ \frac{dy}{d\theta} &= 2 \cos \theta - 2 \cos 2\theta \\ \left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2 &= 8(1 - \sin \theta \cdot \sin 2\theta - \cos \theta \cdot \cos 2\theta) \\ &= 8(1 - \cos \theta)\end{aligned}$$

The area of surface by revolving about x -axis is

$$\begin{aligned}S &= \int_{\theta_1}^{\theta_2} 2\pi y(\theta) \cdot \sqrt{\left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2} d\theta \\ &= 2\pi \int_0^\pi (2 \sin \theta - \sin 2\theta) 2\sqrt{2}\sqrt{1 - \cos \theta} d\theta \\ &= 8\sqrt{2}\pi \int_0^\pi \sin \theta (1 - \cos \theta)^{\frac{3}{2}} d\theta \\ S &= \frac{16\sqrt{2}}{5}\pi (1 - \cos \theta)^{\frac{5}{2}} \Big|_0^\pi = \frac{128\pi}{5}\end{aligned}$$

Example 5: Find the area of the surface generated by revolving the curve with parametric equations

$$x(t) = 3t(t - 2), y(t) = 8t^{\frac{3}{2}}$$

with $0 \leq t \leq 1$, about the y -axis.

Solution: $\frac{dx}{dt} = 6t - 6, \frac{dy}{dt} = 12t^{\frac{1}{2}}$

$$\begin{aligned}\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} &= \sqrt{36(t - 1)^2 + 144t} \\ &= \sqrt{36(t + 1)^2} = 6(t + 1)\end{aligned}$$

Surface area obtained by revolving about y -axis is

$$\begin{aligned}S &= \int 2\pi x(t) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\ &= 2\pi \int_0^1 [3t(t - 2)][6(t + 1)] dt \\ S &= 12\pi \left[\frac{3t^4}{4} - \frac{3t^3}{3} - \frac{6t^2}{2} \right]_0^1 = 39\pi\end{aligned}$$

Example 6: The arc of the cardioid

$$r = a(1 + \cos \theta)$$

included between $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ is rotated about the line $\theta = \frac{\pi}{2}$. Show that the area of the surface thus generated is $48\sqrt{2}\pi a^2/5$.

Solution: Cardioid is symmetric about the initial line OB . As θ varies from $-\frac{\pi}{2}$ to $\frac{\pi}{2}$, the part of arc of the cardioid is ABC (Fig. 6.47). Since this arc ABC is revolved about the line AOC ($\theta = \frac{\pi}{2}$), the area of the surface of the solid of revolution generated is twice the area of the surface generated by revolving the

Fig. 6.47

arc BC about the line $\theta = \frac{\pi}{2}$ (OC). Thus the area of the surface of the solid of revolution generated by rotating the arc ABC (for which θ varies from $-\frac{\pi}{2}$ to $\frac{\pi}{2}$) about the line $\theta = \frac{\pi}{2}$ (OC) is

$$\begin{aligned}S &= \text{twice} \int_0^{\frac{\pi}{2}} 2\pi x \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta \\ S &= 2 \int_0^{\frac{\pi}{2}} 2\pi (r \cos \theta) \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta\end{aligned}$$

Differentiating $\frac{dr}{d\theta} = -a \sin \theta$

$$r^2 + \left(\frac{dr}{d\theta}\right)^2 = a^2(1 + \cos \theta)^2 + a^2 \sin^2 \theta$$

$$\begin{aligned}\sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} &= \sqrt{a^2 2(1 + \cos \theta)} = a\sqrt{2(1 + \cos \theta)} \\ &= a\sqrt{2 \cdot 2 \cdot \cos^2 \frac{\theta}{2}} = 2a \cos \frac{\theta}{2}\end{aligned}$$

Substituting this value and replacing r by

$$\begin{aligned}a(1 + \cos \theta) \\ S &= 4\pi \int_0^{\frac{\pi}{2}} [a(1 + \cos \theta)](\cos \theta) \left(2a \cos \frac{\theta}{2}\right) d\theta \\ &= 8\pi a^2 \int_0^{\frac{\pi}{2}} 2 \cos^2 \frac{\theta}{2} \left(\cos^2 \frac{\theta}{2} - \sin^2 \frac{\theta}{2}\right) \cos \frac{\theta}{2} d\theta\end{aligned}$$

6.42 — HIGHER ENGINEERING MATHEMATICS—II

$$= 32\pi a^2 \left[\int_0^{\frac{\pi}{4}} \cos^5 t \, dt - \int_0^{\frac{\pi}{4}} \cos^3 t \cdot \sin^2 t \, dt \right]$$

where $\frac{\theta}{2} = t$, $d\theta = 2 \, dt$, t : varies from 0 to $\frac{\pi}{4}$

$$= 32\pi a^2 \left[\frac{\cos^4 t \cdot \sin t}{5} + \frac{4}{5} \left\{ \frac{\sin t \cdot \cos^2 t}{3} + \frac{2}{3} \sin t \right\} \right]_0^{\frac{\pi}{4}} \\ - 32\pi a^2 \left[\frac{\sin^3 t \cdot \cos^2 t}{5} + \frac{2}{5} \frac{\sin^3 t}{3} \right]_0^{\frac{\pi}{4}}$$

Since $\sin \frac{\pi}{4} = \cos \frac{\pi}{4} = \frac{1}{\sqrt{2}}$

$$S = 32\pi a^2 \left\{ \frac{1}{5\sqrt{2}} \left[\frac{1}{4} + \frac{4}{3} \left(\frac{1}{2} + 2 \right) \right] - \frac{1}{2\sqrt{25}} \left[\frac{1}{2} + \frac{2}{3} \right] \right\} \\ S = \frac{48\sqrt{2}\pi a^2}{5}$$

EXERCISE

Cartesian Form

- Find the surface area of a sphere of radius a .

Hint:

$$S = 2\pi \int_{-a}^a y \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx \\ = 2\pi \int_{-a}^a y \sqrt{1 + \frac{x^2}{y^2}} dx = 2\pi a \int_{-a}^a dx$$

Ans. $4\pi a^2$

- Determine the area of the curved surface of the reel generated by revolving the part of the parabola $y^2 = 4ax$, cut-off by the latus rectum about the tangent at the vertex.

Hint: y -axis is the tangent to the parabola at the origin. Required surface area = twice surface area generated by the upper half of the parabola

$$= 2 \int_0^a 2\pi x \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx = 4\pi \int_0^a x \sqrt{1 + \frac{a}{x}} dx \\ = 4\pi \int_0^a \sqrt{\left(x + \frac{a}{2} \right)^2 - \left(\frac{a}{2} \right)^2} dx.$$

$$\text{Ans. } \pi a^2 \left[3\sqrt{2} - \ln(\sqrt{2} + 1) \right]$$

- Calculate the area of the surface of revolution generated by revolving the arc of the parabola $y^2 = 12x$ from $x=0$ to $x=3$ about x -axis.

$$\text{Ans. } 24(2\sqrt{2} - 1)\pi$$

- Find the cost of plating of the front portion of the parabolic reflector (Fig. 6.48) of an automobile head light of 12 cm diameter and 4 cm deep if the cost of plating is Rs. 5/cm².

Fig. 6.48

Hint: $6^2 = 4a \cdot 4 \therefore a = \frac{9}{4}$

Equation of parabola: $y^2 = 9x$

$$\text{Surface area} = \int_0^4 2\pi y \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx \\ = 6\pi \int_0^4 \sqrt{x} \sqrt{1 + \frac{9}{4x}} dx = 154 \text{ cm}^2$$

Cost of plating = Rs. (154×5) = Rs. 770.

Ans. Rs. 770

- Show that the area of the surface of revolution generated by revolving about the x -axis the arc of $y^2 + 4x = 2 \ln y$ from $y=1$ to $y=3$ is $32\pi/3$.
- Determine the surface area of the solid “catenoid” obtained by revolving the catenary $y = c \cosh \frac{x}{c}$ from the vertex to any point (x, y) , about the x -axis.

$$\text{Ans. } \pi c \left\{ x + \frac{c}{2} \sinh \left(\frac{2x}{c} \right) \right\}$$

- Prove that the area of the surface generated by revolving the curve $x = y^3$ included between the ordinates $y=0$ and $y=1$, about the y -axis, is $\frac{\pi}{27} [10^{\frac{3}{2}} - 1]$.

8. Find the area of the surface of revolution generated by revolving one arch of the curve $y = \sin x$ about the x -axis.

Hint: x varies from 0 to $\pi/2$.

Ans. $\pi \left[\sqrt{2} + \ln(1 + \sqrt{2}) \right]$

9. Show that the area of the surface formed by rotating the curve $y^2 = x^3$ from $x = 0$ to $x = 4$ about the y -axis is $\frac{128\pi}{1215}(1 + 125\sqrt{10})$.
10. Calculate the area of the surface generated by revolving the arc of the curve $9y^2 = (2x - 1)^3$, with $\frac{1}{2} \leq x \leq 2$ about the y -axis.
11. A sphere of radius ' b ' is cut by two parallel planes which are at a distance ' h ' apart. Find the surface area of the sphere included between the planes. Deduce the surface area of a hemisphere.

Hint: Area $= \int_{x=c}^{x=c+h} 2\pi y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx = \int_c^{c+h} 2\pi y \cdot \left(\frac{b}{y}\right) dx = 2\pi bh$ since $x^2 + y^2 = b^2$.

Special case: hemisphere: $h = b$,
Area $= 2\pi b \cdot b = 2\pi b^2$.

Ans. $2\pi bh$; hemisphere: $2\pi b^2$

12. Determine the surface area of the prolate spheroid generated by revolving an ellipse of eccentricity e about the major axis.

Hint: Given $e < 1$, $b^2 = a^2(1 - e^2)$, equation of ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$. Required area = twice the surface area of revolution generated by revolving the arc of the ellipse in the first quadrant about x -axis

$$\begin{aligned} &= 2 \int_0^a 2\pi y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx \\ &= \frac{4\pi b}{a} \int_0^a \sqrt{a^2 - x^2} \sqrt{1 + (1 - e^2) \frac{x^2}{y^2}} dx \\ &= \frac{4\pi b}{a} \int_0^a \sqrt{a^2 - e^2 x^2} dx \\ &= \frac{4\pi b e}{a} \int_0^a \sqrt{\left(\frac{a}{e}\right)^2 - x^2} dx \end{aligned}$$

Ans. $2 \cdot \pi ab \cdot \left[\sqrt{1 - e^2} + \frac{\sin^{-1} e}{e} \right]$

Find the area of the surface of the solid generated by revolution of the loop of the curve about x -axis:

13. $3ay^2 = x(x - a)^2$

Hint: Loop lies between $x = 0$ and $x = a$.

Ans. $\pi a^2/3$

14. $8a^2 y^2 = a^2 x^2 - x^4$ about x -axis

Ans. $\pi a^2/4$

15. If the closed portion of the curve $9ay^2 = (a - x)(x + 2a)^2$ with $a > 0$ is revolved through two right angles about the x -axis, find the area of the surface of revolution so generated

Ans. $3\pi a^2$.

Parametric Form

Find the area of the surface of revolution of the solid generated by the revolving, the curve whose parametric equations are given, about the indicated line:

1. $x = t^3 - 3t$, $y = 3t^2$, $0 \leq t \leq 1$, about x -axis

Ans. $48\pi/5$

2. $x = t^2$, $y = t - \frac{t^3}{3}$, $0 \leq t \leq \sqrt{3}$, about x -axis

Ans. 3π

3. Tractrix $x = a \cos t + \frac{1}{2} a \ln \tan^2 \frac{t}{2}$,
 $y = a \sin t$ about the x -axis

Hint: Curve is symmetric about both X and Y axis (Fig. 6.49).

Fig. 6.49

Area = twice $\int_{t=0}^{\frac{\pi}{2}} 2\pi y \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt$

6.44 — HIGHER ENGINEERING MATHEMATICS—II

$$= 4\pi \int_0^{\frac{\pi}{2}} a \sin t \cdot \frac{a \cos t}{\sin t} \cdot dt$$

Ans. $4\pi a^2$

4. A quadrant of a circle of radius b about its chord.

Hint: $x = b \cos t$, $y = b \sin t$

$$\begin{aligned} \text{Area} &= \text{twice} \int_0^{\frac{\pi}{4}} 2\pi(PL) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\ &= 4\pi \int_0^{\frac{\pi}{4}} \left(x - b \cos \frac{\pi}{4}\right) (b) dt \end{aligned}$$

where PL is the perpendicular distance from circle to chord.

Ans. $2\sqrt{2}\pi b^2 \left(1 - \frac{\pi}{4}\right)$

5. $x = a \cos^2 t$, $y = a \sin^2 t$, about x -axis

Ans. $12\pi a^2/5$

6. $x = a \cos^3 t$, $y = a \sin^3 t$ about x -axis

Ans. $12\pi a^2/5$

7. Cycloid $x = a(t - \sin t)$, $y = a(1 - \cos t)$, about the base

Ans. $64\pi a^2/3$

8. Arch of cycloid $x = a(t - \sin t)$, $y = a(1 - \cos t)$ about the line $y = 2a$.

Hint:

$$\begin{aligned} \text{Area} &= \text{twice} \int_0^{\pi} 2\pi(PL) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\ &= 4\pi \int_0^{\pi} (2a - y) \left(\sqrt{2(1 - \cos t)}\right) dt \\ &= 4\pi \int_0^{\pi} [2a - a(1 - \cos t)] \left(2 \sin \frac{t}{2}\right) dt \end{aligned}$$

where PL = perpendicular distance from cycloid to the line $y = 2a$.

Ans. $32\pi a^2/3$

9. Cycloid $x = a(t + \sin t)$, $y = a(1 - \cos t)$ about the tangent at the vertex.

Hint: Curve is symmetric about y -axis.

$$\begin{aligned} \text{Area} &= \text{twice} \int_0^{\pi} 2\pi y \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\ &= 16\pi \int_0^{\pi} a^2(1 - \cos \theta) \cdot \cos \frac{\theta}{2} d\theta \end{aligned}$$

Ans. $32\pi a^2/3$

10. Show that the ratio of the areas of the surface formed by revolving the arch of the cycloid $x = a(t + \sin t)$, $y = a(1 + \cos t)$ between two consecutive cusps about the x -axis to the area enclosed by the cycloid and x -axis is $64/9$.

Polar Form

Find the area of the surface of the solid generated by revolving the curve in polar form about the indicated line:

1. $r = a(1 \pm \cos \theta)$, about the initial line

Hint: For $r = a(1 + \cos \theta)$

$$\begin{aligned} \text{Area} &= \int_0^{\pi} 2\pi y \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta \\ &= \int_0^{\pi} 2\pi [a \sin \theta (1 + \cos \theta)] 2a \frac{\cos \theta}{2} d\theta \end{aligned}$$

where $y = r \sin \theta = a(1 + \cos \theta) \sin \theta$. Similar result for $r = a(1 - \cos \theta)$.

Ans. $32\pi a^2/5$

2. $r = 2a \cos \theta$, about the initial line

Hint:

$$\begin{aligned} \text{Area} &= \int_0^{\frac{\pi}{2}} 2\pi (r \sin \theta) [4a^2 \cos^2 \theta \\ &\quad + 4a^2 \sin^2 \theta]^{\frac{1}{2}} d\theta \end{aligned}$$

Ans. $4\pi a^2$

3. $r^2 = a^2 \cos 2\theta$, about the initial line

Hint:

$$\begin{aligned} \text{Area} &= \text{twice} \int_0^{\frac{\pi}{4}} 2\pi \left(a\sqrt{\cos 2\theta} \cdot \sin \theta\right) d\theta \times \\ &\quad \times \frac{a}{\sqrt{\cos 2\theta}} d\theta \end{aligned}$$

Ans. $4\pi a^2 \left(1 - \frac{1}{\sqrt{2}}\right)$

4. $r^2 = a^2 \cos 2\theta$, about the line $\theta = \frac{\pi}{2}$

Ans. $\pi^2 a^3 / (4\sqrt{2})$

5. $r^2 = a^2 \cos 2\theta$, about a tangent at the pole

Hint: $\theta = \frac{\pi}{4}$ and $\theta = \frac{3\pi}{4}$ are the tangents to curve at the pole.

Ans. $4\pi a^2$

6. $r = 4 + 2 \cos \theta$ about the initial line

Ans. $375\pi/5$

6.6 IMPROPER INTEGRALS

By definition of a *regular* (or *proper*) definite integral

$$\int_a^b f(x)dx \quad (1)$$

it is assumed that the limits of integration are finite and that the integrand $f(x)$ is continuous for every value of x in the interval $a \leq x \leq b$. If at least one of these conditions is violated, then the integral is known as an *improper integral* (or *singular* or *generalized* or *infinite integral*). More generally improper integrals are classified into three kinds.

Improper Integral

Improper integral of the *first kind*. It is a definite integral in which one or both limits of integration are infinite i.e. the interval of integration is *not* finite. These are defined by the following relations.

$$(a) \int_a^\infty f(x)dx = \lim_{b \rightarrow \infty} \int_a^b f(x)dx \quad (2)$$

It is said to have a singularity at the upper limit

$$(b) \int_{-\infty}^b f(x)dx = \lim_{a \rightarrow -\infty} \int_a^b f(x)dx \quad (3)$$

$$(c) \int_{-\infty}^\infty f(x)dx = \lim_{\substack{b \rightarrow \infty \\ a \rightarrow -\infty}} \int_a^b f(x)dx \quad (4)$$

or

$$\int_{-\infty}^\infty f(x)dx = \lim_{a \rightarrow -\infty} \int_a^0 f(x)dx + \lim_{b \rightarrow \infty} \int_0^b f(x)dx \quad (4^*)$$

If both the limits exist, we can write

$$\int_{-\infty}^\infty f(x)dx = \lim_{r \rightarrow \infty} \int_{-r}^r f(x)dx \quad (4^{**})$$

The improper integral is said to *converge* (or exist) when the limits in RHS of (2), (3), (4) or (4*) or (4**) exists (and are finite). Otherwise it is said to *diverge* (when either of the limits fail to exist). The limit in the RHS of (4**) is known as the *Cauchy's principal value* of the improper integral.

Geometrically for $f(x) \geq 0$, the improper integral $\int_a^\infty f(x)dx$ denotes the area of an unbounded (infinite region) lying between the curve $y = f(x)$, the ordinate $x = a$ and axis of abscissa, i.e. x -axis.

Example 1: Consider the improper integral $\int_0^\infty \frac{dx}{1+x^2}$. Here $y = f(x) = \frac{1}{1+x^2}$.

Solution: By definition of improper integral $\int_0^\infty \frac{dx}{1+x^2} = \lim_{b \rightarrow \infty} \int_0^b \frac{dx}{1+x^2} = \lim_{b \rightarrow \infty} \tan^{-1} x \Big|_0^b$
 $= \lim_{b \rightarrow \infty} \tan^{-1} b = \frac{\pi}{2}$

Fig. 6.50

Thus while the shaded area in Fig. 6.50 represents the definite integral $\int_0^b \frac{dx}{1+x^2}$, the shaded area in Fig. 6.51 represents the improper integral $\int_0^\infty \frac{dx}{1+x^2}$. Thus this integral represents the area of an infinite curvilinear trapezoid cross-hatched in Fig. 6.51.

Fig. 6.51

For a convergent integral

$$\int_0^\infty f(x)dx = \int_a^b f(x)dx + \int_b^\infty f(x)dx$$

the basic contribution is made by its finite (proper) part (the first integral in the RHS) while the contri-

bution of (the 2nd integral in RHS), the singularity is arbitrarily small for large values of b .

Whereas for a divergent integral, the value of the integral tends to infinity or oscillates (without having a definite limit) since the value of the integral essentially depends on b .

Comparison Test for Convergence or Divergence of an Improper Integral by p -Integral

Book work: Prove that the p -integral

$$\int_1^{\infty} \frac{dx}{x^p}$$

converges when $p > 1$ and diverges when $p \leq 1$.

Proof: For $p \neq 1$, $\int_1^b \frac{dx}{x^p} = \frac{1}{1-p} x^{1-p} \Big|_1^b$

$$= \frac{1}{1-p} (b^{1-p} - 1)$$

Now

$$\int_1^{\infty} \frac{dx}{x^p} = \lim_{b \rightarrow \infty} \int_1^b \frac{dx}{x^p} = \lim_{b \rightarrow \infty} \frac{1}{1-p} (b^{1-p} - 1).$$

Consequently,

Fig. 6.52

If $p > 1$, then $\int_1^{\infty} \frac{dx}{x^p} = \frac{1}{p-1}$ and the integral converges.

If $p < 1$, then $\int_1^{\infty} \frac{dx}{x^p} = \infty$ and the integral diverges.

When $p = 1$, $\int_1^{\infty} \frac{dx}{x} = \ln x \Big|_1^{\infty} = \infty$ and the integral diverges

Results

Theorem 1. Let $f(x)$ and $g(x)$ be non-negative functions. Suppose

1. $0 \leq f(x) \leq g(x)$ for $x \geq a$.

If $\int_a^{\infty} g(x)dx$ converges, then $\int_a^{\infty} f(x)dx$ also converges and $\int_a^{\infty} f(x)dx \leq \int_a^{\infty} g(x)dx$.

Theorem 2. Suppose $0 \leq g(x) \leq f(x)$. If $\int_a^{\infty} g(x)dx$ diverges, then $\int_a^{\infty} f(x)dx$ also diverges.

Thus the convergence or divergence of an improper integral is determined by comparing it with a simple integral, the p -integral (of book work I)

Theorem 3. For a function $f(x)$ which changes its sign, if $\int_a^{\infty} |f(x)|dx$ converges, then $\int_a^{\infty} f(x)dx$ also converges, i.e. $\int_a^{\infty} f(x)dx$ is said to converge absolutely.

Improper Integral of the Second Kind

It is one in which both the limits of integration are finite, but the integrand $f(x)$ is not defined (infinite) or discontinuous at a point between a and b inclusive. Suppose $f(x) \rightarrow \infty$ as $x \rightarrow a$, then the integral has a singularity at the lower limit a . Then this singularity is 'cut-off' by considering

$$\int_{a+\varepsilon}^b f(x)dx$$

where ε is a small positive number. Thus for a convergent improper integral of the second kind

$$\int_a^b f(x)dx = \lim_{\varepsilon \rightarrow 0} \int_{a+\varepsilon}^b f(x)dx \quad (6)$$

which ignores the contribution of the singularity. Similarly when $f(x)$ is discontinuous at the upper limit b then

$$\int_a^b f(x)dx = \lim_{\varepsilon \rightarrow 0} \int_a^{b-\varepsilon} f(x)dx \quad (7)$$

Finally when $f(x)$ has a singularity at an intermediate point c , i.e. $a < c < b$, then

$$\int_a^b f(x)dx = \lim_{\varepsilon \rightarrow 0} \int_a^{c-\varepsilon} f(x)dx + \lim_{\varepsilon \rightarrow 0} \int_{c+\varepsilon}^b f(x)dx \quad (8)$$

The RHS limit above is known as the *Cauchy's principal value of the integral*.

When the limits in the RHS of (6), (7) or (8) fails to exist (or infinite) then the improper integral is said to diverge.

WORKED OUT EXAMPLES

Example 1: Consider the improper integral of the second kind $\int_0^3 \frac{dx}{(x-2)^{2/3}}$ whose integrand $f(x) = (x-2)^{-2/3}$ has a singularity at $x = 2$ which lies in the interval $(0, 3)$. By (8)

$$\int_0^3 \frac{dx}{(x-2)^{2/3}} = \lim_{c \rightarrow 2-\varepsilon} \int_0^c \frac{dx}{(x-2)^{2/3}} + \lim_{c \rightarrow 2+\varepsilon} \int_c^3 \frac{dx}{(x-2)^{2/3}}$$

The first integral in RHS is

$$\lim_{c \rightarrow 2-\varepsilon} [3(6-1)^{1/3} - 3(0-1)^{1/3}] = 6$$

The second integral in RHS is

$$\lim_{c \rightarrow 2+\varepsilon} [3(3-1)^{1/3} - 3(0-1)^{1/3}] = 3(2^{1/3}) - 3$$

Thus the value of the improper integral is $6 + 3\sqrt[3]{2} - 3 = 3 + 3\sqrt[3]{2}$

Fig. 6.53

Example 2: Consider $\int_{-2}^2 \frac{dx}{x^2}$ which has a singularity at $x = 0$. The point of discontinuity $x = 0$ of the integrand $f(x) = x^{-2}$ lies in the interval of integration $(-2, 2)$. Now by (8)

$$\int_{-2}^2 \frac{dx}{x^2} = \lim_{c \rightarrow 0-} \int_{-2}^c \frac{dx}{x^2} + \lim_{c \rightarrow 0+} \int_c^2 \frac{dx}{x^2}$$

$$\begin{aligned} \text{Now } \lim_{c \rightarrow 0-} \int_{-2}^c \frac{dx}{x^2} &= - \lim_{c \rightarrow 0-} \left[\frac{1}{x} \right]_{-2}^c \\ &= - \lim_{c \rightarrow 0-} \left[\frac{1}{c} - \frac{1}{-2} \right] = \infty \end{aligned}$$

The integral diverges in $[-2, 0]$.

Similarly

$$\lim_{c \rightarrow 0+} \int_c^2 \frac{dx}{x^2} = - \lim_{c \rightarrow 0+} \left(2 - \frac{1}{c} \right) = \infty$$

This integral also diverges in $[0, 2]$.

Hence the given integral $\int_{-2}^2 \frac{dx}{x^2}$ diverges on the interval $[-2, 2]$.

Fig. 6.54

Suppose ignoring the presence of the discontinuity at $x = 0$, we evaluate the integral obtaining

$$\int_{-2}^2 \frac{dx}{x^2} = - \frac{1}{x} \Big|_{-2}^2 = - \left(\frac{1}{2} - \frac{1}{-2} \right) = -1$$

which is impossible as is evident from the figure.

Comparison Test for Convergence or Divergence of Improper Integral of the Second Kind

Book work: Prove that $\int_a^c \frac{k dx}{(x-c)^p}$ converges for $p < 1$ and diverges for $p \geq 1$.

Here k is constant.

Proof: For $p = 1$,

$$\begin{aligned} \int_a^c \frac{k dx}{(x-c)^p} &= \int_a^c k \frac{dx}{x-c} = k \ln(x-c) \Big|_a^c \\ \int_a^c \frac{k dx}{(x-c)} &= \lim_{c \rightarrow c+} k \ln(x-c) \Big|_a^c \\ &= k[\ln(a-c) - \ln 0] = \infty \end{aligned}$$

For $p \neq 1$.

$$\int_a^c \frac{k dx}{(x-c)^p} = \lim_{c \rightarrow c+} \left[k \frac{(x-c)^{-p+1}}{-p+1} \right] \Big|_a^c$$

= infinity when $p > 1$

= finite when $p < 1$.

Hence the result.

Note 1: Suppose $f(x)$ has several points of discontinuity at $a_1, a_2, \dots, a_n$ in the interval $[a, b]$. Then the improper integral is defined by

$$\begin{aligned} \int_a^b f(x) dx &= \int_a^{a_1} f(x) dx + \int_{a_1}^{a_2} f(x) dx + \dots \\ &+ \int_{a_n}^b f(x) dx, \end{aligned}$$

converges only when each of the improper integrals on the RHS above converges. Even if one of these integrals diverge, then $\int_a^b f(x) dx$ is said to diverge.

6.48 — HIGHER ENGINEERING MATHEMATICS—II

Note 2: Theorems similar to theorems 1, 2, 3 are applicable to improper integrals of second kind also.

Example 1: The improper integral $\int_0^\infty \cos x \, dx$ diverges by oscillation since

$$\int_0^\infty \cos x \, dx = \lim_{b \rightarrow \infty} \int_0^b \cos x \, dx = \lim_{b \rightarrow \infty} \sin b$$
which takes all values between -1 and 1 as b varies between $2n\pi - \frac{\pi}{2}$ and $2n\pi + \frac{\pi}{2}$ for any integer n . Thus integral diverges without becoming infinite.

In the improper integral of *third kind*, either the limits of integration may be infinite or the integrand is discontinuous or both.

Example 2: $\int_0^\infty e^{-x} x^{n-1} \, dx$ has an infinite upper limit and the integrand $e^{-x} x^{n-1}$ is discontinuous at the lower limit 0.

WORKED OUT EXAMPLES

Test for convergence or divergence of the following improper integrals and hence evaluate them.

Example 1: $\int_{-\infty}^\infty \frac{dx}{a^2 + x^2}$

Solution: Improper integral of first kind, with both limits infinite. Now

$$\begin{aligned} \int_{-\infty}^\infty \frac{dx}{a^2 + x^2} &= \lim_{r \rightarrow \infty} \int_{-r}^r \frac{dx}{a^2 + x^2} = \lim_{r \rightarrow \infty} \frac{1}{a} \tan^{-1} \frac{x}{a} \Big|_{-r}^r \\ &= \lim_{r \rightarrow \infty} \left[\frac{1}{a} \right] \left[\tan^{-1} \frac{r}{a} - \tan^{-1} \left(\frac{-r}{a} \right) \right] \\ &= \frac{2}{a} \lim_{r \rightarrow \infty} \tan^{-1} \frac{r}{a} = \frac{2}{a} \cdot \frac{\pi}{2} = \frac{\pi}{a} \end{aligned}$$

Integral convergent.

Example 2: $\int_0^1 \frac{dx}{x^{0.9999}}$

Solution: Second kind with singularity (discontinuity) at the lower limit 0. So

$$\begin{aligned} \int_0^1 \frac{dx}{x^{0.9999}} &= \lim_{a \rightarrow 0+\epsilon} \int_a^1 \frac{dx}{x^{0.9999}} = \lim_{a \rightarrow 0+} \frac{x^{-0.9999+1}}{-0.9999+1} \Big|_a^1 \\ &= \lim_{a \rightarrow 0+} \frac{1}{0.0001} \left[1^{0.0001} - a^{0.0001} \right] \\ &= \frac{1}{0.0001} [1 - 0] = 10000 \end{aligned}$$

Integral convergent.

Example 3: $\int_0^{\pi/2} \tan x \, dx$

Solution: Second kind with discontinuity at upper limit $\frac{\pi}{2}$. Now

$$\begin{aligned} \int_0^{\pi/2} \tan x \, dx &= \lim_{a \rightarrow \frac{\pi}{2}-\epsilon} \int_0^a \tan x \, dx \\ &= \lim_{a \rightarrow \frac{\pi}{2}-} \ln \sec x \Big|_0^a = \lim_{a \rightarrow \frac{\pi}{2}-} [\ln \sec a - \ln \sec 0] \\ &= [\ln \sec \frac{\pi}{2} - \ln 1] = \ln \infty - 0 = \infty \end{aligned}$$

Integral divergent.

Example 4: $\int_{-a}^a \frac{dx}{\sqrt{a^2 - x^2}}$

Solution: Second kind with discontinuities at both the limits. Now

$$\begin{aligned} \int_{-a}^a \frac{dx}{\sqrt{a^2 - x^2}} &= \lim_{c \rightarrow -a+} \int_c^0 \frac{dx}{\sqrt{a^2 - x^2}} + \lim_{c \rightarrow a-} \int_0^c \frac{dx}{\sqrt{a^2 - x^2}} \\ &= \lim_{c \rightarrow -a+} \sin^{-1} \frac{x}{a} \Big|_c^0 + \lim_{c \rightarrow a-} \sin^{-1} \frac{x}{a} \Big|_0^c \\ &= [\sin^{-1} 0 - \sin^{-1} \left(\frac{-a}{a} \right)] + [\sin^{-1} \frac{a}{a} - \sin^{-1} 0] \\ &= \sin^{-1} 1 + \sin^{-1} 1 = 2 \sin^{-1} 1 = 2 \frac{\pi}{2} = \pi \end{aligned}$$

Example 5: $\int_{-1}^1 \frac{dx}{x^{2/3}}$

Solution: Second kind has discontinuity at an intermediate point $x = 0$ in the interval $(-1, 1)$

$$\begin{aligned} \int_{-1}^1 \frac{dx}{x^{2/3}} &= \lim_{a \rightarrow 0-} \int_{-1}^a \frac{dx}{x^{2/3}} + \lim_{a \rightarrow 0+} \int_a^1 \frac{dx}{x^{2/3}} \\ &= \lim_{a \rightarrow 0-} \left[3x^{1/3} \right]_{-1}^a + \lim_{a \rightarrow 0+} \left[3x^{1/3} \right]_a^1 \\ &= [3 \cdot 0 - 3(-1)^{1/3}] + [3 \cdot 1^{1/3} - 3 \cdot 0] = 3 + 3 \\ &= 6 \end{aligned}$$

Example 6: $\int_0^\infty \frac{dx}{x^3}$

Solution: This is third kind involving infinite upper limit and unboundedness at the lower limit 0. Now

$$\begin{aligned} \int_0^\infty \frac{dx}{x^3} &= \lim_{b \rightarrow \infty} \int_a^b \frac{dx}{x^3} = \lim_{\substack{b \rightarrow \infty \\ a \rightarrow 0+}} \left[-\frac{1}{2x^2} \right]_{x=a}^b \\ &= \lim_{\substack{b \rightarrow \infty \\ a \rightarrow 0+}} -\frac{1}{2} \left[\frac{1}{b^2} - \frac{1}{a^2} \right] = -\frac{1}{2} [0 - \infty] = \infty \end{aligned}$$

Integral diverges.

EXERCISE

Evaluate the following improper integrals

1. $\int_0^{\infty} e^{-x} dx$

Ans. 1, converges

2. $\int_0^1 \ln x \, dx$

Ans. -1, converges

3. $\int_0^1 \frac{x \, dx}{\sqrt{1-x^2}}$

Ans. 1, converges

4. $\int_1^{\infty} \frac{dx}{x\sqrt{x^2-1}}$

Ans. $\frac{\pi}{2}$, converges

5. $\int_{-1}^1 \frac{dx}{x^5}$

Ans. Diverges

6. $\int_1^{\infty} \ln\left(\frac{1}{x}\right) dx$

Ans. Diverges

7. $\int_{-\infty}^0 \frac{dx}{(1-3x)^2}$

Ans. $\frac{1}{3}$, converges

8. $\int_{-\infty}^0 \cos hx \, dx$

Ans. Diverges.

9. $\int_0^{\infty} \frac{dx}{(1+x)\sqrt{x}}$

Ans. π , converges

10. $\int_{-1}^1 \sqrt{\frac{1+x}{1-x}} dx$

Ans. π , converges

Hint: $\sin^{-1} b - \sqrt{1-b^2}$

11. $\int_0^{\infty} \frac{4z^2 dz}{(z^2+1)^2}$

Ans. π , converges

(Integrals 10 and 11 are same. Use substitution

$$z = \sqrt{\frac{1+x}{1-x}})$$

12. $\int_5^{\infty} \frac{dx}{x \log x}$

Ans. Diverges

13. $\int_0^3 \frac{dx}{(x-1)^{2/3}}$

Ans. $3 + 3\sqrt[3]{2}$, converges

14. $\int_1^{\infty} \frac{dx}{x^{1.00001}}$

Ans. 100000, converges

15. $\int_{-1}^1 \frac{dx}{x^{2/5}}$

Ans. converges

16. $\int_{-\infty}^1 e^x \, dx$

Ans. e , converges

17. $\int_{-\infty}^{\infty} \frac{dx}{a+2bx+cx^2}$

Ans. $\frac{\pi}{\sqrt{ac-b^2}}$, converges

Hint: $\frac{1}{c} \left[1 / \left[\left(x + \frac{b}{c} \right)^2 + \left(\sqrt{\frac{ac-b^2}{c^2}} \right)^2 \right] \right]$

Test for convergence

18. $\int_0^{\infty} \frac{dx}{\sqrt[3]{x^2+1}}$

Ans. Diverges

Hint: Compare with $x^{-2/3}$ which is divergent,
 $p = \frac{2}{3} < 1$

19. $\int_0^{\infty} \frac{dx}{\sqrt{x^3+1}}$

Ans. Converges

Hint: Compare with $x^{-3/2}$ which is convergent,
 $p = \frac{3}{2} > 1$

20. $\int_2^{\infty} \frac{3x+5}{x^5+7} dx$

Ans. Converges

Hint: Compare with $\frac{3}{x^4}$ which is convergent,
 $p = 4 > 1$

21. $\int_0^5 \frac{\sin 3x}{x^{5/2}} dx$

Ans. Diverges

Hint: As $x \rightarrow 0$ $\frac{\sin 3x}{x^{5/2}} \sim \frac{3x}{x^{5/2}} = \frac{3}{x^{3/2}}$

6.50 — HIGHER ENGINEERING MATHEMATICS—II

22. $\int_0^{\infty} \frac{dx}{x^4 + 2}$

Ans. Converges

Hint: $\int_0^{\infty} = \int_0^1 + \int_1^{\infty}$, first integral converges, second integral converges by comparison with integrand $\frac{1}{x^4}$ which is p -integral with $p = 4 > 1$.

23. $\int_0^{\infty} \frac{x^{3.2} dx}{x^4 + 100}$

Ans. Diverges

Hint: $\int_0^{\infty} = \int_0^1 + \int_1^{\infty}$, first integral converges, $\int_1^{\infty}$ diverges by comparison with integrand $x^{-0.8}$ which is p -integral with $p < 1$.

24. $\int_0^4 \frac{\sin^2 x \, dx}{\sqrt{x(x-1)}}$

Ans. Converges

Hint: Compare with $x^{-3/2}$ which is p integral with $p = \frac{3}{2} > 1$ and is convergent.

25. $\int_0^1 \frac{dx}{x^2 \cos x}$

Ans. Diverges

Hint: As $x \rightarrow 0$, $\frac{1}{x^2 \cos x} \sim \frac{1}{x^2}$ which is divergent for $p > 1$.

Chapter 7

Multiple Integrals

INTRODUCTION

Double integrals are sometimes easier to evaluate when we change the order of integration or when we change to polar coordinates, over regions whose boundaries are given by polar equations. General change of variables involves evaluation of multiple integrals by substitution. The aim of substitution is to replace complicated integrals by one that are easier to evaluate. Change of variables simplifies the integrand, the limits of integration or both. Evaluation of triple integral is simplified by the use of cylindrical or spherical coordinates in problems of physics, engineering or geometry involving a cylinder, cone, or sphere. Dirichlet's integral is useful in the evaluation of certain double and triple integrals by expressing them in terms of beta and gamma functions.

Multiple integral is a natural extension of an (ordinary) definite integral to a function of two variables (double integral) or three variables (triple integral) or more variables. Double and triple integrals are useful in evaluating area, volume, mass, centroid and moments of inertia of plane and solid regions.

7.1 DOUBLE INTEGRAL

Let D be a closed* and bounded** domain in the XY -plane bounded by a simple closed curve c . Let

*Boundary included i.e., part of the region.

**Can be enclosed in a circle of finite radius.

$f(x, y)$ be a given continuous function in D . Divide D into n parts and form the sum

$$\sum_{i=1}^n f(P_i) \Delta S_i$$

where $f(P_i)$ is the value of f at an arbitrary point P_i of the subdomain whose area is ΔS_i . Double integral of $f(x, y)$ over the domain D is the limit of the above sum as $n \rightarrow \infty$ and is denoted by I_D as

$$\begin{aligned} I_D &= \iint_D f(P) dS = \iint_D f(x, y) dx dy \\ &= \lim_{\Delta S_i \rightarrow 0} \sum_{i=1}^n f(P_i) \Delta S_i \end{aligned} \quad (1)$$

Here D is known as the domain (region) of integration.

The following properties of double integrals follow from the definition (1).

Properties of Double Integral

1. $\iint_D a f(x, y) dS = a \iint_D f(x, y) dS, a = \text{constant.}$
2. $\iint_D [f(x, y) + g(x, y)] dS = \iint_D f(x, y) dS + \iint_D g(x, y) dS$
3. $\iint_D f(x, y) dS = \iint_{D_1} f(x, y) dS + \iint_{D_2} f(x, y) dS$

where D is the union of disjoint domains D_1 and D_2 .

7.2 — HIGHER ENGINEERING MATHEMATICS—II

Regular Domain

A domain D in XY -plane bounded by a curve c is said to be regular in the Y -direction, if straight lines passing through an interior point (a point which does not lie on the boundary c) and parallel to Y -axis meets c in two points A and B (Fig. 7.1).

Fig. 7.1

In such a case, the domain D is bounded by the two curves $c_2 : GHE : y = y_2(x)$ and $c_1 : EFG : y = y_1(x)$ and the ordinates $x = a$ and $x = b$ such that

$$y_2(x) \leq y_1(x)$$

and $a < b$

Here c is the sum of the two curves c_1 and c_2 .

In other words, “A domain D is said to be “regular” domain if it is regular in both X and Y directions”.

Examples of Regular Domain: Regions bounded by rectangle, triangle, circle, ellipses.

Example of Non-regular Domain: Annulus region.

Evaluation of a Double Integral

A double integral can be evaluated by successive single integrations i.e., as a two-fold iterated (repeated) integral as follows (if D is regular in y -direction):

$$I_D = \int_{x=a}^b \left\{ \int_{y=y_1(x)}^{y_2(x)} f(x, y) dy \right\} dx \quad (2)$$

where integration is performed *first* with respect to y (within the braces). With the substitution of the limits $y_1(x)$ and $y_2(x)$, the integrand becomes a function of x alone, which is *then* integrated with respect to x from a to b .

In a similar way, for a domain D (regular in x -direction) which is bounded above by $EHF : x = x_2(y)$ and bounded below by $EGF : x = x_1(y)$ and the abscissa $y = d$ and $y = e$ (Fig. 7.2).

Fig. 7.2

The double integral is evaluated as

$$I_D = \int_{y=d}^e \left\{ \int_{x=x_1(y)}^{x_2(y)} f(x, y) dx \right\} dy \quad (3)$$

In this case the integration is *first* performed with respect to x and *then* later with respect to y .

Note 1: The braces in (2) and (3) can be omitted, since it is conventional to integrate first with respect to a variable whose differential appears first (for example in (2) the order of integration is first y and later x).

Note 2: If all the four limits are constants then the order of integration can be done in either way i.e., integration first with respect to x and later w.r.t. y or first w.r.t. y and later w.r.t. x , yielding the same result, provided the limits are taken (for x and y) accordingly.

Note 3: When D is regular (in both x and y directions), draw a rough sketch of D the domain of integration to fix the limits of integration. Choose (or change) the order of integration (see Section 7.5) and use (2) or (3) whichever is easier for integration.

Note 4: Suppose D is such that the lower curve $AFE : y = y_1(x)$ consists of two different curves

$$AF : y_1 = \phi(x), \quad a \leq x \leq e$$

$$FE : y_1 = \psi(x), \quad e \leq x \leq b$$

while the upper curve is $AGB : y = y_2(x)$ (Fig. 7.3). Then $D = AFE BGA = AFGA + FEBG = D_1 + D_2$, so that

Fig. 7.3

$$\begin{aligned} \iint_D f(x, y) dy dx &= \int_a^b \int_{y_1(x)}^{y_2(x)} f(x, y) dy dx \\ &= \iint_{D_1} f(x, y) dy dx \\ &\quad + \iint_{D_2} f(x, y) dy dx \\ &= \int_a^e \int_{\phi(x)}^{y_2(x)} f(x, y) dy dx \\ &\quad + \int_e^b \int_{\psi(x)}^{y_2(x)} f(x, y) dy dx. \end{aligned}$$

(see Worked Out Example 4).

WORKED OUT EXAMPLES

Evaluate the following double integrals as two-fold iterated integral:

Example 1: $I_D = \int_1^{\ln 8} \int_0^{\ln y} e^{x+y} dx dy$

Solution:

$$\begin{aligned} I_D &= \int_1^{\ln 8} e^{x+y} \Big|_0^{\ln y} dy = \int_1^{\ln 8} (e^{y+\ln y} - e^y) dy \\ I_D &= \int_1^{\ln 8} e^y (y - 1) dy = (ye^y - e^y - e^y) \Big|_1^{\ln 8} \\ &= 8 \ln 8 - 16 + e \end{aligned}$$

Example 2: $I_D = \iint_D (x^2 + y^2) dx dy$ where D is

bounded by $y = x$ and $y^2 = 4x$.

Solution:

Fig. 7.4

$$\begin{aligned} I_D &= \int_0^4 \int_x^{2\sqrt{x}} (x^2 + y^2) dy dx \\ &= \int_0^4 \left(x^2 y + \frac{y^3}{3} \right) \Big|_x^{2\sqrt{x}} dx \\ &= \int_0^4 \left(2x^{\frac{5}{2}} + \frac{8}{3} x^{\frac{3}{2}} - \frac{4}{3} x^3 \right) dx \\ &= \frac{768}{35} \end{aligned}$$

Example 3: $I_D = \iint_D x^3 y dx dy$ where D is the region enclosed by the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ in the first quadrant.

Fig. 7.5

Solution:

$$\begin{aligned} I_D &= \int_0^a \int_0^{\frac{b}{a}\sqrt{a^2-x^2}} x^3 y dy dx \\ I_D &= \int_0^a \frac{x^3 y^2}{2} \Big|_0^{\frac{b}{a}\sqrt{a^2-x^2}} dx = \frac{b^2}{2a^2} \int_0^a (a^2 x^3 - x^5) dx \\ I_D &= \frac{b^2}{2a^2} \left[\frac{a^2 x^4}{4} - \frac{x^6}{6} \right]_0^a = \frac{b^2 a^4}{24} \end{aligned}$$

Example 4: $I_D = \iint_D x^2 dx dy$ where D is the region in the first quadrant bounded by the hyperbola $xy = 16$ and the lines $y = x$, $y = 0$ and $x = 8$.

Solution: If horizontal strips are considered, the upper curve ABE consists of two curves AB and BE . It is necessary to consider the region D as the union of two disjoint regions D_1 and D_2 as

7.4 — HIGHER ENGINEERING MATHEMATICS—II

Fig. 7.6

$$D = OGEBAFO = D_1 + D_2 = FBAF + OGEBF$$

$$\begin{aligned} I_D &= \iint_D x^2 dx dy = \iint_{D_1} + \iint_{D_2} \\ &= \int_2^4 \int_{x=y}^{16/y} x^2 dx dy + \int_0^2 \int_{x=y}^8 x^2 dx dy \\ &= \frac{1}{3} \int_0^4 \left(\frac{16^3}{y^3} - y^3 \right) dy + \frac{1}{3} \int_0^2 (8^3 - y^3) dy = 448 \end{aligned}$$

Note: This example can also be considered with vertical strip as follows: $D = R_1 + R_2 = OGAFO + GEBAG$ with limits for R_1 : $y : 0$ to x ; $x : 0$ to 4 , for R_2 : $y : 0$ to $16/x$; $x : 4$ to 8 .

EXERCISE

Evaluate the following double integrals as two-fold iterated integrals:

1. $\int_3^4 \int_1^2 \frac{dy dx}{(x+y)^2}$

Ans. $\ln (25/24)$

2. $\int_0^a \int_0^{y/2/a} e^{x/y} dx dy$

Ans. $a^2/2$

3. $\int_{-\frac{1}{2}}^1 \int_{-x}^{1+x} (x^2 + y) dy dx$

Ans. $\frac{63}{32}$

4. $\int_0^\pi \int_0^x x \sin y dy dx$

Ans. $2 + \pi^{2/2}$

5. $\iint_D (4xy - y^2) dx dy$ where D is the rectangle bounded by $x = 1$, $x = 2$, $y = 0$, $y = 3$.

Ans. 18

6. $\iint_D (x^2 + y^2) dx dy$ where D is the region bounded by $y = x$, $y = 2x$ and $x = 1$ in the first quadrant.

Ans. $\frac{5}{6}$

7. $\iint_D (1 + x + y) dx dy$ where D is the region bounded by the lines $y = -x$, $x = \sqrt{y}$, $y = 2$, $y = 0$.

Hint: Limits: $x : -y$ to $\sqrt{y}$; $y : 0$ to 2 .

Ans. $\frac{44}{15}\sqrt{2} + \frac{13}{3}$

8. $\iint_D xy dx dy$ where D is the domain bounded by the parabola $x^2 = 4ay$, the ordinates $x = a$ and x -axis.

Ans. $a^4/3$

9. $\int_0^1 \int_0^{\sqrt{1+x^2}} (1 + x^2 + y^2)^{-1} dx dy$

Ans. $\frac{\pi}{4} \log(1 + \sqrt{2})$

10. $\iint_D (x + y)^2 dx dy$ where D is the region bounded by the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$.

Ans. $\pi ab(a^2 + b^2)/4$

11. $\int_0^a \int_{x/a}^x \frac{x dy dx}{x^2 + y^2}$

Ans. $a \left[\frac{\pi}{4} - \tan^{-1} \left(\frac{1}{a} \right) \right]$

12. $\iint_R \sqrt{xy(a - x - y)} dx dy$ where R is the region bounded by $x = 0$, $y = 0$, $x + y = a$.

Ans. $2\pi a^{7/2}/105$

7.2 APPLICATION OF DOUBLE INTEGRAL

Area of a Plane Region

The area A of a plane regular region (domain) D is given by a two-fold iterated integral

$$\begin{aligned} A &= \iint_D ds = \iint_D dx dy \\ &= \int_{x=a}^b \int_{y=y_1(x)}^{y_2(x)} dy dx = \int_{y=d}^e \int_{x=x_1(y)}^{x_2(y)} dx dy \end{aligned}$$

Mass Contained in a Plane Region

Let $f(x, y) > 0$ be the surface density (mass/unit area) of a given plane region D . Then the amount (quantity) of mass M contained in the plane region

D is given by

$$M = \iint_D f(x, y) dx dy$$

Centre of Gravity (Centroid) of a Plane Region D

The coordinates (x_c, y_c) of the centre of gravity (centroid) of a plane region D with surface density $f(x, y)$ and containing mass M are

$$x_c = \frac{\iint_D x \cdot f(x, y) dx dy}{M}, y_c = \frac{\iint_D y \cdot f(x, y) dx dy}{M}$$

Moment of Inertia of a Plane Region

Moments of inertia of a plane region D (with surface density $f(x, y)$) relative to x -axis, y -axis and origin O are respectively given by

$$I_{xx} = \iint_D y^2 f(x, y) dx dy$$

$$I_{yy} = \iint_D x^2 f(x, y) dx dy$$

$$I_o = I_{xx} + I_{yy} = \iint_D (x^2 + y^2) f(x, y) dx dy$$

I_o is also known as polar moment of inertia.

Volume under a Surface of a Solid as a Double Integral

Let $z = f(x, y) > 0$ be the equation of a surface. Let the curve c be the boundary of the plane domain D in the XY -plane. Further let V be the volume of the solid Q , under the surface $z = f(x, y)$ (i.e., bounded above by the surface) and above the XY -plane (i.e., bounded below by $z = 0$) and a cylindrical surface whose generator are parallel to the z -axis, while the directrix Q is c (see Fig. 7.7).

Then the double integral of $f(x, y)$ taken over D gives the volume V under the surface $z = f(x, y)$

$$V = \iint_D f(x, y) dx dy.$$

Fig. 7.7

WORKED OUT EXAMPLES

Area of Plane Region: Cartesian Coordinates

Example 1: Find the area bounded by the curves $y^2 = x^3$ and $x^2 = y^3$.

Solution: Area $A = \iint_D dx dy = \iint_D dy dx$ the plane region D can be covered by varying y from the upper curve $y = y_2(x) = x^{2/3}$ to the lower curve $y = y_1(x) = x^{3/2}$, while x varies from 0 to 1 (refer Fig. 7.8). Thus

Fig. 7.8

$$\begin{aligned} A &= \int_0^1 \int_{x^{3/2}}^{x^{2/3}} dy dx \\ &= \int_0^1 (x^{2/3} - x^{3/2}) dx = \left[\frac{3}{5} x^{5/3} - \frac{2}{5} x^{5/2} \right]_0^1 \\ A &= \frac{3}{5} - \frac{2}{5} = \frac{1}{5} \end{aligned}$$

7.6 — HIGHER ENGINEERING MATHEMATICS—II

Aliter: Alternatively D can be considered as Domain enclosed between the upper curve $x = y^{\frac{2}{3}}$ and lower curve $x = y^{\frac{3}{2}}$ and abscissa $y = 0$ and $y = 1$. Thus

$$\begin{aligned} A &= \int_0^1 \int_{x=y^{\frac{3}{2}}}^{x=y^{\frac{2}{3}}} dx dy \\ &= \int_0^1 (y^{\frac{2}{3}} - y^{\frac{3}{2}}) dy \\ &= \left[\frac{3}{5} y^{\frac{5}{3}} - \frac{2}{5} y^{\frac{5}{2}} \right]_0^1 = \frac{1}{5} \end{aligned}$$

Example 2: Determine the area bounded by the curves $xy = 2$, $4y = x^2$ and $y = 4$.

Solution: Here $A(\frac{1}{2}, 4)$, $B(4, 4)$, $E(2, 1)$, $F(2, 4)$ observe that one of (lower) curve consists of more than one curve (equation) (Fig. 7.9), so the given domain $D = D_1 + D_2$ where $D_1 : AEF A$ bounded by $y = \frac{2}{x}$, $y = 4$, $x = \frac{1}{2}$, $x = 1$ and $D_2 : FEBF$ bounded by $y = \frac{x^2}{4}$, $y = 4$, $x = 1$ and $x = 4$, so that

$$\begin{aligned} A &= \iint_D dx dy = \iint_{D_1} + \iint_{D_2} \\ &= \int_{\frac{1}{2}}^2 \int_{y=\frac{2}{x}}^4 dy dx + \int_2^4 \int_{y=\frac{x^2}{4}}^4 dy dx \\ &= \int_{\frac{1}{2}}^2 \left(4 - \frac{2}{x} \right) dx + \int_2^4 \left(4 - \frac{x^2}{4} \right) dx \\ &= 4x - 2 \ln x \Big|_{\frac{1}{2}}^2 + 4x - \frac{x^3}{12} \Big|_2^4 \\ A &= \frac{28}{3} - 2 \ln 4 \end{aligned}$$

Fig. 7.9

Note: Alternatively by conveniently taking $y = \frac{x^2}{4}$ as the upper curve and $y = 2/x$ as the lower curve (refer Fig. 7.10), this problem can be solved easily as follows:

Fig. 7.10

$$\begin{aligned} \text{Aliter : } A &= \int_{y=1}^4 \int_{x=\frac{2}{y}}^{x=2\sqrt{y}} dx dy = \int_1^4 \left(2\sqrt{y} - \frac{2}{y} \right) dy \\ &= 2 \left[\frac{y^{\frac{3}{2}}}{(3/2)} - 2 \ln y \right]_1^4 = \frac{28}{3} - 2 \ln 4 \end{aligned}$$

EXERCISE

Area of plane region: Cartesian coordinates

Find the area of the following domains in XY -plane bounded by the indicated curves

1. $y = x$, $y = x^2$

Ans. $\frac{1}{6}$

2. $y = 3x - x^2$, $y = x$

Ans. $\frac{4}{3}$

3. $3x = 4 - y^2$, $x = y^2$

Hint: Easy to integrate with,

limits: $x : y^2$ to $(4 - y^2)/3$, $y : -1$ to 1 .

Ans. $\frac{16}{9}$

4. $y = x^2$ and $y = x + 2$

Hint: Easy to integrate with

limits: $y : x^2$ to $x + 2$; $x : -1$ to 2 .

Ans. $\frac{9}{2}$

5. Ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$.

Hint: Limits: $y : \pm b\sqrt{1 - \frac{x^2}{a^2}}$; $x : \pm a$ or

$x : \pm a\sqrt{1 - \frac{y^2}{b^2}}$, $y : \pm b$.

Ans. πab

6. $\sqrt{x} + \sqrt{y} = \sqrt{a}$ and $x + y = a$

Hint: Limits: $y : a + x - 2\sqrt{ax}$ to $(a-x)$,
 $x : 0$ to a .

Ans. $\frac{a^2}{3}$

7. Parabola $y^2 = 4ax$ and straight line $x + y = 3a$

Hint: Easy to integrate with

limits: $x : 3a - y$ to $y^2/4a$; $y : 0$ to a .

Ans. $\frac{10a^2}{3}$

8. Common to the two parabolas

$y^2 = 4a(x + a)$, $y^2 = 4b(b - x)$

Ans. $\frac{8(a+b)\sqrt{ab}}{3}$

9. $y = \sin x$, $y = \cos x$, $x = 0$

Ans. $\sqrt{2} - 1$

10. $3y^2 = 25x$ and $5x^2 = 9y$

Hint: Limits: $y : \frac{5}{9}x^2$ to $5\sqrt{x}/\sqrt{3}$, $x : 0$ to 3

Ans. 5

11. $x = y - y^2$ and $x + y = 0$

Ans. $\frac{4}{3}$

x -axis, y -axis and origin of a rectangle $0 \leq x \leq 4$,
 $0 \leq y \leq 2$ having mass density xy (see Fig. 7.11).

Fig. 7.11

Solution: Here density $f(x, y) = xy$

$$\text{Mass } M = \iint_R f(x, y) dx dy$$

$$M = \int_0^4 \int_0^2 (xy) dy dx = \int_0^4 \left. \frac{xy^2}{2} \right|_0^2 dx$$

$$= \int_0^4 2x dx = 16$$

Let x_c, y_c be the coordinates of the centre of gravity of R then

$$x_c = \frac{1}{M} \iint_R x f(x, y) dx dy = \frac{1}{16} \int_0^4 \int_0^2 x(xy) dy dx$$

$$x_c = \frac{1}{16} \int_0^4 \left. x^2 \frac{y^2}{2} \right|_0^2 dx = \frac{1}{8} \int_0^4 x^2 dx = \frac{8}{3}$$

$$y_c = \frac{1}{M} \iint_R y f(x, y) dx dy = \frac{1}{16} \int_0^4 \int_0^2 y(xy) dy dx$$

$$= \frac{1}{16} \int_0^4 \left. x \frac{y^3}{3} \right|_0^2 dx = \frac{1}{6} \int_0^4 x dx = \frac{4}{3}$$

Moment of inertia relative to x -axis

$$I_x = \iint_R y^2 f(x, y) dx dy = \int_0^4 \int_0^2 y^2(xy) dy dx$$

$$= \int_0^4 \left. x \frac{y^4}{4} \right|_0^2 dx = 4 \int_0^4 x dx = 4 \left. \frac{x^2}{2} \right|_0^4 = 32$$

Similarly

$$I_y = \iint_R x^2 f(x, y) dx dy = \int_0^4 \int_0^2 x^2(xy) dy dx$$

$$I_y = \int_0^4 \left. x^3 \frac{y^2}{2} \right|_0^2 dx = 2 \int_0^4 x^3 dx = 2 \left. \frac{x^4}{4} \right|_0^4 = 128$$

WORKED OUT EXAMPLES

Mass, centroid and moments of inertia

Example 1: Find the mass, coordinates of the centre of gravity and moments of inertia relative to

7.8 — HIGHER ENGINEERING MATHEMATICS—II

$$\begin{aligned}
 I_0 &= \iint_R (x^2 + y^2) f(x, y) dx dy \\
 &= \int_0^4 \int_0^2 (x^2 + y^2) xy dy dx \\
 &= \int_0^4 \left(\frac{x^3 y^2}{2} + \frac{x y^4}{4} \right) \Big|_0^2 dx \\
 &= \int_0^4 (2x^3 + 4x) dx \\
 I_0 &= \left(\frac{2x^4}{4} + \frac{4x^2}{2} \right) \Big|_0^4 = 128 + 32 = 160
 \end{aligned}$$

Thus $I_0 = I_x + I_y$.

Example 2: Find the mass, centroid and moments of inertia relative to x -axis, y -axis and origin of the plane region R having mass density $x + y$ and bounded by the parabola $x = y - y^2$ and the straight line

$$x + y = 0$$

Solution: The plane region R shown in the (Fig. 7.12) is OAB with $O(0, 0)$, $A(0, 1)$, $B(-2, 2)$ since the points of intersection of the parabola $x = y - y^2$ and $x + y = 0$ are $(-2, 2)$ and $(0, 0)$.

Fig. 7.12

This region R can be covered with x varying from $x = y - y^2$ to $x = -y$ and y from 0 to 2. Here the density function is $f(x, y) = x + y$. Thus the mass M contained in R is

$$\begin{aligned}
 M &= \iint_R f(x, y) dx dy = \int_0^2 \int_{x=-y}^{y-y^2} (x + y) dx dy \\
 &= \int_0^2 \left(\frac{x^2}{2} + xy \right) \Big|_{-y}^{y-y^2} dy \\
 &= \int_0^2 \left(\frac{1}{2} y^4 - 2y^3 + 2y^2 \right) dy
 \end{aligned}$$

$$\begin{aligned}
 &= \left(\frac{1}{2} \frac{y^5}{5} - 2y^4 + 2 \frac{y^3}{3} \right) \Big|_0^2 \\
 M &= \frac{8}{15} \\
 x_c &= \frac{1}{M} \iint_R x f(x, y) dx dy \\
 &= \frac{15}{8} \int_0^2 \int_{-y}^{y-y^2} x(x + y) dx dy \\
 &= \int_0^2 \left(\frac{x^3}{3} + \frac{x^2}{2} y \right) \Big|_{-y}^{y-y^2} dy \\
 &= \int_0^2 \frac{y^3}{6} [4 - 12y + 9y^2 - 2y^3] dy \\
 &= \frac{1}{6} \left[\frac{4y^4}{4} - \frac{12y^5}{5} + \frac{9y^6}{6} - \frac{2y^7}{7} \right]_0^2 = \frac{-8}{35} \\
 y_c &= \frac{1}{M} \iint_R y f(x, y) dx dy \\
 &= \frac{15}{8} \int_0^2 \int_{-y}^{y-y^2} y(x + y) dx dy \\
 &= \frac{15}{8} \int_0^2 \left(\frac{yx^2}{2} + y^2 x \right) \Big|_{-y}^{y-y^2} dy \\
 &= \frac{15}{8} \int_0^2 \frac{1}{2} \left(y^5 - 3y^4 + \frac{5}{2} y^3 \right) dy \\
 y_c &= \frac{15}{16} \left[\frac{y^6}{6} - \frac{3y^5}{5} + \frac{5}{2} \frac{y^4}{4} \right]_0^2 = \frac{15}{16} \frac{22}{15} = \frac{11}{8} \\
 I_x &= \int_0^2 \int_{-y}^{y-y^2} y^2 (x + y) dx dy \\
 &= \int_0^2 \left(\frac{y^2 x^2}{2} + y^3 x \right) \Big|_{-y}^{y-y^2} dy \\
 I_x &= \int_0^2 \left(\frac{y^6}{2} - 2y^5 + 2y^4 \right) dy \\
 &= \frac{y^7}{14} - \frac{2y^6}{6} + \frac{2y^5}{5} \Big|_0^2 = \frac{64}{105} \\
 I_y &= \int_0^2 \int_{-y}^{y-y^2} x^2 (x + y) dx dy
 \end{aligned}$$

$$\begin{aligned}
 &= \int_0^2 \left(\frac{x^4}{4} + \frac{x^3}{3} y \right) \Big|_{-y}^{y-y^2} dy \\
 &= \frac{1}{12} \int_0^2 (3y^8 - 16y^7 + 30y^6 - 24y^5 + 8y^4) dy \\
 I_y &= \frac{1}{12} \left[\frac{3y^9}{9} - \frac{16y^8}{8} + \frac{30y^7}{7} - \frac{24y^6}{6} + \frac{8y^5}{5} \right]_0^2 \\
 &= \frac{2^8}{7 \times 3 \times 5} = \frac{256}{105} \\
 I_0 &= I_x + I_y = \frac{64}{105} + \frac{256}{105} = \frac{320}{105} = \frac{64}{21}
 \end{aligned}$$

EXERCISE

Mass, Centroid, and Moments of Inertia

1. Determine the mass of a circular lamina of radius b if the surface density of the material at any point $P(x, y)$ is proportional to the distance of the point (x, y) from the centre of the circle.

Hint: Density = $f(x, y) = k\sqrt{x^2 + y^2}$, k constant.

Ans. $\frac{2}{3}k\pi b^3$

2. Find the mass contained in the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ with surface density $(x + y)^2$.

Hint: Limits: $y = \pm \frac{b}{a}\sqrt{a^2 - x^2}$, $x : \pm a$.

Ans. $\frac{\pi ab}{4}(a^2 + b^2)$

3. Find the centroid of the region in the first quadrant bounded by $\left(\frac{x}{a}\right)^{\frac{2}{3}} + \left(\frac{y}{b}\right)^{\frac{2}{3}} = 1$, $x = 0$, $y = 0$ and having surface density kxy with k constant.

Hint: Put $x = a \cos^3 \theta$, $y = b \sin^3 \theta$ with θ varying from 0 to $\frac{\pi}{2}$.

Ans. $\left(\frac{128}{429}a, \frac{128}{429}b\right)$

4. Find the centroid of the upper half of the circle $x^2 + y^2 = a^2$.

Ans. $\left(0, \frac{\pi a^2}{2}\right)$

5. Find the centroid of the plane region bounded by $y^2 + x = 0$ and $y = x + 2$.

Hint: Points of intersection: $(-1, 1)$, $(-4, -2)$.

Limits: $x = y - 2$ to $-y^2$, $y : -2$ to 1 .

Ans. $\left(-\frac{8}{5}, -\frac{1}{2}\right)$

6. Determine the coordinates of the centre of gravity of the plane region bounded by $y = \ln x$, $y = 1$, $y = 0$, $x = 0$

Hint: Points of intersection $(1, 0)$, $(e, 1)$.

Limits: $x : 0$ to e^y ; $y : 0$ to 1 .

Ans. $\left(\frac{e+1}{4}, \frac{1}{e-1}\right)$

7. Calculate the centroid of the area bounded by the parabola $x^2 + 4y - 16 = 0$ and x -axis.

Hint: $x_c = 0$ due to symmetry about y -axis.

Limits: $y : 0$ to $(16 - x^2)/4$; $x : \pm 4$.

Ans. $\left(0, \frac{8}{5}\right)$

8. Find the centroid of the area bounded by the parabolas $y^2 = 20x$, $x^2 = 20y$.

Hint: Limits: $y : \sqrt{20x}$ to $\frac{x^2}{20}$; $x : 0$ to 20 .

Ans. $(9, 9)$

9. Find moment of inertia of circular region of radius b relative to its centre O .

Ans. $\frac{\pi b^4}{2}$

10. Compute the moment of inertia relative to the origin of the area of a rectangle bounded by the straight lines $x = 0$, $x = a$, $y = 0$, $y = b$.

Ans. $\frac{ab(a^2 + b^2)}{3}$

11. Compute the moment of inertia of the area of the circle $(x - a)^2 + (y - b)^2 = 2a^2$ relative to the y -axis.

Ans. $3\pi a^4$

12. Find the moment of inertia of the region bounded by the parabola $y^2 = ax$ and the straight line $x = a$ relative to the straight line

7.10 — HIGHER ENGINEERING MATHEMATICS—II

$$y = -a.$$

Ans. $\frac{8}{5}a^4$

Calculate I_x, I_y for the regions bounded by

13. $4y = x^3, y = |x|$

Ans. $I_x = \frac{4}{5}, I_y = \frac{4}{3}$

14. $y = e^x, y = e, x = 0$

Ans. $I_x = (1 + 2e^3)/9$
 $I_y = 2(3 - e)/3$

15. Find the centre of gravity and the moments of inertia I_x, I_y, I_0 of the region, $0 \leq y \leq \sqrt{1 - x^2}, 0 \leq x \leq 1$ and $f(x, y) = 1$ be the density of mass.

Ans. Mass $M = \frac{\pi}{4}, \bar{x} = \bar{y} = \frac{4}{3\pi}$ (by symmetry),
 $I_x = \frac{\pi}{16}, I_y = \frac{\pi}{16}, I_v = I_x + I_y = \frac{\pi}{8}$.

16. A thin plate of uniform thickness and constant density ρ covers the region of xy -plane and is bounded by $y = x^2$ and $y = x + 2$. Find the mass M . Find its moment of inertia I_y about the y -axis.

Hint: Limits: $y : x^2$ to $x + 2, x : -1$ to 2 .

Ans. $I_y = \frac{63}{20}\rho, \text{ Mass } M = \frac{9}{2}\rho.$

WORKED OUT EXAMPLES

Volume of solid by double integral

Example 1: Find the volume of the tetrahedron in space cut from the first octant by the plane $6x + 3y + 2z = 6$.

Solution: The tetrahedron is bounded below by $z = 0$ (xy -plane) and bounded above by the surface $z = \frac{6-6x-3y}{2} = f(x, y)$.

The projection R of this surface $z = f(x, y)$ onto the xy -plane is the triangular region OAB bounded by the lines $x = 0, y = 0$ and $6x + 3y = 6$. This

projected region R can be covered by varying y from 0 to $2 - 2x$, and x from 0 to 1 . Thus the required volume V of the tetrahedron is given by (Fig. 7.13)

Fig. 7.13

$$\begin{aligned} V &= \iint_R f(x, y) dx dy \\ &= \int_0^1 \int_{y=0}^{2-2x} \frac{6-6x-3y}{2} dy dx \\ &= \int_0^1 (3-3x)y - \frac{3}{2} \frac{y^2}{2} \Big|_0^{2-2x} dx \\ &= 3 \int_0^1 (1-x)^2 dx = 1 \end{aligned}$$

Example 2: Calculate the volume of a solid whose base is in a xy -plane and is bounded by the parabola $y = 4 - x^2$ and the straight line $y = 3x$, while the top of the solid is in the plane $z = x + 4$ (see Fig. 7.14).

Solution: The points of intersection of the two curves $y = 4 - x^2$ and $y = 3x$ are $(-4, -12), (1, 3)$. The projection R of $z = x + 4$ in the xy -plane is bounded by these curves. So R can be covered by varying y from $3x$ (lower curve) to $4 - x^2$ (top curve) and x from -4 to 1 . Thus the required volume V is

Fig. 7.14

$$V = \int_{-4}^1 \int_{3x}^{4-x^2} (x+4) dy dx$$

$$\begin{aligned}
 &= \int_{-4}^1 (x+4)(4-x^2-3x)dx \\
 &= \int_{-4}^1 (-x^3-7x^2-8x+16)dx \\
 &= \left. \frac{-x^4}{4} - \frac{7x^3}{3} - \frac{8x^2}{2} + 16x \right|_{-4}^1 = \frac{625}{12}
 \end{aligned}$$

Example 3: Determine the volume of the space below the paraboloid $x^2 + y^2 + z - 4 = 0$ and above the square in the xy -plane with vertices at $(0, 0)$, $(0, 1)$, $(1, 0)$, $(1, 1)$.

Solution: As shown in Fig. 7.15 the top surface is $z = 4 - x^2 - y^2 = f(x, y)$. The projection R of this surface on the xy plane into the square is the square itself with vertices $O(0, 0)$, $A(1, 0)$, $B(1, 1)$, $C(0, 1)$. Thus,

Fig. 7.15

$$\begin{aligned}
 V &= \iint_R f(x, y) dx dy = \int_0^1 \int_0^1 (4 - x^2 - y^2) dx dy \\
 V &= \int_0^1 \left(4y - x^2 y - \frac{y^3}{3} \right) \Big|_0^1 dx \\
 &= \int_0^1 \left(\frac{11}{3} - x^2 \right) dx = \left. \frac{11}{3}x - \frac{x^3}{3} \right|_0^1 = \frac{10}{3}
 \end{aligned}$$

Example 4: Find the volume of the solid under the surface $az = x^2 + y^2$ and whose base R is the circle $x^2 + y^2 = a^2$ (Fig. 7.16).

Solution: Here $f(x, y) = (x^2 + y^2)/a$.

$$\begin{aligned}
 V &= \iint_R f(x, y) dx dy \\
 V &= \int_{-a}^a \int_{-\sqrt{a^2-x^2}}^{\sqrt{a^2-x^2}} \frac{x^2 + y^2}{a} dy dx
 \end{aligned}$$

Fig. 7.16

Integration in cartesian coordinates x, y will be cumbersome. Instead by introducing polar coordinates, $x = r \cos \theta$, $y = r \sin \theta$, then $x^2 + y^2 = r^2 \cos^2 \theta + r^2 \sin^2 \theta = r^2$. The base R is covered by varying r from 0 to a and θ from 0 to 2π . Thus, (see Fig. 7.16)

$$\begin{aligned}
 V &= \int_0^{2\pi} \int_0^a \left(\frac{r^2}{a} \right) r dr d\theta \\
 &= \int_0^{2\pi} \left. \frac{r^4}{4a} \right|_0^a d\theta = \frac{a^3}{4} 2\pi = \frac{\pi a^3}{2}
 \end{aligned}$$

EXERCISE

Volume of Solids by Double Integral

By means of double integral, find the volume V of the following solids bounded by

1. $x = 0, y = 0, z = 0, \frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$

Ans. $\frac{abc}{6}$

2. The cylinder: $x^2 + y^2 = 4$ and the planes $y + z = 4$ and $z = 0$.

Hint: $z = f(x, y) = 4 - y$.

Limits: $x : 0$ to $\sqrt{4 - y^2}$, $y : -2$ to 2 .

Ans. 16π

3. $y = x^2, x = y^2, z = 0; z = 12 + y - x^2$.

Ans. $549/144$

4. $z = 0, x^2 + y^2 = 1, x + y + z = 3$.

Ans. 3π

5. Vertical plane $zx + y = z$, coordinate planes, top plane $z = 1 + y$.

Hint: $z = f(x, y) = 1 + y$.

Limits: $y : 0$ to $2 - 2x$, $x : 0$ to 1 .

Ans. $\frac{5}{3}$

7.12 — HIGHER ENGINEERING MATHEMATICS—II

6. Above the square with vertices at $(0, 0)$, $(2, 0)$, $(0, 2)$, $(2, 2)$ and under the plane $z = 8 - x + y$.

Ans. 32

7. Above the triangle with vertices $(0, 0)$, $(2, 0)$ and $(2, 1)$ and below the paraboloid $z = 24 - x^2 - y^2$

Ans. $\frac{131}{6}$

8. Under the surface $z = y(x + 2)$ and over the area bounded by $x + y = 0$, $y = 1$, $y = \sqrt{x}$.

Ans. 9/8

9. Paraboloid $z = 4 - x^2 - y^2$ and the xy -plane.

Hint: $z = f(x, y) = 4 - x^2 - y^2$;
 $R : x^2 + y^2 = 4$.

Limits: $y = \pm\sqrt{4 - x^2}$ and $x : \pm 2$.

Ans. 8π

10. $z = 0$, $z = x + y + 2$ and inside the cylinder $x^2 + y^2 = 16$.

Hint: $z = f(x, y) = x + y + z$.

Limits: $y : 0$ to $\sqrt{16 - x^2}$, $x : 0$ to 4 .

Ans. $(\frac{128}{3} + 8\pi)$

11. Above by paraboloid $x^2 + 4y^2 = z$, below by plane $z = 0$ and laterally by the cylinder $y^2 = x$ and $x^2 = y$.

Hint: $z = f(x, y) = x^2 + 4y^2$.

Limits: $y : x^2$ to $\sqrt{x}$, $x : 0$ to 1 .

Ans. 3/7

12. Find the volume of a sphere of radius b .

Hint: $f(x, y) = \sqrt{b^2 - x^2 - y^2}$.

Limits: $y = \pm\sqrt{a^2 - x^2}$, $x = \pm b$.

Ans. $\frac{4}{3}\pi b^3$.

7.3 CHANGE OF ORDER OF INTEGRATION: DOUBLE INTEGRAL

As already seen, for the double integral with variable limits

$$I_D = \iint_D f(x, y) ds \quad (1)$$

The limits of integration can be fixed from a rough sketch of the domain of integration. Then (1) can be evaluated as a two-fold iterated integral using either

$$I_D = \int_{x=a}^b \int_{y=y_1(x)}^{y_2(x)} f(x, y) dy dx \quad (2)$$

or

$$I_D = \int_{y=d}^e \int_{x=x_1(y)}^{x_2(y)} f(x, y) dx dy \quad (3)$$

In each specific problem, depending upon the type of the domain D and/or the nature of integrand, choose either of the form (2) or (3) whichever is easier to evaluate. Thus in several problems, the evaluation of double integral becomes easier with the change of order of integration, which of course, changes the limits of integration also.

WORKED OUT EXAMPLES

Change the order of integration and then evaluate the following double integrals:

Example 1: $\int_0^2 \int_1^{e^x} dy dx$

Solution: Here integration is done first w.r.t. y and later w.r.t. x . So y varies from 1 to e^x while x varies from 0 to 2 . Thus the domain of integration ABE is shaded as shown in Fig. 7.17, and is bounded by the curve $y = e^x$ and the straight line $y = 1$, $x = 0$ and $x = 2$. Here $A(0, 1)$, $B(2, 1)$, $E(2, e^2)$.

Fig. 7.17

When the order of integration is changed, integrate first w.r.t. x and later w.r.t. y . For this purpose, consider a horizontal strip whose length x varies from $x = \ln y$ to $x = 2$ and width y varies from $y = 1$ to

$y = e^2$. Thus the given integral can be written with change of order of integration as follows:

$$\begin{aligned} I_D &= \int_0^2 \int_1^{e^x} dy dx = \int_1^{e^2} \int_{x=\ln y}^2 dx dy \\ &= \int_1^{e^2} (2 - \ln y) dy \\ &= (2y - y \ln y + y) \Big|_1^{e^2} = e^2 - 3 \end{aligned}$$

Example 2: $\int_{-2}^1 \int_{x^2+4x}^{3x+2} dy dx$

Solution: Since the integration is done first w.r.t. y and later w.r.t. x , the domain D of integration is bounded by the following curves: $y = x^2 + 4x$, and the straight lines $y = 3x + 2$, $x = -2$ and $x = 1$ as shown shaded in Fig. 7.18. Here $A(-2, -4)$, $B(0, 0)$, $E(1, 5)$, $F(0, 2)$, $G(-\frac{2}{3}, 0)$. Considering horizontal strip, x varies from the upper curve $x = \sqrt{4+y} - 2$ to the lower curve $x = (y-2)/3$ and then y varies from -4 to 5 . Changing the order of integration to first x and later to y , the double integral becomes

Fig. 7.18

$$\begin{aligned} \int_{-2}^1 \int_{y=x^2+4x}^{3x+2} dy dx &= \int_{-4}^5 \int_{x=\frac{y-2}{3}}^{\sqrt{y+4}-2} dx dy \\ &= \int_{-4}^5 \left[\sqrt{y+4} - 2 - \left(\frac{y-2}{3} \right) \right] dy \\ &= \left[\frac{2}{3}(y+4)^{3/2} - \frac{y^2}{6} - \frac{4}{3}y \right]_{-4}^5 = \frac{9}{2} \end{aligned}$$

EXERCISE

Change (reverse) the order of integration and then evaluate the following double integrals:

1. $\int_1^2 \int_3^4 (x+y) dx dy$.

Hint: $\int_3^4 \int_1^2 (x+y) dx dy$.

Ans. 5

2. $\int_0^1 \int_x^{\sqrt{x}} xy dy dx$

Hint: Limits: $x : y^2$ to y ; $y : 0$ to 1 .

Ans. $\frac{1}{24}$

3. $\int_0^1 \int_{x^2}^{2-x} xy dy dx$.

Hint: $D = \text{Domain} = \text{sum of two domains} = D_1 + D_2$.

Limits: $D_1 : x : 0$ to $\sqrt{y}$, $y : 0$ to 1 ; $D_2 : x : 0$ to $2-y$; $y : 1$ to 2 .

Ans. $\frac{3}{8}$

4. $\int_0^2 \int_{y^3}^{4\sqrt{2y}} y^2 dx dy$.

Hint:

Limits: $y : x^2/32$ to $x^{1/3}$; $y : 0$ to 8 .

Ans. $\frac{160}{21}$

5. $\int_0^a \int_{\frac{y^2}{a}}^{2a-y} xy dx dy$.

Hint: Domain $D = D_1 + D_2$.

Limits: $D_1 : y : 0$ to $\sqrt{ax}$, $x : 0$ to a ; $D_2 : y : 0$ to $2a-x$, $x : 0$ to $2a$.

Ans. $\frac{3a^4}{8}$

6. $\int_0^1 \int_{y^2}^{y^{1/3}} f(x, y) dx dy$.

Ans. $\int_0^1 \int_{x^3}^{\sqrt{x}} f(x, y) dy dx$

7. $\int_{-1}^2 \int_{-x}^{2-x^2} f(x, y) dy dx$.

Ans. $\int_{-2}^1 \int_{-y}^{\sqrt{2-y}} f(x, y) dx dy$
 $+ \int_1^2 \int_{-\sqrt{2-y}}^{\sqrt{2-y}} f(x, y) dx dy$

8. $\int_0^a \int_0^{\sqrt{2ay-y^2}} f(x, y) dx dy$.

Ans. $\int_0^a \int_{a-\sqrt{a^2-x^2}}^a f(x, y) dy dx$

7.14 — HIGHER ENGINEERING MATHEMATICS—II

9. $\int_0^{\sqrt{2}} \int_{-\sqrt{4-2y^2}}^{\sqrt{4-2y^2}} y \, dx \, dy.$

Hint:

Limits: $y : 0$ to $\sqrt{(4-x^2)/2}$, $x : -2$ to 2 .

Ans. $\frac{8}{3}$

10. $\int_0^a \int_{\frac{x}{a}}^{\sqrt{\frac{x}{a}}} (x^2 + y^2) \, dy \, dx.$

Hint:

Limits: $x : ay^2$ to ay ; $y : 0$ to 1 .

Ans. $\frac{a^3}{28} + \frac{a}{20}$

11. $\int_0^a \int_0^{\sqrt{a^2-x^2}} \sqrt{a^2-x^2-y^2} \, dy \, dx.$

Hint:

Limits: $x : 0$ to $\sqrt{a^2-y^2}$, $y : 0$ to a .

Ans. $\frac{\pi a^3}{6}$

12. $\int_0^{2a} \int_0^{\sqrt{2ay-y^2}} dx \, dy.$

Hint:

Limits: $y : a \pm \sqrt{a^2-x^2}$, $x : 0$ to a .

Ans. $\frac{\pi a^2}{2}$

7.4 GENERAL CHANGE OF VARIABLES IN DOUBLE INTEGRAL

In several cases, the evaluation of double integrals becomes easy when there is a change of variables.

Let D be domain in xy -plane and let x, y be the rectangular cartesian coordinates of any point P in D . Let u, v be new variables in domain D^* such that x, y and u, v are connected through the continuous functions (transformations).

$$x = g(u, v), y = h(u, v) \quad (1)$$

Then u, v are said to be curvilinear coordinates of point P^* in D^* which uniquely corresponds to P in D . Solving (1) for u and v , we get

$$u = g^*(x, y), v = h^*(x, y) \quad (2)$$

Then a given double integral in the given (old) variables x, y can be transformed to a double integral

in terms of new variables u, v as follows:

$$\iint_D f(x, y) \, dx \, dy = \iint_{D^*} F(u, v) |J| \, du \, dv \quad (3)$$

Here $f(x, y) = F(x(u, v), y(u, v)) = F(u, v)$ and J is the Jacobian (functional determinant) defined as

$$J = J\left(\frac{x, y}{u, v}\right) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix}$$

(3) is known as formula for transformation of coordinates in double integral.

WORKED OUT EXAMPLES

Example 1: Evaluate $\iint_R (x+y)^2 \, dx \, dy$ where R is region bounded by the parallelogram $x+y=0$, $x+y=2$, $3x-2y=0$, $3x-2y=3$.

Solution: By changing the variables x, y to the new variables u, v , by the substitution (transformation) $x+y=u$, $3x-2y=v$, the given parallelogram R reduces to a rectangle R^* as shown in the (Fig. 7.19):

$$\frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 3 & -2 \end{vmatrix} = -5$$

Fig. 7.19

So required Jacobian $J = \frac{\partial(x, y)}{\partial(u, v)} = -\frac{1}{5}$.

Since, $u = x+y=0$ and $u = x+y=2$, u varies from 0 to 2, while v varies from 0 to 3 since $3x-2y=v=0$, $3x-2y=v=3$. Thus the

given integral in terms of the new variables u, v is

$$\begin{aligned}\iint_R (x+y)^2 dx dy &= \iint_{R^*} u^2 \left| \frac{1}{-5} \right| du dv \\ &= \frac{1}{5} \int_0^3 \int_0^2 u^2 du dv \\ &= \frac{1}{5} \int_0^3 \frac{u^3}{3} \Big|_0^2 dv = \frac{8}{15} \cdot v \Big|_0^3 = \frac{8}{5}\end{aligned}$$

Example 2: Evaluate $\iint_R (x^2 + y^2) dx dy$ where R is the region in the first quadrant bounded by $x^2 - y^2 = a$, $x^2 - y^2 = b$, $2xy = c$, $2xy = d$, $0 < a < b$, $0 < c < d$.

Solution: Introducing $x^2 - y^2 = u$, $xy = v$, the given region R gets transformed to a rectangle R^* in the uv plane given by

$$a < u < b; \quad \frac{c}{2} < v < \frac{d}{2}$$

Since

$$\frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix} = \begin{vmatrix} 2x & -2y \\ y & x \end{vmatrix} = 2(x^2 + y^2)$$

Fig. 7.20

so that Jacobian $= J = \frac{\partial(x, y)}{\partial(u, v)} = \frac{1}{2(x^2 + y^2)}$. Thus,

$$\begin{aligned}\iint_R (x^2 + y^2) dx dy &= \iint_{R^*} (x^2 + y^2) \left| \frac{1}{2(x^2 + y^2)} \right| du dv \\ &= \int_{\frac{c}{2}}^{\frac{d}{2}} \int_a^b du dv = \frac{1}{2}(b-a) \cdot \left(\frac{d}{2} - \frac{c}{2} \right) \\ &= \frac{(b-a)(d-c)}{4}\end{aligned}$$

Fig. 7.21

Example 3: Evaluate $\iint_R e^{-(x+y)} \sin\left(\frac{\pi y}{x+y}\right) dx dy$ where R is the entire first quadrant in the xy -plane.

Solution: In the first quadrant both x and y vary from 0 to ∞ . Put $x + y = u$, $y = v$ so that $x = u - v$, $y = v$ (Fig. 7.22).

Fig. 7.22

- i. **Origin** $O(0, 0)$ in xy -plane: $0 = u - v$, $0 = v$, $u = 0$. Thus $(0, 0)$ in xy -plane corresponds to $(0, 0)$ in u, v -plane.
- ii. **x -axis:** $y = 0$ i.e., $v = 0$, so $x = u - 0 = u$ since $x \geq 0$, $u = x \geq 0$.
Thus x -axis gets transformed to u -axis ($v = 0$, $u \geq 0$)
- iii. **y -axis:** $x = 0$ so $0 = x = u - v$, so that $u = v$ since $y \geq 0$, $u = v = y \geq 0$.

Thus y -axis gets mapped to the line $u = v$ in the uv -plane.

- iv. **Any point** $x > 0$, $y > 0$.

Since $v = y > 0$ and $u - v = x > 0$ so that $u > v$.

Thus any point $(x > 0, y > 0)$ corresponds to (u, v) where $u > v > 0$. Thus the entire first quadrant in xy -plane gets transformed to the region between u -axis and the line $u = v$.

7.16 — HIGHER ENGINEERING MATHEMATICS—II

Thus

$$\begin{aligned} I &= \iint_R e^{-(x+y)} \sin\left(\frac{\pi y}{x+y}\right) dx dy \\ &= \int_0^\infty \int_0^\infty e^{-(x+y)} \sin\left(\frac{\pi y}{x+y}\right) dy dx \\ &= \int_0^\infty \int_{v=0}^u e^{-u} \sin\left(\frac{\pi v}{u}\right) \cdot 1 \cdot dv du \end{aligned}$$

since

$$\begin{aligned} \text{the Jacobian } J &= \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1 & -1 \\ 0 & 1 \end{vmatrix} = 1 \\ &= \int_0^\infty e^{-u} \cdot \left(-\cos \frac{\pi v}{u}\right) \cdot \frac{u}{\pi} \cdot \frac{u}{\pi} \Big|_0^u du \\ &= \int_0^\infty -\frac{u}{\pi} e^{-u} \cdot (-1 - 1) du \\ &= \frac{2}{\pi} \int_0^\infty u e^{-u} du \\ &= \frac{2}{\pi} \left[\frac{u e^{-4}}{-1} - e^{-u} \right]_0^\infty = \frac{2}{\pi} \end{aligned}$$

Example 4: $\int_0^1 \int_0^x \sqrt{x^2 + y^2} dx dy$

Solution: Region of integration R is the triangle bounded by $y = 0$, $x = 1$ and $y = x$ (Fig. 7.23).

Fig. 7.23

Put $x = u$, $y = uv$

$$\begin{aligned} J = \text{Jacobian} &= \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} \\ &= \begin{vmatrix} 1 & 0 \\ v & u \end{vmatrix} = u \end{aligned}$$

In the given region R , x : varies from 0 to 1 while y varies from 0 to x . Since $u = x$, so u varies from 0 to 1. Similarly since $0 \leq y = uv \leq x = u$ so v varies from 0 to 1. Thus,

$$\begin{aligned} &\int_0^1 \int_0^x \sqrt{x^2 + y^2} dx dy \\ &= \int_0^1 \int_0^1 u \sqrt{1 + v^2} u dv du = \frac{1}{3} \int_0^1 \sqrt{1 + v^2} dv \\ &= \frac{1}{3} \left[\frac{v \sqrt{1 + v^2}}{2} + \frac{1}{2} \sinh^{-1} v \right]_0^1 \\ &= \frac{1}{3} \left[\frac{\sqrt{2}}{2} + \frac{1}{2} \sinh^{-1} 1 \right] \end{aligned}$$

EXERCISE

Evaluate the following integrals by changing the variables:

1. $\iint_D (y - x) dx dy$; D : region in xy -plane bounded by the straight lines $y = x + 1$, $y = x - 3$, $y = -\frac{1}{3}x + \frac{7}{3}$, $y = -\frac{1}{3}x + 5$.

Hint: Put $u = y - x$, $v = y + \frac{1}{3}x$; $J = -\frac{3}{4}$
 D^* : Rectangle: $-3 \leq u \leq 1$, $\frac{7}{3} \leq v \leq 5$.

Ans. -8

2. $\iint_R (x + y)^2 dx dy$; R : parallelogram in the xy -plane with vertices $(1, 0)$, $(3, 1)$, $(2, 2)$, $(0, 1)$.

Hint: Put $u = x + y$, $v = x - 2y$, $J = -\frac{1}{3}$
 D^* : Rectangle: $-2 \leq u \leq 1$, $1 \leq v \leq 4$.

Ans. 21

3. $\int_0^1 \int_0^{1-x} e^{\frac{y}{x+y}} dy dx$.

Hint: Put $u = x + y$, $uv = y$.

Ans. $\frac{(e-1)}{2}$

4. $\iint_D [xy(1 - x - y)]^{\frac{1}{2}} dx dy$; D : is region bounded by the triangle with the sides $x = 0$, $y = 0$, $x + y = 1$.

Hint: Put $u = x + y$, $uv = y$, $J = u$,
 D^* : square $0 \leq u \leq 1$, $0 \leq v \leq 1$.

Ans. $\frac{2\pi}{105}$

5. $\iint_R (x-y)^4 e^{x+y} dx dy$; R : square with vertices at $(1, 0)$, $(2, 1)$, $(1, 2)$, $(0, 1)$.

Hint: Since the square is bounded by the lines $x+y=1$, $x+y=3$; $x-y=1$, $x-y=-1$, put $x+y=u$, $x-y=v$; $J=-\frac{1}{2}$, D^* : rectangle: $1 \leq u \leq 3$, $-1 \leq v \leq 1$.

Ans. $\frac{(e^3-e)}{5}$

6. $\iint_R xy dx dy$; R : Region in the first quadrant bounded by the hyperbolas $x^2 - y^2 = a^2$ and $x^2 - y^2 = b^2$ and the circles $x^2 + y^2 = c^2$, $x^2 + y^2 = d^2$ with $0 < a < b < c < d$.

Hint: Put $x^2 - y^2 = u$, $x^2 + y^2 = v$; $J = 8xy$, R^* : rectangle $a^2 \leq u \leq b^2$, $c^2 \leq v \leq d^2$.

Ans. $\frac{1}{8}(b^2 - a^2)(d^2 - c^2)$

7. Find the area of the curvilinear quadrilateral bounded by the four parabolas $y^2 = ax$, $y^2 = bx$, $x^2 = cy$, $x^2 = dy$.

Hint: Put $y^2 = u^3 x$, $x^2 = b^3 y$; $J = -3u^2 v^2$. Limits: $u : a^{\frac{1}{3}}$ to $b^{\frac{1}{3}}$; $v : c^{\frac{1}{3}}$ to $d^{\frac{1}{3}}$.

Ans. $\frac{(b-a)(d-c)}{3}$

8. $\iint_D e^{(x-y)/(x+y)} dx dy$; D : triangle bounded by $y=0$, $x=1$ and $y=x$. Use $x=u-uv$, $y=uv$ to transform the double integrals.

Ans. $\frac{(e^2-1)}{4e}$

9. $\int_0^e \int_{\alpha x}^{\beta x} f(x, y) dy dx$.

Ans. $\int_{\frac{\beta}{1+\beta}}^{\frac{\beta}{1+\alpha}} \int_0^{\frac{e}{1-v}} f(u-uv, uv) u du dv$

10. $\int_0^c \int_0^b f(x, y) dy dx$.

Ans. $\int_0^{\frac{b}{b+c}} \int_0^{\frac{c}{1-v}} f(u-uv, uv) u du dv + \int_{\frac{b}{b+c}}^{\frac{b}{b+c}} \int_0^{\frac{b}{v}} f(u-uv, uv) u du dv$

11. $\int_0^\infty \int_0^\infty \frac{x^2+y^2}{1+(x^2-y^2)^2} e^{-2xy} dx dy$.

Hint: Use the substitution: $u = x^2 - y^2$, $v = 2xy$.

Ans. $\frac{\pi}{4}$

12. Evaluate $\iint_R (x^2 + y^2) dx dy$ where R is the region shown in Fig. 7.24.

Fig. 7.24

Hint: Use $x+y=u$, $x-y=v$, so that $x = \frac{1}{2}(u+v)$, $y = \frac{1}{2}(u-v)$, $J = -\frac{1}{2}$, $0 \leq u \leq 2$, $0 \leq v \leq 2$.

Ans. $\frac{8}{3}$

Change of Variables: Cartesian to Polar Coordinates

Double Integrals in Polar Coordinates

For a double integral in cartesian coordinates x, y , the change of variables to polar coordinates r, θ can be done through the transformation

$$x = r \cos \theta, y = r \sin \theta$$

(i.e., $u = r$, $v = \theta$ in general change of variables.)

The Jacobian in this case is

$$J = J \left(\begin{matrix} x, y \\ r, \theta \end{matrix} \right) = \frac{\partial(x, y)}{\partial(r, \theta)} = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} \end{vmatrix} = \begin{vmatrix} \cos \theta & -r \sin \theta \\ \sin \theta & r \cos \theta \end{vmatrix} = r(\cos^2 \theta + \sin^2 \theta) = r$$

Thus the double integral in cartesian coordinates x, y gets transformed to double integral in polar coordinates as follows:

$$\iint_D f(x, y) dx dy = \iint_{D^*} f(r \cos \theta, r \sin \theta) |r| dr d\theta = \int_{\theta=\alpha}^{\beta} \int_{r=\phi_1(\theta)}^{\phi_2(\theta)} F(r, \theta) r dr d\theta$$

where $F(r, \theta) = f(r \cos \theta, r \sin \theta) = f(x, y)$ and D^* is the corresponding domain in polar coordinates. Area in polar coordinates

$$A = \iint_D ds = \iint_D dx dy = \iint_{D^*} r dr d\theta$$

WORKED OUT EXAMPLES

Area, Mass, Centroid and Moments of Inertia: In Polar Coordinates

Example 1: Evaluate, $I = \int_0^{2\pi} \int_{a \sin \theta}^a r \, dr \, d\theta$.

Solution:

$$\begin{aligned} I &= \int_{\theta=0}^{2\pi} \int_{r=a \sin \theta}^a r \, dr \, d\theta \\ I &= \int_0^{2\pi} \left[\frac{r^2}{2} \right]_{a \sin \theta}^a d\theta = \frac{1}{2} \int_0^{2\pi} (a^2 - a^2 \sin^2 \theta) d\theta \\ &= \frac{a^2}{2} \int_0^{2\pi} \cos^2 \theta \, d\theta = \frac{a^2}{2} \int_0^{2\pi} \left(\frac{1 + \cos 2\theta}{2} \right) d\theta \\ I &= \frac{a^2}{4} [\theta - \sin 2\theta]_0^{2\pi} = \frac{\pi a^2}{2} \end{aligned}$$

Example 2: $I = \int_0^\infty \int_0^\infty e^{-(x^2+y^2)} dx \, dy$.

Solution: Using polar coordinates

$$I = \int_0^{\frac{\pi}{2}} \int_0^\infty e^{-r^2} r \, dr \, d\theta$$

Fig. 7.25

since the first quadrant in xy -plane ($x : 0$ to ∞ and $y : 0$ to ∞) is covered when $r : 0$ to ∞ and $\theta = 0$ to $\pi/2$ (refer Fig. 7.25)

$$I = \frac{\pi}{2} \frac{1}{2} \int_0^\infty e^{-r^2} d(r^2) = \frac{\pi}{4} \left[\frac{e^{-r^2}}{-1} \right]_0^\infty = \frac{\pi}{4}$$

Example 3: Calculate the area which is inside the cardioid $r = 2(1 + \cos \theta)$ and outside the circle $r = 2$.

Solution: $r = 2$ is a circle centred at origin and of radius 2. The shaded area in Fig. 7.26 is the region R which is outside the given circle and inside the

cardioid. So r varies from the circle 2 to the cardioid $2(1 + \cos \theta)$, while θ varies from $-\pi/2$ to $\pi/2$. Since R is symmetric about x -axis, the required area A of the region R is given by

Fig. 7.26

$$\begin{aligned} A &= \iint_R dA = \int_{-\pi/2}^{\pi/2} \int_{r=2}^{2(1+\cos \theta)} r \, dr \, d\theta \\ &= 2 \int_0^{\pi/2} \int_2^{2(1+\cos \theta)} r \, dr \, d\theta = 2 \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_2^{2(1+\cos \theta)} d\theta \\ &= 4 \int_0^{\pi/2} (2 \cos \theta + \cos^2 \theta) d\theta \\ &= 4 \left[2 \sin \theta + \frac{1}{2} \theta + \frac{1}{4} \sin 2\theta \right]_0^{\pi/2} = \pi + 8. \end{aligned}$$

Example 4: Find the centroid of the area inside $\rho = \sin \theta$ and outside $\rho = 1 - \cos \theta$.

Solution: In the required region R , shaded in Fig. 7.27, r varies from the top curve the circle $r = \sin \theta$ to the lower curve the cardioid $r = 1 - \cos \theta$; while θ varies from 0 to $\pi/2$. Thus,

Fig. 7.27

$$\text{Area of region } R = A = \iint_R dA =$$

$$\begin{aligned} A &= \int_0^{\pi/2} \int_{r=1-\cos \theta}^{\sin \theta} r \, dr \, d\theta = \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_{1-\cos \theta}^{\sin \theta} d\theta \\ A &= \frac{1}{2} \int_0^{\pi/2} (2 \cos \theta - 1 - \cos 2\theta) d\theta = \frac{4 - \pi}{4}. \end{aligned}$$

Let the coordinates of the centroid be (x_c, y_c) . Then

$$\begin{aligned} x_c &= \frac{\iint_R x \, dA}{A} = \frac{4}{(4-\pi)} \int_0^{\frac{\pi}{2}} \int_{1-\cos\theta}^{\sin\theta} r \cos\theta \, r \, dr \, d\theta \\ &= \frac{4}{4-\pi} \int_0^{\frac{\pi}{2}} \left. \frac{r^3}{3} \right|_{1-\cos\theta}^{\sin\theta} d\theta \\ &= \frac{4}{3(4-\pi)} \cdot \int_0^{\frac{\pi}{2}} (\sin^3\theta - 1 + 3\cos\theta - 3\cos^2\theta \\ &\quad + \cos^3\theta) \cos\theta \, d\theta \end{aligned}$$

$$x_c = (15\pi - 44)/48$$

$$\begin{aligned} y_c &= \frac{\iint_R y \, dA}{A} = \frac{4}{4-\pi} \int_0^{\frac{\pi}{2}} \int_{1-\cos\theta}^{\sin\theta} (r \sin\theta) r \, dr \, d\theta \\ &= \frac{4}{(4-\pi)} \cdot \frac{1}{3} \int_0^{\frac{\pi}{2}} (\sin^3\theta - 1 + 3\cos\theta - 3\cos^2\theta \\ &\quad + \cos^3\theta) \sin\theta \, d\theta \\ y_c &= \frac{3\pi - 4}{12(4-\pi)}. \end{aligned}$$

Example 5: Determine the moments of Inertia I_x , I_y and I_0 of the plane region in the first quadrant which is inside the circle $r = 4a \cos \theta$ and outside the circle $r = 2a$.

Solution: For the shaded region R shown in Fig. 7.28, r varies from (inside) curve $r = 2a$ to the (outside) curve $r = 4a \cos \theta$, while θ varies from 0 to $\frac{\pi}{3}$ (since $\theta = \pi/3$ is the point of intersection of the two circles in the first quadrant i.e., $2a = \rho = 4a \cos \theta$; $\cos \theta = \frac{1}{2}$ so $\theta = \frac{\pi}{3}$).

Thus area A is

$$\begin{aligned} A &= \iint_R dA = \int_0^{\frac{\pi}{3}} \int_{2a}^{4a \cos \theta} r \, dr \, d\theta \\ &= \frac{1}{2} \int_0^{\frac{\pi}{3}} [(4a \cos \theta)^2 - (2a)^2] d\theta \\ &= 2a^2 \int_0^{\frac{\pi}{3}} \left[\frac{4(1 + \cos 2\theta)}{2} - 1 \right] d\theta \\ A &= 2a^2 \frac{\pi}{3} + 4a^2 \cdot \sin \frac{2\pi}{3} = \frac{2\pi + 3\sqrt{3}}{3} a^2. \end{aligned}$$

Now

$$\begin{aligned} I_x &= \iint_R y^2 \, dA = \int_0^{\frac{\pi}{3}} \int_{2a}^{4a \cos \theta} (r \sin \theta)^2 r \, dr \, d\theta \\ &= \frac{1}{4} \int_0^{\frac{\pi}{3}} [(4a \cos \theta)^4 - (2a)^4] \sin^2 \theta \, d\theta \\ I_x &= 4a^4 \int_0^{\frac{\pi}{3}} (16 \cos^4 \theta - 1) \sin^2 \theta \, d\theta = \frac{4\pi + 9\sqrt{3}}{6} a^4 \end{aligned}$$

Fig. 7.28

Similarly,

$$\begin{aligned} I_y &= \iint_R x^2 \, dA = \int_0^{\frac{\pi}{3}} \int_{2a}^{4a \cos \theta} (r \cos \theta)^2 r \, dr \, d\theta \\ &= \frac{1}{4} \int_0^{\frac{\pi}{3}} [(4a \cos \theta)^4 - (2a)^4] \cos^2 \theta \, d\theta \\ I_y &= 4a^4 \int_0^{\frac{\pi}{3}} (16 \cos^6 \theta - \cos^2 \theta) d\theta = \frac{12\pi + 11\sqrt{3}}{2} a^4 \end{aligned}$$

Then,

$$I_0 = I_x + I_y = \frac{20\pi + 21\sqrt{3}}{3} a^4$$

EXERCISE

Area, mass centroid and moments of inertia: In polar coordinates

Using polar coordinates, evaluate the following double integrals:

$$1. \int_{\frac{b}{2}}^b \int_0^{\frac{\pi}{2}} \rho \, d\theta \, d\rho.$$

$$\text{Ans. } \frac{3\pi b^2}{16}$$

$$2. \int_0^{\pi} \int_{2 \sin \theta}^{4 \sin \theta} r^3 \, dr \, d\theta.$$

$$\text{Ans. } \frac{45\pi}{2}$$

$$3. \int_0^{\pi} \int_0^{\cos \theta} \rho \sin \theta \, d\rho \, d\theta.$$

$$\text{Ans. } \frac{1}{3}$$

7.20 — HIGHER ENGINEERING MATHEMATICS—II

4. $\int_0^{2a} \int_0^{\sqrt{2ax-x^2}} dy dx.$

Hint: Limits: $r : 0$ to $2a \cos \theta$, $\theta : 0$ to $\frac{\pi}{2}$.

Ans. $\frac{\pi a^2}{2}$

5. $\int_0^a \int_0^{\sqrt{a^2-y^2}} (x^2 + y^2) dx dy.$

Hint: Limits: $r : 0$ to a , $\theta : 0$ to $\frac{\pi}{2}$.

Ans. $\frac{\pi a^4}{8}$

6. $\int_0^a \int_{\sqrt{ax-x^2}}^{\sqrt{a^2-x^2}} \frac{dy dx}{\sqrt{a^2-x^2-y^2}}.$

Ans. a

7. $\iint_R \frac{x^2 y^2 dx dy}{(x^2 + y^2)^2}$; R : annulus region between the circles $x^2 + y^2 = a^2$ and $x^2 + y^2 = b^2$, with $b > a$.

Ans. $\frac{\pi(b^4 - a^4)}{16}$

8. $\iint_D xy(x^2 + y^2)^{\frac{n}{2}} dx, dy$; D is the region in the first quadrant bounded by the circle $x^2 + y^2 = 4$. Assume that $n + 3 > 0$.

Ans. $\frac{2^{n+3}}{n+4}$

9. Evaluate $\int_0^\pi \int_0^a r^3 \sin \theta \cos \theta dr d\theta$ by transforming it into cartesian coordinates.

Hint: $\int_{-a}^a \int_0^{\sqrt{a^2-x^2}} xy dy dx = 0$.

Ans. 0

10. Find the area inside the circle $\rho = 4 \sin \theta$ and outside the Lemniscate $\rho^2 = 8 \cos 2\theta$.

Hint: $A = A_1 + A_2$.

Limit:

$A_1 : \rho : 2\sqrt{2 \cos 2\theta}$ to $4 \sin \theta$; $\theta : \frac{\pi}{6}$ to $\frac{\pi}{4}$

$A_2 : \rho : 0$ to $4 \sin \theta$; $\theta : \frac{\pi}{4}$ to $\frac{\pi}{2}$

Ans. $\left(\frac{8\pi}{3} + 4\sqrt{3} - 4\right)$

11. Compute the area of a loop of the curve $r = a \sin 2\theta$.

Ans. $\frac{\pi a^2}{8}$

12. Find the entire area bounded by the lemniscate $\rho^2 = a^2 \cos 2\theta$.

Ans. a^2

13. Find the centre of gravity of the area of the cardioid $r = a(1 \pm \cos \theta)$.

Hint: Solve $r = a(1 + \cos \theta)$, results for $r = a(1 - \cos \theta)$ is exactly similar. $\bar{y} = 0$ due to symmetry.

Limit: $r = 0$ to $a(1 - \cos \theta)$; $\theta : -\pi$ to π .

Ans. $\left(\pm \frac{5a}{6}, 0\right)$

14. Determine I_x for the region: $0 \leq y \leq \sqrt{1-x^2}$, $0 \leq x \leq 1$ and $f(x, y) = 1$ density mass.

Hint: Use polar coordinates, $0 \leq r \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$.

Ans. $I_x = \frac{\pi}{16}$

15. Find the moment of inertia, about the y-axis of the area enclosed by the cardioid

$$r = a(1 - \cos \theta)$$

Hint: Put $x = r \cos \theta$, Jacobian : r .

Limit: $r : 0$ to $a(1 - \cos \theta)$, $\theta : 0$ to 2π . Use the reduction formula

$$\int_0^{2\pi} \cos^n \theta d\theta = \frac{\cos^{n-1} \theta \sin \theta}{n} \Big|_0^{2\pi} + \frac{n-1}{n} \int_0^{2\pi} \cos^{n-2} \theta d\theta$$

for $n = 2, 3, 4, 5, 6$.

Ans. $I_y = \frac{49\pi a^4}{32}$

16. Find the area of the cardioid $r = a(1 + \cos \theta)$.

Hint: Limits: $r : 0$ to $a(1 + \cos \theta)$, $\theta : -\pi$ to π

Ans. $\frac{3\pi a^2}{2}$

17. Find the area which is inside the circle $r = 3a \cos \theta$ and outside the cardioid $r = a(1 + \cos \theta)$

Hint: Limits: $r : a(1 + \cos \theta)$ to $3a \cos \theta$, $\theta : -\frac{\pi}{3}$ to $\frac{\pi}{3}$.

Ans. πa^2

18. Find the centroid of a loop of the lemniscate $r^2 = a^2 \cos 2\theta$.

Hint: Limits: $r : 0$ to $a\sqrt{\cos 2\theta}$, $\theta : -\frac{\pi}{4}$ to $\frac{\pi}{4}$ (one loop) use polar coordinates (put $x = r \cos \theta$; $J = r$).

Ans. $x = \frac{\pi a \sqrt{2}}{8}$, centroid lies on the initial line.

7.5 TRIPLE INTEGRALS

Triple integral is a generalization of a double integral. Let V be a given three-dimensional domain in space, bounded by a closed surface S . Let $f(x, y, z)$ be a continuous function in V of the rectangular coordinates x, y, z .

Divide V into subdomains Δv_i . Let $f(P_i)$ be the value of f at an arbitrary point P_i of Δv_i . Then a triple integral of f over the domain V , denoted by $\iiint_V f(P) dV$, is defined as

$$\lim_{\Delta v_i \rightarrow 0} \sum f(P_i) \Delta v_i = \iiint_V f(P) dV = \iiint_V f(x, y, z) dx dy dz \quad (1)$$

However, the triple integral is seldom evaluated directly from its definition (1) as a limit of a sum.

Evaluation of a Triple Integral

Regular three-dimensional domain

V is said to be a regular three-dimensional domain if (i) every straight line parallel to z -axis and drawn through an interior (i.e., not lying on the boundary S) point of V cuts the surface S at two points (ii) entire V is projected on the xy -plane into a regular two-dimensional domain D .

Examples: Parallelopiped, ellipsoid, tetrahedron.

Let the equations of the surfaces bounding a regular domain V below and above be $z = z_1(x, y)$ and $z = z_2(x, y)$ respectively (see Fig. 7.29).

Let the projection D of V onto xy -plane be bounded by the curves $y = y_1(x)$ and $y = y_2(x)$ and $x = a, x = b$.

Then the three fold integral I_V of a continuous function $f(x, y, z)$ over a regular domain V is

Fig. 7.29

defined as

$$I_V = \int_{x=a}^{x=b} \left[\int_{y=y_1(x)}^{y=y_2(x)} \left\{ \int_{z=z_1(x,y)}^{z=z_2(x,y)} f(x, y, z) dz \right\} dy \right] dx$$

Here the limits of integration are chosen to cover the domain V by varying z from lower surface $z = z_1(x, y)$ to the upper surface $z = z_2(x, y)$ and covering the projection D by varying y from $y_1(x)$ to $y_2(x)$ and x from a to b .

In the three-fold iterated integral, integration is done first with respect to z (i.e., within the braces) with the substitution of limits for z , the next integration is carried with respect to y (i.e., within the square brackets). This results in an integrand which is a function of x alone which is then integrated w.r.t. x between a and b .

Note: When V is projected on to xz -plane or yz -plane instead of xy -plane, then the order of integration and the limits are to be rewritten appropriately.

Applications of Triple Integrals

Volume

Volume of a solid contained in the domain V is given by the triple integral (1) with $f(x, y, z) = 1$ i.e., volume $= \iiint_V dx dy dz$.

Mass

If $\gamma(x, y, z) > 0$ is the volume density (mass/unit volume) of distribution of mass over V then the triple

7.22 — HIGHER ENGINEERING MATHEMATICS—II

integral (1) gives the entire mass contained in V

$$\text{Mass} = \iiint_V \gamma(x, y, z) dx dy dz$$

Moment of inertia of a solid

The moment of inertia of a solid relative to the z -axis is

$$I_{zz} = \iiint_V (x^2 + y^2) \gamma(x, y, z) dx dy dz$$

where $\gamma(x, y, z)$ is the density of the substance. Similarly, moment of inertia of a solid relative to x -axis and y -axis are respectively

$$I_{xx} = \iiint_V (y^2 + z^2) \gamma \cdot dx dy dz$$

$$I_{yy} = \iiint_V (x^2 + z^2) \gamma dx dy dz$$

Centre of gravity of a solid: (x_c, y_c, z_c)

$$x_c = \frac{\iiint_V x \gamma dV}{\iiint_V \gamma dV}, y_c = \frac{\iiint_V y \gamma dV}{\iiint_V \gamma dV}$$

$$z_c = \frac{\iiint_V z \gamma dV}{\iiint_V \gamma dV}.$$

WORKED OUT EXAMPLES

Example 1: Evaluate

$$I_V = \int_0^1 \int_0^x \int_0^{x+y} (x + y + z) dz dy dx$$

Solution: First integrating with respect to z , we get

$$\begin{aligned} I_V &= \int_0^1 \int_0^x (x + y)z + \frac{z^2}{2} \Big|_0^{x+y} dy dx \\ &= \frac{3}{2} \int_0^1 \int_0^x (x + y)^2 dy dx \\ &= \frac{3}{2} \int_0^1 \int_0^x (x^2 + y^2 + 2xy) dy dx \end{aligned}$$

Integrating now with respect to y , we get

$$I_V = \frac{3}{2} \int_0^1 x^2 y + \frac{y^3}{3} + xy^2 \Big|_0^x dx = \frac{7}{2} \int_0^1 x^3 dx$$

Finally integrating with respect to x

$$I_V = \frac{7}{2} \frac{x^4}{4} \Big|_0^1 = \frac{7}{8}$$

Example 2: Find the volume bounded by the elliptic paraboloids $z = x^2 + 9y^2$ and $z = 18 - x^2 - 9y^2$

Solution: The two surfaces intersect on the elliptic cylinder $x^2 + 9y^2 = z = 18 - x^2 - 9y^2$ i.e., $x^2 + 9y^2 = 9$. The projection of this volume onto xy -plane is the plane region D enclosed by ellipse having the same equation $\frac{x^2}{3^2} + \frac{y^2}{1^2} = 1^2$ as shown in (Fig. 7.30).

Fig. 7.30

This volume can be covered as follows:

z : from $z_1(x, y) = x^2 + 9y^2$ to

$z_2(x, y) = 18 - x^2 - 9y^2$

y : from $y_1(x) = -\sqrt{\frac{9-x^2}{9}}$ to $y_2(x) = \sqrt{\frac{9-x^2}{9}}$

x : from -3 to 3

Thus the volume V bounded by the elliptic paraboloids

$$\begin{aligned}
 V &= \int_{-3}^3 \int_{y_1(x)}^{y_2(x)} \int_{z_1(x,y)}^{z_2(x,y)} dz \, dy \, dx \\
 &= \int_{-3}^3 \int_{y_1(x)}^{y_2(x)} [(18 - x^2 - 9y^2) - (x^2 + 9y^2)] \, dy \, dx \\
 &= 2 \int_{-3}^3 \int_{y_1(x)}^{y_2(x)} (9 - x^2 - 9y^2) \, dy \, dx \\
 &= 2 \int_{-3}^3 (9y - x^2y - 3y^3) \Big|_{-\sqrt{\frac{9-x^2}{9}}}^{\sqrt{\frac{9-x^2}{9}}} dx \\
 &= \frac{8}{9} \int_{-3}^3 (9 - x^2)^{\frac{3}{2}} dx \\
 &= 72 \int_0^{\pi} \sin^4 \theta \, d\theta \quad \text{where } x = 3 \cos \theta \\
 &= 72 \int_0^{\pi} \left(\frac{1 - \cos 2\theta}{2} \right)^2 d\theta = 27\pi
 \end{aligned}$$

Example 3: Find the total mass of the region in the cube $0 \leq x \leq 1, 0 \leq y \leq 1, 0 \leq z \leq 1$ with density at any point given by xyz .

Solution:

$$\begin{aligned}
 \text{Mass} &= \int_0^1 \int_0^1 \int_0^1 xyz \, dx \, dy \, dz \\
 &= \int_0^1 \int_0^1 \frac{x^2}{2} yz \Big|_0^1 dy \, dz \\
 &= \frac{1}{2} \int_0^1 z \frac{y^2}{2} \Big|_0^1 dz = \frac{1}{4} \int_0^1 z \, dz \\
 &= \frac{1}{4} \frac{z^2}{2} \Big|_0^1 = \frac{1}{8}
 \end{aligned}$$

Example 4: Find the mass, centroid of the tetrahedron bounded by the coordinate planes and the plane $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$.

Solution: Yet ρ be the constant density of the substance (mass/unit volume). Mass M in the

tetrahedron $= \iiint_V \rho \, dx \, dy \, dz$ (refer Fig. 7.31).

$$\begin{aligned}
 M &= \rho \int_{x=0}^a \int_{y=0}^{b(1-\frac{x}{a})} \int_{z=0}^{c(1-\frac{x}{a}-\frac{y}{b})} dz \, dy \, dx \\
 &= \rho \int_0^a \int_0^{b(1-\frac{x}{a})} c \left(1 - \frac{x}{a} - \frac{y}{b} \right) dy \, dx \\
 &= \rho c \int_0^a \left[\left(1 - \frac{x}{a} \right) y - \frac{y^2}{2b} \right] \Big|_0^{b(1-\frac{x}{a})} dx \\
 &= \frac{cb\rho}{2} \int_0^a \left(1 - \frac{x}{a} \right)^2 dx = \frac{\rho bc}{2} \cdot \frac{a}{3} = \frac{\rho abc}{6}
 \end{aligned}$$

Fig. 7.31

Let (x_c, y_c, z_c) be the coordinates of the centroid. Then,

$$\begin{aligned}
 M \cdot x_c &= \rho \int_0^a \int_0^{b(1-\frac{x}{a})} \int_0^{c(1-\frac{x}{a}-\frac{y}{b})} x \, dz \, dy \, dx \\
 &= \rho \int_0^a \int_0^{b(1-\frac{x}{a})} cx \left(1 - \frac{x}{a} - \frac{y}{b} \right) dy \, dx \\
 &= c\rho \int_0^a \left[x \left(1 - \frac{x}{a} \right) y - \frac{xy^2}{2b} \right] \Big|_0^{b(1-\frac{x}{a})} dx \\
 &= c\rho b \int_0^a x \left(1 - \frac{x}{a} \right)^2 dx = \rho bc \cdot \frac{a^2}{12} \\
 x_c &= \frac{\rho a^2 bc}{12} \cdot \frac{6}{\rho abc} = \frac{a}{4}
 \end{aligned}$$

Similarly, $y_c = \frac{b}{4}, \quad z_c = \frac{c}{4}.$

EXERCISE

Evaluate the following triple integrals:

$$1. \int_0^2 \int_1^z \int_0^{yz} xyz \, dx \, dy \, dz.$$

Ans. $\frac{7}{2}$

7.24 — HIGHER ENGINEERING MATHEMATICS—II

$$2. \int_1^2 y \, dy \int_y^{y^2} dx \int_0^{\ln x} e^z \, dz = \int_1^2 \int_y^{y^2} \int_0^{\ln x} e^z \, dz \, dx \, dy.$$

$$\text{Ans. } \frac{47}{24}$$

$$3. \int_0^a \int_0^x \int_0^{y+x} e^{x+y+z} \, dz \, dy \, dx.$$

7.6 GENERAL CHANGE OF VARIABLES IN A TRIPLE INTEGRAL

Let the functions $x = f(u, v, w)$, $y = g(u, v, w)$ and $z = h(u, v, w)$ be the transformations from cartesian coordinates x, y, z to the curvilinear coordinates u, v, w . Then the Jacobian $J \left(\frac{x, y, z}{u, v, w} \right)$ is given

by the 3rd order determinant.

$$J = J \left(\begin{matrix} x, y, z \\ u, v, w \end{matrix} \right) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix}.$$

Let $F(x, y, z)$ be a continuous function defined in a domain V in the xyz coordinate system. Then a triple integral in cartesian coordinates x, y, z can be transformed to a triple integral in the curvilinear coordinates u, v, w as follows:

$$\iiint_V F(x, y, z) dx dy dz = \iiint_{V^*} F^*(u, v, w) \times |J| du dv dw$$

where $F^*(u, v, w) = F(f(u, v, w), g(u, v, w), h(u, v, w))$ and V^* is the corresponding domain in the curvilinear coordinates u, v, w .

Triple Integral in Cylindrical Coordinates

Cylindrical coordinates ρ, θ, z are particularly useful in problems of solids having axis of symmetry. The transformation of cartesian coordinates x, y, z in terms of cylindrical coordinates ρ, θ, z are given by $x = \rho \cos \theta, y = \rho \sin \theta, z = z (\rho = u, \theta = v, z = w)$ so that the Jacobian is given by

$$J = J \left(\begin{matrix} x, y, z \\ \rho, \theta, z \end{matrix} \right) = \begin{vmatrix} \cos \theta & -\rho \sin \theta & 0 \\ \sin \theta & \rho \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = \rho$$

Thus,

$$\begin{aligned} \iiint_V F(x, y, z) dx dy dz \\ = \iiint_{V^*} F^*(\rho, \theta, z) |\rho| d\rho d\theta dz \end{aligned}$$

where $F(x, y, z) = F(\rho \cos \theta, \rho \sin \theta, z)$
 $= F^*(\rho, \theta, z)$

Triple Integral in Spherical Coordinates

In problems having symmetry with respect to a point 0 (generally the origin), it would be convenient to use spherical coordinates with this point chosen as origin.

Coordinate transformations from x, y, z to the spherical coordinates ρ, θ, ϕ are given by $x = \rho \sin \theta \cos \phi, y = \rho \sin \theta \sin \phi, z = \rho \cos \theta$ (i.e., $u = \rho, v = \theta, w = \phi$) so that the Jacobian

$$\begin{aligned} J &= J \left(\begin{matrix} x, y, z \\ \rho, \theta, \phi \end{matrix} \right) \\ &= \begin{vmatrix} \sin \theta \cos \phi & \rho \cos \theta \cos \phi & -\rho \sin \theta \sin \phi \\ \sin \theta \sin \phi & \rho \cos \theta \sin \phi & \rho \sin \theta \cos \phi \\ \cos \theta & -\rho \sin \theta & 0 \end{vmatrix} = \rho^2 \sin \theta \end{aligned}$$

Thus

$$\begin{aligned} \iiint_V F(x, y, z) dx dy dz \\ = \iiint_{V^*} F^*(\rho, \theta, \phi) |\rho^2 \sin \theta| d\rho d\theta d\phi \end{aligned}$$

where $F(x, y, z) = F(\rho \sin \theta \cos \phi, \rho \sin \theta \sin \phi, \rho \cos \theta) = F^*(\rho, \theta, \phi)$.

WORKED OUT EXAMPLES

Example 1: By transforming into cylindrical coordinates evaluate the integral $\iiint (x^2 + y^2 + z^2) dx dy dz$ taken over the region $0 \leq z \leq x^2 + y^2 \leq 1$.

Solution: Introducing cylindrical polar coordinates $x = r \cos \theta, y = r \sin \theta, z = z$, the given integral becomes

$$\begin{aligned} \int_0^1 \iint_R (x^2 + y^2 + z^2) dx dy dz \\ = \int_0^1 \int_0^{2\pi} \int_0^1 (r^2 \cos^2 \theta + r^2 \sin^2 \theta + z^2) r dr d\theta dz \end{aligned}$$

where R : circular region bounded by the circle of radius one and centre at origin: $x^2 + y^2 = 1$, so that r varies from 0 to 1 and θ from 0 to 2π .

$$\begin{aligned} &= 2\pi \int_0^1 \left[\frac{r^4}{4} + \frac{r^2}{2} z^2 \right]_0^1 dz = 2\pi \int_0^1 \left(\frac{1}{4} + \frac{z^2}{2} \right) dz \\ &= 2\pi \left[\frac{z}{4} + \frac{z^3}{6} \right]_0^1 = 2\pi \left[\frac{1}{4} + \frac{1}{6} \right] = \frac{5\pi}{6} \end{aligned}$$

Example 2: Use spherical coordinates to evaluate the integral $\iiint \frac{dx dy dz}{\sqrt{x^2 + y^2 + z^2}}$ taken over the region V

7.26 — HIGHER ENGINEERING MATHEMATICS—II

in the first octant bounded by the cones $\theta = \frac{\pi}{4}$ and $\theta = \arctan z$ and the sphere $x^2 + y^2 + z^2 = 6$ (Fig. 7.32).

Solution: Introducing spherical coordinate

$$x = \rho \sin \theta \cos \phi,$$

$$y = \rho \sin \theta \sin \phi$$

$$z = \rho \cos \theta$$

we have

$$\begin{aligned} \sqrt{x^2 + y^2 + z^2} \\ &= \sqrt{\rho^2 \sin^2 \theta \cos^2 \phi + \rho^2 \sin^2 \theta \sin^2 \phi + \rho^2 \cos^2 \theta} \\ &= \rho \end{aligned}$$

Jacobian = $\rho^2 \sin \theta$.

Radius of the sphere is $\sqrt{6}$.

Thus the given integral in spherical coordinates is

$$\begin{aligned} I &= \iiint \frac{dx dy dz}{\sqrt{x^2 + y^2 + z^2}} \\ &= \int_0^{\frac{\pi}{2}} \int_{\frac{\pi}{4}}^{\arctan 2} \int_0^{\sqrt{6}} \frac{1}{\rho} \cdot \rho^2 \sin \theta \cdot d\rho d\theta d\phi \end{aligned}$$

since restricted to first octant, ρ varies from 0 to $\sqrt{6}$, θ : cone angle varies from $\theta_1 = \frac{\pi}{4}$ to $\theta_2 = \arctan 2$ and ϕ from 0 to $\frac{\pi}{2}$.

$$\begin{aligned} I &= 3 \int_0^{\frac{\pi}{2}} \int_{\frac{\pi}{4}}^{\arctan 2} \sin \theta d\theta d\phi \\ &= -3 \int_0^{\frac{\pi}{2}} \left(\frac{1}{\sqrt{5}} - \frac{1}{\sqrt{2}} \right) d\phi \\ &= \frac{3\pi}{2} \left(\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{5}} \right). \end{aligned}$$

Fig. 7.32

Example 3: Evaluate

$$\iiint_V xyz(x^2 + y^2 + z^2)^{\frac{n}{2}} dx dy dz$$

taken through the positive octant of the sphere $x^2 + y^2 + z^2 = b^2$ provided $n + 5 > 0$.

Solution: Since the geometry involves sphere, introduce spherical coordinates $x = \rho \sin \theta \cos \phi$, $y = \rho \sin \theta \sin \phi$, $z = \rho \cos \theta$ and the Jacobian $J = \rho^2 \sin \theta$. Substituting these transformations.

$$\begin{aligned} &\iiint_V xyz(x^2 + y^2 + z^2)^{\frac{n}{2}} dx dy dz \\ &= \int_{\phi=0}^{\frac{\pi}{2}} \int_{\theta=0}^{\frac{\pi}{2}} \int_0^b (\rho \sin \theta \cos \phi)(\rho \sin \theta \sin \phi) \times \\ &\quad \times (\rho \cos \theta) \cdot (\rho^2)^{\frac{n}{2}} \rho^2 \sin \theta d\rho d\theta d\phi \\ &= \int_0^b \rho^{n+5} d\rho \int_0^{\frac{\pi}{2}} \sin^3 \theta \cos \theta d\theta \int_0^{\frac{\pi}{2}} \cos \phi \sin \phi d\phi \\ &= \frac{\rho^{n+6}}{n+6} \Big|_0^b \cdot \frac{2}{4 \cdot 2} \cdot \frac{1 \cdot 1}{2} = \frac{b^{n+6}}{8(n+6)} \text{ provided } n + 5 > 0. \end{aligned}$$

Example 4: Find the volume of the solid surrounded by the surface $\left(\frac{x}{a}\right)^{\frac{2}{3}} + \left(\frac{y}{b}\right)^{\frac{2}{3}} + \left(\frac{z}{c}\right)^{\frac{2}{3}} = 1$.

Solution: The desired volume V of the solid is

$$V = \iiint dx dy dz$$

Here the limits of integration is not easy. Instead, by a transformation the given surface becomes a sphere as follows.

Put $\frac{x}{a} = u^3$, $\frac{y}{b} = v^3$, $\frac{z}{c} = w^3$ so that

$$\left(\frac{x}{a}\right)^{\frac{2}{3}} + \left(\frac{y}{b}\right)^{\frac{2}{3}} + \left(\frac{z}{c}\right)^{\frac{2}{3}} = u^2 + v^2 + w^2 = 1$$

which is the equation of a sphere of radius 1 and with centre at origin in the new variables u, v, w .

The Jacobian J

$$\begin{aligned} J = \frac{\partial(x, y, z)}{\partial(u, v, w)} &= \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} \\ &= \begin{vmatrix} 3au^2 & 0 & 0 \\ 0 & 3bv^2 & 0 \\ 0 & 0 & 3cw^2 \end{vmatrix} \end{aligned}$$

$$J = 27abc u^2 v^2 w^2.$$

Thus the required volume in terms of the new variables u, v, w is

$$\begin{aligned} V &= \iiint_V dx dy dz \\ &= \iiint_{V^*} 27abc u^2 v^2 w^2 du dv dw \end{aligned}$$

where V^* is sphere $u^2 + v^2 + w^2 = 1$.

To evaluate this integral, introduce again spherical coordinates

$$u = r \sin \theta \cos \phi, v = r \sin \theta \sin \phi, w = r \cos \theta$$

$$\begin{aligned} V &= 27abc \int_0^{\frac{\pi}{2}} \int_0^{\frac{\pi}{2}} \int_0^1 (r^2 \sin^2 \theta \cos^2 \phi) \times \\ &\quad \times (r^2 \sin^2 \theta \sin^2 \phi)(r^2 \cos^2 \theta)(r^2 \sin \theta) dr d\theta d\phi \end{aligned}$$

since the Jacobian $J^* = \frac{\partial(u,v,w)}{\partial(r,\theta,\phi)} = r^2 \sin \theta$ and since to describe the positive octant of the sphere, $0 \leq r \leq 1$, $0 \leq \phi \leq \frac{\pi}{2}$, $0 \leq \theta \leq \frac{\pi}{2}$.

Since all the limits are constant, V can be rewritten as

$$\begin{aligned} V &= 216abc \int_0^1 r^8 dr \int_0^{\frac{\pi}{2}} \sin^5 \theta \cos^2 \theta d\theta \\ &\quad \int_0^{\frac{\pi}{2}} \sin^2 \phi \cos^2 \phi d\phi \\ V &= 216abc \frac{r^9}{9} \Big|_0^1 \left(\frac{\pi}{16} \right) \cdot \left(\frac{8}{35.3} \right) \\ &= 216 \cdot \frac{abc}{9} \cdot \frac{\pi}{16} \cdot \frac{8}{35.3} = \frac{4abc}{35}. \end{aligned}$$

Example 5: Evaluate $\iiint \left[\frac{(1-x-y-z)}{xyz} \right]^{\frac{1}{2}} dx dy dz$ taken over the volume bounded by the planes $x=0, y=0, z=0$ and $x+y+z=1$ (Fig. 7.33).

Fig. 7.33

Solution: Put

$$x + y + z = u, y + z = uv \text{ and } z = uvw \quad (1)$$

Solving (1)

$$x = u(1-v), y = uv(1-w) \text{ and } z = uvw \quad (2)$$

The Jacobian J is

$$J = \frac{\partial(x,y,z)}{\partial(u,v,w)} = \begin{vmatrix} 1-v & -u & 0 \\ v(1-w) & u(1-w) & -uv \\ vw & uw & uv \end{vmatrix} = u^2v \quad (3)$$

Let D , the triangular region OAB be the projection of the surface on the xy -plane. Then the tetrahedral volume is covered with the following limits:

$$0 \leq z \leq 1 \quad (4)$$

$$0 \leq y \leq 1-z \quad (5)$$

$$0 \leq x \leq 1-z-y \quad (6)$$

Since $z = uvw$, from (4),

$$0 \leq uvw \leq 1 \quad (7)$$

Since $y = uv(1-w)$, from (5),

$$0 \leq uv(1-w) \leq 1-uvw$$

$$\text{or } 0 \leq uv \leq 1 \quad (8)$$

Since $x = u(1-v)$, from (6)

$$0 \leq u(1-v) \leq 1-uvw-uv(1-w)$$

$$\text{or } 0 \leq u \leq 1 \quad (9)$$

Using (9) in (7) and (8) the limits of integration for the new variables u, v, w are

$$0 \leq u \leq 1, \quad 0 \leq v \leq 1, \quad 0 \leq w \leq 1 \quad (10)$$

Using (1), (2) and (10) the given integral gets transformed to

$$\begin{aligned} I &= \int_0^1 \int_0^{1-z} \int_0^{1-z-y} \left(\frac{1-x-y-z}{xyz} \right)^{\frac{1}{2}} dx dy dz \\ &= \int_0^1 \int_0^1 \int_0^1 \left\{ \frac{(1-u)}{[u(1-v)][uv(1-w)][uvw]} \right\}^{\frac{1}{2}} \times \\ &\quad \times u^2v du dv dw \end{aligned}$$

Since all the limits are constants, this integral can be

7.28 — HIGHER ENGINEERING MATHEMATICS—II

rewritten as

$$= \int_0^1 \sqrt{u(1-u)} du \int_0^1 \frac{dv}{\sqrt{1-v}} \int_0^1 \frac{dw}{\sqrt{w(1-w)}}$$

put $u = \sin^2 \theta$, $v = \sin^2 \phi$, $w = \sin^2 t$

$$\begin{aligned} &= \int_0^{\frac{\pi}{2}} \sin \theta \cdot \cos \theta \cdot 2 \sin \theta \cos \theta d\theta \\ &\quad \cdot \int_0^{\frac{\pi}{2}} \frac{2 \sin \phi \cos \phi}{\cos \phi} d\phi \int_0^{\frac{\pi}{2}} \frac{2 \sin t \cos t}{\sin t \cos t} dt \\ &= 2 \cdot \frac{1 \cdot 1}{4 \cdot 2} \cdot \frac{\pi}{2} \cdot 2 \cdot 1 \cdot 2 \cdot \frac{\pi}{2} = \frac{\pi^2}{4}. \end{aligned}$$

Example 6: Determine the mass M of a hemisphere of radius b with centre at the origin (Fig. 7.34), if the density F of its substance at each point (x, y, z) is proportional to the distance of this point from the base i.e., $F = kz$.

Solution: Equation of sphere $x^2 + y^2 + z^2 = b^2$.
Equation of the upper part of the hemisphere

$$z = \sqrt{b^2 - x^2 - y^2}.$$

In cylindrical coordinates $x = r \cos \theta$,
 $y = r \sin \theta$ the equation of the hemisphere becomes

$$z = \sqrt{b^2 - r^2 \cos^2 \theta - r^2 \sin^2 \theta} = \sqrt{b^2 - r^2}.$$

Hence mass M is

$$M = \iiint_V (kz) r dr d\theta dz$$

Fig. 7.34

The hemisphere can be covered as follows:

z : varying from $z = 0$ to $z = \sqrt{b^2 - x^2 - y^2}$ (upper surface)

r : varying from 0 to b

θ : varying from 0 to 2π .

Thus

$$\begin{aligned} M &= \int_0^{2\pi} \left\{ \int_0^b \left(\int_0^{\sqrt{b^2 - r^2}} kz dz \right) r dr \right\} d\theta \\ &= 2\pi \int_0^b k \frac{z^2}{2} \bigg|_0^{\sqrt{b^2 - r^2}} r dr \\ &= \pi k \int_0^b (b^2 - r^2) r dr = \pi k \left[b^2 \frac{r^2}{2} - \frac{r^4}{4} \right]_0^b \\ M &= \frac{\pi k b^4}{4}. \end{aligned}$$

Example 7: Compute the mass of a sphere of radius b if the density varies inversely as the square of the distance from the centre.

Solution: Density $F(x, y, z) = \frac{k}{x^2 + y^2 + z^2}$.

$$M = \iiint_V F(x, y, z) dv$$

In spherical coordinates

$$\begin{aligned} M &= \iiint_V \frac{k}{x^2 + y^2 + z^2} dx dy dz \\ &= 8 \int_0^{\frac{\pi}{2}} \int_0^{\frac{\pi}{2}} \int_0^b \frac{k}{r^2} (r^2 \sin \theta) dr d\theta d\phi \\ &= 8kb \cdot 1 \cdot \frac{\pi}{2} = 4k\pi b. \end{aligned}$$

Example 8: Compute the moment of inertia of a right circular cylinder of altitude $2h$ and radius b , relative to the diameter of its median section with density equals to k , a constant.

Solution: Choose z -axis along the axis of the cylinder and the origin at its centre of symmetry as shown

Fig. 7.35

in Fig. 7.35. Moment of inertia of the cylinder relative to the x -axis:

$$I_{xx} = \iiint_V (y^2 + z^2)k \, dx \, dy \, dz$$

Introducing cylindrical coordinates $x = r \cos \theta$, $y = r \sin \theta$, we have

$$\begin{aligned} I_{xx} &= k \int_0^{2\pi} \int_0^b \int_{-h}^h (z^2 + r^2 \sin^2 \theta) dz \, r \, dr \, d\theta \\ &= k \int_0^{2\pi} \int_0^b \left(\frac{z^3}{3} + zr^2 \sin^2 \theta \right) \Big|_{-h}^h r \, dr \, d\theta \\ &= k \int_0^{2\pi} \int_0^b \left(\frac{2h^3}{3} + 2hr^2 \sin^2 \theta \right) r \, dr \, d\theta \\ &= k \int_0^{2\pi} \left(\frac{h^3}{3} \frac{r^2}{2} + 2h \frac{r^4}{4} \sin^2 \theta \right) \Big|_0^b d\theta \\ &= k \int_0^{2\pi} \left(\frac{h^3 b^2}{3} + \frac{hb^4}{2} \sin^2 \theta \right) d\theta \\ &= k \left[\frac{2\pi h^3 b^2}{3} + \frac{hb^4}{2} \right]. \end{aligned}$$

EXERCISE

- Find the volume of the portion of the sphere $x^2 + y^2 + z^2 = b^2$ lying inside the cylinder $x^2 + y^2 = bx$.

Hint: Use cylindrical coordinate $x = r \cos \theta$, $y = r \sin \theta$, $z = z$ then equation of sphere is $r^2 + z^2 = b^2$ and equation of cylinder is $r = b \cos \theta$.

$$\text{Volume } V = 2 \int_0^\pi \int_0^{b \cos \theta} \int_0^{\sqrt{b^2 - r^2}} r \, dz \, dr \, d\theta.$$

Ans. $\frac{2b^3(3\pi-4)}{9}$

- Evaluate $\iiint xyz \, dx \, dy \, dz$ over the positive octant of the sphere $x^2 + y^2 + z^2 = b^2$ by transforming to spherical polar coordinates.

Hint: Limits: $r : 0$ to a ; $\theta : 0$ to $\frac{\pi}{2}$, $\phi : 0$ to $\frac{\pi}{2}$

Ans. $\frac{b^6}{48}$

- Evaluate $\iiint \frac{dx \, dy \, dz}{\sqrt{(x^2 + y^2 + z^2)}}$ taken over the common region between the cone $z = x^2 + y^2$ and the cylinder $x^2 + y^2 = 1$ bounded by the plane $z = 1$ in the positive octant.

Hint: Limits:

a. In cartesian coordinates

$z : 1$ to $\sqrt{x^2 + y^2}$, $y : 0$ to $\sqrt{1 - x^2}$; $x : 0$ to 1

b. In spherical coordinates

$r : 0$ to $\sec \theta$; $\theta : 0$ to $\frac{\pi}{4}$; $\phi : 0$ to $\frac{\pi}{2}$.

Ans. $\frac{(\sqrt{2}-1)\pi}{4}$

- Evaluate $\iiint z^2 \, dx \, dy \, dz$ taken over the volume bounded by the surfaces $x^2 + y^2 = a^2$, $x^2 + y^2 = z$ and $z = 0$.

Hint: Transform into spherical coordinates.

Ans. $\frac{\pi a^8}{12}$

- Evaluate $\iiint (x^2 + y^2 + z^2)^{-1} \, dx \, dy \, dz$ taken throughout the volume of the sphere $x^2 + y^2 + z^2 = b^2$.

Hint: Limits: $r : 0$ to b , $\theta : 0$ to π , $\phi : 0$ to 2π .

Ans. $4\pi b$

- Use cylindrical coordinates, to evaluate

$$\iiint_V (x^2 + y^2) \, dx \, dy \, dz$$

taken over the region V bounded by the paraboloid $z = 9 - x^2 - y^2$ and the plane $z = 0$.

Hint: Equation of paraboloid is $z = 9 - \rho^2$ so that z varies from 0 to $9 - \rho^2$, $\rho : 0$ to 3 , $\theta : 0$ to 2π Jacobian: r , and integrand $x^2 + y^2 = \rho^2$. Thus,

$$\int_0^{2\pi} \int_0^3 \int_0^{9-\rho^2} (\rho^2)(\rho \, dz \, d\rho \, d\theta).$$

Ans. $\frac{243\pi}{2}$

- Use spherical coordinates to evaluate

$$\int_0^1 \int_0^{\sqrt{1-x^2}} \int_0^{\sqrt{1-x^2-y^2}} \frac{dx \, dy \, dz}{\sqrt{1-x^2-y^2-z^2}}$$

Ans. $\frac{\pi^2}{8}$

7.30 — HIGHER ENGINEERING MATHEMATICS—II

8. Evaluate the triple integrals taken over the tetrahedral volume enclosed by the planes $x = 0$, $y = 0$, $z = 0$ and $x + y + z = 1$.

a. $\iiint [xyz(1 - x - y - z)]^{\frac{1}{2}} dx dy dz.$

b. $\iiint (x + y + z)^2 xyz dx dy dz.$

c. $\iiint \cdot e^{(x+y+z)^3} dx dy dz.$

Hint: Use the transformation $u = x + y + z$, $uv = y + z$, $uvw = z$, so that $x = u(1 - v)$, $y = uv(1 - w)$ and $z = uvw$ with limits for $u, v, w : 0$ to 1 and Jacobian u^2v .

See Worked Out Example 5 on Page 192.

Ans. a. $\frac{\pi^2}{1920}$
b. $\frac{1}{960}$
c. $\frac{(e-1)}{6}$

9. Find the volume cut from the sphere of radius b by the cone $\phi = \alpha$. Hence deduce the volumes of the hemisphere and sphere.

Hint: Use spherical coordinates.

Limit: $r : 0$ to a ; $\theta : 0$ to 2π , $\phi : 0$ to α .

Ans. $\frac{2\pi b^3(1 - \cos \alpha)}{3}$

hemisphere volume: $(\alpha = \frac{\pi}{2}) : \frac{2\pi b^3}{3}$

sphere volume: $(\alpha = \pi) : \frac{4\pi b^3}{3}$

10. Find the mass M of the tetrahedron bounded by the coordinate planes and the plane $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ given that the density F at any point (x, y, z) is $kxyz$.

Hint: Limits: $z : 0$ to $1 - \frac{x}{a} - \frac{y}{b}$; $y : 0$ to $b(1 - \frac{x}{a})$, $x : 0$ to a .

Ans. $\frac{ka^2b^2c^2}{720}$

11. Find the mass of a solid in the form of the positive octant of the sphere $x^2 + y^2 + z^2 = 9$ given that the density at any point is $2xyz$.

Ans. 30.375

12. Find the centroid of the tetrahedron bounded by the coordinate planes and the plane $x + y + z = 1$. The density at any point is varying as its distance from the face $z = 0$.

Ans. $(\frac{1}{5}, \frac{1}{5}, \frac{2}{5})$

13. Find the centroid of the solid octant of the ellipsoid $(\frac{x}{a})^2 + (\frac{y}{b})^2 + (\frac{z}{c})^2 = 1$ if the density at any point of the solid varies as xyz .

Ans. $(\frac{16a}{35}, \frac{16b}{35}, \frac{16c}{35})$

14. Find the centre of gravity of a homogeneous solid sphere of radius b .

Hint: With cylindrical coordinates, the equation of hemisphere is $z = \sqrt{b^2 - x^2 - y^2} = \sqrt{b^2 - r^2}$ so that limits are: $z : 0$ to $\sqrt{b^2 - r^2}$; $r : 0$ to a , $\theta : 0$ to 2π .

Ans. $\bar{x} = \bar{y} = 0; \bar{z} = \frac{3b}{8}$

15. Compute the moment of inertia of a circular cone relative to the diameter of the base.

Ans. $\frac{\pi hr^2(2h^2 + 3r^2)}{60}$

Note: h is the altitude and r is the radius of the base of the cone.

16. Find the moment of inertia of a right circular cone relative to its axis.

Ans. $\frac{\pi hr^4}{10}$

17. Find the volume of the cone

$0 \leq z \leq h(a - r)/a.$

Hint: Limits: $r : 0$ to a , $\theta : 0$ to 2π .

Ans. $\frac{\pi a^2 h}{3}$

18. Find the volume and mass contained in a solid below the plane $z = 1 + y$, bounded by the coordinate planes and the vertical plane $2x + y = 2$ and having density $f(x, y, z) = x + z$.

Hint: Limits: $z : 0$ to $1 + y$, $y : 0$ to $2 - 2x$, $x : 0$ to 1 .

Ans. Volume: $\frac{5}{3}$, Mass: 2

19. Find the z -coordinate of the centroid of a uniform solid cone of height h equal to the radius of the base r (i.e., $h = r$). Also find the moment of inertia of the solid about its axis. Assume ρ to be the constant density of the solid.

Ans. Mass $M = \frac{\rho \pi h^3}{3}$

z coordinate of centroid $= \bar{z} = \frac{3h}{4}$

M.I. about z -axis: $I = \frac{\rho \pi h^5}{10} = \frac{3}{10} Mh^2$

20. Find the moment of inertia about the z -axis of the solid ellipsoid inside

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

Hint: Make the change of variables $x = ax^*$, $y = by^*$, $z = cz^*$ then equation is $x^{*2} + y^{*2} + z^{*2} = 1$ i.e., sphere of radius 1. By symmetry $\iiint x^{*2} dV^* = \iiint y^{*2} dV^* = \iiint z^{*2} dV^* = \frac{1}{3} \iiint r^{*2} dV^*$ where $r^{*2} = x^{*2} + y^{*2} + z^{*2}$.

Ans. $I = \rho abc(a^2 + b^2) \frac{4\pi}{15} = \frac{1}{5} M(a^2 + b^2)$

where $M = \text{mass} = \frac{4}{3} \pi \rho abc$.

7.7 DIRICHLET'S INTEGRAL

Dirichlet's integral is useful in the evaluation of certain double and triple integrals by expressing them in terms of beta and gamma functions which can be evaluated numerically.

Using Dirichlet integral, plane area, volume of a solid region, mass, centroid can be calculated in a simpler way.

Book work I Let D be the triangular region in the xy -plane bounded by $x \geq 0$, $y \geq 0$, $x + y \leq b$. Then prove that the double integral over D

Fig. 7.36

$$\iint_D x^p y^q dx dy = b^{p+q+2} \frac{\Gamma(p+1)\Gamma(q+1)}{\Gamma(p+q+3)}$$

Proof: Introducing $X = \frac{x}{b}$, $Y = \frac{y}{b}$ the given integral in X, Y becomes

$$\iint_D x^p y^q dx dy = \iint_{D^*} (bX)^p (bY)^q b^2 dX dY$$

* Peter Gustav Lejeune Dirichlet (1805-1859), German mathematician

where the transformed region D^* is the triangular region bounded by $X \geq 0$, $Y \geq 0$, $X + Y \leq 1$.

$$\begin{aligned} &= b^{p+q+2} \int_{X=0}^1 \int_{Y=0}^{1-X} X^p Y^q dY dX \\ &= b^{p+q+2} \int_{X=0}^1 X^p \left. \frac{Y^{q+1}}{q+1} \right|_{Y=0}^{1-X} dX \\ &= \frac{b^{p+q+2}}{q+1} \int_0^1 X^p (1-X)^{q+1} dX \\ &= \frac{b^{p+q+2}}{q+1} \cdot \beta(p+1, q+2) \text{ from the definition of } \beta \text{ function} \\ &= \frac{b^{p+q+2}}{(q+1)} \cdot \frac{\Gamma(p+1)\Gamma(q+2)}{\Gamma(p+q+3)} = \frac{b^{p+q+2}}{(q+1)} \cdot \frac{\Gamma(p+1)(q+1)\Gamma(q+1)}{\Gamma(p+q+3)} \\ &\text{since } \Gamma(q+2) = (q+1)\Gamma(q+1). \text{ Hence the result.} \end{aligned}$$

Book work II Dirichlet's integral

Let V be the solid region, tetrahedron in the first octant, bounded by the coordinate plane and the plane $x + y + z = b$. Then the triple integral taken over V .

$$\iiint_V x^p y^q z^r dx dy dz = b^{p+q+r+3} \cdot \frac{\Gamma(p+1)\Gamma(q+1)\Gamma(r+1)}{\Gamma(p+q+r+4)}$$

Proof: Introducing $X = \frac{x}{b}$, $Y = \frac{y}{b}$, $Z = \frac{z}{b}$, the region V^* in xyz -system transforms to V^* in XYZ coordinate system given by $X \geq 0$, $Y \geq 0$, $Z \geq 0$ and $X + Y + Z \leq 1$, which is a tetrahedron in the first octant. Then the triple integral T.I.

Fig. 7.37

$$\begin{aligned} \text{T.I.} &= \iiint_V x^p y^q z^r dx dy dz \\ &= \iiint_{V^*} (bX)^p (bY)^q (bZ)^r b^3 dX dY dZ \\ &= b^{p+q+r+3} \int_{X=0}^1 \int_{Y=0}^{1-X} \int_{Z=0}^{1-X-Y} X^p Y^q Z^r dZ dY dX \\ &= \frac{b^{p+q+r+3}}{r+1} \int_{X=0}^1 \int_{Y=0}^{1-X} X^p Y^q (1-X-Y)^{r+1} dY dX \end{aligned}$$

Introducing the variables $u = X + Y$ and $uv = Y$,

7.32 — HIGHER ENGINEERING MATHEMATICS—II

the triangular region AOX in the XY -plane (given by $X = 0, Y = 0, X + Y = 1$) gets transformed to a square in the uv -plane (given by $u = 0, v = 0, u = 1, v = 1$). The jacobian $\frac{\partial(X,Y)}{\partial(u,v)} = \begin{vmatrix} 1-v & v \\ -u & u \end{vmatrix} = u$ and $X = u(1-v), Y = uv$ with this,

$$\begin{aligned} \text{T.I.} &= \frac{b^{p+q+r+3}}{r+1} \int_{v=0}^1 \int_{u=0}^1 u^p (1-v)^p (uv)^q \times \\ &\quad \times (1-u)^{r+1} \cdot u \, du \, dv \\ &= \frac{b^{p+q+r+3}}{r+1} \left[\int_{u=0}^1 u^{p+q+1} (1-u)^{r+1} du \right] \times \\ &\quad \times \left[\int_{v=0}^1 v^q (1-v)^p dv \right] \\ &= \frac{b^{p+q+r+3}}{r+1} \beta(p+q+2, r+2) \cdot \beta(q+1, p+1) \\ &= \frac{b^{p+q+r+3}}{(r+1)} \frac{\Gamma(p+q+2)\Gamma(r+2)}{\Gamma(p+q+r+4)} \cdot \frac{\Gamma(q+1)\Gamma(p+1)}{\Gamma(p+q+2)} \\ &= b^{p+q+r+3} \cdot \frac{\Gamma(p+1)\Gamma(q+1)\Gamma(r+1)}{\Gamma(p+q+r+4)} \end{aligned}$$

since $\Gamma(r+2) = (r+1)\Gamma(r+1)$. Hence the result.

Note: This triple integral can also be evaluated directly by putting $x + y + z = u, y + z = uv, z = uvw$.

WORKED OUT EXAMPLES

Example 1: Find the area and the mass contained in the first quadrant enclosed by the curve $\left(\frac{x}{a}\right)^\alpha + \left(\frac{y}{b}\right)^\beta = 1$, where $\alpha > 0, \beta > 0$ given that density at any point $p(x, y)$ is $k\sqrt{xy}$.

Solution: The area A of the plane region is

$$A = \iint_D dx \, dy$$

put $\left(\frac{x}{a}\right)^\alpha = X, \left(\frac{y}{b}\right)^\beta = Y$ then $x = aX^{1/\alpha}, y = bY^{1/\beta}$. Then

$$A = \iint_{D^*} a^{\frac{1}{\alpha}} X^{\frac{1}{\alpha}-1} \cdot dX \cdot b^{\frac{1}{\beta}} Y^{\frac{1}{\beta}-1} dY$$

where $X \geq 0, Y \geq 0, X + Y \leq 1$. So

$$A = \frac{ab}{\alpha\beta} \int_{D^*} X^{\frac{1}{\alpha}-1} Y^{\frac{1}{\beta}-1} dX \, dY$$

Using book work I

$$A = \frac{ab}{\alpha\beta} \cdot \beta\left(\frac{1}{\alpha}, \frac{1}{\beta}\right) = \frac{ab}{\alpha\beta} \frac{\Gamma\left(\frac{1}{\alpha}\right)\Gamma\left(\frac{1}{\beta}\right)}{\Gamma\left(\frac{1}{\alpha} + \frac{1}{\beta}\right)}$$

Now the total mass M contained in the plane region A is

$$\begin{aligned} M &= \iint_D P(x, y) dx \, dy = \iint_D k\sqrt{xy} dx \, dy \\ &= k \iint_{D^*} \sqrt{a} X^{\frac{1}{2\alpha}} \cdot \sqrt{b} Y^{\frac{1}{2\beta}} \cdot \frac{a}{\alpha} X^{\frac{1}{\alpha}-1} \frac{b}{\beta} Y^{\frac{1}{\beta}-1} dX \, dY \\ &= k \frac{(ab)^{\frac{3}{2}}}{\alpha\beta} \iint_{D^*} X^{\frac{3}{2\alpha}-1} Y^{\frac{3}{2\beta}-1} dX \, dY \\ &= k \frac{(ab)^{\frac{3}{2}}}{\alpha\beta} \cdot \frac{\Gamma\left(\frac{3}{2\alpha}\right)\Gamma\left(\frac{3}{2\beta}\right)}{\Gamma\left(\frac{3}{2\alpha} + \frac{3}{2\beta}\right)} \end{aligned}$$

Example 2: Find the volume and the mass contained in the solid region in the first octant of the ellipsoid $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$ if the density at any point $\rho(x, y, z)$ is $kxyz$. Also find the coordinates of the centroid (UPTU 2002).

Solution: Volume V of the solid region is $V = \iiint_V dx \, dy \, dz$. Here V is the region $x \geq 0, y \geq 0, z \geq 0, \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} \leq 1$.

Put $\left(\frac{x}{a}\right)^2 = X, \left(\frac{y}{b}\right)^2 = Y, \left(\frac{z}{c}\right)^2 = Z$. Then

$x = a\sqrt{X}, y = b\sqrt{Y}, z = c\sqrt{Z}$. The new region in XYZ -system is $X \geq 0, Y \geq 0, Z \geq 0, X + Y + Z \leq 1$

$$V = \iiint_{V^*} \frac{a}{2} \frac{1}{\sqrt{X}} \frac{b}{2} \frac{1}{\sqrt{Y}} \frac{c}{2} \frac{1}{\sqrt{Z}} dX \, dY \, dZ$$

$$= \frac{abc}{8} \iiint_{V^*} X^{-\frac{1}{2}} Y^{-\frac{1}{2}} Z^{-\frac{1}{2}} dX \, dY \, dZ$$

$$= \frac{abc}{8} \frac{\Gamma\left(\frac{1}{2}\right)\Gamma\left(\frac{1}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(-\frac{1}{2} - \frac{1}{2} - \frac{1}{2} + 4\right)} = \frac{abc}{8} \frac{\pi^{3/2}}{\Gamma\left(\frac{3}{2}\right)}$$

$$V = \frac{abc}{8} \frac{\pi \cdot \sqrt{\pi}}{\frac{3}{2} \cdot \frac{1}{2} \sqrt{\pi}} = \frac{\pi abc}{6}$$

Now the mass M contained is

$$M = \iiint_V \rho(x, y, z) dx \, dy \, dz = k \iiint_V xyz \, dx \, dy \, dz.$$

With the change of variables.

$$M = k \iiint_{V^*} a\sqrt{X} b\sqrt{Y} c\sqrt{Z} \times$$

$$\times \frac{a}{2\sqrt{X}} \cdot \frac{b}{2\sqrt{Y}} \frac{c}{2\sqrt{Z}} dX \, dY \, dZ$$

$$= k \frac{a^2 b^2 c^2}{8} \iiint_{V^*} dX dY dZ. \text{ Using book work II}$$

$$= k \frac{a^2 b^2 c^2}{8} \frac{\Gamma(1)\Gamma(1)\Gamma(1)}{\Gamma(0+0+0+4)} \text{ since } p = q = r = 0$$

$$M = \frac{ka^2 b^2 c^2}{8} \cdot \frac{1}{3!} = \frac{ka^2 b^2 c^2}{48}$$

Let $(\bar{X}, \bar{Y}, \bar{Z})$ be the coordinates of the centroid of the solid region V . Then

$$\bar{X} = \frac{\iiint_V x \rho(x, y, z) dx dy dz}{\iiint_V \rho(x, y, z) dx dy dz}$$

The denominator integral is the mass M calculated as $ka^2 b^2 c^2 / 48$. Now consider

$$\iiint_V x \rho(x, y, z) dx dy dz$$

$$= k \iiint_{V^*} a \cdot \sqrt{X} \cdot a \cdot \sqrt{X} \cdot b \cdot \sqrt{Y} \cdot c \cdot \sqrt{Z} \times$$

$$\times \frac{a}{2\sqrt{X}} \cdot \frac{b}{2\sqrt{Y}} \cdot \frac{c}{2\sqrt{Z}} \cdot dX dY dZ$$

$$= \frac{ka^3 b^2 c^2}{8} \iiint_{V^*} X^{\frac{1}{2}} dX dY dZ. \text{ Using book work II}$$

with $p = \frac{1}{2}, q = r = 0$

$$= \frac{ka^3 b^2 c^2}{8} \frac{\Gamma(\frac{3}{2}) \cdot \Gamma(1) \Gamma(1)}{\Gamma(\frac{1}{2} + 0 + 0 + 4)} = \frac{ka^3 b^2 c^2}{8} \frac{\frac{1}{2} \Gamma(\frac{1}{2})}{\Gamma(\frac{9}{2})}$$

$$= \frac{ka^3 b^2 c^2}{8} \frac{\frac{1}{2} \cdot \Gamma(\frac{1}{2})}{\frac{7}{2} \cdot \frac{5}{2} \cdot \frac{3}{2} \cdot \frac{1}{2} \cdot \Gamma(\frac{1}{2})} = \frac{ka^3 b^2 c^2}{105}$$

$$\bar{X} = \frac{ka^3 b^2 c^2}{105} \frac{48}{ka^2 b^2 c^2} = \frac{16}{35} a. \text{ Similarly } \bar{Y} = \frac{16}{35} b,$$

$$\bar{Z} = \frac{16}{35} c$$

EXERCISE

1. Evaluate $\iint_D x^p y^q dx dy$ where D is the region bounded by $x = 0, y = 0$ and $(\frac{x}{a})^m + (\frac{y}{b})^n = 1$.

$$\text{Ans. } \frac{a^{p+1} b^{q+1}}{mn} \frac{\Gamma(\frac{p+1}{m}) \Gamma(\frac{q+1}{n})}{\Gamma(\frac{p+1}{m} + \frac{q+1}{n} + 1)}$$

2. Find the mass of the region in the xy -plane bounded by $x = 0, y = 0, x + y = 1$ with density $k\sqrt{xy}$.

$$\text{Ans. } k \frac{\pi}{24}$$

3. Find the area enclosed by the curve $(\frac{x}{a})^{2m} + (\frac{y}{b})^{2n} = 1, m, n$ being positive integers

$$\text{Ans. } \frac{ab}{4mn} \frac{\Gamma(\frac{1}{2m}) \Gamma(\frac{1}{2n})}{\Gamma(\frac{1}{2m} + \frac{1}{2n} + 1)}$$

Hint: Put $(\frac{x}{a})^{2m} = X, (\frac{y}{b})^{2n} = Y$, area =

$$\iint a \frac{1}{2m} X^{\frac{1}{2m}-1} \cdot b \frac{1}{2n} Y^{\frac{1}{2n}-1} dX dY.$$

Hence find the area bounded by the astroid $(\frac{x}{a})^{2/3} + (\frac{y}{b})^{2/3} = 1$

$$\text{Ans. } \frac{3ab\pi}{32}. \text{ Hint put } m = n = \frac{1}{3}.$$

4. Determine the area enclosed by the curve $(\frac{x}{a})^4 + (\frac{y}{b})^{10} = 1$

$$\text{Ans. } \frac{ab}{40} \frac{\Gamma(\frac{1}{4}) \Gamma(\frac{1}{10})}{\Gamma(\frac{27}{20})}$$

Hint: Take $m = 2, n = 5$ in above example 3.

5. Express $\iint_D x^p y^q dx dy$ in terms of gamma functions where D is the region of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ in the first octant.

$$\text{Ans. } \frac{1}{4} a^{p+1} b^{q+1} \frac{\Gamma(\frac{p+1}{2}) \Gamma(\frac{q+1}{2})}{\Gamma(\frac{p+1}{2} + \frac{q+1}{2} + 1)}$$

Hint: Take $m = 2, n = 2$ in above example 1.

6. Evaluate $\iiint_V x^{\alpha-1} y^{\beta-1} z^{\gamma-1} dx dy dz$ where V is the closed region in the first octant bounded by the surface $(\frac{x}{a})^p + (\frac{y}{b})^q + (\frac{z}{c})^r = 1$ and coordinate planes $x = 0, y = 0, z = 0$.

$$\text{Ans. } \frac{a^\alpha b^\beta c^\gamma}{pqr} \frac{\Gamma(\frac{\alpha}{p}) \Gamma(\frac{\beta}{q}) \Gamma(\frac{\gamma}{r})}{\Gamma(\frac{\alpha}{p} + \frac{\beta}{q} + \frac{\gamma}{r} + 1)}$$

Hint: Put $(\frac{x}{a})^p = X, (\frac{y}{b})^q = Y, (\frac{z}{c})^r = Z$, then $X + Y + Z = 1$. Integrand of the triple integral is

$$a^{\alpha-1} X^{(\alpha-1)/p} \cdot b^{\beta-1} Y^{(\beta-1)/q} c^{\gamma-1} Z^{(\gamma-1)/r} \times \\ \times \frac{a}{p} X^{\frac{1}{p}-1} \cdot \frac{b}{q} Y^{\frac{1}{q}-1} \cdot \frac{c}{r} Z^{\frac{1}{r}-1} \\ = \frac{a^\alpha b^\beta c^\gamma}{pqr} \iiint X^{\frac{\alpha}{p}-1} Y^{\frac{\beta}{q}-1} Z^{\frac{\gamma}{r}-1} dX dY dZ.$$

Apply book work II.

7. Find the volume of the solid bounded by the coordinate planes and the surface $(\frac{x}{a})^{\frac{1}{2}} + (\frac{y}{b})^{\frac{1}{2}} + (\frac{z}{c})^{\frac{1}{2}} = 1$

$$\text{Ans. } \frac{abc}{90}$$

Hint: Put $p = q = r = \frac{1}{2}, \alpha = \beta = \gamma = 1$ in

7.34 — HIGHER ENGINEERING MATHEMATICS—II

above example

$$\frac{a^1 \cdot b^1 \cdot c^1}{\frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2}} \cdot \frac{\Gamma(2)\Gamma(2)\Gamma(2)}{\Gamma(2+2+2+1)} = \frac{8abc}{6!} = \frac{abc}{90}$$

8. If V is the solid region in the first octant bounded by the unit sphere $x^2 + y^2 + z^2 = 1$.

Find the mass of the ellipsoid

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1 \quad \text{with density}$$

$$\rho(x, y, z) = (x + y + z)^4$$

$$\text{Ans. } 4\pi(a^2 + b^2 + c^2)abc/35$$

Hint: Put $x + y + z = u$, $y + z = uv$, $z = uvw$.

$$\text{Jacobian} = \frac{\partial(x, y, z)}{\partial(u, v, w)} = u^2v, \quad x = u(1 - v), \quad y = uv, \quad z = uvw$$

Ordinary Differential Equations: First Order and First Degree

INTRODUCTION

To describe, understand and predict the behaviour of a physical process or system, a "mathematical model" is constructed by relating the variables by means of one or more equations. Usually these equations describing the system in motion are "differential equations" involving derivatives which measures the rates of change. The behaviour and interaction of components of the system at later times is described by the "solutions" of these differential equations.

In this chapter we consider the simplest of these differential equations which is of first order. We study the solutions of differential equations which are: variables separable, homogeneous, non-homogeneous, exact, non-exact using integrating factors, linear, Bernoulli, higher degree, Clairaut's, Lagrange's. We consider geometrical applications and physical problems of law of natural growth, natural decay, Newton's law of cooling, velocity of escape from earth and simple electrical circuits.

8.1 INTRODUCTION TO MATHEMATICAL MODELING

Scientific model is an abstract and simplified description of a given phenomenon and is most often based on mathematical structures.

Historically following the invention of calculus by Newton (1642-1727) and Leibnitz (1646-1716), there is a burst of activity in mathemati-

cal sciences. Early mathematical modeling problems include boundary value problems in vibration of strings, elastic bars and columns of air due to Taylor (1685-1731), Daniel Bernoulli (1700-1782), Euler (1707-1783) and d'Alembert (1717-1783).

Modeling is a technique of transforming a physical problem to a "mathematical model". Thus a mathematical model describes a natural process or a physical system in mathematical terms, representing an idealization by simplifying the reality by ignoring negligible details of the natural process and emphasizing on only its essential manifestations. Such model yielding reproducible results, can be used for prediction. Thus a mathematical model essentially expresses a physical system in terms of a functional relationship of the kind:

Dependent variable = function of independent variables, parameters and forcing functions

A model should be general enough to explain the phenomenon but not too complicated precluding analysis. Mathematical formulation of problems involving continuously or discretely changing quantities leads to ordinary or partial differential equations, linear or non-linear equations, integral equations or a combination of these.

Example of a Mathematical Model of a Mechanical System

Consider a mechanical oscillator consisting of a block of a mass m lying on a table and restrained laterally by an ordinary spring. The displacement $x(t)$ of the spring as a function of time t is governed by

8.2 — HIGHER ENGINEERING MATHEMATICS—III

Fig. 8.1 Scheme of mathematical modeling

a second order differential equation which arises out of the Newton's second law as follows:

(mass)(acceleration) = sum of forces

or

$$m \frac{d^2 x}{dt^2} = F - F_s - F_f - F_a$$

Fig. 8.2

Here $F(t)$, the applied force, is the forcing function. The force F_s exerted by the spring on the mass is generally assumed to be of the form $F_s(x) = kx$; where k the spring stiffness is the parameter of the material. The sliding friction force F_f exerted on the bottom of the mass may be assumed to be proportional to the velocity i.e. $F_f = c \frac{dx}{dt}$, where c is known as the damping coefficient, another parameter. Neglecting the aerodynamic drag F_a we get an approximate model of the system described by

$$m \frac{d^2 x}{dt^2} = F - kx - c \frac{dx}{dt} - 0$$

or

$$m \frac{d^2 x}{dt^2} + c \frac{dx}{dt} + kx = f(t)$$

Thus the mathematical model of the physical mechanical oscillator is described by a differential equation which expresses the relationship between the dependent variable, x the displacement as a function of the independent variable t , the parameters k and c and the forcing $F(x)$. Models representing the electrical, chemical, mechanical, and civil systems are abundant.

A mechanical system describing the forced oscillations of a mass-spring system and an electrical system describing an RLC-circuit are both represented by a linear second order non-homogeneous ordinary differential equation. This demonstrates the unifying power of “mathematical modeling” through which entirely different physical systems can be studied by the same mathematical model. The analogy between mechanical and electrical systems simplifies the study of mechanical systems since the electrical systems are easy to construct and easy to measure accurately.

The power of modeling is seen from the differential equation

$$\frac{d^2 x}{dt^2} + \omega^2 x = 0$$

which represents simple harmonic motion, also the motion of a particle with constant angular velocity along a circle and also the free undamped vertical motion of a mass-spring system and finally the motion of the bob of a simple pendulum in a vertical plane.

8.2 BASIC DEFINITIONS

A “**differential equation**” (D.E.) is an equation involving (connecting) an unknown (or sought-for) function y of one or more independent variables $x, t, \dots$ and its derivatives.

Differential equations are classified into two categories “ordinary and partial” depending on the number of independent variables appearing in the equation.

Ordinary Differential Equation (O.D.E.)

An ordinary differential equation is a D.E. in which the dependent variable y depends only on one inde-

pendent variable say x (so that the derivatives of y are ordinary derivatives).

Example: $F(x, y, y', y'', \dots, y^{(n)}) = 0$.

Notation: The first derivative $\frac{dy}{dx}$ is denoted by y' , second derivative $\frac{d^2y}{dx^2}$ by y'' , etc.

Partial Differential Equation (P.D.E.)

A partial differential equation is one in which y depends on two or more independent variables say $x, t, \dots$ (so that the derivatives of y are partial derivatives.)

Example: $F\left(x, t, y, \frac{\partial y}{\partial x}, \frac{\partial y}{\partial t}, \frac{\partial^2 y}{\partial x^2}, \dots, \frac{\partial^m y}{\partial x^k \partial t^l}\right) = 0$.

Order

of a D.E. is the order of the highest derivative appearing in the equation.

Degree

of a D.E. is the degree of the highest ordered derivative (when the derivatives are cleared of radicals and fractions).

Linear

An n th order O.D.E. in the dependent variable y is said to be linear in y if

- i. y and all its derivatives are of degree one.
- ii. No product terms of y and/or any of its derivatives are present.
- iii. No transcendental functions of y and/or its derivatives occur.

Non-linear

O.D.E. is an O.D.E. that is *not* linear. The general form of an n th order linear O.D.E. in y with variable coefficient is

$$a_0(x) \frac{d^n y}{dx^n} + a_1(x) \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_{n-1}(x) \frac{dy}{dx} + a_n(x)y = b(x)$$

where R.H.S. $b(x)$ and all the coefficients $a_0(x), a_1(x), \dots, a_n(x)$ are given functions of x and $a_0(x) \neq 0$.

If all the coefficients $a_0, a_1, \dots, a_n$ are constants then the above equation is known as n th order linear O.D.E. with constant coefficients.

Note: A linear D.E. is of first degree but a first degree D.E. need not be linear since it may contain nonlinear terms such as $y^2, y^{\frac{-1}{2}}, e^y, \sin y$, etc.

[see Examples 3 and 6 in Exercise]

Solution or integral or primitive

Solution or integral or primitive of a D.E. is any function which satisfies the equation i.e., reduces it to an identity.

Note 1: A D.E. may have a unique solution or several solution, or no solution.

In *Explicit* solutions the dependent variable can be expressed explicitly in terms of the independent variable, like $y = f(x)$. Otherwise the solution is said to be an *implicit* solution where $F(x, y) = 0$ where $F(x, y)$ is an implicit function.

Note 2: *General* (or *complete*) solution of an n th order D.E. will have n arbitrary constants.

Particular solution

Particular solution is a solution obtained from the general solution by choosing particular values of the arbitrary constants. *Integral curve* of D.E. is the graph of the general/particular solution of D.E.

Initial (boundary) value problem

Initial (boundary) value problem is one in which a solution to a D.E. is obtained subject to conditions on the unknown function and its derivative specified at one (two or more) value(s) of the independent variable. Such conditions are called *initial (boundary) conditions*.

General (or *complete*) integral of a D.E. is an implicit function $\phi(x, y, c) = 0$.

8.4 — HIGHER ENGINEERING MATHEMATICS—III

Particular integral

Particular integral is one obtained from general integral for a particular value of constant C .

Singular solutions of a D.E. are (unusual or odd) solutions of D.E. which can not be obtained from the general solution.

In Chapter 8, first order first degree (both linear and non-linear) O.D.E's are studied.

EXERCISE

Classify each of the following D.Es by its kind, order, degree and linearity:

S. No.	Differential Equation	Ans: Kind	Order	Degree	Linearity
1.	$\frac{dy}{dx} = kx^2$	ordinary	1	1	yes
2.	$\frac{dy}{dx} + P(x)y = y^n Q(x)$	ordinary	1	1	no (yes for $n = 0, 1$)
3.	$e^x dx + e^y dy = 0$	ordinary	1	1	nonlinear (in x and y)
4.	$\left(\frac{d^3y}{dx^2}\right)^4 - 6x^2\left(\frac{dy}{dx}\right)^8 + e^y = \sin x y$	ordinary	3	4	no
5.	$y \frac{d^2y}{dx^2} + \sin x = 0$	ordinary	2	1	no
6.	$x^2 dy + y^2 dx = 0$	ordinary	1	1	no
7.	$\frac{d^4y}{dx^4} + 3\left(\frac{d^2y}{dx^2}\right)^5 + 5y = 0$	ordinary	4	1	no
8.	$y^2 dx + (3xy - 1)dy = 0$	ordinary	1	1	nonlinear in y linear in x
9.	$k(y'')^2 = [1 + (y'')^2]^3$	ordinary	2	2	no
10.	$\frac{\partial u}{\partial t} = k\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right)$	partial	2	1	yes
11.	$\frac{\partial^2 y}{\partial t^2} = a^2 \frac{\partial^2 y}{\partial x^2}$	partial	2	1	yes
12.	$\left(\frac{dr}{ds}\right)^3 = \sqrt{\frac{d^2r}{ds^2} + 1}$	ordinary	2	1	no

8.3 FIRST ORDER FIRST DEGREE DIFFERENTIAL EQUATIONS

A first order first degree ordinary differential equation contains only y' , known functions of x and perhaps terms of y itself. Thus the general form is

$$F(x, y, y') = 0$$

which may be solved for y' and rewritten in the explicit form

$$\frac{dy}{dx} = f(x, y)$$

The Cauchy or initial value problem (IVP) is the problem of finding the solution (function) $y = y(x)$ of the above D.E. satisfying the initial condition $y(x_0) = y_0$ (i.e., value of y is y_0 when $x = x_0$ where x_0 and y_0 are given number). Thus for the first order D.E., the general solution (G.S.) $y = \phi(x, c)$ contains one arbitrary constant C . Geometrically, infinitely many (integral) curves are obtained by varying the one "parameter" C , forming a "one-parameter family of (integral) curves." So a particular solution is a particular (specific) integral curve of this family.

Normally it is easy to verify that a given function is a solution of a D.E. while it is very difficult to find the solution of even the first order first degree O.D.E.

$$\frac{dy}{dx} = f(x, y)$$

But on the other hand, there are certain standard types of first order first degree D.E's for which solutions can be readily obtained by standard methods such as

- Variables separable (Section 8.4)
- Homogeneous equation (Section 8.5)
- Non-homogeneous equation reducible to homogeneous equation (Section 8.6)
- Exact differential equation (Section 8.7)
- Non-exact differential equations that can be made exact with the help of integrating factors (Section 8.8)
- Linear first order equation (Section 8.9)
- Bernoulli's equation (Section 8.10).

8.4 VARIABLES SEPARABLE OR SEPARABLE EQUATION

An equation of the form

$$F(x) G(y) dx + f(x) g(y) dy = 0 \quad (1)$$

is called an equation with variables separable or simply a separable equation, because the variables x and y can be *separated*.

Rewriting

$$\frac{F(x)}{f(x)} dx + \frac{g(y)}{G(y)} dy = 0 \quad (2)$$

$$\text{or } M(x)dx + N(y)dy = 0 \quad (3)$$

where $M(x) = F(x)/f(x)$ is a function of x only and $N(y) = g(y)/G(y)$ is a function of y only.

Integrating, we get the one-parameter family of solutions as

$$\int M(x)dx + \int N(y)dy = C \quad (4)$$

where C is the arbitrary constant. Since division by $f(x)$ and $G(y)$ are involved in (2), meaningful valid solutions can be obtained provided $f(x) \neq 0$ and $G(y) \neq 0$.

Note: In an equation of the form

$$\frac{dy}{dx} = f(ax + by + c)$$

(i.e., R.H.S. is a function of the variable $ax + by + c$) can be changed into a separable equation by the substitution $z = ax + by + c$.

WORKED OUT EXAMPLES

Variables separable

Solve the following:

Example 1: $\tan x \cdot \sin^2 y \, dx + \cos^2 x \cdot \cot y \, dy = 0$

Solution: Rewriting

$$\tan x \cdot \sec^2 x \cdot dx + \cot y \cdot \operatorname{cosec}^2 y \, dy = 0$$

Integrating

$$\tan x \cdot d(\tan x) - \cot y \, d(\cot y) = 0$$

$$\therefore \frac{\tan^2 x}{2} - \frac{\cot^2 y}{2} = C$$

Example 2: $\frac{dy}{dx} = e^{2x-y} + x^3 e^{-y}$

Solution: Rewriting $\frac{dy}{dx} = (e^{2x} + x^3)e^{-y}$
Separating the variables, we get

$$e^y dy = (e^{2x} + x^3) dx$$

Integrating

$$e^y = \frac{e^{2x}}{2} + \frac{x^4}{4} + C$$

Example 3: $y' = \sin^2(x - y + 1)$

Solution: Put $z = x - y + 1$, so $\frac{dz}{dx} = 1 - \frac{dy}{dx} + 0$.
Substituting z and $\frac{dy}{dx}$, we get a separable equation as

$$1 - \frac{dz}{dx} = \sin^2 z$$

$$\text{or } \frac{dz}{dx} = 1 - \sin^2 z = \cos^2 z$$

Separating the variables

$$\sec^2 z \, dz = dx$$

Integrating

$$\tan z = x + c$$

$$\text{or } \tan(x - y + 1) = x + c$$

Example 4: Show that the particular solution of

$$(x^2 + 1) \frac{dy}{dx} + (y^2 + 1) = 0, y(0) = 1, \text{ is } y = \frac{1-x}{1+x}$$

Solution: Separating the variables

$$\frac{dy}{y^2 + 1} + \frac{dx}{x^2 + 1} = 0$$

Integrating $\tan^{-1} y + \tan^{-1} x = c_0$.

$$\tan(\tan^{-1} y + \tan^{-1} x) = \tan c$$

$$\text{Using } \tan(a + b) = \frac{\tan a + \tan b}{1 - \tan a \cdot \tan b}$$

$$\frac{y + x}{1 - xy} = \tan c$$

$$\text{when } x = 0, y = 1 \text{ then } \frac{1+0}{1-0} = \tan c$$

$$\therefore \frac{y + x}{1 - xy} = 1$$

Solving, $y = \frac{1-x}{1+x}$ is the required particular solution.

EXERCISE

Variables separable

Solve the following:

$$1. \, 4xy \, dx + (x^2 + 1) \, dy = 0$$

$$\text{Ans. } y(x + 1)^2 = c$$

$$2. \, (x + 4)(y^2 + 1) \, dx + y(x^2 + 3x + 2) \, dy = 0$$

$$\text{Ans. } 3(x^2 + x)y = x^3 - 3x + c$$

$$3. \, (xy + x) \, dx = (x^2 y^2 + x^2 + y^2 + 1) \, dy$$

$$\text{Ans. } \ln(x^2 + 1) = y^2 - 2y + 4 \ln|c(y + 1)|$$

$$4. \, y' = x \tan(y - x) + 1$$

$$\text{Ans. } \log \sin(y - x) = \frac{x^2}{2} + c$$

$$5. \, (x - y)^2 y' = a^2$$

8.6 — HIGHER ENGINEERING MATHEMATICS—III

Ans. $a \log\left(\frac{x-y-a}{x-y+a}\right) = 2y + c$

6. Obtain particular solution $2xyy' = 1 + y^2$;
 $y(2) = 3$.

Ans. $y^2 = 5x - 1$

7. $y' = (x + y)^2$

Hint: Put $x + y = z$.

Ans. $(x + y) = \tan(x + c)$

8. $(2x - 4y + 5)y' + x - 2y + 3 = 0$

Hint: Put $z = x - 2y$.

Ans. $4x - 8y + \ln|4x - 8y + 11| = c$

9. Solve $\frac{dy}{dx} = (4x + y + 1)^2$, $y(0) = 1$.

Hint: Put $4x + y + 1 = z$.

Ans. $4x + y + 1 = 2 \tan\left(2x + \frac{\pi}{4}\right)$

10. $xyy' = \left(\frac{1+y^2}{1+x^2}\right)(1 + x + x^2)$

Ans. $\frac{1}{2} \ln(1 + y^2) = \ln x + \tan^{-1} x + c$

11. $x^3 e^{2x^2+3y^2} dx - y^3 e^{-x^2-2y^2} dy = 0$

Ans. $25(3x^2 - 1)e^{3x^2} + 9(5y^2 + 1)e^{-5y^2} = c$

12. $y' = \frac{(y-1)(x-2)(y+3)}{(x-1)(y-2)(x+3)}$

Ans. $(x + 1)(y + 3)^5 = c(y - 1)(x + 3)^5$.

8.5 HOMOGENEOUS EQUATION—REDUCTION TO SEPARABLE FORM

Differential Equation of the Form $y' = g\left(\frac{y}{x}\right)$

Homogeneous function

A function $f(x, y)$ is said to be homogeneous function of degree n in the variables x and y if for any t ,

$$f(tx, ty) = t^n f(x, y)$$

Examples:

1. $f(x, y) = 4x^2 - 3xy + y^2$, homogeneous of degree 2

$$\begin{aligned} \text{since } f(tx, ty) &= 4t^2x^2 - 3tx \cdot ty + t^2y^2 \\ &= t^2(4x^2 - 3xy + y^2) = t^2 f(x, y) \end{aligned}$$

2. $f(x, y) = (x^3 + y^3)e^{\frac{2x}{y}} + 4xy^2$, homogeneous of degree 3.

3. $f(x, y) = x^3 + \sin x \cdot e^y$ is not homogeneous.

A first order equation $y' = f(x, y)$ is said to be homogeneous* if $f(x, y)$ is a homogeneous function of degree zero. i.e., $f(x, y)$ will depend only on $\frac{y}{x}$ i.e., $f(x, y)$ is of the form $g\left(\frac{y}{x}\right)$.

Alternatively $M(x, y)dx + N(x, y)dy = 0$ is said to be homogeneous if $M(x, y)$ and $N(x, y)$ are both homogeneous of the same degree.

Method to Solve Homogeneous Equation
 $y' = f(x, y) = g\left(\frac{y}{x}\right)$

I. Put

$$u = \frac{y}{x} \quad \text{or} \quad y = ux$$

$$\text{and} \quad \frac{dy}{dx} = u + x \frac{du}{dx}$$

in the given D.E., which reduces to a separable equation.

$$u + x \frac{du}{dx} = g(u)$$

II. Separating the variables and integrating, the solution is obtained as

$$\int \frac{du}{g(u) - u} = \int \frac{dx}{x} + c$$

III. Replace u by y/x , in the solution obtained in II.

WORKED OUT EXAMPLES

Solve the following:

Example 1: $(x + 2y)dx + (2x + y)dy = 0$

Solution: Rewriting $y' = -\frac{(x+2y)}{(2x+y)} = f(x, y)$

This D.E. is a homogeneous, as the R.H.S. function $f(x, y)$ is homogeneous of degree 0.

Put $u = \frac{y}{x}$, $\frac{xdy}{dx} + u = \frac{dy}{dx}$ in given D.E., we get

*The term "homogeneous" is used here loosely in the sense that $f(x, y)$ or $M(x, y)$, $N(x, y)$ are homogeneous functions. But strictly speaking homogeneous D.E. is defined later in a more appropriate way.

$$u + \frac{xdu}{dx} = \frac{-(1+2u)}{(2+u)}$$

Rearranging

$$\frac{xdu}{dx} = \frac{-(1+2u)}{(2+u)} - u = \frac{-(u^2+4u+1)}{u+2}$$

Separating the variables, we get

$$-\frac{dx}{x} = \frac{(u+2)du}{(u^2+4u+1)} = \frac{1}{2} \frac{d(u^2+4u+1)}{(u^2+4u+1)}$$

Integrating

$$-2 \ln x = \ln(u^2+4u+1) + c_0$$

$$x^2(u^2+4u+1) = c$$

$$x^2 \left(\frac{y^2}{x^2} + 4\frac{y}{x} + 1 = c \right)$$

Thus $y^2 + 4xy + x^2 = c$

Example 2: $(1 + 2e^{\frac{x}{y}}) + 2e^{\frac{x}{y}} \cdot (1 - \frac{x}{y})y' = 0$

Solution: Rewriting

$$(1 + 2e^{\frac{x}{y}})dx + 2e^{\frac{x}{y}}(1 - \frac{x}{y})dy = 0$$

Put $\frac{x}{y} = u$, so that $dx = ydu + udy$

D.E. becomes

$$(1 + 2e^u)(udy + ydu) + 2e^u(1 - u)dy = 0$$

$$(u + 2e^u)dy + y(1 + 2e^u)du = 0$$

Separating the variables

$$\frac{dy}{y} + \frac{1 + 2e^u}{u + 2e^u} du = 0$$

Integrating

$$\ln y + \ln(u + 2e^u) = \ln c$$

$$y(u + 2e^u) = c$$

Replacing u , we get

$$y \left(\frac{x}{y} + 2e^{\frac{x}{y}} \right) = c$$

Example 3: $(y + \sqrt{x^2 + y^2})dx - xdy = 0$, $y(1) = 0$.

Solution: Rewriting

$$\frac{dy}{dx} = \frac{y + \sqrt{x^2 + y^2}}{x} = \frac{y}{x} + \sqrt{1 + \left(\frac{y}{x}\right)^2}$$

is homogeneous. Put $y = ux$ and $\frac{dy}{dx} = u + x \frac{du}{dx}$ in D.E., we get

$$u + x \frac{du}{dx} = u + \sqrt{1 + u^2}$$

or $x \frac{du}{dx} = \sqrt{1 + u^2}$

Separating the variables

$$\frac{dx}{x} = \frac{du}{\sqrt{u^2 + 1}}$$

Integrating

$$\ln|x| + \ln|c| = \ln|u + \sqrt{u^2 + 1}|$$

or $u + \sqrt{u^2 + 1} = cx$

Replacing u , we have

$$\frac{y}{x} + \sqrt{\frac{y^2}{x^2} + 1} = cx$$

or $y + \sqrt{x^2 + y^2} = cx^2$

Put $y = 0$, when $x = 1$, then $c = 1$

So the required solution is

$$y + \sqrt{x^2 + y^2} = x^2.$$

EXERCISE

Solve the following:

1. $(2xy + 3y^2)dx - (2xy + x^2)dy = 0$

Ans. $y^2 + xy = cx^3$

2. $(x^3 + y^2\sqrt{x^2 + y^2})dx - xy\sqrt{x^2 + y^2}dy = 0$

Ans. $(x^2 + y^2)^{\frac{3}{2}} = x^3 \ln cx^3$

3. $(2x - 5y)dx + (4x - y)dy = 0$, $y(1) = 4$

Ans. $(2x + y)^2 = 12(y - x)$

4. $x \cdot \sin \frac{y}{x} \frac{dy}{dx} = y \sin \frac{y}{x} + x$

Ans. $\cos \frac{y}{x} + \log cx = 0$

5. $x^2 y^1 = 3(x^2 + y^2) \tan^{-1} \frac{y}{x} + xy$

Ans. $y = x \tan cx^3$

8.8 — HIGHER ENGINEERING MATHEMATICS—III

$$6. (x^2 + xy)dy = (x^2 + y^2)dx$$

$$\text{Ans. } (x - y)^2 = cx \cdot e^{\frac{-y}{x}}$$

$$7. x^2 y dy + (x^3 + x^2 y - 2xy^2 - y^3)dx = 0$$

$$\text{Ans. } \log \left\{ \frac{c(y-x)}{x^4(y+x)} \right\} = \frac{2x}{x+y}$$

$$8. xy^1 = y + x \cdot \cos^2\left(\frac{y}{x}\right), y(1) = \frac{\pi}{4}$$

$$\text{Ans. } 1 + \ln x = \tan \frac{y}{x}$$

$$9. y^1 = \frac{6x^2 - 5xy - 2y^2}{6x^2 - 8xy + y^2}$$

$$\text{Ans. } (y - x)(y - 3x)^9 = c(y - 2x)^{12}$$

$$10. [2x \cdot \sin \frac{y}{x} + 2x \cdot \tan \frac{y}{x} - y \cos \frac{y}{x} - y \sec^2 \frac{y}{x}]dx + [x \cdot \cos \frac{y}{x} + x \sec^2 \frac{y}{x}]dy = 0.$$

$$\text{Ans. } x^2(\sin \frac{y}{x} + \tan \frac{y}{x} = c).$$

8.6 NON-HOMOGENEOUS EQUATIONS REDUCIBLE TO HOMOGENEOUS FORM

Consider the non-homogeneous equation

$$\frac{dy}{dx} = \frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2} \quad (1)$$

where $a_1, b_1, c_1, a_2, b_2, c_2$ are all constants.

Case 1: If $\frac{a_1}{a_2} \neq \frac{b_1}{b_2}$, i.e., $\left| \begin{array}{cc} a_1 & b_1 \\ a_2 & b_2 \end{array} \right| \neq 0$ then the transformation, (shift of origin)

$$x = x_1 + h, y = y_1 + k \quad (2)$$

reduces the non-homogeneous Equation (1) to the homogeneous equation of the form

$$\frac{dy_1}{dx_1} = \frac{a_1x_1 + b_1y_1}{a_2x_1 + b_2y_1} \quad (3)$$

Here the unknown constants h, k in (2) are determined by solving the pair of equations

$$a_1h + b_1k + c_1 = 0$$

$$a_2h + b_2k + c_2 = 0$$

Now that Equation (3) is homogeneous in the new variables x_1 and y_1 , it can be solved as in 8.5.

Case 2: If $\frac{a_1}{a_2} = \frac{b_1}{b_2}$, i.e., $\left| \begin{array}{cc} a_1 & b_1 \\ a_2 & b_2 \end{array} \right| = 0$, then the transformation

$$z = a_1x + b_1y$$

reduces (1) to a separable equation in the variables x and z , which can be solved as in 8.4.

WORKED OUT EXAMPLES

Solve the following:

Example 1: $(2x^2 + 3y^2 - 7)xdx = (3x^2 + 2y^2 - 8)y dy$

Solution: Put $x^2 = X, y^2 = Y$, so that $2x dx = dX, 2y dy = dY$

$$(2X + 3Y - 7)dX = (3X + 2Y - 8)dY$$

$$\frac{dY}{dX} = \frac{2X + 3Y - 7}{3X + 2Y - 8}, \text{ not homogeneous}$$

Put $X = X_1 + h, Y = Y_1 + k$

$$\frac{dY_1}{dX_1} = \frac{2X_1 + 3Y_1 + (2h + 3k - 7)}{3X_1 + 2Y_1 + (3h + 2k - 8)}$$

To convert this into a homogeneous equation,

Put $2h + 3k - 7 = 0, 3h + 2k - 8 = 0$.

Solving $h = 2, k = 1$, with these values

$$\frac{dY_1}{dX_1} = \frac{2X_1 + 3Y_1}{3X_1 + 2Y_1}$$

To solve this put $u = \frac{Y_1}{X_1}$

$$u + X_1 \frac{du}{dX_1} = \frac{2X_1 + 3uX_1}{3X_1 + 2uX_1} = \frac{2 + 3u}{3 + 2u}$$

$$X_1 \frac{du}{dX_1} = \frac{2 + 3u}{3 + 2u} - u = \frac{2(1 - u^2)}{3 + 2u}$$

Separating

$$\frac{2dX_1}{X_1} = \left(\frac{3 + 2u}{1 - u^2} \right) du = \frac{3du}{1 - u^2} + \frac{2udu}{1 - u^2}$$

$$\text{But } \frac{1}{1 - u^2} = \frac{1}{(1 - u)(1 + u)} = \frac{1}{2} \left[\frac{1}{(1 - u)} + \frac{1}{1 + u} \right]$$

Integrating

$$2 \int \frac{dX_1}{X_1} = 3 \cdot \frac{1}{2} \left[\int \frac{du}{1 - u} + \frac{du}{1 + u} \right] - 2 \int \frac{udu}{u^2 - 1}$$

$$4 \ln X_1 + 2 \ln c = 3 \ln \left(\frac{u + 1}{u - 1} \right) - 2 \ln (u^2 - 1)$$

$$c^2 X_1^4 = \frac{(u+1)^3}{(u-1)^3} \cdot \frac{1}{(u^2-1)^2}$$

$$c^2 X_1^4 = \frac{u+1}{(u-1)^5}$$

Replacing $u = \frac{Y_1}{X_1}$, we get

$$c^2 = \frac{(Y_1 + X_1)}{(Y_1 - X_1)^5}$$

Replacing $X_1 = X - 2$, $Y_1 = Y - 1$, we have

$$c^2 = \frac{(Y - 1 + X - 2)}{[Y - 1 - (X - 2)]^5}$$

$$c^2(x^2 - y^2 + 1)^5 = (x^2 + y^2 - 3)$$

Example 2: $\frac{dy}{dx} = \frac{y-x}{y-x+2}$

Solution: Since this is non-homogeneous, if $x = x_1 + h$, $y = y_1 + k$ then

$$\begin{aligned} \frac{dy}{dx} &= \frac{y_1 + k - (x_1 + h)}{y_1 + k - (x_1 + h) + 2} \\ &= \frac{(y_1 - x_1) + (k - h)}{(y_1 - x_1) + (k - h) + 2} \end{aligned}$$

To convert this to homogeneous, put

$$k - h = 0$$

$$k - h = 2$$

which has *no* solution. So this substitute method *fails* in this case. But on the other hand observe that by introducing

$$z = y - x$$

The given equation becomes separable.

$$\frac{dz}{dx} = \frac{dy}{dx} - 1$$

or
$$\frac{dy}{dx} = \frac{dz}{dx} + 1 = \frac{z}{z+2}$$

$$\frac{dz}{dx} = \frac{z}{z+2} - 1 = \frac{-2}{z+2}$$

Separating the variables and integrating

$$\int (z+2)dz + 2 \int \frac{1}{z+2} dx = c$$

$$\frac{z^2}{2} + 2z + 2x = c$$

Replacing z by $y - x$, we get

$$(y-x)^2 + 4(y-x) + 4x = c$$

or
$$(y-x)^2 + 4y = c$$

Example 3: $(x-2y+1)dx + (4x-3y-6)dy = 0$

Solution: This equation is nonhomogeneous.

Since
$$\frac{a_1}{a_2} = \frac{1}{4} \neq \frac{b_1}{b_2} = \frac{-2}{-3} = \frac{2}{3}$$

i.e.,
$$\begin{vmatrix} 1 & -2 \\ 4 & -3 \end{vmatrix} = 5 \neq 0$$

we can make the substitution

$$x = x_1 + h, y = y_1 + k$$

with this, the given equation becomes

$$\begin{aligned} &[x_1 + h - 2(y_1 + k) + 1]dx_1 \\ &+ [4(x_1 + h) - 3(y_1 + k) - 6]dy_1 = 0 \end{aligned}$$

or
$$[(x_1 - 2y_1) + (h - 2k + 1)]dx_1 + [(4x_1 - 3y_1) + (4h - 3k - 6)]dy_1 = 0$$

This reduces to homogeneous if

$$h - 2k + 1 = 0 \quad \text{and} \quad 4h - 3k - 6 = 0$$

Solving $h = 3, k = 2$.

Thus the homogeneous equation in the new variables x_1 and y_1 is

$$\frac{dy_1}{dx_1} = \frac{x_1 - 2y_1}{3y_1 - 4x_1}$$

Introduce $u = \frac{y_1}{x_1}$, $x_1 \frac{du}{dx_1} + u = \frac{dy_1}{dx_1}$

$$x_1 \frac{du}{dx_1} + u = \frac{1 - 2u}{3u - 4}$$

$$x_1 \frac{du}{dx_1} = \frac{1 - 2u}{3u - 4} - u = \frac{1 - 2u - 3u^2 + 4u}{3u - 4}$$

$$x_1 \frac{du}{dx_1} = \frac{1 + 2u - 3u^2}{3u - 4}$$

Separating the variables

$$\left(\frac{3u - 4}{3u^2 - 2u - 1} \right) du = \frac{-dx_1}{x_1}$$

Integrating

$$\frac{1}{2} \ln |3u^2 - 2u - 1| - \frac{3}{4} \ln \left| \frac{3u - 3}{3u + 1} \right| = -\ln |x_1| + \ln |c_1|$$

8.10 — HIGHER ENGINEERING MATHEMATICS—III

$$\ln (3u^2 - 2u - 1)^2 - \ln \left| \frac{3u-3}{3u+1} \right|^3 = \ln \left(\frac{c_1^4}{x_1^4} \right)$$

$$\ln \left| \frac{(3u+1)^5}{3(u-1)} \right| = \ln \left(\frac{c_1^4}{x_1^4} \right)$$

$$x_1^4(3u+1)^5 = c|u-1| \text{ where } c = 3c_1^4$$

$$\text{Replacing } u, |3y_1 + x_1|^5 = c|y_1 - x_1|.$$

$$\text{Replacing } y_1 = y - 2, x_1 = x - 3,$$

$$\text{we get } |x + 3y - 9|^5 = c|y - x + 1|.$$

EXERCISE

Solve the following:

$$1. (3x - y - 9)y' = (10 - 2x + 2y)$$

$$\text{Ans. } y - 2x + 7 = c(x + y + 1)^4$$

$$2. y' = \frac{ax+by-a}{bx+ay-b}$$

$$\text{Ans. } (y - x + 1)^{(a+b)/a} (y + x - 1)^{(a-b)/a}$$

$$3. (2x - 5y + 3)dx - (2x + 4y - 6)dy = 0$$

$$\text{Ans. } (4y - x - 3)(y + 2x - 3)^2 = c$$

$$4. (3y - 7x + 7)dx + (7y - 3x + 3)dy = 0$$

$$\text{Ans. } (y - x + 1)^2(y + x - 1)^5 = c$$

$$5. y' = \frac{2x+3y+1}{3x-2y-5}$$

$$\text{Ans. } \ln [(x-1)^2 + (y+1)^2] - 3 \tan^{-1} \left(\frac{y+1}{x-1} \right) = c$$

$$6. y' = \frac{2x+y-1}{4x+2y+5}$$

Hint: Put $2x + y = z$

$$\text{Ans. } 10y - 5x + 7 \ln(10x + 5y + 9) = c$$

$$7. (2x + 2y + 1)dx + (x + y - 1)dy = 0$$

Hint: Put $x + y = z$.

$$\text{Ans. } 3 \ln (x + y + 2) - 2x - y = c$$

$$8. y' = (x - 2y + 3)/(2x - 4y + 5)$$

Hint: Put $x - 2y = z$.

$$\text{Ans. } x^2 - 4xy + 4y^2 + 6x - 10y = c$$

$$9. y' + \frac{ax+hy+g}{hx+by+f} = 0$$

$$\text{Ans. } ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0.$$

8.7 EXACT DIFFERENTIAL EQUATIONS

The (total) differential of a function $f(x, y)$ is denoted by df and is given by

$$df = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy \quad (1)$$

Consider the differential equation

$$M(x, y)dx + N(x, y)dy = 0 \quad (2)$$

Suppose there exists a function $f(x, y)$ such that

$$\frac{\partial f}{\partial x} = M(x, y) \quad (3)$$

$$\text{and} \quad \frac{\partial f}{\partial y} = N(x, y) \quad (4)$$

Using (3) and (4) then the given D.E. (2) becomes

$$0 = Mdx + Ndy = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy = df$$

i.e., $df = 0$

Integrating $f(x, y) = c = \text{arbitrary constant.}$

In this case, the L.H.S. expression of (2) $Mdx + Ndy$ is said to be an *exact differential* and the differential Equation (2) is called an *exact differential equation*.

Necessary Condition for Exactness

Differentiating (3) and (4) partially w.r.t. y and x respectively, we get

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial^2 f}{\partial y \partial x} = \frac{\partial^2 f}{\partial x \partial y} \\ &= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) = \frac{\partial N}{\partial x} \end{aligned}$$

Thus the necessary condition for D.E. (1) to be an exact D.E. is

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Method of Finding f

Step I. Integrating (3) partially w.r.t. x , we get

$$f(x, y) = \int M(x, y)dx + g(y) \quad (5)$$

where $g(y)$ is the constant of integration which depends only on y .

Step II. To find $f(y)$.

Differentiate (5) partially w.r.t. y and equating it to (4), we get

$$\frac{\partial}{\partial y} \int M dx + \frac{dg}{dy} = \frac{\partial f}{\partial y} = N$$

so that

$$\frac{dg}{dy} = N - \frac{\partial}{\partial y} \int M dx$$

Integrating w.r.t. y , we have

$$g(y) = \int \left[N - \frac{\partial}{\partial y} \int M dx \right] dy + c_1 \quad (6)$$

Note: Similar result can be obtained from the above procedure starting with (4) also.

Step III. Substituting $g(y)$ from (6) in (5)

The required general solution of the exact D.E. (2) is

$$f(x, y) = c_2$$

To sum up:

Test for exactness of D.E. (1): $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$

Method to find f : f is determined from (5) and (6). Then the general solution of (1) is the equation

$$f(x, y) = c$$

(and *not* simply the function $f(x, y)$).

WORKED OUT EXAMPLES

Determine which of the following equations are exact and solve the ones that are exact:

Example 1: $e^y dx + (xe^y + 2y) dy = 0$

Solution: $M = e^y$, $N = xe^y + 2y$

$$\text{so that } \frac{\partial M}{\partial y} = e^y = \frac{\partial N}{\partial x}$$

Hence the given equation is exact.

Integrating w.r.t. x , $\frac{\partial f}{\partial x} = e^y = M$ yields

$$f = \int e^y dx + g(y) = xe^y + g(y)$$

Differentiating w.r.t. y

$$xe^y + \frac{dg}{dy} = \frac{\partial f}{\partial y} = N = xe^y + 2y$$

$$\text{i.e., } \frac{dg}{dy} = 2y$$

Integrating $g(y) = y^2 + c_1$.

Substituting $g(y)$ in f

$$f = xe^y + y^2 + c_1$$

Thus the desired solution is

$$f = xe^y + y^2 + c_1 = c_2$$

i.e., $xe^y + y^2 = c_3$ where $c_3 = c_2 - c_1$.

Example 2: $(3x^2y + \frac{y}{x})dx + (x^3 + \ln x)dy = 0$.

Solution: $M = 3x^2y + \frac{y}{x}$, $N = x^3 + \ln x$

$$\frac{\partial M}{\partial y} = 3x^2 + \frac{1}{x} = \frac{\partial N}{\partial x}$$

So equation is exact.

Integrating w.r.t. x , $\frac{\partial f}{\partial x} = M = 3x^2y + \frac{y}{x}$ yields

$$f = x^3y + y \ln x + g(y)$$

Differentiating w.r.t. y and equating the result to N , we have

$$x^3 + \ln x + \frac{dg}{dy} = \frac{\partial f}{\partial y} = N = x^3 + \ln x$$

$$\text{so that } \frac{dg}{dy} = 0$$

i.e., $g(y) = \text{constant} = c_1$.

Required solution is

$$x^3y + y \ln x + c_1 = c_2$$

i.e., $x^3y + y \ln x = c_3$, where $c_3 = c_2 - c_1$.

Example 3: $(\cos x - x \cos y)dy - (\sin y + y \sin x)dx = 0$

Solution: $M = -\sin y - y \sin x$

$$N = \cos x - x \cos y$$

$$\frac{\partial M}{\partial y} = -\cos y - \sin x = \frac{\partial N}{\partial x}, \text{ exact.}$$

Integrating $\frac{\partial f}{\partial x} = M = -\sin y - y \sin x$ w.r.t. x we get

$$f(x, y) = -x \sin y + y \cos x + h(y)$$

8.12 — HIGHER ENGINEERING MATHEMATICS—III

Differentiating w.r.t. y and equating it to N

$$-x \cdot \cos y + \cos x + \frac{\partial h}{\partial y} = \frac{\partial f}{\partial y} = N$$

$$= \cos x - x \cos y$$

$\therefore \frac{dh}{dy} = 0$ i.e., $h = \text{constant}$.

The required solution is

$$y \cos x - x \sin y = c$$

Example 4: $xdy + 2y^2dx = 0$

Solution: $M = 2y^2$, $N = x$, Differentiating

$$\frac{\partial M}{\partial y} = 4y, \quad \frac{\partial N}{\partial x} = 0$$

$$\text{So that } \frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$$

The D.E. is not exact.

EXERCISE

Determine which of the following equations are exact and solve the ones that are exact:

1. $(2x^3 - xy^2 - 2y + 3)dx - (x^2y + 2x)dy = 0$

Ans. $x^4 - x^2y^2 - 4xy + 6x = c$

2. $(\cos x \cdot \cos y - \cot x)dx - (\sin x \sin y)dy = 0$

Ans. $\sin x \cdot \cos y = \ln(c \sin x)$

3. $(y - x^3)dx + (x + y^3)dy = 0$

Ans. $4xy - x^4 + y^4 = c$

4. $(y + xy^2 + x^2y^3)dx + (x - x^2y + x^3y^2)dy = 0$

Ans. not exact

5. $(y^2e^{xy^2} + 4x^3)dx + (2xye^{xy^2} - 3y^2)dy = 0$

Ans. $x^4 - y^3 + e^{xy^2} = c$

6. $(\sin x \cdot \tan y + 1)dx + \cos x \cdot \sec^2 y dy = 0$

Ans. not exact

7. $(\sin x \cdot \sin y - xe^y)dy = (e^y + \cos x \cdot \cos y) dx$

Ans. $xe^y + \sin x \cdot \cos y = c$

8. $(x^2 + y^2 - a^2)xdx + (x^2 - y^2 - b^2)ydy = 0$

Ans. $x^4 + 2x^2y^2 - y^4 - 2a^2x^2 - 2b^2y^2 = c$

9. $(\sin x \cdot \cosh y)dx - (\cos x \sinh y)dy = 0$,
 $y(0) = 3$

Ans. $\cos x \cdot \cosh y = 10.07$

10. $\left[\frac{y}{(x+y)^2} - 1 \right] dx + \left[1 - \frac{x}{(x+y)^2} \right] dy = 0$

Ans. $x + y^2 - x^2 = c(x + y)$

11. $y' = \frac{y-2x}{2y-x}$; $y(1) = 2$

Ans. $x^2 - xy + y^2 = 3$.

8.8 REDUCTION OF NON-EXACT DIFFERENTIAL EQUATIONS: USING INTEGRATING FACTORS

Consider a D.E.

$$M(x, y)dx + N(x, y)dy = 0 \quad (1)$$

which is *not* exact. Suppose there exists a function $F(x, y)$ such that

$$F(x, y)[Mdx + Ndy] = 0 \quad (2)$$

is exact, then $F(x, y)$ is called an **integrating factor** (I.F.) of D.E. (1). There may exist several integrating factors or may not, since exact D.E. are relatively rare.

Some methods to find an I.F. to a nonexact D.E. $Mdx + Ndy = 0$ are

Case 1: Method of inspection (or “Grouping” of terms)

Case 2: $(My - Nx)/N = g(x)$

Case 3: $(Nx - My)/M = h(y)$

Case 4: Homogeneous D.E. with $xM + yN \neq 0$

Case 5: D.E. of the form
 $yg(xy)dx + xh(xy)dy = 0$

Case 6: D.E. of the form
 $x^a y^b (mydx + nx dy) + x^c y^d (pydx + qx dy) = 0$

Case 1: Integrating Factors by Inspection (Grouping of Terms)

Not very often, but sometimes I.F. can be obtained by inspection largely upon experience and recognition of “regrouping” the terms of the given equation appropriately such that they form the part of certain common exact differentials listed below for ready reference:

S. No.	Group of terms	Integrating factor	Exact differential
1	$xdy + ydx$	1	$d(x, y)$
2	$xdy + ydx$	$\frac{1}{xy}$	$\frac{xdy + ydx}{xy} = d\{\ln(xy)\}$
3	$xdy + ydx$	$\frac{1}{(xy)^n}, n \neq 1$	$\frac{xdy + ydx}{(xy)^n} = d\left\{\frac{(xy)^{1-n}}{(1-n)}\right\}$
4	$xdx + ydy$	$\frac{1}{x^2 + y^2}$	$\frac{xdx + ydy}{x^2 + y^2} = \frac{1}{2} d\{\ln(x^2 + y^2)\}$
5	$xdx + ydy$	$\frac{1}{(x^2 + y^2)^n}, n \neq 1$	$\frac{xdx + ydy}{(x^2 + y^2)^n} = d\left\{\frac{(x^2 + y^2)^{1-n}}{2(1-n)}\right\}$
6	$xdx + ydy$	2	$2(xdx + ydy) = d(x^2 + y^2)$
7	$xdy - ydx$	$\frac{1}{x^2}$	$\frac{xdy - ydx}{x^2} = d\left(\frac{y}{x}\right)$
8	$xdy - ydx$	$\frac{1}{y^2}$	$\frac{-(ydx - xdy)}{y^2} = -d\left(\frac{x}{y}\right)$
9	$xdy - ydx$	$\frac{1}{xy}$	$\frac{dy}{y} - \frac{dx}{x} = d\left(\ln \frac{y}{x}\right)$
10	$xdy - ydx$	$\frac{1}{x^2 + y^2}$	$\frac{xdy - ydx}{x^2 + y^2} = \frac{\frac{xdy - ydx}{x^2}}{1 + \left(\frac{y}{x}\right)^2} = d\left(\tan^{-1} \frac{y}{x}\right)$

Note: A very simple D.E. $ydx - xdy = 0$ has several I.F. like x^{-2} , y^{-2} , $(xy)^{-1}$, $(x^2 + y^2)^{-1}$. Use the appropriate D.E. depending on the given D.E.

WORKED OUT EXAMPLES

Case 1: Solve the following:

Example 1: $y(y^3 - x)dx + x(y^3 + x)dy = 0$

Solution: $y^4dx - xydx + xy^3dy + x^2dy = 0$
Regrouping the terms,

$$y^3(ydx + xdy) + x(xdy - ydx) = 0$$

$$y^3d(xy) + x \cdot x^2d\left(\frac{y}{x}\right) = 0$$

$$d(xy) + \left(\frac{x}{y}\right)^3 d\left(\frac{y}{x}\right) = 0$$

$$d(xy) + \left(\frac{y}{x}\right)^{-3} d\left(\frac{x}{y}\right) = 0$$

or

Integrating

$$xy - \frac{1}{2} \left(\frac{y}{x}\right)^{-2} = c_1$$

Rearranging $2xy^3 - x^2 = cy^2$ where $c = 2c_1$

Example 2: $(x^3y^3 + 1)dx + x^4y^2dy = 0$

Solution: $x^3y^3dx + dx + x^4y^2dy = 0$
Dividing by x throughout

$$x^2y^3dx + \frac{dx}{x} + x^3y^2dy = 0$$

Regrouping

$$x^2y^2(ydx + xdy) + \frac{dx}{x} = 0$$

$$(xy)^2d(xy) + \frac{dx}{x} = 0$$

$$\frac{(xy)^3}{3} + \ln x = c.$$

Example 3: $y(x^3e^{xy} - y)dx + x(xy + x^3e^{xy})dy = 0.$

Solution: $yx^3e^{xy}dx - y^2dx + xydy + x^4e^{xy}dy = 0.$

Regrouping, $x^3e^{xy}(ydx + xdy) + y(xdy - ydx) = 0$

$$x^3d(e^{xy}) + y \cdot x^2 \cdot \left(\frac{xdy - ydx}{x^2}\right) = 0.$$

Dividing throughout by x^3 ,

$$d(e^{xy}) + \frac{y}{x} \cdot d\left(\frac{y}{x}\right) = 0$$

Integrating $e^{xy} + \left(\frac{y}{x}\right)^2 \frac{1}{2} = c.$

Example 4:

$$(x^{n+1} \cdot y^n + ay)dx + (x^n y^{n+1} + ax)dy = 0$$

Solution: Regrouping the terms

8.14 — HIGHER ENGINEERING MATHEMATICS—III

$$x^n y^n (x dx + y dy) + a(y dx + x dy) = 0$$

Dividing throughout by $x^n y^n$

$$(x dx + y dy) + \frac{a d(xy)}{(xy)^n} = 0$$

If $n \neq 1$, Integrating

$$\frac{x^2 + y^2}{2} + a \cdot \frac{1}{(-n+1)(xy)^{n-1}} = c_0$$

$$(n-1)(x^2 + y^2 - c)(xy)^{n-1} = 2a, \text{ where } c = 2c_0$$

$$\text{If } n = 1, \frac{x^2 + y^2}{2} + a \ln xy = c.$$

Example 5: $y(x^2 y^2 - 1)dx + x(x^2 y^2 + 1)dy = 0$.

Solution: $x^2 y^3 dx - y dx + x^3 y^2 dy + x dy = 0$

Regrouping $x^2 y^2 (y dx + x dy) + (x dy - y dx) = 0$

$$x^2 y^2 d(xy) + x^2 \frac{(x dy - y dx)}{x^2} = 0$$

$$x^2 y^2 d(xy) + x^2 d\left(\frac{y}{x}\right) = 0$$

The second term in L.H.S. is *not* an exact differential,

Dividing by x^2 ; $y^2 d(xy) + d\left(\frac{y}{x}\right) = 0$.

Now multiply throughout by $x^k y^n$, we get

$$x^k y^{n+2} d(xy) + x^k y^n d\left(\frac{y}{x}\right) = 0$$

The first term in the L.H.S. becomes an exact differential if $k = n + 2$, while the second term in L.H.S. becomes an exact differential if $n = -k$. Solving these two equations

$$k = n + 2$$

$$n = -k$$

We get $n = -1, k = 1$.

Substituting these values, the D.E. reduces to

$$x^1 \cdot y^{-1+2} d(xy) + x^1 y^{-1} d\left(\frac{y}{x}\right) = 0$$

or $xy d(xy) + \frac{x}{y} d\left(\frac{y}{x}\right) = 0$

$$xy d(xy) + \frac{d\left(\frac{y}{x}\right)}{\left(\frac{y}{x}\right)} = 0$$

Integrating

$$\frac{(xy)^2}{2} + \ln\left(\frac{y}{x}\right) = c$$

Example 6: $(y + x)dy = (y - x)dx$

Solution: $y dy + x dy - y dx + x dx = 0$

Regrouping $(y dy + x dx) + (x dy - y dx) = 0$

$$\frac{1}{2} d(y^2 + x^2) + (x dy - y dx) = 0$$

Dividing throughout by $(x^2 + y^2)$, we get

$$\frac{1}{2} \frac{1}{(x^2 + y^2)} d(x^2 + y^2) + \frac{x dy - y dx}{x^2 + y^2} = 0$$

Rewriting $\frac{1}{2} d(\ln(x^2 + y^2)) + \left(\frac{\frac{x dy - y dx}{x^2 + y^2}}{1 + \left(\frac{y}{x}\right)^2}\right) = 0$

$$\frac{1}{2} d(\ln(x^2 + y^2)) + d\left(\tan^{-1}\left(\frac{y}{x}\right)\right) = 0$$

Integrating

$$\ln \sqrt{x^2 + y^2} + \tan^{-1} \frac{y}{x} = c$$

EXERCISE

Solve the following D.E. (by regrouping the terms):

1. $(4x^3 y^3 - 2xy)dx + (3x^4 y^2 - x^2)dy = 0$

Ans. $x^4 y^3 - x^2 y = c$

2. $3x^2 y dx + (y^4 - x^3)dy = 0$

Ans. $3x^3 + y^4 = cy$

3. $(x^3 + xy^2 + y)dx + (y^3 + x^2 y + x)dy = 0$

Ans. $(x^2 + y^2) = c - 4xy$

4. $y dx + (x + x^3 y^2)dy = 0$

Ans. $2x^2 y^2 \cdot \ln(cy) = 1$

5. $y(x^3 - y)dx - x(x^3 + y)dy = 0$

Hint: After regrouping multiply by $x^k y^n$ and determine k and n to make the D.E. exact.

Ans. $x^2 + 2y = cxy^2$

6. $y dx - x dy = xy^3 dy$

Ans. $\ln \frac{x}{y} = \frac{1}{3} y^3 + c$

7. $x dy = (x^5 + x^3 y^2 + y)dx$

Ans. $\tan^{-1} \frac{x}{y} = -\frac{1}{4} x^4 + c$

8. $x dy = (y + x^2 + 9y^2)dx$

Ans. $\tan^{-1} \frac{3y}{x} = 3x + c$

9. $y(2xy + e^x)dx = e^x dy$

Ans. $\frac{e^x}{y} + x^2 = c$

10. $(y^2 e^{xy^2} + 4x^3)dx + (2xy e^{xy^2} - 3y^2)dy = 0$

Ans. $e^{xy^2} + x^4 - y^3 = c$.

Case 2: When I.F. is a Function of x alone: ($My - Nx)/N = g(x)$)

When $F(x, y)$ is an I.F. then

$$F(Mdx + Ndy) = 0$$

is exact therefore

$$\frac{\partial}{\partial y}(FM) = \frac{\partial}{\partial x}(FN)$$

or $F \frac{\partial M}{\partial y} + M \frac{\partial F}{\partial y} = F \frac{\partial N}{\partial x} + N \frac{\partial F}{\partial x}$

Solving we get the formula for I.F. $f(x, y)$ as

$$\frac{1}{F} \left(N \frac{\partial F}{\partial x} - M \frac{\partial F}{\partial y} \right) = \frac{\partial M}{\partial y} - \frac{\partial N}{\partial x} \quad (1)$$

(which is a very difficult partial D.E.)

Suppose I.F. 'F' is a function of x alone. In this case (1) reduces to

$$\frac{1}{F} \frac{dF}{dx} = \frac{1}{N} \left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x} \right) \quad (2)$$

Since L.H.S. of (2) is a function of x alone say $g(x)$

i.e., $\frac{1}{F} \frac{dF}{dx} = g(x) = \frac{1}{N} \left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x} \right) \quad (3)$

Then integrating $\frac{1}{F} \frac{dF}{dx} = g(x)$, we get

$$F(x) = e^{\int g(x)dx}$$

where $g(x) = (M_y - N_x)/N$.

Case 3: When I.F. is a Function of y alone: ($Nx - My)/M = h(y)$)

Suppose I.F. 'F' is a function of y alone, in which case (1) reduces to

$$\frac{1}{F} \frac{dF}{dy} = - \frac{\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x} \right)}{M} = h(y)$$

then the I.F. 'F' is obtained by integration as

$$F(y) = e^{\int h(y)dy}$$

where $h(y) = (Nx - My)/M$.

Case 4

If $M(x, y)$ and $N(x, y)$ are homogeneous functions of the same degree then $(xM + yN)^{-1}$ is an I.F. of $Mdx + Ndy = 0$, provided $xM + yN \neq 0$.

In case $xM + yN = 0$ then $\frac{1}{x^2}$ or $\frac{1}{y^2}$ or $\frac{1}{xy}$ are I.F.'s.

WORKED OUT EXAMPLES

Case 2:

Solve the following:

Example 1: $y(2x^2 - xy + 1)dx + (x - y)dy = 0$

Solution: Here $M = 2yx^2 - xy^2 + y$, $N = x - y$

$$\frac{\partial M}{\partial y} = 2x^2 - 2xy + 1 \neq 1 = \frac{\partial N}{\partial x}, \quad \text{not exact}$$

Since

$$\frac{1}{N} \left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x} \right) = \frac{2x^2 - 2xy + 1 - 1}{x - y} = 2x = f(x),$$

is a function of x only, we get an I.F. as

$$I.F. = e^{\int 2xdx} = e^{x^2}$$

Multiplying the given D.E. by I.F. e^{x^2} , we get

$$ye^{x^2}(2x^2 - xy + 1)dx + e^{x^2}(x - y)dy = 0$$

which is of the form

$$M^*dx + N^*dy = 0$$

[This is exact since $\frac{\partial M^*}{\partial y} = (2x^2 - 2xy + 1)e^{x^2} = \frac{\partial N^*}{\partial x}$]

Integrate

$$\frac{\partial f}{\partial y} = e^{x^2}(x - y) = N^*$$

partially w.r.t. y , we have

$$f(x, y) = e^{x^2} \cdot \left(xy - \frac{y^2}{2} \right) + h(x)$$

Differentiating partially w.r.t. x and equating it to M^* , we get

$$\begin{aligned} e^{x^2} \left[xy - \frac{y^2}{2} \right] \cdot 2x + e^{x^2} [y] + \frac{dh}{dx} \\ = M^* = ye^{x^2}(2x^2 - xy + 1) \end{aligned}$$

8.16 — HIGHER ENGINEERING MATHEMATICS—III

Simplifying, $\frac{dh}{dx} = 0$ so $h = \text{constant}$.

Thus the general solution is

$$e^{x^2}(2xy - y^2) = c$$

Example 2: $(x - y)dx - dy = 0$, $y(0) = 2$.

Solution: $M = x - y$, $N = -1$, $M_y = -1$,

$N_x = 0$, not exact.

$\frac{1}{N}(M_y - N_x) = \frac{1}{-1}[-1 - 0] = 1$ is a function of x .

I.F. = $e^{\int 1 dx} = e^x$.

Multiplying D.E. by I.F.

$$(x - y)e^x dx - e^x dy = 0$$

Rewriting $xe^x dx - ye^x dx - e^x dy = 0$

$$xe^x dx - d(ye^x) = 0$$

$$xe^x dx + e^x dx - e^x dx - d(ye^x) = 0$$

$$(x - 1)e^x dx + e^x dx - d(ye^x) = 0$$

$$d((x - 1)e^x) - d(ye^x) = 0$$

Solution

$$(x - 1)e^x - ye^{-x} = c$$

Put $x = 0$, $y = 2$, so that $c = -3$.

$\therefore (x - 1)e^x - ye^{-x} = -3$ is the particular solution.

Case 3:

Solve the following:

Example 3: $(3x^2y^4 + 2xy)dx + (2x^3y^3 - x^2)dy = 0$

Solution: Here $M = 3x^2y^4 + 2xy$, $N = 2x^3y^3 - x^2$.
 $M_y = 12x^2y^3 + 2x \neq 6x^2y^3 - 2x = N_x$, not exact.
 Since

$$\begin{aligned} \frac{1}{M}(N_x - M_y) &= \frac{6x^2y^3 - 2x - (12x^2y^3 + 2x)}{3x^2y^4 + 2xy} \\ &= -\frac{2}{y} = g(y) = \text{function of } y \text{ alone,} \end{aligned}$$

we get an I.F. = $e^{\int g(y) dy}$

$$= e^{-\int \frac{2}{y} dy} = e^{-2 \ln y} = \frac{1}{y^2}$$

Multiplying the given D.E. throughout by $\frac{1}{y^2}$, we have

$$\left(3x^2y^2 + \frac{2x}{y}\right)dx + \left(2x^3y - \frac{x^2}{y^2}\right)dy = 0$$

[Since $M_y^* = 6x^2y - \frac{2x}{y^2} = N_x^*$, this D.E. is exact]

Rearranging the terms

$$(3x^2y^2 dx + 2x^3y dy) + \left(\frac{2x}{y} dx - \frac{x^2}{y^2} dy\right) = 0$$

$$y^2 d(x^3) + x^3 d(y^2) + \frac{1}{y} d(x^2) + x^2 d\left(\frac{1}{y}\right) = 0$$

Regrouping

$$d(x^3y^2) + d\left(\frac{x^2}{y}\right) = 0$$

Integrating

$$x^3y^2 + \frac{x^2}{y} = c$$

is the general solution.

Case 4:

Example 4: $y(y^2 - 2x^2)dx + x(2y^2 - x^2)dy = 0$

Solution: Here $M = y(y^2 - 2x^2)$ and

$N = x(2y^2 - x^2)$ are both homogeneous functions of degree 3.

Since $xM + yN = xy(y^2 - 2x^2) + yx(2y^2 - x^2) = 3(xy)(y^2 - x^2) \neq 0$ unless $y = x$, D.E. has an

$$\text{I.F.} = \frac{1}{xM + yN} = \frac{1}{3xy(y^2 - x^2)}$$

Multiplying the D.E. by I.F., we get

$$\frac{y(y^2 - 2x^2)}{3xy(y^2 - x^2)} dx + \frac{x(2y^2 - x^2)}{3xy(y^2 - x^2)} dy = 0$$

Rewriting

$$\frac{(y^2 - x^2) - x^2}{x(y^2 - x^2)} dx + \frac{y^2 + (y^2 - x^2)}{y(y^2 - x^2)} dy = 0$$

$$\text{or } \frac{dx}{x} - \frac{xdx}{y^2 - x^2} + \frac{ydy}{y^2 - x^2} + \frac{dy}{y} = 0$$

Regrouping

$$d(\ln xy) + \frac{1}{2} \frac{d(y^2 - x^2)}{(y^2 - x^2)} = 0$$

Integrating

$$d\left(\ln \left\{x^2y^2(y^2 - x^2)\right\}\right) = 0$$

we get

$$\ln x^2 y^2 (y^2 - x^2) = c$$

$$\text{or } x^2 y^2 (y^2 - x^2) = c_1, \quad \text{where } c_1 = e^c.$$

Case 5: D.E. of the Form— $yg(xy)dx + xh(xy)dy = 0$

If the D.E. $Mdx + Ndy = 0$ is in the form

$$yg(xy)dx + xh(xy)dy = 0$$

where $g(xy)$ and $h(xy)$ are functions of the argument (product) xy and $g(xy) \neq h(xy)$ then

$$\frac{1}{xM - yN} = \frac{1}{xy\{g(xy) - h(xy)\}}$$

is an integrating factor provided $xM - yN \neq 0$.

Note: If $xM - yN = 0$ then $\frac{M}{N} = \frac{y}{x}$ and the given D.E. reduces to $x dy + y dx = 0$ with $xy = c$ as its solution.

WORKED OUT EXAMPLES

Example 1:

$$(x^2 y^2 + xy + 1)ydx + (x^2 y^2 - xy + 1)xdy = 0$$

Solution: Here $M = (x^2 y^2 + xy + 1)y$,
 $N = (x^2 y^2 - xy + 1)x$ so

$$M_y = 3x^2 y^2 + 2xy + 1 \neq 3x^2 y^2 - 2xy + 1 = N_x$$

D.E. is not exact. But $M = yg(xy)$ and $N = xh(xy)$ so the given D.E. is of the form

$$yg(xy)dx + xh(xy)dy = 0$$

which has an integrating factor given by

$$\begin{aligned} \frac{1}{xM - yN} &= \frac{1}{xy(x^2 y^2 + xy + 1) - xy(x^2 y^2 - xy + 1)} \\ &= \frac{1}{2x^2 y^2} \end{aligned}$$

Multiplying D.E. with I.F. $\frac{1}{x^2 y^2}$, we get

$$\frac{(x^2 y^2 + xy + 1)ydx}{x^2 y^2} + \frac{(x^2 y^2 - xy + 1)x}{x^2 y^2} dy = 0$$

Rearranging

$$\left(ydx + \frac{dx}{x} + \frac{dx}{x^2 y}\right) + \left(xdy - \frac{dy}{y} + \frac{dy}{xy^2}\right) = 0$$

Regrouping the terms

$$(ydx + xdy) + \left(\frac{ydx}{x^2 y^2} + \frac{xdy}{x^2 y^2}\right) + \left(\frac{dx}{x} - \frac{dy}{y}\right) = 0$$

$$\text{or } d(xy) + \frac{d(xy)}{(xy)^2} + d\left(\ln \frac{x}{y}\right) = 0$$

Integrating

$$xy - \frac{1}{xy} + \ln \frac{x}{y} = c$$

Case 6

The D.E. is of the form

$$x^a y^b (mydx + nxdy) + x^c y^d (pydx + qxdy) = 0$$

where a, b, m, n, c, d, p, q are all constants and $mp - nq \neq 0$ has an integrating factor of the form $x^h y^k$

where the unknown constants h, k are determined from the two equations

$$\frac{a + h + 1}{m} = \frac{b + k + 1}{n}$$

and

$$\frac{c + h + 1}{p} = \frac{d + k + 1}{q}$$

WORKED OUT EXAMPLES

Example 1: $(2y^2 + 4x^2 y)dx + (4xy + 3x^3)dy = 0$

Solution: Here $M = 2y^2 + 4x^2 y$, $N = 4xy + 3x^3$,
 $M_y = 4y + 4x^2 \neq 4y + 9x^2 = N_x$, not exact. It is also not homogeneous. It is *not* $M = yh(xy)$ and $N = xg(xy)$ form. So let us try to find an integrating factor of the form

$$x^h y^k$$

Consider the D.E.

$$2y^2 dx + 4x^2 y dx + 4xy dy + 3x^3 dy = 0$$

Rearranging the terms

$$x^2(4ydx + 3xdy) + y(2ydx + 4xdy) = 0$$

Comparing this with

$$x^a y^b (mydx + nxdy) + x^c y^d (pydx + qxdy) = 0$$

$$\text{here } a = 2, b = 0, m = 4, n = 3,$$

8.18 — HIGHER ENGINEERING MATHEMATICS—III

$$c = 0, d = 1, p = 2, q = 4$$

$$\text{Also } mp - nq = 8 - 12 = -4 \neq 0$$

The unknown constants in the integrating factor are determined from the following:

$$\frac{a+h+1}{m} = \frac{b+k+1}{n} \text{ i.e., } \frac{2+h+1}{4} = \frac{0+k+1}{3}$$

$$\text{i.e., } 4k - 3h = 5$$

$$\frac{c+h+1}{p} = \frac{d+k+1}{q} \text{ i.e., } \frac{0+h+1}{2} = \frac{1+k+1}{4}$$

$$\text{i.e., } k - 2 = 0$$

Solving for h, k , we get $h = 1, k = 2$.

Thus the required integrating factor is

$$x^1 \cdot y^2.$$

Multiplying the given D.E. by this integrating factor xy^2 , we get

$$xy^2(2y^2 + 4x^2y)dx + xy^2(4xy + 3x^3)dy = 0$$

$$2xy^4 + 4x^3y^3dx + 4x^2y^3dy + 3x^4y^2dy = 0$$

Regrouping the terms (1st and 3rd) and (2nd and 4th)

$$d(x^2y^4) + d(x^4y^3) = 0$$

Integrating $x^2y^4 + x^4y^3 = c$ is the solution.

EXERCISE

Case 2: Solve the following:

$$1. (4xy + 3y^2 - x)dx + x(x + 2y)dy = 0$$

$$\text{Ans. } x^3(4xy + 4y^2 - x) = c$$

$$2. y(x + y)dx + (x + 2y - 1)dy = 0$$

$$\text{Ans. } y(x - 1 + y) = ce^{-x}$$

$$3. 2xydy - (x^2 + y^2 + 1)dx = 0$$

$$\text{Ans. } y^2 - x^2 + 1 = cx$$

$$4. (3xy - 2ay^2)dx + (x^2 - 2axy)dy = 0$$

$$\text{Ans. } x^3y - ax^2y^2 = c$$

$$5. 2 \sin(y^2)dx + xy \cos(y^2)dy = 0, y(2) = \sqrt{\frac{\pi}{2}}$$

$$\text{Ans. } x^4 \sin(y^2) = 16$$

$$6. (2x^3y^2 + 4x^2y + 2xy^2 + xy^4 + 2y)dx + 2(y^3 + x^2y + x)dy = 0$$

$$\text{Ans. } (2x^2y^2 + 4xy + y^4)e^{x^2} = c.$$

Case 3: Solve the following:

$$1. (y + xy^2)dx - xdy = 0$$

$$\text{Ans. } \frac{x}{y} + \frac{x^2}{2} = c$$

$$2. y(x + y + 1)dx + x(x + 3y + 2)dy = 0$$

$$\text{Ans. } xy^2(x + 2y + 2) = c$$

$$3. 3(x^2 + y^2)dx + x(x^2 + 3y^2 + 6y)dy = 0$$

$$\text{Ans. } xe^y(x^2 + 3y^2) = c$$

$$4. (xy^3 + y)dx + 2(x^2y^2 + x + y^4)dy = 0$$

$$\text{Ans. } 3x^2y^4 + 6xy^2 + 2y^6 = c$$

$$5. (y^4 + 2y)dx + (xy^3 + 2y^4 - 4x)dy = 0$$

$$\text{Ans. } (y^3 + 2)x + y^4 = cy^2$$

$$6. 2xydx + (y^2 - x^2)dy = 0, y(2) = 1$$

$$\text{Ans. } x^2 + y^2 = 5y.$$

Case 4: Solve the following:

$$1. x^2ydx - (x^3 + y^3)dy = 0$$

$$\text{Ans. } y = ce^{-x^3/(3y^3)}$$

$$2. (x^2y - 2xy^2)dx - (x^3 - 3x^2y)dy = 0$$

$$\text{Ans. } \frac{x}{y} - 2 \log x + 3 \log y = c$$

$$3. (x^4 + y^4)dx - xy^3dy = 0$$

$$\text{Ans. } y^4 = 4x^4 \ln x + cx^4$$

$$4. y^2dx + (x^2 - xy - y^2)dy = 0$$

$$\text{Ans. } (x - y)y^2 = c(x + y)$$

$$5. (y - x)dx + (y + x)dy = 0$$

$$\text{Ans. } \ln(x^2 + y^2)^{\frac{1}{2}} - \tan^{-1}\left(\frac{x}{y}\right) = c.$$

Case 5: Solve the following:

$$1. y(x^2y^2 + 2)dx + x(2 - 2x^2y^2)dy = 0$$

$$\text{Ans. } x = cy^2e^{\frac{1}{(x^2y^2)}}$$

$$2. y(xy + 2x^2y^2)dx + x(xy - x^2y^2)dy = 0$$

Ans. $\frac{2}{3} \ln x - \frac{1}{3} \ln y - \frac{1}{3xy} = c$

3. $(xy \sin xy + \cos xy)ydx + (xy \sin xy - \cos xy)xdy = 0$

Ans. $x \sec xy = cy$

4. $y(1 + xy)dx + (1 - xy)xdy = 0$

Ans. $\ln \frac{x}{y} - \frac{1}{xy} = c$

5. $(x^3y^3 + x^2y^2 + xy + 1)ydx + (x^3y^3 - x^2y^2 + xy + 1)xdy = 0$

Ans. $x^2y^2 - 2xy \log cy = 1$

6. $(2xy^2 + y)dx = (x + 2x^2y - x^4y^3)dy = 0$

Ans. $y = ce^{\frac{(-3xy+1)}{(3x^3y^3)}}$

Case 6: Solve the following:

1. $x(4ydx + 2xdy) + y^3(3ydx + 5xdy) = 0$

Ans. $x^4y^2 + x^3y^3 = c$

2. $(8ydx + 8xdy) + x^2y^3(4ydx + 5xdy) = 0$

Ans. $4x^2y^2 + x^4y^5 = c$

3. $x^3y^3(2ydx + xdy) - (5ydx + 7xdy) = 0$

Ans. $x^3y^3 + 2 = cx^{\frac{5}{3}}y^{\frac{7}{3}}$

4. $y(xy + 2x^2y^2)dx + x(xy - x^2y^2)dy = 0$

Ans. $2 \ln x - \ln y - \frac{1}{xy} = c$

8.9 LINEAR DIFFERENTIAL EQUATION: FIRST ORDER

“Leibnitz’s Linear Equation”

The general form of a first order linear differential equation in the dependent variable y is

$$A(x) \frac{dy}{dx} + B(x)y = c(x)$$

By dividing throughout by $A(x)$ we get the standard form of the linear equation of first order which is also known as Leibnitz’s* linear equation.

$$\frac{dy}{dx} + P(x)y = Q(x) \quad (1)$$

The important feature of this equation is that it is linear (i.e., of first degree) in y and its derivative y' , and does not contain product terms of y and y' .

Here $P(x)$ and $Q(x)$ may be any given functions of x .

Because of this, note that a linear equation is of first degree but first degree equation need not be linear (in y i.e., it can contain terms like $y^{\frac{23}{5}}y \sin y$, e^y etc.)

Homogeneous: If the R.H.S. $Q(x)$ is zero for all x then Equation (1) is said to be homogeneous; otherwise (i.e., $Q(x) \neq 0$) it is said to be non-homogeneous.

The non-homogeneous Equation (1) has an integrating factor $v(x)$ depending only on x . Multiplying (1) by $v(x)$ and rewriting it, we get

$$[v(x)P(x)y - v(x)Q(x)]dx + v(x)dy = 0 \quad (2)$$

This Equation (2) which is in the form $Mdx + Ndy = 0$ with $M = vPy - vQ$ and $N = v$ is exact and should satisfy the condition.

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x} \quad \text{i.e.,} \quad vP = \frac{dv}{dx}$$

which is a separable equation.

To get v , we integrate

$$\int \frac{dv}{v} = \int P dx \quad \text{i.e.,} \quad \ln v = \int P dx$$

or $v(x) = e^{\int P(x)dx} \quad (3)$

Thus $v(x)$ given by (3) is the required integrating factor of the first order non-homogeneous linear differential Equation (1).

To find the solution of (1), multiply (1) throughout by the integrating factor (3).

$$\frac{dy}{dx} \cdot e^{\int P dx} + Py \cdot e^{\int P dx} = Q \cdot e^{\int P dx}$$

Rewriting

$$d(ye^{\int P dx}) = Qe^{\int P dx}$$

Integrating, we get

$$ye^{\int P dx} = \int Qe^{\int P dx} dx \quad (4)$$

* Gottfried Wilhelm Leibnitz (1646–1716), German mathematician.

8.20 — HIGHER ENGINEERING MATHEMATICS—III

Method of solving linear equation:

- I. Put the given equation in the standard form (1).
- II. Determine the integrating factor $v(x) = e^{\int P dx}$.
- III. Multiply equation throughout by the integrating factor $v(x)$.
- IV. Solve the resultant exact equation.

Note 1: The L.H.S. of (4) is *always* the product of y and the integrating factor $v(x)$.

Note 2: In some cases, when given D.E. in non-linear in y , it would be much convenient to treat x as the dependent variable instead of y and solve the equation $\frac{dx}{dy} + P^*(y)x = Q^*(y)$ which is linear in x (see Worked Out Examples 6, 7 and also Exercise Examples 11–15).

WORKED OUT EXAMPLES

Example 1: Solve $y' = 4y + 2x - 4x^2$.

Solution: Standard form $y' - 4y = 2x - 4x^2$ with $P(x) = -4$, $Q(x) = 2x - 4x^2$

I.F. $e^{\int P dx} = e^{\int -4 dx} = e^{-4x}$

Multiplying by I.F.

$$e^{-4x} \cdot y' - 4ye^{-4x} = (2x - 4x^2)e^{-4x}$$

Rewriting

$$\frac{d}{dx}(ye^{-4x}) = (2x - 4x^2)e^{-4x}$$

Integrating

$$\begin{aligned} ye^{-4x} &= \int (2x - 4x^2)e^{-4x} dx \\ &= 2 \int xe^{-4x} dx + \int x^2 d(e^{-4x}) \end{aligned}$$

Integrating by parts

$$ye^{-4x} = \int 2xe^{-4x} dx + x^2e^{-4x} - \int e^{-4x} \cdot 2x dx + c$$

$$ye^{-4x} = x^2e^{-4x} + c$$

Solution is $y = x^2 + ce^{4x}$.

Example 2: Solve $xy' + 2y - x \sin x = 0$.

Solution: Standard form $y' + \frac{2y}{x} = \sin x$

with $Q = \sin x$, $P = 2/x$

I.F. $= e^{\int P dx} = e^{\int \frac{2}{x} dx} = e^{\ln x^2} = x^2$

Multiplying by I.F. x^2

$$x^2 y' + 2xy = x^2 \sin x$$

$$\frac{d}{dx}(yx^2) = x^2 \sin x$$

Integrating

$$yx^2 = \int x^2 \sin x \cdot dx = \int x^2 d(\cos x)$$

Integrating by parts

$$yx^2 = -x^2 \cos x + \int 2x \cdot \cos x dx$$

$$yx^2 = -x^2 \cos x + 2x \sin x + 2 \cos x + c$$

Example 3:

$$\{y(1 - x \tan x) + x^2 \cos x\} dx - x dy = 0.$$

Solution: Standard form

$$y' + \frac{(x \tan x - 1)}{x} y = x \cos x$$

with $P(x) = \frac{x \tan x - 1}{x}$, $Q(x) = x \cos x$

I.F. $\exp \left\{ \int \left(\frac{x \tan x - 1}{x} \right) dx \right\} = \exp \{-\ln \cos x - \ln x\}$

$$\text{I.F.} = \frac{1}{x \cos x}$$

$$\frac{1}{x \cos x} \cdot y' + \frac{(x \tan x - 1)}{x} \cdot \frac{1}{x \cos x} \cdot y = 1$$

Rewriting

$$\frac{d}{dx} \left(\frac{y}{x \cos x} \right) = 1$$

Integrating

$$\frac{y}{x \cos x} = \int dx + c = x + c$$

Solution is $y = x^2 \cos x + cx \cos x$.

Example 4: Solve $x(1 - 4y)dx - (x^2 + 1)dy = 0$ with $y(2) = 1$.

Solution: Standard form

$$y' + \frac{4x}{x^2 + 1} \cdot y = \frac{x}{x^2 + 1}$$

with $P(x) = \frac{4x}{x^2+1}$ and $Q(x) = \frac{x}{x^2+1}$

I.F. = $e^{\int P dx} = e^{\int \frac{4x}{x^2+1} dx} = e^{2 \ln (x^2+1)} = (x^2+1)^2$

Multiplying by I.F. $(x^2+1)^2$, we get an exact equation

$$(x^2+1)^2 y' + 4x(x^2+1)y = x(x^2+1)$$

Rewriting

$$\frac{d}{dx}\{y(x^2+1)^2\} = x^3 + x$$

Integrating

$$y \cdot (x^2+1)^2 = \int (x^3+x) dx + c = \frac{x^4}{4} + \frac{x^2}{2} + c$$

$$4y(x^2+1)^2 = x^4 + 2x^2 + 4c$$

Since $y(2) = 1$, put $x = 2$ and $y = 1$

$$4.25 = 16 + 8 + 4c \quad \therefore c = 19$$

The particular solution is

$$4y(x^2+1)^2 = x^4 + 2x^2 + 76$$

Example 5: Solve $\frac{dy}{dx} = \frac{1}{(1+x^2)}(e^{\tan^{-1} x} - y)$.

Solution: Standard form

$$\frac{dy}{dx} + \frac{1}{1+x^2}y = \frac{e^{\tan^{-1} x}}{1+x^2}$$

with $P(x) = \frac{1}{1+x^2}$, $Q(x) = \frac{e^{\tan^{-1} x}}{1+x^2}$.

I.F. = $e^{\int P(x) dx} = e^{\int \frac{dx}{1+x^2}} = e^{\tan^{-1} x}$

Multiplying by I.F. $e^{\tan^{-1} x}$, we get

$$e^{\tan^{-1} x} \cdot \frac{dy}{dx} + \frac{1}{1+x^2} \cdot y \cdot e^{\tan^{-1} x} = \frac{(e^{\tan^{-1} x})^2}{(1+x^2)}$$

Rewriting

$$\frac{d}{dx}\{y \cdot e^{\tan^{-1} x}\} = \frac{(e^{\tan^{-1} x})^2}{(1+x^2)}$$

Integrating

$$\begin{aligned} y \cdot e^{\tan^{-1} x} &= \int \frac{(e^{\tan^{-1} x})^2}{(1+x^2)} dx + c \\ &= \int (e^{\tan^{-1} x})^2 \cdot d \cdot (\tan^{-1} x) + c \end{aligned}$$

$$y \cdot e^{\tan^{-1} x} = \frac{(e^{\tan^{-1} x})^2}{2} + c$$

Example 6: Solve $y^2 dx + (3xy - 1) dy = 0$.

Solution: Rewriting in standard form

$$\frac{dy}{dx} = \frac{y^2}{1-3xy}$$

This is *not* linear in y (because of the presence of the term y^2). This is also *not* exact, not homogeneous, nor separable. Instead if we swap the roles of x and y by treating x as dependent variable and y as the independent variable, the given equation can be rearranged as

$$\frac{dx}{dy} + \frac{3}{y}x = \frac{1}{y^2}$$

with $P(y) = \frac{3}{y}$ and $Q(y) = \frac{1}{y^2}$

Now we get.

I.F. = $e^{\int P(y) dy} = e^{\int \frac{3}{y} dy} = e^{3 \ln y} = e^{\ln y^3} = y^3$

Multiplying by I.F. y^3 , we have

$$y^3 \frac{dx}{dy} + 3xy^2 = y$$

Rewriting

$$\frac{d}{dy}(xy^3) = y$$

Integrating w.r.t. y

$$xy^3 = \int y dy + c = \frac{y^2}{2} + c$$

$$2xy^3 - y^2 = 2c$$

Example 7: Solve $\frac{dy}{dx} + \frac{y \ln y}{x - \ln y} = 0$.

Solution: This equation is *not* linear in y because of the presence of the term $\ln y$. It is neither separable, nor homogeneous nor exact. But with x taken as dependent variable the equation can be rewritten as

$$\frac{dx}{dy} + \frac{1}{y \ln y} \cdot x = \frac{1}{y}$$

which is the standard form of first order linear differential equation with $P(y) = \frac{1}{y \ln y}$, $Q(y) = \frac{1}{y}$ so that

I.F. is $e^{\int P(y) dy} = \exp \left\{ \int \frac{dy}{y \ln y} \right\} = e^{\ln(\ln y)} = \ln y$

Multiplying with the I.F. $\ln y$, we get the exact equation

$$\ln y \cdot \frac{dx}{dy} + \frac{1}{y}x = \frac{\ln y}{y}$$

8.22 — HIGHER ENGINEERING MATHEMATICS—III

or
$$\frac{d}{dy}(x \cdot \ln y) = \frac{\ln y}{y}$$

Integrating w.r.t. y

$$x \cdot \ln y = \int \frac{\ln y}{y} dy = \int \ln y d(\ln y) = \frac{(\ln y)^2}{2} + c$$

So the solution is

$$2x \ln y = (\ln y)^2 + 2c$$

EXERCISE

Solve the following:

1. $2(y - 4x^2)dx + xdy = 0$

Ans. $x^2y = 2x^4 + c$

2. $y' + y \cot x = 2x \operatorname{cosec} x$

Ans. $y = (x^2 + c) \operatorname{cosec} x$

3. $y' + y = \frac{1}{1+e^{2x}}$

Ans. $y = e^{-x} \cdot \tan^{-1} e^x + ce^{-x}$

4. $(1+x^2)dy + 2xydx = \cot x dx$

Ans. $y = \frac{\log(\sin x) + c}{(1+x^2)}$

5. $y' + 2y = e^x(3 \sin 2x + 2 \cos 2x)$

Ans. $y = ce^{-2x} + e^x \cdot \sin 2x$

6. $y' + y \tan x + \sin 2x, y(0) = 1$

Ans. $y = 3 \cos x - 2 \cos^2 x$

7. $y' + y = e^{e^x}$

Ans. $ye^x = e^{e^x} + c$

8. $[y + (x+1)^2 e^{3x}]dx - (x+1)dy = 0$

Ans. $y = (\frac{1}{3}e^{3x} + c)(x+1)$

9. $dx + (3y - x)dy = 0$

Ans. $x - 3y - 3 = ce^y$

10. $\frac{dI}{dt} + 2I = 10e^{-2t}, I = 0$ when $t = 0$

Ans. $I = 10te^{-2t}$

11. $ydx + (3x - xy + 2)dy = 0$

Hint: Examples 11 to 15 are linear when x is considered as the dependent variable.

Ans. $xy^3 = 2y^2 + 4y + 4 + ce^y$

12. $(1 + y^2)dx + (x - \tan^{-1} y)dy = 0$

Ans. $x = \tan^{-1} y - 1 + ce^{-\tan^{-1} y}$

13. $y^2 dx + (xy - 2y^2 - 1)dy = 0$

Ans. $xy = y^2 + \ln y + c$

14. $dx - (x + y + 1)dy = 0$

Ans. $x = -(y + 2) + ce^y$

15. $ydx - (x + 2y^3)dy = 0$

Ans. $x = y^3 + cy$

8.10 BERNOULLI* EQUATION

Nonlinear Equation Reducible to Linear Form

A first order first degree differential equation of the form

$$\frac{dy}{dx} + P(x)y = Q(x) \cdot y^a \quad (1)$$

is known as Bernoulli equation, which is nonlinear for any value of the real number a (except for $a = 0$ and 1).

For $a = 0$, (1) reduces to Linear first order D.E. discussed in Section 8.9.

For $a = 1$, (1) reduces to linear separable D.E., considered in Section 8.4.

For any a , other than 0 and 1, the nonlinear first order D.E. (1) can be reduced to linear D.E. by the substitution

$$z = y^{1-a} \quad (2)$$

Substituting $\frac{dz}{dx} = (1-a)y^{-a} \frac{dy}{dx}$ and (2) in (1), we get

$$\frac{1}{1-a} y^a \frac{dz}{dx} + P(x) \cdot y^a z = Q(x) y^a$$

Simplifying, we get

$$\frac{dz}{dx} + (1-a)P(x)z = (1-a)Q(x)$$

which is a linear first order D.E. in the standard form, discussed in Section 8.9.

* Jakob Bernoulli (1654–1705), Swiss mathematician.

Method of finding solution to Bernoulli equation.

Step I. Rewrite the given equation in standard Bernoulli equation.

Step II. Identify a , $P(x)$ and $Q(x)$.

Step III. Introduce a new variable

$$z = y^{1-a}$$

and obtain the resultant first order linear equation in z .

Step IV. Solve linear equation in z by the method discussed in Section 8.9.

Note: A nonlinear equation of the form

$$f'(y)\frac{dy}{dx} + P(x)f(y) = Q(x) \quad (3)$$

can be reduced to linear equation in z by the substitution

$$z = f(y)$$

(see Worked Out Example 5 and Exercise Examples 7, 8, 9, 10 on pages 8.24 and 8.25)

Now consider the Bernoulli equation

$$\frac{dy}{dx} + P(x)y = Q(x)y^a \quad (1)$$

Multiplying throughout by $(1-a)y^{-a}$, we get

$$(1-a)y^{-a}\frac{dy}{dx} + (1-a)P(x)y^{1-a} = (1-a)Q(x) \quad (4)$$

Let $f(y) = y^{1-a}$, so that $f'(y) = (1-a)y^{-a}$

The Equation (4) becomes

$$f'(y)\frac{dy}{dx} + (1-a)P(x)f(y) = (1-a)Q(x)$$

Thus we observe that Bernoulli Equation (1) is a special case of Equation (3).

WORKED OUT EXAMPLES

Example 1: Solve $3y' + xy = xy^{-2}$.

Solution: Rewriting $y' + \frac{x}{3}y = \frac{x}{3}y^{-2}$
This is a Bernoulli equation with $a = -2$

Introducing $z = y^{1-a} = y^{1-(-2)} = y^3$, so that

$$\frac{dz}{dx} = 3y^2\frac{dy}{dx}$$

Substituting in D.E.

$$\frac{1}{3}\frac{dz}{dx} + \frac{1}{3}xz = \frac{1}{3}x$$

This is a linear equation but is also a separable equation

$$\frac{dz}{dx} = x(1-z)$$

$$\text{or} \quad \frac{dz}{z-1} = -xdx$$

Integrating $\ln(z-1) = -\frac{x^2}{2} + c_0$

$$(z-1) = e^{-\frac{x^2}{2}} \cdot c$$

where $c = e^{c_0}$

Replacing z , we get the solution as

$$y^3 = 1 + ce^{-\frac{x^2}{2}}$$

Example 2: Solve $\cos x dy = y(\sin x - y)dx$.

Solution: $y' - y \cdot \tan x = -\sec x \cdot y^2$
Bernoulli with $a = 2$

Put $z = y^{1-a} = y^{1-2} = y^{-1}$,

$$\frac{dz}{dx} = -\frac{1}{y^2} \frac{dy}{dx}$$

Substituting

$$\frac{dz}{dx} + z \cdot \tan x = \sec x$$

which is a linear equation with I.F. $= e^{\int \tan x dx} = \sec x$.

Multiplying throughout by I.F. $\sec x$, we get

$$\sec x \cdot \frac{dz}{dx} + z \cdot \sec x \cdot \tan x = \sec^2 x$$

$$\text{or} \quad \frac{d}{dx}(z \sec x) = \sec^2 x$$

Integrating $z \sec x = \int \sec^2 x dx + c$

$$z \sec x = \tan x + c$$

8.24 — HIGHER ENGINEERING MATHEMATICS—III

Replacing z ,

$$\frac{1}{y} \sec x = \tan x + c$$

or $\sec x = y(\tan x + c)$.

Example 3: Solve $2xyy' = y^2 - 2x^3$, $y(1) = 2$.

Solution: Rewriting $y' - \frac{1}{2x}y = -x^2y^{-1}$ which is a Bernoulli equation with $a = -1$ so that the substitution is $z = y^{1-a} = y^{1-(-1)} = y^2$, and $\frac{dz}{dx} = 2y \frac{dy}{dx}$. With these the D.E. takes the linear form as

$$\frac{dz}{dx} - \frac{1}{x}z = -2x^2$$

The I.F. is $e^{\int -\frac{1}{x}dx} = e^{-\ln x} = e^{\ln \frac{1}{x}} = \frac{1}{x}$

By multiplying D.E. with I.F.: $\frac{1}{x}$, we get

$$\frac{1}{x} \frac{dz}{dx} - \frac{1}{x^2}z = -2x$$

$$\text{or } \frac{d}{dx}\left(z \cdot \frac{1}{x}\right) = -2x$$

Integrating $z \cdot \frac{1}{x} = \int -2x dx + c = -x^2 + c$

$$z = -x^3 + cx$$

Replacing z , $y^2 = cx - x^3$

Since $y(1) = 2$, $2^2 = c \cdot 1 - 1^3 \therefore c = 5$. Thus the required solution is $y^2 = x(5 - x^2)$.

Example 4: Solve $(xy^5 + y)dx - dy = 0$.

Solution: Rewriting $y' - y = xy^5$. This is Bernoulli equation with $a = 5$ so that put $z = y^{1-a} = y^{1-5} = y^{-4}$. Also $\frac{dz}{dx} = -4 \cdot y^{-5} \frac{dy}{dx}$.

Substituting in the D.E., we get

$$\frac{dz}{dx} + 4z = -4x$$

I.F. for this linear equation is $e^{\int 4dx} = e^{4x}$

Multiplying D.E. with I.F. e^{4x} , we get

$$e^{4x} \cdot \frac{dz}{dx} + 4z \cdot e^{4x} = -4xe^{4x}$$

$$\text{or } \frac{d}{dx}(z \cdot e^{4x}) = -4xe^{4x}$$

Integrating $z \cdot e^{4x} = -4 \int xe^{4x} dx + c$

Integrating by parts

$$ze^{4x} = -xe^{4x} + \frac{1}{4}e^{4x} + c$$

Replacing z by y^{-4} , we have

$$y^{-4}e^{4x} = -xe^{4x} + \frac{1}{4}e^{4x} + c$$

Example 5: Solve

$$y' - 2 \cos x \cdot \cot y + \sin^2 x \cdot \operatorname{cosec} y \cdot \cos x = 0$$

Solution: Rewriting $\sin y \cdot y' = 2 \cos x \cdot \cos y - \cos x \cdot \sin^2 x$ or
 $-\sin y \frac{dy}{dx} + (\cos y)(2 \cos x) = \sin^2 x \cdot \cos x$

$$\text{Put } v = \cos y, \text{ so that } \frac{dv}{dy} = -\sin y$$

with this substitution the given equation becomes

$$\frac{dv}{dx} + 2v \cos x = \sin^2 x \cdot \cos x$$

This is a linear equation for which the I.F. is $e^{\int 2 \cos x dx} = e^{2 \sin x}$

Then the solution is

$$\begin{aligned} ve^{2 \sin x} &= \int e^{2 \sin x} \cdot \sin^2 x \cdot \cos x dx \\ &= \frac{1}{2}e^{2 \sin x} \cdot \sin^2 x - \frac{1}{2}e^{2 \sin x} \cdot \sin x + \frac{1}{4}e^{2 \sin x} + c \end{aligned}$$

Replacing v by $\cos y$, we get the required solution as

$$\cos y = \frac{1}{2} \sin^2 x - \frac{1}{2} \sin x + \frac{1}{4} + ce^{-2 \sin x}$$

EXERCISE

1. $(y - y^2x^2 \sin x)dx + xdy = 0$

Ans. $yx(c + \cos x) = 1$

2. $y^1 + y + y^2(\sin x - \cos x) = 0$

Ans. $y(ce^x - \sin x) = 1$

3. $\frac{dz}{dx} + \left(\frac{z}{x}\right) \log z = \frac{z}{x}(\log z)^2$

Hint: Put $v = \log z$

Ans. $(1 + cx) \log z = 1$

4. $y^1 + \frac{y}{2x} = \frac{x}{y^3}$, $y(1) = 2$

Ans. $x^2y^4 = x^4 + 15$

Hint: Take x as dependent variable in examples 5, 6.

5. $dx - (x^2y^3 + xy)dy = 0$

Ans. $x(2 - y^2) + cxe^{\frac{-y^2}{2}} = 1$

6. $y^2 dx + (xy - x^3) dy = 0$

Ans. $2x^2 - 3y = cx^2 y^3$

7. $xy'' - 3y' = 4x^2$

Hint: Put $y' = v$

Ans. $y = c_1 x^4 - \frac{4}{3} x^3 + c_2$

8. $y' = Ay - By^n$ with A, B, n ; constants and $n \neq 0, 1$

Ans. $y^{1-n} = \left[\frac{B}{A} + ce^{(1-n)Ax} \right]$

9. $xy' + y = x^3 y^6$

Ans. $(cx^2 + 2.5)x^3 y^5 = 1$

10. $y^2 \cdot y' - y^3 \tan x - \sin x \cdot \cos^2 x = 0$

Ans. $2y^3 + \cos^3 x = 2c \sec^3 x$

Hint: Put $f(y) = v$ in Examples 11, 12, 13, 14, to reduce the given equation to linear form.

11. $y' + x \sin 2y = x^3 \cos^2 y$

Ans. $2y = (x^2 - 1) + 2ce^{-x^2}$

12. $[(x+1)^4 + 2 \sin y^2] dx - 2y(x+1) \times \cos y^2 dy = 0$

Ans. $2 \sin y^2 = (x+1)^4 + 2c(x+1)^2$

13. $(4e^{-y} \sin x - 1) dx - dy = 0$

Ans. $e^y = 2(\sin x - \cos x) + ce^{-x}$

14. $y' - \cot y + x \cot y = 0$

Ans. $\sec y = x + 1 + ce^x$

15. $x(4y - 8y^{-3}) dx + dy = 0$

Ans. $y^4 = (2 + ce^{-8x^2})$

8.11 FIRST ORDER NONLINEAR DIFFERENTIAL EQUATIONS

A differential equation of first order and higher (more than first) degree is of the form

$$f(x, y, y') = 0 \quad (1)$$

or $f(x, y, p) = 0 \quad (1^*)$

where $\frac{dy}{dx} \equiv y' = p$. The degree of D.E. (of p) in (1) is more than one. So (1*) is a nonlinear first order D.E.

Example: $p^3 - p^2 (\cos x + e^x) + 5py + 2y^2 = 0$, first order, 3rd degree, nonlinear

A first order D.E. of n th degree has the general form

$$p^n + a_1(x, y)p^{n-1} + a_2(x, y)p^{n-2} + \dots + a_{n-1}(x, y)p + a_n(x, y) = 0 \quad (2)$$

Here the coefficients $a_1(x, y), a_2(x, y), \dots, a_n(x, y)$ are functions of x and y .

In several cases, (2) can be solved by reducing (2) to first order and first degree (n) equation (s), by (a) solving for p (b) solving for y (c) solving for x .

Equations Solvable for p

If the LHS of (2), which is an n th degree polynomial in p , can be resolved into n linear real factor then (2) takes the form

$$(p - b_1)(p - b_2) \dots (p - b_n) = 0 \quad (3)$$

where $b_1, b_2, \dots, b_n$ are all functions of x and y . Equating the n factors in the RHS of (3) to zero, the solution of the n th degree equation (2) reduces to the problem of solving n first order and first degree differential equations given by

$$\frac{dy}{dx} = b_1(x, y), \frac{dy}{dx} = b_2(x, y), \dots, \frac{dy}{dx} = b_n(x, y)$$

Solving these n equations, we obtain

$$f_1(x, y, c) = 0, f_2(x, y, c) = 0, \dots, f_n(x, y, c) = 0 \quad (4)$$

Thus the solution of (2) is given by (4) or by the product of the functions in (4)

$$\text{i.e., } f_1(x, y, c) \cdot f_2(x, y, c) \dots f_n(x, y, c) = 0$$

Equations Solvable for y

Solving the given equation $f(x, y, p) = 0$ for y , we get

$$y = F(x, p) \quad (1)$$

Differentiating (1) w.r.t. ' x ' we get

$$\frac{dy}{dx} = \frac{\partial F}{\partial x} + \frac{\partial F}{\partial p} \frac{dp}{dx}$$

8.26 — HIGHER ENGINEERING MATHEMATICS—III

Since $p = \frac{dy}{dx}$, this equation takes the form

$$p = \phi \left(x, p, \frac{dp}{dx} \right) \quad (2)$$

which is a first order and first degree differential equation in the variable p . Solving (2), suppose we obtain its solution as

$$\psi(x, p, c) = 0 \quad (3)$$

Then eliminating ' p ' between (1) and (3), we get the required solution of (1). When it is not possible to eliminate p , equations expressing x and y in terms of p as $x = x(p, c)$, $y = y(p, c)$ will give the parametric representation of the solution of (1) in the parameter p .

Equations Solvable for x

Solving $f(x, y, p) = 0$ for x , we obtain

$$x = F(y, p) \quad (4)$$

which on differentiation w.r.t. y gives

$$\frac{dx}{dy} = \frac{1}{p} = \frac{\partial F}{\partial y} + \frac{\partial F}{\partial p} \frac{dp}{dy} \quad (5)$$

which is first order and first degree differential equation in p ,

$$\frac{1}{p} = \phi \left(x, p, \frac{dp}{dy} \right). \quad (6)$$

Suppose $\psi(x, p, c) = 0$ be the solution of (6). Then the required solution is obtained by eliminating p between the equations $x = F(y, p)$ and $\psi(x, p, c) = 0$. When elimination of p is not possible we can express $x = x(p, c)$ and $y = y(p, c)$ which will be the parametric representation of the solution.

WORKED OUT EXAMPLES

Equations Solvable for p

Example 1: Solve $x^2 \left(\frac{dy}{dx} \right)^2 + xy \frac{dy}{dx} - 6y^2 = 0$

Solution: This is a first order, second degree, non-linear homogeneous DE (all the three terms are

non-linear). Introducing $\frac{dy}{dx} = p$, the given equation takes the form

$$x^2 p^2 + xyp - 6y^2 = 0$$

Factorizing, $(px + 3y)(px - 2y) = 0$

or $(px + 3y) = 0$ and $(px - 2y) = 0$

Solving

$$x \frac{dy}{dx} + 3y = 0, \quad \frac{dy}{y} + 3 \frac{dx}{x} = 0, \quad yx^3 = c$$

$$x \frac{dy}{dx} - 2y = 0, \quad \frac{dy}{y} - \frac{2dx}{x} = 0, \quad \frac{y}{x^2} = c$$

The primitive of the given DE is

$$(yx^3 - c)(y - cx^2) = 0$$

Example 2: Solve $p^3 + 2xp^2 - y^2p^2 - 2xy^2p = 0$

Solution: This is a first order, 3rd degree, nonlinear homogeneous DE. Rewriting

$$\begin{cases} p^2(p + 2x) - y^2p(p + 2x) = \\ = (p + 2x)p(p - y^2) = 0 \end{cases}$$

Thus $p + 2x = 0$, $p = 0$, $p - y^2 = 0$.

Solving $y + x^2 = c$, $y = c$, $-\frac{1}{y} = x + c$.

So the general solution is

$$(y + x^2 - c)(y - c)(xy + cy + 1) = 0$$

Example 3: Solve $2p^3 - (2x + 4 \sin x - \cos x) \cdot p^2 - (x \cos x - 4x \sin x + \sin 2x)p + x \cdot \sin 2x = 0$

Solution: Observe that $p = x$ satisfies the given DE. i.e., $2x^3 - (2x + 4 \sin x - \cos x) x^2 - (x \cos x - 4x \sin x + \sin 2x)x + x \sin 2x = 0$. Thus $(p - x)$ is factor. Rewriting the given DE $(p - x)[2p^2 - (4 \sin x - \cos x)p - \sin 2x] = 0$ or $(p - x)[2p(p - 2 \sin x) + \cos x(p - 2 \sin x)] = 0$ Thus $(p - x)(p - 2 \sin x)(2p + \cos x) = 0$.

Equating the three factors to zero

$$p - x = 0 \text{ or } \frac{dy}{dx} = x \quad \therefore y = \frac{x^2}{2} + c$$

$$p - 2 \sin x = 0 \text{ or } dy - 2 \sin x dx = 0$$

$$\therefore y + 2 \cos x = c$$

$$2p + \cos x = 0 \text{ or } 2dy + \cos x dx = 0$$

$$\therefore 2y + \sin x = c$$

The general solution is

$$(2y - x^2 - c)(y + 2 \cos x - c)(2y + \sin x - c) = 0$$

Equations Solvable for p

EXERCISE

Solve

1. $p^2 - 5p + 6 = 0$

Ans. $(y - 3x - c)(y - 2x - c) = 0$

Hint: $(p - 3)(p - 2) = 0$

2. $4y^2 p^2 + 2pxy(3x + 1) + 3x^3 = 0$

Ans. $(x^2 + 2y^2 - c)(x^3 + y^2 - c) = 0$

Hint: $(2py + x)(2py + 3x^2) = 0$

3. $p^2 + 2py \cot x - y^2 = 0$

Ans. $[y(1 + \cos x) - c][y(1 - \cos x) - c] = 0$

Hint: $(p + y \cot x - y \operatorname{cosec} x)(p + y \cot x + y \operatorname{cosec} x) = 0$

4. $p - \frac{1}{p} - \frac{x}{y} + \frac{y}{x} = 0$

Ans. $(xy - c)(x^2 - y^2 - c) = 0$

Hint: $(p + \frac{y}{x})(p - \frac{x}{y}) = 0$

5. $xy p^2 + p(3x^2 - 2y^2) - 6xy = 0$

Ans. $(y - cx^2)(y^2 + 3x^2 + c) = 0$

Hint: $(py + 3x)(px - 2y) = 0$

6. $p^3 - (y + 2x - e^{x-y})p^2 + (2xy - 2xe^{x-y} - ye^{x-y})p + 2xye^{x-y} = 0$

Ans. $(y - ce^x)(y - x^2 - c)(e^y + e^x - c) = 0$

Hint: $(p - y)(p - 2x)(p + e^{x-y}) = 0$

7. $yp^2 + (x - y)p - x = 0$

Ans. $(y - x - c)(y^2 + x^2 - c) = 0$

Hint: $(p - 1)(p + \frac{x}{y}) = 0$

8. $p^4 - (x + 2y + 1)p^3 + (x + 2y + 2xy)p^2 - 2xyp = 0$

Ans. $(y - c)(y - x - c)(2y - x^2 - c) \times (y - ce^{2x}) = 0$

Hint: $p(p - 1)(p - x)(p - 2y) = 0$

9. $xy p^2 + (x^2 + xy + y^2)p + x^2 + xy = 0$

Ans. $(2xy + x^2 - c)(x^2 + y^2 - c) = 0$

Hint: $(xp + x + y)(yp + x) = 0$

10. $(x^2 + x)p^2 + (x^2 + x - 2xy - y)p + y^2 - xy = 0$

Ans. $[y - c(x + 1)][y + x \ln cx] = 0$

Hint: $[(x + 1)p - y][xp + x - y] = 0$

WORKED OUT EXAMPLES

Equations Solvable for y

Example 1: Find the general solution of $3x^4 p^2 - xp - y = 0$

Solution: This is a first order, second degree, non-linear homogeneous DE which can be solved for y . Thus

$$y = 3x^4 p^2 - xp$$

Differentiating w.r.t. x both sides, we get

$$\begin{aligned} \frac{dy}{dx} &= 12x^3 p^2 + 6x^4 p \frac{dp}{dx} - p - x \frac{dp}{dx} \\ \text{or } (2p - 12x^3 p^2) + (x - 6x^4 p) \frac{dp}{dx} \\ &= (1 - 6x^3 p) \left(2p + x \frac{dp}{dx} \right) = 0 \end{aligned}$$

Equating the second order to zero we have

$$2p + x \frac{dp}{dx} = 0 \text{ or } 2 \frac{dx}{x} + \frac{dp}{p} \text{ so } px^2 = c$$

Eliminating p from the given DE by using $p = \frac{c}{x^2}$, we get

$$y = 3x^4 \left(\frac{c}{x^2} \right)^2 - x \cdot \frac{c}{x^2} = 3c^2 - \frac{c}{x}$$

8.28 — HIGHER ENGINEERING MATHEMATICS—III

The required general solution is

$$xy = c(3cx - 1)$$

Example 2: Solve $p \tan p - y + \log \cos p = 0$

Solution: Solving $y = p \tan p + \log \cos p$.
Differentiating w.r.t. x both sides, we get

$$\begin{aligned} \frac{dy}{dx} &= \tan p \cdot \frac{dp}{dx} + p \cdot \sec^2 p \cdot \frac{dp}{dx} \\ &+ \frac{1}{\cos p} \cdot (-\sin p) \cdot \frac{dp}{dx} \end{aligned}$$

$$\text{or } p \left(1 - \sec^2 p \cdot \frac{dp}{dx} \right) = 0$$

Considering the second factor,

$$1 - \sec^2 p \frac{dp}{dx} = 0$$

solving $dx = \sec^2 p dp$ or $x = \tan p + c$.

Since p cannot be eliminated, the general solution in the parametric form (with parametric p) is $x = \tan p + c$, $y = p \tan p + \log \cos p$

EXERCISE

Solve

1. $p^2 x^4 - px - y = 0$

Ans. $y = c^2 x - c$

Hint: $\left(2p + x \frac{dp}{dx} \right) (1 - 2x^3 p) = 0$

2. $2p^2 y - p^3 x + 16x^2 = 0$

Ans. $2 + c^2 y - c^3 x^2 = 0$

Hint: $(p^3 + 32x) \left(p - x \frac{dp}{dx} \right) = 0$

3. $yp + p^2 - x = 0$

Ans. $x = -\frac{p}{p_1} \ln \left((p + p_1) + \frac{cp}{p_1} \right)$, $y = -p - \frac{1}{p_1} \ln \left((p + p_1) + \frac{c}{p_1} \right)$ where $p_1 = \sqrt{p^2 - 1}$

Hint: $\frac{dx}{dp} + x \cdot \frac{1}{p^3 - p} = -\frac{p}{p^2 - 1}$

4. $2x + p^2 - y + px = 0$

Ans. $x = 2(2 - p) + ce^{-p/2}$, $y = 8 - p^2 + (2 + p)ce^{-p/2}$

Hint: $\frac{dx}{dp} + \frac{1}{2}x = -p$

5. $p^3 + mp^2 - ay - amx = 0$

Ans. $ax = c + \frac{3p^2}{2} - mp + m^2 \log(p + m)$ and $ay = -m \left[c + \frac{3}{2}p^2 - mp + m^2 \log(p + m) \right] + mp^2 + p^3$

Hint: $adx = \frac{p(3p+2m)}{(p+m)} dp$
 $= \left(3p - m + \frac{m^2}{p+m} \right) dp$

6. $2px + \tan^{-1}(xp^2) - y = 0$

Ans. $y = 2\sqrt{cx} + \tan^{-1} c$

Hint: $\left(p + 2x \frac{dp}{dx} \right) \left(1 + \frac{p}{1+x^2 p^4} \right) = 0$

WORKED OUT EXAMPLES

Equations Solvable for x

Example 1: Find the primitive of $p^2 - xp + y = 0$

Solution: Solving for x , we obtain

$$x = \frac{p^2 + y}{p}$$

Differentiating w.r.t. 'y', we get

$$\begin{aligned} \frac{dx}{dy} &= \frac{1}{p} = \frac{dp}{dy} + \frac{\left(p - y \frac{dp}{dy} \right)}{p^2} \\ (p^2 - y) \frac{dp}{dy} &= 0 \end{aligned}$$

so $\frac{dp}{dy} = 0$ with solution $p = c = \text{constant}$. Eliminating p from the given equation

$$c^2 - xc + y = 0 \text{ or } y = cx - c^2$$

which is the required primitive.

Example 2: Solve $xp^2 - yp - y = 0$

Solution: Solving for x we obtain

$$x = \frac{y(1 + p)}{p^2}$$

Differentiating w.r.t. 'y', we get

$$\frac{dx}{dy} = \frac{1}{p} = \frac{1+p}{p^2} + y \left(\frac{p^2 - (1+p)2p}{p^4} \right) \frac{dp}{dy}$$

or $\frac{dp}{dy} = \frac{p}{2+p} \cdot \frac{1}{y}$

Separating the variables and integrating

$$\frac{2+p}{p} dp = \frac{dy}{y}$$

$$\ln p^2 + p = \ln y + c_1 \text{ or}$$

$$\ln (p^2 e^p) = \ln y + c_1 \text{ so}$$

$y = cp^2 e^p$ and $x = \frac{1+p}{p^2} \cdot y = c(1+p)e^p$ which is required primitive in the parametric form.

EXERCISE

Equation Solvable for x

Obtain the primitive for the following equations:

1. $6p^2 y^2 - y + 3px = 0$

Ans. $y^3 = 3cx + 6c^2$

Hint: $2p + y \frac{dp}{dy} = 0$, $py^2 = c$

2. $4y^2 + p^3 = 2xyp$

Ans. $2y = c(c-x)^2$

Hint: $p - 2y \frac{dp}{dy} = 0$, $p^2 = cy$

3. $3py + 4x = p^3 y$

Ans. $y = c \cdot P$, $x = \frac{1}{4} cp(p^2 - 3) \cdot P$ where $P^{-1} = -(p^2 - 4)^{9/10} \cdot (p^2 + 1)^{3/5}$

Hint: $\frac{dy}{y} + \frac{3p(p^2-1)dp}{(p^2-4)(p^2+1)} = 0$; $\frac{3p(p^2-1)}{(p^2-4)(p^2+1)} = \frac{9}{10} \left(\frac{1}{p+2} + \frac{1}{p-2} \right) + \frac{3}{5} \frac{2p}{p^2+1}$

4. $y^2 p^3 - y + 2px = 0$

Ans. $y^2 = 2cx + c^3$

Hint: $p + y \frac{dp}{dy} = \frac{d}{dy}(py) = 0$, $py = c$

5. $3px - y + 6p^2 y^2 = 0$

Ans. $y^3 = 3c(x + 2c)$

Hint: $2p + y \frac{dp}{dy} = 0$, $py^2 = c$

6. $p^2 + y - x = 0$

Ans. $x = c - 2[p + \log(p-1)]$,
 $y = c - 2\left[\frac{1}{2}p^2 + p + \log(p-1)\right]$

Hint: $\frac{dp}{dy} = \frac{1-p}{2p^2}$

8.12 CLAIRAUT'S* EQUATION

Clairaut's equation is a first order and higher degree DE of the form

$$y = x \frac{dy}{dx} + \psi \left(\frac{dy}{dx} \right) \quad (1)$$

This equation (1) is linear in y and x . Here ψ is a known function of $\frac{dy}{dx}$.

Introducing $\frac{dy}{dx} = p$, equation (1) takes the form

$$y = xp + \psi(p) \quad (2)$$

Differentiating both sides of (2) w.r.t. x , we have

$$\frac{dy}{dx} = p + x \frac{dp}{dx} + \frac{d\psi}{dp} \cdot \frac{dp}{dx}$$

since p itself is a function of x . On simplification

$$\left[x + \frac{d\psi}{dp} \right] \frac{dp}{dx} = 0$$

Thus $\frac{dp}{dx} = 0$ (3)

and $x + \frac{d\psi}{dp} = 0$ (4)

Integrating (3), we get $p = \text{constant} = c$. Substituting $p = c$ in (2), the *complete integral* of the Clairaut's equation (1) is given by

$$y = x \cdot c + \psi(c) \quad (5)$$

which is a one parameter family of straight lines; with c as the parameter. Thus the complete solution of Clairaut's equation is obtained simply by replacing $\frac{dy}{dx}$ (i.e., p) by constant c . Besides the complete integral (5), one may obtain a "singular solution"

* Alexis Claude Clairaut (1713-1765), French mathematician.

8.30 — HIGHER ENGINEERING MATHEMATICS—III

of Clairaut's equation which satisfies the Clairaut's equation (1) but *not* obtained from the complete integral (5) for any value of c .

Now solving (4), we get p as a function of x . Thus (2) becomes

$$y = x \cdot p(x) + \psi(p(x)) \quad (6)$$

Differentiating (6) w.r.t. x , we get

$$\begin{aligned} \frac{dy}{dx} &= p + x \frac{dp}{dx} + \frac{d\psi}{dp} \cdot \frac{dp}{dx} \\ &= p + \left[x + \frac{d\psi}{dp} \right] \frac{dp}{dx}. \end{aligned}$$

Using (4), $\frac{dy}{dx} = p + 0 \cdot \frac{dp}{dx} = p$

Substituting (6), Clairaut's DE (1), is satisfied, i.e., $x \cdot p + \psi(p) = y = x \cdot \frac{dy}{dx} + \psi\left(\frac{dy}{dx}\right) = x \cdot p + \psi(p)$ since $\frac{dy}{dx} = p$.

Thus the singular solution (6) known as *p-discriminant* equation is readily obtained by eliminating the parameter p from the two equations (2) and (4):

$$\begin{aligned} y &= xp + \psi(p) \\ x + \frac{d\psi}{dp} &= 0 \end{aligned}$$

Note 1: Singular solution (6) is the envelope of the family of straight lines represented by the complete integral (5).

Note 2: Singular solution can also be obtained by eliminating the constant c from the two equations (5) and (4):

$$\begin{aligned} y &= xc + \psi(c) \\ x + \frac{d\psi}{dc} &= 0 \end{aligned}$$

Note 3: Equations which are not in the Clairaut's form can be reduced to Clairaut's form by suitable substitutions (transformations) (see W.E. 3, 4, 5, 6).

WORKED OUT EXAMPLES

Example 1: Solve $y = xy' - (y')^2$

Solution: Clairaut's equation is $y = xp - p^2$. Its general solution is obtained by replacing p by a constant c . Thus $y = xc - c^2$ is the required complete integral.

To obtain the singular solution, differentiate the general solution w.r.t. ' c '. Then

$$0 = x - 2c \quad \therefore \quad c = \frac{x}{2}$$

Eliminating c from the G, S, we get

$$\begin{aligned} y &= cx - c^2 = \frac{x}{2} \cdot x - \frac{x^2}{4} = \frac{x^2}{4} \\ \text{or} \quad x^2 &= 4y \end{aligned}$$

Fig. 8.3

Thus the singular solution $x^2 = 4y$ (which is a parabola) is the envelope of the one parameter family of straight lines $y = cx - c^2$ (representing the general solution).

Example 2: Solve $p = \ln(px - y)$.

Solution: Rewriting $e^p = px - y$ or $y = xp - e^p$ which is Clairaut's equation. The complete solution is obtained by replacing p by c . Thus $y = cx - e^c$ is the complete integral or $c = \ln(cx - y)$.

To obtain the singular solution, differentiate

$$c = \ln(cx - y)$$

w.r.t. c then $1 = \frac{x}{cx - y}$. Solving $c = \frac{x+y}{x}$. Eliminating c from the complete integral.

$$y = \frac{x+y}{x} \cdot x - e^{\frac{x+y}{x}} \quad \text{or} \quad \ln x = \frac{x+y}{x}$$

The singular solution is $y = x(\ln x - 1)$ (which cannot be obtained from the complete solution for any value of c).

Example 3: Find the primitive $y = 4xp - 16y^3p^2$

Solution: This equation is *not* in the Clairaut's form. Multiplying the given equation by y^3 , we have

$$y^4 = 4xy^3p - 16y^6p^2$$

put $y^4 = v$ so $4y^3 \frac{dy}{dx} = \frac{dv}{dx}$. Then

$$v = x \frac{dv}{dx} - \left(\frac{dv}{dx} \right)^2$$

which is a Clairaut's equation in v . Its general solution is obtained by replacing $\frac{dv}{dx}$ by a constant c . Thus the general solution is

$$v = xc - c^2$$

or $y^4 = cx - c^2$

Example 4: Solve $\sin y \cos^2 x = \cos^2 yp^2 + \sin x \cdot \cos x \cos yp$.

Solution: To reduce to Clairaut's form, put $\sin y = u$ and $\sin x = v$. Then $\frac{\cos y}{\cos x} \cdot \frac{dy}{dx} = \frac{du}{dv}$. Dividing the given equation throughout by $\cos^2 x$, we get

$$\sin y = \frac{\cos^2 y}{\cos^2 x} \cdot p^2 + \sin x \cdot \frac{\cos y}{\cos x} \cdot p$$

Substituting for $p \equiv \frac{dy}{dx} = \frac{\cos x}{\cos y} \frac{du}{dv}$ the DE transforms to

$$u = \left(\frac{du}{dv} \right)^2 + v \left(\frac{du}{dv} \right)$$

which is in the Clairaut's form. The general solution is

$$u = cv + c^2$$

or $\sin y = c \cdot \sin x + c^2$

Example 5: Solve $(p - 1)e^{3x} + p^3e^{2y} = 0$.

Solution: To reduce to Clairaut's form, put $e^x = X$, $e^y = Y$; then $P = \frac{dY}{dX} = \frac{e^y}{e^x} \frac{dy}{dx} = \frac{Y}{X} p$.

Substituting for $p = \frac{X}{Y} \frac{dY}{dX} = \frac{X}{Y} P$ the given equation reduces to

$$\left(\frac{X}{Y} P - 1 \right) X^3 + \frac{X^3}{Y^3} P^3 Y^2 = 0$$

or $Y = YP + P^3$

which is Clairaut's DE. Its general solution is

$$Y = Xc + c^3$$

or $e^y = ce^x + c^3$

Example 6: Solve $(x^2 + y^2)(1 + p)^2 = 2(x + y)(1 + p)(x + yp) - (x + yp)^2$

Solution: Rewriting $x^2 + y^2 = \frac{2(x+y)(x+yp)}{(1+p)} - \left(\frac{x+yp}{1+p} \right)^2$. Put $x^2 + y^2 = v$ so $2x + 2yp = \frac{dv}{dx}$ and put $x + y = u$ so $1 + p = \frac{du}{dx}$. Then

$$\frac{dv}{du} = \frac{2(x + yp)}{(1 + p)}$$

Substituting the given equation reduces to

i.e., $v = u \frac{dv}{du} - \frac{1}{4} \left(\frac{dv}{du} \right)^2$ which is a Clairaut's DE. Its general solution is $v = uc - \frac{1}{4}c^2$ or $x^2 + y^2 = c(x + y) - \frac{1}{4}c^2$

EXERCISE

Clairaut's Equations (CE)

1. Find the general solution (GS) and singular solution (SS) the Clairaut's equation $y = xp + \frac{ap}{\sqrt{1+p^2}}$.

Ans. GS: $y = cx + \frac{ac}{\sqrt{1+c^2}}$; SS: $x^{2/3} + y^{2/3} = a^{2/3}$

Hint: Parametric form of SS: $x = -a/(1 + c^2)^{3/2}$, $y = ac^3/(1 + c^2)^{3/2}$

2. Determine GS and SS of $p = \sin(y - xp)$.

Ans. GS: $y = cx + \sin^{-1} c$, SS: $y = (x^2 - 1) + \sin^{-1} \left(\frac{x^2 - 1}{x} \right)$

Hint: $y = px + \sin^{-1} p$ is CE.

3. Find GS and SS of $y = px + p^3$

Ans. GS: $y = cx + c^3$, SS: $27y^2 = -4x^3$

4. Solve $(x^2 - 1)p^2 - 2xyp + y^2 - 1 = 0$

Ans. GS: $(x^2 - 1)c^2 - 2xyc + y^2 - 1 = 0$, SS: $x^2 + y^2 = 1$.

8.32 — HIGHER ENGINEERING MATHEMATICS—III

Hint: $(y - xp)^2 - 1 - p^2 = 0$, $y = xp \pm \sqrt{1 - p^2}$, two DE's each of Clairaut's form.

5. Solve $y = px + \log p$

Ans. GS: $y = cx + \log c$

6. Solve $p^2y + px^3 - x^2y = 0$

Ans. $y^2 = cx^2 + c^2$

Hint: use $u = x^2$, $v = y^2$

7. Solve $y = xy' + \frac{a}{2y'}$

Ans. GS: $y = cx + \frac{a}{2c}$, one parameter family of straight lines. SS: $y^2 = 2ax$ parabola, which is the envelope of the family of straight lines.

8. Solve $y = px + 2p^2$

Ans. GS: $y = cx + c^2$, SS: $x^2 = -8y$ (parabola)

9. Solve $y = 3px + 6p^2y^2$

Ans. GS: $y^3 = cx + \frac{2}{3}c^2$, SS: $8y^3 + 3x^2 = 0$ (semicubical parabola)

10. Solve $a^2p = (py + x)(px - y)$

Ans. $y^2 = cx^2 - a^2c/(c + 1)$

Hint: Use $u = x^2$, $v = y^2$, $v = uP - a^2P/(P + 1)$

11. $y + y^2 + p(2y - 2xy - x + 2) + xp^2(x - 2) = 0$

Ans. GS: $(y - cx + 2c)(y - cx + 1) = 0$

Hint: $(y - px + 2p)(y - px + 1) = 0$, each of Clairaut's form

12. $(px^2 + y^2)(px + y) = (p + 1)^2$

Ans. $c^2(x + y) - cxy - 1 = 0$

Hint: Use $x + y = u$, $xy = v$, $P = \frac{dv}{du}$, $v = Pu - \frac{1}{P}$.

Here ϕ and ψ are known functions of $\frac{dy}{dx}$. Equation (1) is linear in x and y . Note that Clairaut's equation is a particular case of Lagrange's equation when $\phi\left(\frac{dy}{dx}\right) \equiv \frac{dy}{dx}$.

Putting $y' \equiv \frac{dy}{dx} = p$, equation (1) takes the form

$$y = x\phi(p) + \psi(p) \quad (2)$$

Differentiating both sides of (2) w.r.t. x , we get

$$\frac{dy}{dx} = \phi(p) + x \cdot \frac{d\phi}{dp} \cdot \frac{dp}{dx} + \frac{d\psi}{dp} \cdot \frac{dp}{dx}$$

or $p - \phi(p) = [x\phi'(p) + \psi'(p)] \frac{dp}{dx} \quad (3)$

Rewriting (3) with x as a function of p , we get

$$\frac{dx}{dp} - x \cdot \frac{\phi'(p)}{p - \phi(p)} = \frac{\psi'(p)}{p - \phi(p)} \quad (4)$$

which is a linear DE in x . Integrating (4), we obtain

$$x = \chi(p, c) \quad (5)$$

Now the p -discriminant equation obtained by eliminating the parameter p from the two equations (2) and (5) is of the form $\Phi(x, y, c) = 0$ which is the required *complete integral* of the Lagrange's equation.

The general solution of (1) is also written in the parametric form

$$x = \chi(p, c)$$

$$\text{and } y = \chi(p, c) \cdot \phi(p) + \psi(p)$$

Here p is the parameter.

When $p = \text{constant} = c$, equation (3) is satisfied provided LHS of (3) is zero i.e., c is the root of the equation $c - \phi(c) = 0$. Thus the singular solution of (1) is

$$y = x\phi(c) + \psi(c)$$

where c satisfies the condition $\phi(c) = c$.

Lagrange's Equation

8.13 LAGRANGE'S EQUATION

Lagrange's equation is a first order and higher degree DE of the form

$$y = x\phi\left(\frac{dy}{dx}\right) + \psi\left(\frac{dy}{dx}\right) \quad (1)$$

WORKED OUT EXAMPLES

Example 1: Solve $y = xy'^2 - \frac{1}{y'}$.

Solution: This is a Lagrange's equation. Put $y' = p$ then $y = xp^2 - \frac{1}{p}$. Differentiating

$$dy = p dx = x \cdot 2p \cdot dp + p^2 dx + \frac{1}{p^2} dp$$

since $\frac{dy}{dx} = p$ i.e., $dy = p dx$. Rewriting

$$(p - p^2) \frac{dx}{dp} + x(-2p) = \frac{1}{p^2}$$

$$\text{or } \frac{dx}{dp} + x \frac{2}{(p-1)} = \frac{-1}{p^3(p-1)}$$

This is a linear DE in x with I.F. $\int \left(\frac{2 dp}{p-1} \right) = (p-1)^2$.

Integrating

$$\begin{aligned} x \cdot (p-1)^2 &= \int \frac{-1}{p^3(p-1)} \cdot (p-1)^2 \cdot dp \\ &= \int \frac{1-p}{p^3} dp = -\frac{1}{2p^2} + \frac{1}{p} + c^* \end{aligned}$$

$$\therefore x = \frac{cp^2 + 2p - 1}{2p^2(p-1)^2} \quad (1)$$

Substituting x in the expression for y , we get

$$y = xp^2 - \frac{1}{p} = \frac{cp^2 + 2p - 1}{2p^2(p-1)^2} \cdot p^2 - \frac{1}{p}$$

$$\text{i.e., } y = \frac{cp^2 + 2p - 1}{2(p-1)^2} - \frac{1}{p} \quad (2)$$

The general solution in the parametric form is given by (1) and (2) with parameter p .

EXERCISE

Integrate the following equations

1. $y = 2xy' + \ln y'$

Ans. $x = \frac{c}{p^2} - \frac{1}{p}$, $y = \ln p + \frac{2c}{p} - 2$

Hint: $\frac{dx}{dp} + \frac{2}{p}x = -\frac{1}{p^2}$

2. $y = 2xy' + \sin y'$

Ans. $x = \frac{c}{p^2} - \frac{\cos p}{p^2} - \frac{\sin p}{p}$, $y = \frac{2c}{p} - \frac{2 \cos p}{p} - \sin p$

Note: $y = 0$ is SS satisfying DE.

Hint: $\frac{dx}{dp} + \frac{2}{p}x = -\frac{\cos p}{p^2}$

3. $y = xy'^2 + y'^2$

Ans. GS: $y = (c + \sqrt{x+1})^2$

Hint: $\frac{dx}{dp} + x \frac{2}{p-1} = \frac{2}{1-p}$

Note: $y = 0$ is SS

4. $y = x(1 + y') + y'^2$

Ans. $x = ce^{-p} - 2p + 2$,
 $y = c(p+1)e^{-p} - p^2 + 2$

5. $y = y \left(\frac{dy}{dx} \right)^2 + 2xy'$

Ans. $4cx = 4c^2 - y^2$

8.14 FORMATION OF ORDINARY DIFFERENTIAL EQUATIONS BY ELIMINATION OF ARBITRARY CONSTANTS

Consider the equation

$$y = x^2 + c \quad (1)$$

where c is an "arbitrary constant".

For each particular value of c , equation (1) represents a different parabola. Since c can vary, c is often called a "parameter" to distinguish it from the main variables x and y . Thus equation (1) represents a "one-parameter family of curves" in the xy -plane, namely a family of parabolas.

Thus the general equation

$$f(x, y, c) = 0 \quad (2)$$

represents a one-parameter family of curves with c as the parameter.

Now differentiating (1) w.r.t. x , we get

$$\frac{dy}{dx} = 2x \quad (3)$$

Thus, *each* member of the one-parameter family of parabolas (1) has the "property" that the slope at any point is $2x$.

Hence differential Equation (3), satisfied by *all* members of the family (1), is often called the "differential equation of the family".

Now differentiating (2) w.r.t. x and eliminating the arbitrary constant c we obtain a D.E.

$$F(x, y, y') = 0 \quad (4)$$

Thus (4) is the "differential equation" of the "one-parameter family of curves (2)", expressing the

8.34 — HIGHER ENGINEERING MATHEMATICS—III

“property” common to *all* the curves of the family (2).

Similarly all circles of unit radius represented by

$$(x - c_1)^2 + (y - c_2)^2 = 1$$

with c_1 and c_2 as arbitrary constants forms a “two-parameter family” of curves (in this case circles). Method of forming D.E. by elimination of arbitrary constants.

Step I. Differentiate (2) w.r.t. x .

Step II. Eliminate the arbitrary constant c between (2) and equation obtained in Step I.

Note 1: If there are n arbitrary constants present in the equation of an “ n -parameter family of curves” then in step I, differentiate successively n times and eliminate the n constants from the $n + 1$ equations.

Note 2: Sometimes, during differentiation itself, the arbitrary constants may get eliminated.

WORKED OUT EXAMPLES

Example 1: Obtain (form) the differential equation from each of the following functions by the elimination of arbitrary constants:

a. $y = c_1 e^x + c_2 e^{-2x}$ (1)

Solution: Differentiating w.r.t. x

$$y' = c_1 e^x - 2c_2 e^{-2x}$$
 (2)

Since elimination of c_1 and c_2 is not possible at this stage, (see note 1) differentiate once more w.r.t. x

$$y'' = c_1 e^x + 4c_2 e^{-2x}$$
 (3)

From (1) $c_1 e^x = y - c_2 e^{-2x}$ (4)

Eliminate c_1 by substituting (4) in (2) and (3)

$$y' = (y - c_2 e^{-2x}) - 2c_2 e^{-2x} = y - 3c_2 e^{-2x}$$
 (5)

$$y'' = (y - c_2 e^{-2x}) + 4c_2 e^{-2x} = y + 3c_2 e^{-2x}$$
 (6)

Eliminate c_2 by adding (5) and (6)

$$y' + y'' = 2y$$

Thus the D.E. is $y'' + y' - 2y = 0$.

b. $y = ax^2 + bx + c$

Solution: Differentiating w.r.t. x

$$y' = 2ax + b$$

Differentiating again

$$y'' = 2a$$

Differentiating once more, we get the required D.E.

$$y''' = 0$$

which is free of the given 3 arbitrary constants.

c. $y = a \cos (\ln x) + b \sin (\ln x)$

Solution: Differentiating w.r.t. x

$$y' = \frac{-a}{x} \sin (\ln x) + \frac{b}{x} \cdot \cos (\ln x)$$

$$xy' = -a \sin (\ln x) + b \cos (\ln x)$$

Differentiating once again w.r.t. x

$$y' + xy'' = \frac{-a}{x} \cdot \cos (\ln x) - \frac{b}{x} \sin (\ln x)$$

$$xy' + x^2 y'' = -[a \cos (\ln x) + b \sin (\ln x)] = -y$$

Thus the required D.E. is

$$x^2 y'' + xy' + y = 0.$$

Example 2: Obtain the differential equation of the family of plane curves which are:

a. *all circles of unit radius:*

Solution: The general evaluation of all circles with unit radius and centre at any point (a, b) is

$$(x - a)^2 + (y - b)^2 = 1^2$$
 (1)

Here a and b are arbitrary constants. Differentiating (1) w.r.t. x , we get

$$2(x - a) + 2(y - b)y' = 0$$
 (2)

Differentiating this once more w.r.t. x

$$1 + (y - b)y'' + y'^2 = 0$$
 (3)

Solving (3),

$$(y - b) = \frac{-(1 + y'^2)}{y''}$$
 (4)

Substituting (4) in (2), we get

$$x - a = -(y - b)y' = \frac{(1 + y'^2)}{y''} y' \quad (5)$$

Substituting (4) and (5) in (1), we have

$$\begin{aligned} (x - a)^2 + (y - b)^2 &= \left[\frac{1 + y'^2}{y''} \cdot y' \right]^2 \\ &+ \left[\frac{1 + y'^2}{y''} \right]^2 = 1 \\ (1 + y'^2)^2 [y^2 + 1] &= y''^2 \end{aligned}$$

Thus the required D.E. is

$$(1 + y'^2)^3 = y''^2$$

- b.** family of parabolas with foci at the origin and axes along the x -axis:

Solution: The equation is

$$y^2 = 4ax + 4a^2 \quad (1)$$

Differentiating (1) w.r.t. x

$$2yy' = 4a \quad (2)$$

Substituting 'a' from (2) in (1), we get

$$y^2 = \left(2yy'x + 4 \cdot \left(\frac{yy'}{2} \right) \right)^2$$

So the required D.E. is

$$2xy' + y(y')^2 - y = 0$$

- c.** family of confocal central conics:

$$\frac{x^2}{a^2 + c} + \frac{y^2}{b^2 + c} = 1 \quad (1)$$

with a, b fixed, c arbitrary constant.

Solution: Differentiating (1) w.r.t. x

$$\frac{2x}{a^2 + c} + \frac{2yy'}{b^2 + c} = 0 \quad (2)$$

Solving $yy'(a^2 + c) = -x(b^2 + c)$

$$c = \frac{-(xb^2 + yy'a^2)}{yy' + x} \quad (3)$$

Substituting c from (3) in (1)

$$\frac{x^2}{\left(\frac{x(a^2 - b^2)}{yy' + x} \right)} + \frac{y^2}{\left(\frac{yy'(b^2 - a^2)}{yy' + x} \right)} = 1$$

Simplifying, we get

$$(yy' + x)(xy' - y) = (a^2 - b^2)y'$$

EXERCISE

1. Form (obtain) the differential equation by eliminating the arbitrary constants from each of the following equations:

a. $x^3 - 3x^2y = c$

Ans. $xy' + 2y - x = 0$

b. $y \sin x - xy^2 = c$

Ans. $y' = \frac{y(y - \cos x)}{(\sin x - 2xy)}$

c. $y = c(1 - e^{-\frac{x}{c}})$

Ans. $y \ln y' + x(1 - y') = 0$

d. $y = A \sin (Bx + c)$

where B is a parameter, *not* to be eliminated.

Ans. $y'' + B^2y = 0$

e. $y = a e^{3x} + b e^{-x}$

Ans. $y'' + 2y' - 3y = 0$

f. $y = c_1 e^{ax} \cdot \cos bx + c_2 e^{ax} \sin bx$

Here a, b are parameters *not* to be eliminated.

Ans. $y'' - 2a y' + (a^2 + b^2)y = 0$

g. $y = cx + \frac{b}{c}$, parameter ' b ' *not* to be eliminated.

Ans. $x(y')^2 - yy' + b = 0$

h. $y = c_1 e^x + c_2 e^{2x} + c_3 e^{3x}$

Ans. $y''' - 3y'' + 11y' - 6y = 0$

i. $y = c_1 e^x + c e^{-x} + c_3 \cos x + c_4 \sin x$

Ans. $y'^2 - y = 0$

2. Obtain (form) the differential equation of family of plane curves which are:

- a.** family of circles having their centres on the y -axis

8.36 — HIGHER ENGINEERING MATHEMATICS—III

Hint: $x^2 + (y - b)^2 = r^2$

Ans. $xy'' - (y')^3 - y' = 0$

- b.** parabolas having their vertices at the origin and their foci on the y-axis

Hint: $x^2 = 4ay$

Ans. $y' = \frac{2y}{x}$

- c.** all tangents to the parabola $y^2 = 2x$

Hint: $cy = x + \frac{c^2}{2}$

Ans. $2x(y')^2 - 2yy' + 1 = 0$

- d.** all straight lines at a unit distance from the origin

Ans. $(xy' - y)^2 = 1 + (y')^2$

- e.** all circles $r = 2a(\sin \theta - \cos \theta)$

Ans. $(\cos \theta - \sin \theta)dr + r(\cos \theta + \sin \theta)d\theta = 0$

- f.** all cissoids $r = a \sin \theta \tan \theta$

Ans. $\sin \theta \cdot \cos \theta dr - r(1 + \cos^2 \theta)d\theta = 0$

- g.** all strophoids $r = a(\sec \theta + \tan \theta)$

Ans. $dr - r \sec \theta d\theta = 0$.

Fig. 8.4

Fig. 8.5

8.15 GEOMETRICAL APPLICATIONS

Tangent, Normal, Subtangent and Subnormal

If the analytical representation of a “property” of a curve involves the derivative, then the solution of the resulting differential equation represents a one-parameter family of curves, such that each member of the family having this “property”.

The following “properties” of curves involving derivatives are listed below:

Rectangular coordinates Let $P(x, y)$ be any (general) point of a curve QPR given by $f(x, y) = 0$ (Fig. 8.4).

Let (X, Y) be any (general) point on the tangent AP (refer Fig. 8.5). Then the equation of the tangent AP at the point $P(x, y)$ is

$$\text{a. } Y - y = \frac{dy}{dx}(X - x) \quad (1)$$

Similarly if (X, Y) is any point on the normal PB

then the equation of the normal line PB at $P(x, y)$ is

$$\text{b. } Y - y = -\frac{dx}{dy}(X - x) \quad (2)$$

c. Intercept of tangent line:

$$\text{on x-axis: } x - \frac{y}{y'} \quad (3)$$

$$\text{on y-axis: } y - xy' \quad (4)$$

(3) and (4) are obtained from (1) by putting $Y = 0$ and $X = 0$ respectively.

d. Intercept of normal line:

$$\text{on x-axis: } x + yy' \quad (5)$$

$$\text{on y-axis: } y + \frac{x}{y'} \quad (6)$$

(5) and (6) obtained from (2) by putting $Y = 0$ and $X = 0$ respectively.

e Length of tangent line from P:

$$\text{to } x\text{-axis: } \frac{y\sqrt{1+y'^2}}{y'} \quad (7)$$

$$\text{to } y\text{-axis: } x\sqrt{1+y'^2} \quad (8)$$

f. Length of normal line from P:

$$\text{to } x\text{-axis: } y\sqrt{1+y'^2} \quad (9)$$

$$\text{to } y\text{-axis: } \frac{x\sqrt{1+y'^2}}{y'} \quad (10)$$

g. Length of subtangent AD: $\frac{y}{y'}$ (11)

h. Length of subnormal DB: yy' (12)

WORKED OUT EXAMPLES

Example 1: The slope at any point (x, y) of a curve is $1 + y/x$. If the curve passes through $(1, 1)$ find its equation.

Solution:

$$\frac{dy}{dx} = 1 + \frac{y}{x}$$

This is a linear equation

$$\frac{dy}{dx} - \frac{1}{x}y = 1$$

$$\text{with I.F.} = e^{\int -\frac{dx}{x}} = e^{-\ln x} = \frac{1}{x}$$

The general solution is

$$y \cdot \frac{1}{x} = \int \frac{1}{x} \cdot 1 \cdot dx + c = \ln x + c$$

$$y = cx + x \ln x$$

Since it passes through $(1, 1)$, we put $x = 1, y = 1$ then

$$1 = c \cdot 1 + 1 \cdot 0 \quad \therefore c = 1$$

Thus the required equation of the curve is

$$y = x(1 + \ln x)$$

Example 2: The tangent line to a curve at any point (x, y) on it has its intercept on the x -axis always

equal to $\frac{x}{2}$. Find the equation of the curve if it passes through $(1, 2)$.

Solution: Let (X, Y) be any point on the normal line to the curve at a point (x, y) on the curve. Then the equation of the tangent line, having slope y' is

$$Y - y = y'(X - x)$$

The x -intercept: X is obtained by putting $Y = 0$.

$$X = x - \frac{y}{y'}$$

It is given that this x -intercept = $\frac{x}{2}$

$$\text{Thus } x - \frac{y}{y'} = \frac{x}{2}$$

$$\text{or } \frac{y}{y'} = \frac{x}{2}$$

$$\text{i.e., } y' = \frac{2y}{x}$$

Integrating $y = cx^2$.

Since it passes through $(1, 2)$

$$2 = c \cdot 1 \quad \therefore c = 2$$

The required curve is

$$y = 2x^2$$

Example 3: Determine the equation of the tangent, equation of the normal, lengths of the tangent, normal, subtangent and subnormal to the curve $y = 3x^2$ at the point $P(-1, 3)$.

Solution:

$$y' = 6x, \quad y'|_P = -6, y|_P = 3$$

Equation of tangent:

$$Y - 3 = -6(X + 1) \quad \text{i.e., } Y + 6X + 3 = 0$$

Equation of normal:

$$Y - 3 = \frac{1}{6}(X + 1) \quad \text{i.e., } 6Y - X - 4 = 0$$

Length of tangent:

$$\left| y\sqrt{1 + \left(\frac{dx}{dy}\right)^2} \right| = 3\sqrt{1 + \frac{1}{36}} = \sqrt{\frac{37}{4}}$$

8.38 — HIGHER ENGINEERING MATHEMATICS—III

Length of normal:

$$\left| y \sqrt{1 + \left(\frac{dy}{dx} \right)^2} \right| = 3 \sqrt{1 + 36} = 3 \sqrt{37}$$

Length of subtangent:

$$\left| y \frac{dx}{dy} \right| = \left| 3 \cdot \frac{1}{-6} \right| = -\frac{1}{2}$$

Length of subnormal:

$$\left| y \frac{dy}{dx} \right| = \left| 3 \cdot (-6) \right| = 18$$

Example 4: For the curve $y = a \ln (x^2 - a^2)$, show that the sum of the (lengths of) tangent and subtangent varies as the product of the coordinates of the point.

Solution:

$$y' = \frac{2ax}{x^2 - a^2}, \quad 1 + y'^2 = \left(\frac{x^2 + a^2}{x^2 - a^2} \right)^2$$

Length of tangent:

$$\begin{aligned} T &= \frac{y \sqrt{1 + y'^2}}{y'} = a \cdot \ln (x^2 - a^2) \cdot \frac{x^2 + a^2}{x^2 - a^2} \cdot \frac{x^2 - a^2}{2ax} \\ &= \frac{(x^2 + a^2)}{2x} \ln (x^2 - a^2) \end{aligned}$$

Length of subtangent:

$$S.T. = \frac{y}{y'} = a \ln (x^2 - a^2) \cdot \frac{(x^2 - a^2)}{2ax}$$

Thus

$$\begin{aligned} T + S.T. &= \frac{(x^2 + a^2)}{2x} \ln (x^2 - a^2) + \frac{x^2 - a^2}{2x} \ln (x^2 - a^2) \\ &= x \cdot \ln (x^2 - a^2) = x \cdot \frac{y}{a} = \frac{xy}{a} \\ &= \text{product of the coordinates.} \end{aligned}$$

Example 5: Determine the curve in which the length of the subnormal is proportional to the square of the ordinate.

Solution: Length of subnormal $= y \frac{dy}{dx} \propto y^2$

$$y \frac{dy}{dx} = a y^2$$

where a is proportionality constant.

$$\begin{aligned} \text{Solving} \quad \frac{dy}{y} &= a dx \\ \ln y &= ax + c_1 \\ y &= c e^{ax} \end{aligned}$$

Example 6: Find the equation of the curve in which the portion of the tangent included between the co-ordinate axes is divided in the ratio $m : n$ at the point of contact. Hence or otherwise show that when the point of contact is the mid point, then the curve is a rectangular hyperbola (see Fig. 8.6).

Solution: Let $V(X, Y)$ be any point on the tangent QPR . Then the equation of the tangent QPR to the curve SPT at the point of contact $P(x, y)$ is

$$Y - y = \frac{dy}{dx}(X - x)$$

x -intercept of the tangent (obtained by putting $Y=0$) is $x - \frac{y}{y'}$

Fig. 8.6

Similarly y -intercept is $y + xy'$

Thus $Q(0, y + xy')$ and $R(x - \frac{y}{y'}, 0)$.

Since P divide QR in the ratio $m : n$, the abscissa x of the point of contact P is

$$x = \frac{m \left(x - \frac{y}{y'} \right) + n \cdot 0}{m + n}$$

$$\text{Rewriting} \quad y' = -\frac{my}{nx}$$

which is a separable equation.

Integrating

$$n \frac{dy}{y} = -m \frac{dx}{x}$$

we have

$$x^m y^n = \text{constant}.$$

Special Case: When p is the midpoint $m = n$ so that the curve is

$$xy = c$$

which is a rectangular hyperbola.

EXERCISE

- Find the curve passing through (2, 1) and having the property that at any point (x, y) of the curve, the intercept of the tangent on the y -axis is equal to $2xy^2$.

Ans. $x - x^2y + 2y = 0$

- Find the equation of a curve through (2, 1) and having y intercept of its tangent line at any point is always equal to the slope at that point.

Ans. $3y = x + 1$

- Find the equation of the tangent, normal and lengths of tangent, normal, subtangent and subnormal to the curve $y = \cos 2x$ at the point $P(0, 1)$.

Ans. Equation of tangent: $y = 1$

Equation of normal: $x = 0$

Length of tangent: ∞

Length of normal: 1

Length of subtangent: ∞

Length of subnormal: 0

- Show that the subnormal at any point of the curve

$$y^2 x^2 = a^2(x^2 - a^2)$$

varies inversely as the cube of its abscissa.

- Prove that the subtangent at any point of the curve

$$x^m y^n = a^{m+n}$$

varies as the abscissa.

- For the exponential curve

$$y = ae^{\frac{x}{b}}$$

show that the subtangent at any point is constant b .

- Find the equation of the curve for which the subnormal at any point has a constant value b .

Ans. $y^2 = 2bx + c$

- Find the shape of a reflector such that the light coming from a fixed source is reflected in parallel rays.

Ans. parabolic reflector: $y^2 = 2cx + c^2$

- Determine the curve which passes through (1, e) and is such that at each point of the curve the subtangent is proportional to the square of the abscissa.

Ans. $k \ln y = -\frac{1}{x} + k + 1$

(k is the proportionality constant)

- Prove that a curve, for which the slope of the tangent at any point of the curve is proportional to the abscissa of the point of tangency, is a parabola.

8.16 ORTHOGONAL* TRAJECTORIES** OF CURVES

In Cartesian and Polar Coordinates

Given one (first) family of curves, if there exists another (second) family of curves such that each curve of the first family cuts each curve of the second family at right angles,*** then the first family is said to be orthogonal trajectories of the second family and vice versa. In other words each curve in either family is orthogonal (i.e., perpendicular) to every curve in the other family. In such a case the two families are said to be mutually orthogonal and each family is said to be the orthogonal trajectories of the other family.

*Greek: orthogonal (right angle, 90° or perpendicular).

**Latin: trajectories (cut across).

***Two curves cut at right angles if the angle between their corresponding tangents at the point of intersection is 90° .

8.40 — HIGHER ENGINEERING MATHEMATICS—III

Classical examples of orthogonal trajectories are:

- i. Meridians and parallels on world globe.
- ii. Curves of steepest descent and contour lines on a map.
- iii. Curves of electric force and equipotential lines (constant voltage).
- iv. Stream lines and equipotential lines (of constant velocity potential).
- v. Lines of heat flow and isothermal curves.

Case I: Rectangular coordinates: method of finding orthogonal trajectories of a family of curves

$$F(x, y, c) = 0 \quad (1)$$

Step I. Obtain the differential equation of the family of curves (1) by eliminating the arbitrary constant c , resulting in

$$\frac{dy}{dx} = f(x, y) \quad (2)$$

Step II. Consider the differential equation

$$\frac{dy}{dx} = -\frac{1}{f(x, y)} \quad (3)$$

which will be the differential equation of the family of orthogonal trajectories (since the slope of curves of first family is $f(x, y)$, while the slope of curves of second family is $-\frac{1}{f(x, y)}$, so that their product $f \cdot \left(-\frac{1}{f}\right) = -1$ i.e., the curves of first family are at right angles to the curves of the second family).

Step III. Solving Equation (3) yields

$$G(x, y, d) = 0 \quad (4)$$

The family of curves (4) is the required orthogonal trajectories (O.T.) of the family of curves (1), with d as the parameter.

Case II: Polar coordinates Consider a curve c whose equation is expressed in polar coordinates

$$\tan \psi = r \frac{d\theta}{dr} \quad (5)$$

where ψ is the angle measured positive in counter clockwise direction from radius vector to the tangent line at any point P (see Fig. 8.7).

Fig. 8.7

Orthogonality The two curves c_1 and c_2 are said to intersect orthogonally at the point P (Fig. 8.8) if

$$\psi_2 = \psi_1 + \frac{\pi}{2} \quad (6)$$

Fig. 8.8

so that

$$\tan \psi_2 = \tan \left(\psi_1 + \frac{\pi}{2} \right) = -\cot \psi_1 = -\frac{1}{\tan \psi_1} \quad (7)$$

i.e., $\tan \psi_2 \cdot \tan \psi_1 = -1$

From (5) we observe that at the point of intersection P , the value of the product $r \frac{d\theta}{dr}$ for one curve c_1 must be the negative reciprocal (see (7)) of value of that product for the other curve i.e., if (5) is the differential equation corresponding to c_1 then the differential equation corresponding to its orthogonal trajectory c_2 is given by $\tan \psi = -\frac{1}{r \frac{d\theta}{dr}}$.

Method of obtaining orthogonal trajectories in polar coordinates

Step I. Suppose the first family of curves has differential equation

$$P(r, \theta)dr + Q(r, \theta)d\theta = 0 \quad (8)$$

Then

$$\begin{aligned}\frac{d\theta}{dr} &= -\frac{P}{Q} \\ r \frac{d\theta}{dr} &= -r \frac{P}{Q}\end{aligned}\quad (9)$$

Step II. The differential equation corresponding to the orthogonal trajectories (by (7)) is

$$\begin{aligned}r \frac{d\theta}{dr} &= \frac{Q}{rP} \\ \text{i.e., } Q dr - r^2 P d\theta &= 0\end{aligned}\quad (10)$$

Step III. Solve (10). The solution of (10) is the required orthogonal trajectories.

Self-orthogonal A given family of curves is said to be “self-orthogonal” if its family of orthogonal trajectories is the same as the given family (see Worked Out Example 6 and Exercise Examples 18, 19, 20).

WORKED OUT EXAMPLES

O.T.: In rectangular coordinates

Find the orthogonal trajectories (O.T.) of each of the following one-parameter family of curves:

Example 1: $xy = c$

Solution:

$$\text{D.E. } y + x \frac{dy}{dx} = 0$$

$$\therefore \frac{dy}{dx} = -\frac{y}{x}$$

D.E. corresponding to O.T. is

$$\frac{dy}{dx} = \frac{x}{y}$$

Solving, $y^2 - x^2 = 2c$ is the required orthogonal trajectories.

Example 2: $e^x + e^{-y} = c$.

Solution:

$$\text{D.E. } e^x - e^{-y} \cdot y' = 0 \quad \text{or} \quad y' = e^{x+y}.$$

D.E. corresponding to O.T. is

$$y' = -e^{-(x+y)}$$

Solving

$$\begin{aligned}\frac{dy}{dx} &= \frac{-e^{-x}}{e^y} \\ e^y dy + e^{-x} dx &= 0 \\ e^y - e^{-x} &= k\end{aligned}$$

Example 3: $y^2 = cx$.

Solution:

$$\text{D.E. } 2yy' = c$$

Eliminating c , we get

$$\begin{aligned}2yy' = c &= \frac{y^2}{x} \\ y' &= \frac{y}{2x}\end{aligned}$$

D.E. corresponding to O.T. is

$$y' = -\frac{2x}{y}$$

$$\text{Solving } \frac{y^2}{2} + x^2 = c.$$

Example 4: Show that family of curves $x^2 + 4y^2 = c_1$ and $y = c_2 x^4$ are (mutually) orthogonal (to each other).

Solution: Slope of tangent of any curve of the first family of curves is obtained by differentiating it w.r.t. x .

$$\text{i.e., } 2x + 8yy' = 0$$

$$\text{or } y'_1 = -\frac{2x}{8y} = -\frac{x}{4y} \quad (*)$$

Similarly for the second family by eliminating c_2

$$\frac{dy}{dx} = 4x^3 c_2 = 4x^3 \cdot \frac{y}{x^4} = \frac{4y}{x}$$

$$\text{i.e., } y'_2 = \frac{4y}{x} \quad (**)$$

The given two families are orthogonal if the product of their slopes is -1 . From (*) and (**)

$$y'_1 \cdot y'_2 = \left(-\frac{x}{4y}\right) \left(\frac{4y}{x}\right) = -1$$

Hence the result.

Example 5: Find particular member of orthogonal trajectories of $x^2 + cy^2 = 1$ passing through the point (2, 1).

8.42 — HIGHER ENGINEERING MATHEMATICS—III

Solution:

$$\text{D.E. } 2x + 2cyy' = 0$$

Eliminating c

$$x + yy'c = 0, x + yy' \cdot \left(\frac{1-x^2}{y^2} \right) = 0$$

$$\text{i.e., } y' = \frac{xy}{x^2 - 1}$$

D.E. corresponding to O.T.

$$y' = \frac{1-x^2}{xy}$$

Solving

$$\begin{aligned} y \, dy &= \frac{1-x^2}{x} dx = \frac{dx}{x} - x \, dx \\ \frac{y^2}{2} + \frac{x^2}{2} &= \ln x + c_1 \\ x^2 &= c_2 e^{x^2+y^2} \end{aligned} \quad (*)$$

(*) is the required O.T.

To find the particular member of this O.T.

Put $x = 2$ when $y = 1$ in (*)

$$4 = c_2 e^5 \quad \therefore c_2 = 4e^{-5}$$

Thus the particular curve of O.T. passing through the point (2, 1) is

$$x^2 = 4e^{-5} e^{x^2+y^2}$$

Example 6: Show that the family of parabolas $y^2 = 4cx + 4c^2$ is “self-orthogonal”.

Solution:

$$\text{D.E. } 2yy' = 4c + 0$$

Substituting $c = \frac{yy'}{2}$ in given equation, we get

$$\begin{aligned} y^2 &= 4x \cdot \left(\frac{yy'}{2} \right) + 4 \left(\frac{yy'}{2} \right)^2 \\ y^2 &= 2xyy' + y^2 y'^2 \end{aligned} \quad (*)$$

Put $p = y'$ so that

$$y^2 = 2xyp + y^2 p^2 \quad (**)$$

This is the D.E. of the given family of parabolas.

In order to get D.E. corresponding to the O.T. replace y' by $-\frac{1}{p}$ in (*). Then

$$\begin{aligned} y^2 &= 2xy \left(-\frac{1}{p} \right) + y^2 \left(-\frac{1}{p} \right)^2 \\ p^2 y^2 &= 2xy(-p) + y^2 \end{aligned}$$

Rewriting

$$y^2 = 2xyp + p^2 y^2$$

which is same as equation (**). Thus D.E. (*) is D.E. for the given family and its orthogonal trajectories. Hence the given family is “self-orthogonal”.

EXERCISE

Rectangular coordinates

Find the orthogonal trajectories (O.T.) of each of the following family of curves. [Here c, a, b, k are all constants.]

$$1. \, x - 4y = c$$

$$\text{Ans. } 4x + y = k$$

$$2. \, x^2 + y^2 = c^2$$

$$\text{Ans. } y = kx$$

$$3. \, x^2 - y^2 = c$$

$$\text{Ans. } xy = k$$

$$4. \, y^2 = cx^3$$

$$\text{Ans. } (x+1)^2 + y^2 = a^2$$

$$5. \, y = c (\sec x + \tan x)$$

$$\text{Ans. } y^2 = 2(k - \sin x)$$

$$6. \, x^2 - y^2 = cx$$

$$\text{Ans. } y(y^2 + 3x^2) = k$$

$$7. \, y^2 = \frac{x^3}{a-x}$$

$$\text{Ans. } (x^2 + y^2)^2 = b(2x^2 + y^2)$$

$$8. \, (a+x)y^2 = x^2(3a-x)$$

$$\text{Ans. } (x^2 + y^2)^5 = cy^3(5x^2 + y^2)$$

$$9. \, y = cx^2$$

$$\text{Ans. } \frac{x^2}{2} + y^2 = c^*$$

10. Circles through origin with centres on the x -axis.

Ans. Circles through origin with centres on y -axis.

11. Family of parabolas through origin and foci on y -axis.

Ans. Ellipses with centres at origin and foci on x -axis.

12. The family of ellipses having centre at the origin, a focus at the point $(c, 0)$ and semi-major axis of length $2c$.

Ans. $y = cx^{\frac{4}{3}}$

13. Given $x^2 + 3y^2 = cy$, find that member of the orthogonal trajectories which passes through the point $(1, 2)$

Ans. $y^2 = x^2(3x + 1)$

14. Given $y = ce^{-2x} + 3x$, find that member of the O.T. which passes through point $(0, 3)$

Ans. $9x - 3y + 5 = -4e^{6(3-y)}$

15. Find constant ' e ' such that $y^3 = c_1x$ and $x^2 + ey^2 = c_2$ are orthogonal to each other.

Ans. $e = \frac{1}{3}$

16. Find the value of constant d such that the parabolas $y = c_1x^2 + d$ are the orthogonal trajectories of the family of ellipses $x^2 + 2y^2 - y = c_2$.

Ans. $d = \frac{1}{4}$

17. Show that the family of parabolas $y^2 = 2cx + c^2$ is "self-orthogonal".

18. Show that the family of confocal conics

$$\frac{x^2}{a} + \frac{y^2}{a-b} = 1$$

is "self-orthogonal". Here a is an arbitrary constant.

19. Find the orthogonal trajectories of a system of confocal and coaxial parabolas.

Ans. The family of confocal and coaxial parabolas by having x -axis as their axis is given by $y^2 = 4a(x + a)$ is "self-orthogonal".

20. Show that the family of confocal conics

$$\frac{x^2}{a^2 + c} + \frac{y^2}{b^2 + c} = 1$$

is "self-orthogonal". Here a and b are given constants.

21. Find the O.T. of $x^p + cy^p = 1$, $p = \text{constant}$.

Ans. $y^2 = \frac{2x^{2-p}}{2-p} - x^2 + c$, if $p \neq 2$

$$c_1x^2 = e^{x^2+y^2} \text{ if } p = 2$$

22. Show that the two families of one parameter family of curves $u(x, y) = c_1$ and $v(x, y) = c_2$ are mutually orthogonal provided they satisfy the (Cauchy-Riemann) equations $u_x = v_y$ and $u_y = -v_x$.

WORKED OUT EXAMPLES

O.T.: In polar coordinates

Find the orthogonal trajectories (O.T.) of each of the following family of curves:

Example 1: $r = a \cos^2 \theta$

Solution:

Differentiating $r = a \cos^2 \theta$ w.r.t. r

$$dr = 2a \cos \theta (-\sin \theta) d\theta$$

Eliminating $a = \frac{r}{\cos^2 \theta}$, we get

$$dr = -2 \cdot \frac{r}{\cos^2 \theta} \cdot \cos \theta \cdot \sin \theta \cdot d\theta$$

$$r \frac{d\theta}{dr} = -\frac{1}{2 \tan \theta}$$

D.E. corresponding to O.T. is

$$r \frac{d\theta}{dr} = 2 \tan \theta$$

Solving

$$\frac{d\theta}{\tan \theta} = 2 \frac{dr}{r}$$

$$\ln \sin \theta = 2 \ln r + c$$

So the O.T. is given by

$$r^2 = b \sin \theta.$$

8.44 — HIGHER ENGINEERING MATHEMATICS—III

Example 2: $r^2 = a \sin 2\theta$

Solution:

Differentiating w.r.t. r

$$2r \, dr = 2a \cos 2\theta \, d\theta$$

Eliminating $a = \frac{r^2}{\sin 2\theta}$, we get

$$r \, dr = \frac{r^2}{\sin 2\theta} \cdot \cos 2\theta \, d\theta$$

$$r \frac{d\theta}{dr} = \tan 2\theta$$

D.E. of O.T. is

$$r \frac{d\theta}{dr} = -\cot 2\theta$$

Solving

$$-\frac{\sin 2\theta}{\cos 2\theta} d\theta = \frac{dr}{r}$$

Integrating $\ln \cos 2\theta = 2 \ln r + c$

$$\text{O.T. } \therefore r^2 = b \cos 2\theta$$

EXERCISE

Polar coordinates

Find the orthogonal trajectories (O.T.) of each of the following family of curves:

1. Cardioids: $r = a(1 + \cos \theta)$

Ans. $r = b(1 - \cos \theta)$

Note: Family of cardioids is self-orthogonal.

2. Confocal and coaxial parabolas (self-orthogonal)

$$r = \frac{2a}{(1 + \cos \theta)}$$

Ans. $r = \frac{2b}{1 - \cos \theta}$

3. $\left(r^2 + \frac{k^2}{r}\right) \cos \theta = d$

d being a parameter

Ans. $(r^2 - k^2) \sin \theta = cr$

4. $r = 2a(\sin \theta + \cos \theta)$

Ans. $r = 2b(\sin \theta - \cos \theta)$

5. $r = 4a \sec \theta \cdot \tan \theta$

Ans. $r^2(1 + \sin^2 \theta) = b^2$

6. $r = a(1 + \sin^2 \theta)$

Ans. $r^2 = b \cos \theta \cdot \cot \theta$

7. Cissoids $r = a \sin \theta \tan \theta$

Ans. $r^2 = b(1 + \cos^2 \theta)$

8. $r = \frac{k}{1 + 2 \cos \theta}$

Ans. $r^2 \sin^3 \theta = b(1 + \cos \theta)$

9. Strophoids $r = a(\sec \theta + \tan \theta)$

Ans. $r = b e^{-\sin \theta}$

8.17 LAW OF NATURAL GROWTH

Let $x(t)$ be the population at any time t . Assume that population grows at a rate directly proportional to the amount of population present at that time. Then the D.E. governing this phenomena is the first order, first degree linear equation

$$\frac{dx}{dt} = kx$$

where k is the proportionality constant. Here $k > 0$ since this is a growth phenomena. The solution of the D.E. is

$$x(t) = c e^{kt}$$

where c is constant of integration. Here, c, k are determined from the two given (initial) conditions.

WORKED OUT EXAMPLES

Example: A bacterial population B is known to have a rate of growth $\propto$ to B itself. If between noon and 2 PM the population triples, at what time, no controls being exerted, should B become 100 times what it was at noon.

Solution: Equation is

$$\frac{dB}{dt} = kB$$

whose solution is $B(t) = ce^{kt}$. Let B_0 be the initial population at $t = 0$, using this condition

$$B_0 = ce^0 \quad \therefore c = B_0$$

Thus $B = B_0 e^{kt}$

Since population triples i.e., becomes $3B_0$ between noon and 2 PM i.e., in two hours, we use this condition to find k

$$3B_0 = B_0 e^{k \cdot 2}$$

Thus $k = \frac{1}{2} \ln 3 = 0.54930$

Hence the population rule is

$$B(t) = B_0 e^{0.54930t}$$

To find the time at which population becomes 100 times the original i.e., $100 B_0$ we put $B = 100 B_0$ in the above equation and solve for t .

$$100 B_0 = B_0 e^{0.54930t}$$

Solving

$$t = \frac{\ln 100}{0.54930} = 8.3837015$$

i.e., at 8.383 PM population becomes 100 times the original population.

EXERCISE

1. In a certain culture of bacteria the rate of increase is proportional to the number present. (a) If it is found that the number doubles in 4 hours, how many may be expected at the end of 12 hours. (b) If there are 10^4 at the end of 3 hours and $4 \cdot 10^4$ at the end of 5 hours, how many were in the beginning.

Ans. a. 8 times the original number

b. $\frac{10^4}{8}$ bacteria at the beginning

2. If the population of a country doubles in 50 years, in how many years will it treble under the assumption that the rate of increase is proportional to the number of inhabitants.

Ans. 79 years

3. In a certain bacteria culture the rate of increase in the number of bacteria is $\propto$ to the number present. (a) If the number triples in 5 hrs how many will be present in 10 hrs, (b) when will the number present be 10 times the number initially present.

Ans. a. 9 times the original number

b. 10.48 hours

4. The number N of bacteria in a culture grew at a rate proportional to N . The value of N was initially 100 and increased to 332 in one hour, what would be the value of N after $1\frac{1}{2}$ hours.

Ans. $604.9 \approx 605$

5. In a culture of yeast, the active ferment doubles itself in 3 hours. Assuming that the quantity increases at a rate proportional to itself, determine the number of times it multiplies itself in 15 hours.

Ans. It multiplies itself 32 times.

6. Find the time required for a sum of money to double itself at 5% per annum compounded continuously.

Ans. 13.9 years.

8.18 LAW OF NATURAL DECAY

The DE

$$\frac{dm}{dt} = -km, \quad k > 0$$

describes the decay phenomena where it is assumed that the material $m(t)$ at any time t decays at a rate which is proportional to the amount present. The solution is

$$m(t) = ce^{-kt}$$

If initially at, $t = 0$, m_0 is the amount present then

$$m(t) = m_0 e^{-kt}$$

WORKED OUT EXAMPLES

Example: Radium decomposes at a rate $\propto$ the quantity of radium present. Suppose that it is found

8.46 — HIGHER ENGINEERING MATHEMATICS—III

that in 25 years approximately 1.1% of a certain quantity of radium has decomposed. Determine approximately how long will it take for one-half of the original amount of radium to decompose.

Solution: Let m be the amount of radioactive material radium present at time t . Let m_0 be initial (original) amount of radium at $t = 0$. By the decay rule

$$\frac{dm}{dt} = -km$$

whose solution is

$$m(t) = ce^{-kt} \quad (1)$$

using the initial condition $m(0) = m_0$ in (1), we get

$$m_0 = m(0) = ce^0$$

$$\therefore c = m_0$$

Thus

$$m = m_0 e^{-kt}$$

Since 1.1% of original mass of radium decays in 25 years, the amount of mass of radium present when $t = 25$ years is $(1 - \frac{1.1}{100})m_0$. Using this in (1)

$$\left(1 - \frac{1.1}{100}\right)m_0 = m(25) = m_0 e^{-k(25)}$$

Thus

$$k = -\frac{1}{25} \ln(1 - 0.011) = 0.000443$$

In order to find the time taken for half the radium to disintegrate (to decay) put $m(t = t^*) = \frac{1}{2}m_0$ in (1).

$$\frac{1}{2}m_0 = m_0 e^{-kt^*}$$

Solving for $t = \frac{\ln 2}{k} = 1564.66 \approx 1565$ years.

EXERCISE

1. Radium decomposes at a rate $\propto$ to the amount present. If a fraction p of the original amount disappears in 1 year, how much will remain at the end of 21 years?

Ans. $\left(1 - \frac{1}{p}\right)^{21}$ times the original amount.

2. Find the half-life of uranium, which disintegrates at a rate $\propto$ to the amount present at any instant given that m_1 and m_2 grams of uranium are present at t_1 and t_2 respectively.

$$\text{Ans. } T = \frac{(t_2 - t_1) \log 2}{\log(m_1/m_2)}$$

3. If half-life of uranium is 1500 years. (a) Find percentage of original amount that will remain after 4500 years, (b) Find in how many years will only $\frac{1}{10}$ of the original amount remain?

Ans. $m = m_0 e^{-0.00046t}$; (a) $\frac{1}{8}$ th or 12.5% of the original amount will remain after 4500 years; (b) $t = 4985$ years.

4. Radium disintegrates at a rate $\propto$ to its mass. When mass is 10 mgm, the rate of disintegration is 0.051 mgm per day. How long will it take for the mass to be reduced to 10 to 5 mgm?

Ans. 135.9 days.

8.19 NEWTON'S* LAW OF COOLING

Physical experiments show that the time (t) rate of change $\frac{dT}{dt}$ of the temperature T of a body is proportional to the difference between T and the temperature T_A of the (ambient) surrounding medium. This is known as Newton's law of cooling. Taking the unknown proportionality constant as k , the equation governing the Newton's law of cooling is a first order first degree linear separable differential equation.

$$\frac{dT}{dt} = -k(T - T_A)$$

Here proportionality constant is taken as $-k$ so that $k > 0$. Separating the variables

$$\frac{dT}{(T - T_A)} = -k dt$$

Integrating

$$\ln(T - T_A) = -kt + c_0$$

Solution is

*Sir Isaac Newton (1642–1727), English physicist and mathematician.

$$T - T_A = e^{-kt+c_0} = c e^{-kt}$$

where $c = e^{c_0}$. Thus the solution to Newton's law of cooling is

$$T(t) = T_A + c e^{-kt} \quad (1)$$

where the arbitrary constant c will be found by using the initial condition $T(t = 0) = T_0$.

Method of Solving the Problem of Newton's Law of Cooling

- I. Identify T_A , the temperature of the surrounding medium, so that the general solution is given by (1).
- II. Use two conditions given to determine the constant of integration c and unknown proportionality constant k .
- III. Substituting c and k , obtained from step II, in (1) (a) the value of T for a given time t or (b) the value of time t for a given temperature T can be determined from (1).

WORKED OUT EXAMPLES

Example 1: A body of temperature 80°F is placed in a room of constant temperature 50°F at time $t = 0$. At the end of 5 minutes the body has cooled to a temperature of 70°F . (a) Find the temperature of the body at the end of 10 minutes. (b) When will the temperature of the body be 60°F ? (c) After how many minutes will the temperature of the body be within 1°F of the constant 50°F temperature of the room?

Solution: Let T be the temperature of the body. Then the $T(t) = 50 + c e^{-kt}$ since $T_A = 50$. Apply the condition $T(0) = 80$, to find c :

$$80 = 50 + c e^0 \quad \therefore c = 30$$

Thus $T(t) = 50 + 30 e^{-kt}$

use the condition $T(5) = 70$ to determine k :

$$70 = 50 + 30 e^{-k \cdot 5}$$

so that

$$k = \frac{1}{5} \ln \left(\frac{3}{2} \right)$$

i.e., $k = 0.08109$

Thus the required solution which gives the temperature of the body at any time t is

$$T(t) = 50 + 30 e^{-0.08109t}$$

a. $T(10) = 50 + 30 e^{-0.08109(10)} \simeq 63.33^\circ\text{F}$

b. $60 = 50 + 30 e^{-0.08109t}$

Solving

$$t = 5 \left(\frac{\ln \frac{1}{3}}{\ln \frac{2}{3}} \right) \approx 13.55 \text{ mts}$$

c. $51 = 50 + 30 e^{-0.08109t}$

Solving

$$t = 5 \left(\frac{\ln \frac{1}{30}}{\ln \frac{2}{3}} \right) \approx 41.91 \text{ mts}$$

Example 2: If a substance cools from 370 k to 330 k in 10 mts, when the temperature of the surrounding air is 290 k , find the temperature of the substance after 40 mts.

Solution: Here $T_A = 290$ so that the solution is

$$T(t) = 290 + c e^{-kt}$$

Use condition $T(0) = 370$ to find c

$$370 = 290 + c \cdot e^0$$

$\therefore c = 80$

Thus

$$T(t) = 290 + 80 e^{-kt}$$

Use condition $T(10) = 330$ to find k

Thus

$$330 = 290 + 80 e^{-k \cdot 10}$$

so that

$$k = \frac{\ln 2}{10} = 0.069314718$$

The required solution is

$$T(t) = 290 + 80 e^{-0.0693t}$$

8.48 — HIGHER ENGINEERING MATHEMATICS—III

Putting $t = 40$ mts in the above solution

$$\begin{aligned} T(40) &= 290 + 80 \cdot e^{-0.0693[40]} \\ &= 295 \end{aligned}$$

EXERCISE

- Water at temperature 100°C cools in 10 min to 80°C in a room of temperature 25°C . (a) Find the temperature of water after 20 min. when is the temperature (b) 40°C (c) 26°C ?

Ans. (a) 65.3°C ; (b) 52 min, (c) 139 min.

- Water at temperature 10°C takes 5 min to warm up to 20°C in a room at temperature 40°C . (a) Find the temperature after 20 min; after $\frac{1}{2}$ hr, (b) When will the temperature be 25°C ?

Ans. (a) 34.1°C , 37.4°C ; (b) 8.5 min.

- A copper ball is heated to a temperature of 100°C . Then at time $t = 0$ it is placed in water which is maintained at a temperature of 30°C . At the end of 3 mts the temperature of the ball is reduced to 70°C . Find the time at which the temperature of the ball drops to 31°C .

Ans. $22.78 \approx 23$ mts.

- A thermometer reading 18°F is brought into a room the temperature of which is 70°F . One minute later the thermometer reading is 31°F . Find the temperature reading 5 minutes after the thermometer is first brought into the room.

Ans. $57.80235 \approx 58^\circ\text{F}$.

- A body is heated to 110°C and placed in air at 10°C . After 1 hour its temperature is 60° . How much additional time is required for it to cool to 30°C ?

Ans. $\frac{\log 5}{\log 2} - 1 = 2.3223 - 1 = 1.3223$ hours.

8.20 VELOCITY OF ESCAPE FROM EARTH

Consider the problem of determining the minimum velocity with which a body (projectile) be projected vertically upwards in the radial direction from the

earth so that the body will escape from earth and will not return to earth. Here it is assumed that retardation effect due to air resistance and gravitational pull of other celestial bodies is neglected.

Let m be the mass of the body and M be the mass of earth. Let r be the distance between the (centre of the) earth and (the centre of gravity of) the body. Let R be the radius of earth.

According to Newton's second law and the universal law of gravitation and ignoring all forces (frictional, magnetic or other) except for gravity, the vertical motion of the body is described by the second order differential equation

$$m \frac{d^2 r}{dt^2} = -k \frac{M \cdot m}{r^2} \quad (1)$$

where k is the gravitational constant. The minus sign indicates that the acceleration is negative.

Expressing the acceleration in terms of velocity and distance $\frac{d^2 r}{dt^2} = \frac{dv}{dt} = \frac{dv}{dr} \frac{dr}{dt} = v \frac{dv}{dr}$, the equation (1) can be written as

$$v \frac{dv}{dr} = -\frac{kM}{r^2}$$

Here v is the velocity of the body. Separating the variables and integrating, we get

$$\frac{v^2}{2} = \frac{kM}{r} + c \quad (2)$$

Suppose v_0 is the launching velocity with which the body leaves the earth's surface then the initial conditions are:

$$\text{for } t = 0, r = R, \frac{dr}{dt} = v_0 \quad (3)$$

Using (3) in (2), we have

$$\frac{v_0^2}{2} = \frac{kM}{R} + c \text{ or } c = \frac{v_0^2}{2} - \frac{kM}{R}$$

Substituting c in (2), we get

$$\frac{v^2}{2} = \frac{kM}{r} + \frac{v_0^2}{2} - \frac{kM}{R}$$

$$\text{or } v^2 = \frac{2kM}{r} + \left(v_0^2 - \frac{2kM}{R} \right) \quad (4)$$

As $r \rightarrow \infty$, $\frac{kM}{r} \rightarrow 0$, the velocity is always positive if $v^2 > 0$. Thus for any r and m , $v^2 > 0$ provided

$$v_0^2 - \frac{2kM}{R} \geq 0$$

or
$$v_0 \geq \sqrt{\frac{2kM}{R}}$$

Thus the minimum velocity for the body to escape from earth is

$$v_0 = \sqrt{\frac{2kM}{R}}.$$

Since the acceleration due to gravity g is given by

$$g = \frac{kM}{R^2}$$

We have $M = \frac{gR^2}{k}$ (5)

Hence the velocity of escape v_0 is rewritten as

$$v_0 = \sqrt{\frac{2k}{R} \cdot \frac{gR^2}{k}} = \sqrt{2gR} \quad (6)$$

Note that velocity of escape v_0 is independent of m , the mass of the body. It depends only on M and R .

For radius of earth $R = 63.10^7$ cm and $g = 981$ cm/sec², the velocity of escape from earth is

$$\begin{aligned} v_0 &= \sqrt{2(981)(63.10^7)} \approx 11.2 \cdot 10^5 \text{ cm} \\ &= 11.2 \text{ km/sec} \end{aligned}$$

Using (5) in (4) we get

$$v^2 = \frac{2gR^2}{r} + v_0^2 - 2gR \quad (7)$$

Thus the body projected with an initial (launching) velocity v_0 from the earth's surface in a radial direction will travel with velocity v given by (7). If $v_0^2 < 2gR$ then for some critical value r , the velocity v given by (7) becomes zero, in which case the body will stop and return to earth since the velocity will change from positive to negative.

Cor: If the body is carried by a rocket and is separated from the rocket at a distance of r^* miles from the earth's surface then the velocity of escape

$$v_0 = \sqrt{\frac{2gr^2}{R+r^*}}$$

In this case the differential equation is

$$v \frac{dv}{dr} = -\frac{Mg}{(R+r^*)^2}$$

which on integrating gives

$$v^2 = \frac{2R^2g}{r} + \left(v_0^2 - 2\frac{R^2g}{R+r^*} \right)$$

WORKED OUT EXAMPLES

Example 1: Assuming the radius of moon as $R = 1080$ miles and acceleration of gravity at the surface of the moon as $0.165g$ where g is the acceleration of gravity at the surface of the earth, determine the velocity of escape for the moon.

Solution: Velocity of escape $v_0 = \sqrt{2g^*R^*}$. Here $R^* = 1080$ miles, $g^* = .165g = (.165)(6.09) \times 10^{-3}$ so $v_0^2 = 2(.165)(6.09) \times 10^{-3} \times 1080 = 2.170476$ or $v_0 = 1.47325 \approx 1.5$ miles/sec.

Example 2: Determine the velocity of escape for a body which is carried by a rocket and is separated from it at a distance of 1000 miles from the earth's surface.

Solution: The velocity of escape in this case is $v_0 = \sqrt{\frac{2gR^2}{R+r^*}}$. Here $R =$ radius of earth $= 3960$ miles, $r^* = 1000$ miles, $g = 6.1 \times 10^{-3}$ miles/sec². So

$$\begin{aligned} v_0 &= \sqrt{\frac{2(6.1 \times 10^{-3}) \times (3960)^2}{3960 + 1000}} \\ &= \sqrt{\frac{(1.218)(156816)}{4960}} \end{aligned}$$

$v_0 = \sqrt{38.5084} = 6.2055173$ miles/sec² (or 9.985 km/sec²) which is smaller than $v_0 = 6.95$ miles/sec when launched from the surface of earth ($r^* = 0$).

EXERCISE

- Suppose a body is carried by a rocket and is separated from the rocket at a distance of 200 miles from the earth's surface, determine the minimum velocity at this point, sufficient for escape from the earth.

Ans. $v_0 = 6.7923$ miles/sec (10.913 km/sec)

Hint: $v_0 = \sqrt{\frac{2gR^2}{R+200}} = \sqrt{\frac{(1.218)(156816)}{4160}} = \sqrt{45.90}$

- Determine the escape velocities from the following bodies in the solar system with g^* as

8.50 — HIGHER ENGINEERING MATHEMATICS—III

the acceleration of gravity at the surface of the body and R^* the radius in miles.

(a) Venus : $g^* = 0.85$ g, $R^* = 3800$

(b) Mars: $g^* = 0.38$ g, $R^* = 2100$

(c) Jupiter: $g^* = 2.6$ g, $R^* = 43,000$

(d) Sun: $g^* = 28$ g, $R^* = 432000$

Ans. (a) 6.3 (b) 3.1 (c) 37 (d) 380 miles/sec

Hint: $g = 6.1 \times 10^{-3}$ miles/sec

8.21 SIMPLE ELECTRIC CIRCUITS

Electric current is a flow of charges, measured in *amperes* (A). Electric current flows due to a difference in the electric potential or *voltage* measured in *volts* (v), just as heat flows from one point to the other due to a temperature difference. An *electric circuit* consists of a source of electric energy (*electromotive force*) and elements such as *resistors*, *inductors* or *voltage* and *capacitors*. A mathematical model of an electric circuit is represented by linear (first or second order) differential equations. To form such an equation, the following relationships are needed:

The voltage drop E_R across a resistor is proportional to the instantaneous current $I(t)$ through it:

$$E_R = RI \quad (\text{Ohm's law}) \quad (1)$$

Here t is the time and the constant of proportionality R is known as the *resistance* of the resistor, measured in ohms (Ω). Resistor uses (consumes) energy. Resistor is represented by $\sim\sim\sim\sim$. The voltage drop E_L across an inductor is proportional to the instantaneous time rate of change of the current:

$$E_L = L \frac{dI}{dt} \quad (2)$$

Here the constant of proportionality L is known as *inductance* of the inductor and is measured in *henrys* (H). An inductor opposes a change in current and is represented by $\sim\sim\sim\sim$. Inductor causes inertia effect in electricity just as mass in mechanics. The voltage drop E_c across a capacitor is proportional to the instantaneous electric charge Q on the capacitor.

$$E_c = \frac{1}{c} Q \quad (3)$$

Here c is called the *capacitance* and is measured in farads (F) and is represented by $\text{—}||\text{—}$. A capacitor stores energy. The charge Q is measured in *coulombs*. Since current is the time rate of change of charge,

$$I(t) = \frac{dQ}{dt} \quad (4)$$

Equation (3) may be written as

$$E_c = \frac{1}{c} \int_{t_0}^t I(u) du \quad (5)$$

To determine the current $I(t)$ in an electric circuit, a differential equation is formed using the Kirchhoff's* voltage law (KVL) which states that *the algebraic sum of all the instantaneous voltage drops around any closed loop is zero or the voltage impressed on a closed loop is equal to the sum of the voltage drops in the rest of the loop*. Consider two simple cases of *series* or *one-loop* electric circuits.

I. RL-circuit

By (1), the voltage drop across the resistor is RI . By (2), the voltage drop across the inductor is $L \frac{dI}{dt}$. Now applying Kirchhoff's law to the RL -circuit, the sum of the two voltage drops must be equal to electromotive force $E(t)$. Thus the current $I(t)$ in the RL -circuit is determined by the first order linear differential equation

$$L \frac{dI}{dt} + RI = E(t) \quad (6)$$

Rewriting (6), we have

$$\frac{dI}{dt} + \frac{R}{L} I = \frac{E(t)}{L}$$

which has an integrating factor $e^{\int \frac{R}{L} dt} = e^{\frac{R}{L}t} = e^{\alpha t}$ where $\alpha = \frac{R}{L}$.

*Gustav Robert Kirchhoff (1824-1887), German physicist.

Fig. 8.9

Then the general solution of (6) is

$$I(t) \cdot e^{\alpha t} = \int \frac{E(t)}{L} \cdot e^{\alpha t} dt + c$$

or
$$I(t) = e^{-\alpha t} \left[\int \frac{E(t)}{L} \cdot e^{\alpha t} dt + c \right] \quad (7)$$

Case (a): Suppose $E = E_0 = \text{constant}$. Then (7) simplifies to

$$I(t) = e^{-\alpha t} \left[\frac{E_0}{L} \cdot \frac{e^{\alpha t}}{\alpha} + c \right] = \frac{E_0}{R} + c e^{-\alpha t} \quad (8)$$

As $t \rightarrow \infty$, $I(t) \rightarrow \frac{E_0}{R} = \text{constant}$. Here $\frac{L}{R} = \frac{1}{\alpha}$ is known as *inductive time constant*.

Case (b): Suppose $E = E_0 \sin \omega t$. Then (7) reduces

$$I(t) = e^{-\alpha t} \left[\frac{E_0}{L} \int e^{\alpha t} \sin \omega t dt + c \right]$$

since $\int e^{at} \sin bt dt = \frac{e^{at}}{(a^2 + b^2)} (a \sin bt - b \cos bt)$,

$$I(t) = c e^{-\frac{R}{L}t} + \frac{E_0}{L \left(\frac{R^2}{L^2} + \omega^2 \right)} \left(\frac{R}{L} \sin \omega t - \omega \cos \omega t \right)$$

or

$$I(t) = c e^{-\frac{R}{L}t} + \frac{E_0}{R^2 + \omega^2 L^2} (R \sin \omega t - \omega L \cos \omega t)$$

Using $a \cos x + b \sin x = \sqrt{a^2 + b^2} \sin(x \pm \theta)$, where $\tan \theta = \frac{\sin \theta}{\cos \theta} = \pm \frac{a}{b}$, the trigonometric terms can be expressed in “phase-angle” form as

$$I(t) = c e^{-\frac{R}{L}t} + \frac{E_0}{\sqrt{R^2 + \omega^2 L^2}} \sin(\omega t - \theta) \quad (9)$$

where $\theta = \tan^{-1} \frac{\omega L}{R}$. The current I in (9) is expressed as the sum of an exponential and sinusoidal terms. As $t \rightarrow \infty$, the first term tends to zero. It is known as the *transient* term. The second sinusoidal term corresponds to the *steady-state* which is free of e^{-t} . The period is $2\pi/\omega$ and phase is θ . The steady-state solution is permanent, periodic and has the same period as that of the applied external force.

Case (c): Suppose $E = E_0 \cos \omega t$. Then (7) reduces to

$$I(t) = e^{-\alpha t} \left[\frac{E_0}{L} \int e^{\alpha t} \cos \omega t dt + c \right]$$

Since $\int e^{at} \cos bt dt = \frac{e^{at}}{(a^2 + b^2)} (a \cos bt + b \sin bt)$,

$$I(t) = c e^{-\frac{R}{L}t} + \frac{E_0}{R^2 + \omega^2 L^2} (R \cos \omega t + \omega L \sin \omega t)$$

Using $a \cos x + b \sin x = \sqrt{a^2 + b^2} \cos(x \pm \theta)$ where

$$\tan \theta = \frac{\sin \theta}{\cos \theta} = \mp \frac{b}{a}$$

we have

$$I(t) = c e^{-\frac{R}{L}t} + \frac{E_0}{\sqrt{R^2 + \omega^2 L^2}} \cos(\omega t - \theta) \quad (10)$$

where $\theta = \tan^{-1} \frac{\omega L}{R}$.

II. RC-circuit

Using (1), (5) and Kirchhoff's law, we get the integro-differential equation.

$$RI + \frac{1}{c} \int I(t) dt = E(t)$$

which on differentiation reduces to

$$R \frac{dI}{dt} + \frac{1}{c} I = \frac{dE}{dt} \quad (11)$$

or
$$\frac{dI}{dt} + \frac{1}{Rc} I = \frac{1}{R} \frac{dE}{dt}$$

8.52 — HIGHER ENGINEERING MATHEMATICS—III

This is a first order linear differential equation with integrating factor $e^{\int \frac{1}{cR} dt} = e^{\frac{t}{cR}}$.

Fig. 8.10

The general solution of (11) is

$$I(t) \cdot e^{\frac{t}{cR}} = \int \frac{1}{R} \frac{dE}{dt} \cdot e^{\frac{t}{cR}} \cdot dt + c$$

or
$$I(t) = e^{-\frac{t}{cR}} \left[\int \frac{1}{R} \frac{dE}{dt} e^{\frac{t}{cR}} dt + c \right] \quad (12)$$

Case (a): Suppose $E = E_0 = \text{constant}$. Then $\frac{dE}{dt} = 0$. The solution (12) reduces to

$$I(t) = ce^{-\frac{t}{cR}} \quad (13)$$

Here RC is known as capacitive time constant of the circuit.

Case (b): Suppose $E = E_0 \sin \omega t$. Then

$$\frac{dE}{dt} = \omega E_0 \cos \omega t$$

From (12), we have

$$\begin{aligned} I(t) &= ce^{-\frac{t}{cR}} + \frac{1}{R} \int e^{\frac{t}{cR}} \cdot \omega E_0 \cdot \cos \omega t \, dt \\ &= ce^{-\frac{t}{cR}} + \frac{\omega E_0}{R} \frac{e^{\frac{t}{cR}}}{\left(\frac{1}{cR}\right)^2 + \omega^2} \left[\frac{1}{cR} \cos \omega t + \omega \sin \omega t \right] \\ &= ce^{-\frac{t}{cR}} + \frac{\omega E_0 c}{1 + (\omega c R)^2} (\cos \omega t + \omega R c \cdot \sin \omega t) \end{aligned}$$

$$I(t) = ce^{-\frac{t}{cR}} + \frac{\omega E_0 c}{1 + (\omega c R)^2} \sin(\omega t - \theta) \quad (14)$$

where $\tan \theta = -\frac{1}{\omega R c}$. The first term which is transient tends to zero as $t \rightarrow \infty$ while the second sinusoidal term corresponds to steady-state.

Case (b) Suppose $E = E_0 \cos \omega t$. Then

$$\frac{dE}{dt} = -\omega E_0 \sin \omega t$$

From (12), we have

$$\begin{aligned} I(t) &= ce^{-\frac{t}{cR}} - \frac{\omega E_0}{R} \int e^{\frac{t}{cR}} \cdot \sin \omega t \, dt \\ &= ce^{-\frac{t}{cR}} - \frac{\omega E_0}{R} \cdot \frac{e^{\frac{t}{cR}}}{\left(\frac{1}{cR}\right)^2 + \omega^2} \left[\frac{1}{cR} \sin \omega t - \omega \cos \omega t \right] \\ &= ce^{-\frac{t}{cR}} + \frac{\omega E_0 c}{1 + (\omega R c)^2} (\omega R c \cos \omega t - \sin \omega t) \end{aligned}$$

$$I(t) = ce^{-\frac{t}{cR}} + \frac{\omega E_0 c}{\sqrt{1 + (\omega R c)^2}} \cos(\omega t + \theta) \quad (15)$$

where $\tan \theta = -\frac{1}{\omega R c}$

WORKED OUT EXAMPLES

RL-circuit

Example 1: Find the current at any time $t > 0$ in a circuit having in series a constant electromotive force 40 V, a resistor $10 \, \Omega$, and an inductor $0.2 \, \text{H}$ given that initial current is zero. Find the current when $E(t) = 150 \cos 200 t$.

Solution: Equation for RL circuit is

$$L \frac{dI}{dt} + RI = E(t)$$

Fig. 8.11

(a) $L = 0.2$, $R = 10$, $E = 40$

$$0.2 \frac{dI}{dt} + 10I = 40$$

$$\frac{dI}{dt} + 50I = 200$$

Its general solution is

$$I(t) \cdot e^{50t} = \int 200 \cdot e^{50t} + c = 200 \cdot \frac{e^{50t}}{50} + c$$

$$I(t) = e^{-50t} [4e^{50t} + c]$$

At $t = 0$, $I = 0$, so $0 = [4 + c]$ or $c = -4$. The current $I(t)$ is given by

$$I(t) = 4(1 - e^{-50t})$$

(b) Here $E(t) = 150 \cos 200t$ v. So equation is

$$\frac{dI}{dt} + 50I = 750 \cos 200t$$

The general solution is

$$\begin{aligned} I(t) \cdot e^{50t} &= 750 \int e^{50t} \cdot \cos 200t dt + c \\ &= c + 750 \cdot \frac{e^{50t}}{(2500 + 40000)} (50 \cos 200t \\ &\quad + 200 \sin 200t) \end{aligned}$$

At $t = 0$, $I = 0$ so

$$0 = \frac{3}{170} 50 + c \quad \therefore c = -\frac{15}{17}$$

The current $I(t)$ is given by

$$I(t) = \frac{3}{170} (50 \cos 200t + 200 \sin 200t) - \frac{15}{17} e^{-50t}$$

RC-circuit

Example 1: A capacitor $c = 0.01$ F in series with a resistor $R = 20$ ohms is charged from a battery $E_0 = 10$ V. Assuming that initially the capacitor is completely uncharged, determine the charge $Q(t)$, voltage $v(t)$ on the capacitor and the current $I(t)$ in the circuit.

Solution: Equation is

$$RI + \frac{Q}{c} = E$$

$$20I + \frac{Q}{0.01} = 10$$

$$\text{or} \quad \frac{dQ}{dt} + 5Q = 0.5$$

The general solution is

$$Q \cdot e^{5t} = 0.5 \int e^{5t} dt = 0.5 \cdot \frac{e^{5t}}{5} + c$$

$$Q = 0.1 + ce^{-5t}$$

At $t = 0$, $Q = 0$, so $0 = 0.1 + c \quad \therefore c = -0.1$

Thus the charge $Q(t) = 0.1(1 - e^{-5t})$

Voltage $v(t) = \frac{Q(t)}{c} = \frac{0.1(1 - e^{-5t})}{0.01} = 10(1 - e^{-5t})$.

The current $I(t) = \frac{dQ}{dt} = 0.5e^{-5t}$.

EXERCISE

1. A generator having emf 100 volts is connected in series with a 10 ohm resistor and an inductor of 2 henries. If the switch is closed at a time $t = 0$, determine the current at time $t > 0$.

Ans. $I = 10(1 - e^{-5t})$

Hint: $\dot{I} + 5I = 50$, $I(0) = 0$.

2. Solve the above example when the generator is replaced by one having an emf of $20 \cos 5t$ volts.

Ans. $I = \cos 5t + \sin 5t - e^{-5t}$

Hint: $\dot{I} + 5I = 10 \cos 5t$, $I(0) = 0$, $c = -1$

3. A decaying emf $E = 200e^{-5t}$ is connected in series with a 20 ohm resistor and 0.01 farad capacitor. Find the charge and current at any time assuming $Q = 0$ at $t = 0$. Show that the charge reaches a maximum, calculate it and find the time when it is reached.

Ans. $Q(t) = 10te^{-5t}$, $I(t) = 10e^{-5t} - 50te^{-5t}$.
Maximum of $Q = 10 \cdot \frac{1}{5} \cdot e^{-1} = \frac{2}{e} \sim 0.74$ coulombs when $t = \frac{1}{5}$ sec.

Hint: $\dot{Q} + 5Q = 10e^{-5t}$, to find maximum $\frac{dQ}{dt} = 0$.

4. Find the current $I(t)$ in the RL-circuit with $R = 10$ ohms, $L = 100$ henries, $E = 40$ volts

8.54 — HIGHER ENGINEERING MATHEMATICS—III

when $0 \leq t \leq 100$ and $E = 0$ when $t > 100$ and $I(0) = 4$

Ans. $I = 4$ when $0 \leq t \leq 100$, $I = 4 \cdot e^{10} e^{-t/10}$ when $t > 100$

Hint: $\dot{I} + 0.1I = 0.4$, $0 \leq t \leq 100$, $\dot{I} + 0.1I = 0$ when $t > 100$, use $I = 4$ when $t = 100$.

5. Find $I(t)$ in an RL -circuit with $E = 10$ V, $R = 5$ ohms $L = (10 - t)$ henry, when $0 \leq t \leq 10$ sec, and $L = 0$ when $t > 10$ sec and $I(0) = 0$.

Ans. $I = 2 - 2(1 - 0.1t)^5$ when $0 \leq t \leq 10$; when $t > 10$, $I = 2$

Hint: $(10 - t)\dot{I} + 5I = 10$ when $0 \leq t \leq 10$.

6. Solve the (RL -circuit) equation $L \frac{dI}{dt} + RI = E(t)$ when (a) $E(t) = E_0$ and the initial current is I_0 .

(b) Solve the problem when $L = 3$ henries, $R = 15$ ohms, emf is the 60 cycle sine wave of amplitude 110 volts and $I(t = 0) = 0$.

Ans. (a) $I(t) = \frac{E_0}{R}(1 - e^{-Rt/L}) + I_0 e^{-Rt/L}$

(b) $I(t) = \frac{22}{3} \cdot \frac{\sin 120\pi t - 24\pi \cos 120\pi t + 24\pi e^{-5t}}{1 + 576\pi^2}$

Hint: $3\dot{I} + 15I = 100 \sin 120\pi t$.

7. Solve the (RC -circuit) equation $R \frac{dQ}{dt} + \frac{Q}{c} = E$ with $R = 10$ ohms, $c = 10^{-3}$ farad and $E(t) = 100 \sin 120\pi t$ assuming $Q(t = 0) = 0$. Find $I(t)$ given $I(t = 0) = 5$.

Ans. $Q(t) = \frac{\sin(120\pi t - \phi)}{2\sqrt{(25 + 36\pi^2)}} + \frac{3\pi e^{-100t}}{25 + 36\pi^2}$

$$I(t) = \frac{60\pi}{\sqrt{25 + 36\pi^2}} \cos(120\pi t - \phi) - \left(\frac{300\pi}{25 + 36\pi^2} - 5 \right) e^{-100t}$$

Hint: $\dot{Q} + 100Q = 10 \sin 120\pi t$, $\sin \phi = \frac{12\pi}{\sqrt{100 + 144\pi^2}}$, $\cos \phi = \frac{10}{\sqrt{100 + 144\pi^2}}$

8. Determine the current at time $t > 0$ in a series RL -circuit having an emf given by $E(t) = 100 \sin 40t$ V, a resistor of 10Ω and an inductor of 0.5 H given that initial current is zero. Find the period and the phase angle.

Ans. $I(t) = 2(\sin 40t - 2 \cos 40t) + 4e^{-20t}$, period $\frac{\pi}{20}$, phase angle $\phi \approx -1.11$

Hint: $\dot{I} + 20I = 200 \sin 40t$,
 $I(t) = 4.47 \sin(40t - 1.11) + 4e^{-20t}$.

9. Find the current in RC -circuit with $R = 10$, $c = 0.1$, $E(t) = 110 \sin 314t$, $I(0) = 0$

Ans. $I(t) = 0.035(\cos 314t + 314 \sin 314t - e^{-t})$

10. Determine the charge and current at time $t > 0$ in a RC -circuit with $R = 10$, $c = 2 \times 10^{-4}$, $E = 100$ V given that $Q(t = 0) = 0$.

Ans. $Q(t) = (1 - e^{-500t})/50$, $I(t) = 10e^{-500t}$.

Chapter 9

Linear Differential Equations of Second Order and Higher Order

INTRODUCTION

The simple harmonic motion, oscillations of mass-spring system, RLC-circuit, oscillations of a simple pendulum are all described by nonhomogeneous (or homogeneous) linear second order differential equations. Higher order differential equations appear in problems involving deflections of loaded beams (4th order), mechanical spring systems having several springs connected in tandem or series of electrical circuits containing several loops. In this chapter, we consider methods of obtaining solutions of homogeneous and nonhomogeneous differential equations of second and higher order with constant coefficients. We also consider the Cauchy's and Legendre differential equations with variable coefficients. We present two powerful general methods: method of variation of parameters and method of undetermined coefficients. Method of obtaining solution of system of simultaneous linear differential equations is presented. Finally we consider four important engineering applications: the simple harmonic motion, mass-spring system, RLC-circuit and simple pendulum.

9.1 LINEAR INDEPENDENCE AND DEPENDENCE

Two functions $y_1(x)$ and $y_2(x)$ are said to be linearly independent if

$$k_1 y_1(x) + k_2 y_2(x) = 0 \quad (1)$$

implies k_1 and k_2 are both zeros i.e., when y_1 or y_2 can not be expressed as proportional to the other.

Otherwise, y_1 and y_2 are linearly dependent if (1) holds for some constants k_1 and k_2 not both zero.

Criterion for linear dependence or independence of two functions y_1 and y_2

Define the Wronski* determinant or Wronskian

$$w(y_1, y_2) = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix} = y_1 y_2' - y_2 y_1' \quad (2)$$

Results:

- i. y_1, y_2 are linearly independent if $w \neq 0$
- ii. otherwise linearly dependent when $w = 0$.

WORKED OUT EXAMPLES

Determine whether the following functions y_1 and y_2 are linearly dependent or independent:

Example 1: $y_1 = \cos ax, y_2 = \sin ax$ with $a \neq 0$.

Solution:

$$w = \begin{vmatrix} \cos ax & \sin ax \\ -a \sin ax & a \cos ax \end{vmatrix} = a(\cos^2 ax + \sin^2 ax) \\ = a \neq 0$$

So y_1 and y_2 are linearly independent.

Example 2: $y_1 = \ln x, y_2 = \ln x^n$ with n non negative integer.

Solution:

$$w = \begin{vmatrix} \ln x & \ln x^n \\ \frac{1}{x} & \frac{nx^{n-1}}{x^n} \end{vmatrix} = \frac{n}{x} \ln x - \frac{1}{x} \ln x^n = 0$$

So y_1 and y_2 are linearly dependent.

*I.M. Hone (1778–1853) Polish mathematician, who changed his name to Wronski.

9.2 — HIGHER ENGINEERING MATHEMATICS—III

EXERCISE

Show that the following pair of functions are linearly independent (with $w \neq 0$):

- | | |
|-------------------------------|---|
| 1. e^x, xe^x | 7. $x^{\frac{3}{2}}, x^{-\frac{3}{2}}$ |
| 2. e^x, x^2 | 8. $x^4, x^4 \ln x$ |
| 3. $1, x$ | 9. $x^a \cos(2 \ln x), x^a \sin(2 \ln x)$ |
| 4. $x^2, x^2 \ln x$ | 10. $e^{ax} \sin bx, e^{ax} \cos bx$ |
| 5. $x^2, x^{\frac{1}{2}}$ | 11. e^{ax}, e^{-ax} |
| 6. $\cos 2\pi x, \sin 2\pi x$ | |

9.2 LINEAR DIFFERENTIAL EQUATIONS OF SECOND ORDER WITH VARIABLE COEFFICIENTS

Standard form of linear D.E. of 2nd order with variable coefficients is

$$y'' + P(x)y' + Q(x)y = F(x) \quad (1)$$

Here $P(x)$, $Q(x)$ and $F(x)$, are known functions of x . P and Q are known as coefficients of D.E. (1).

Non-homogeneous

D.E. (1) is said to be non-homogeneous if the R.H.S. of (1) $F(x) \neq 0$. Otherwise

Homogeneous

when $F(x) = 0$. Thus

$$y'' + P(x)y' + Q(x)y = 0 \quad (2)$$

is known as the reduced or corresponding or *complementary* homogeneous linear Equation of (1).

Superposition or Linearity Principle or Fundamental Theorem for Homogeneous D.E.

Theorem: If $y_1(x)$ and $y_2(x)$ are any two linearly independent solutions of the homogeneous D.E. (2), then the general solution of the homogeneous D.E. (2) is given by

$$y(x) = c_1 y_1(x) + c_2 y_2(x) \quad (3)$$

where c_1 and c_2 are two arbitrary constants.

Proof: Differentiating (3) w.r.t. x twice, we get

$$y' = c_1 y_1' + c_2 y_2' \quad (4)$$

$$y'' = c_1 y_1'' + c_2 y_2'' \quad (5)$$

Substituting (3), (4), (5) in (2), we have

$$(c_1 y_1'' + c_2 y_2'') + P(c_1 y_1' + c_2 y_2') + Q(c_1 y_1 + c_2 y_2) = 0$$

Rewriting

$$c_1(y_1'' + P y_1' + Q y_1) + c_2(y_2'' + P y_2' + Q y_2) = 0 \quad (6)$$

Since y_1 and y_2 are solutions of (2) i.e.,

$$y_1'' + P y_1' + Q y_1 = 0 \quad \text{and} \quad y_2'' + P y_2' + Q y_2 = 0$$

Equation (2) is identically satisfied by (3). Thus (3) is the general solution of (2) (since it contains two arbitrary constants c_1 and c_2).

Note: Above superposition principle is *not* applicable to non-homogeneous or nonlinear equations.

9.3 SECOND ORDER DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS; HOMOGENEOUS

Standard form

$$y'' + ay' + by = 0 \quad (1)$$

where the coefficients a and b are constants. Consider the function

$$y = e^{mx} \quad (2)$$

then $y' = m e^{mx}$, $y'' = m^2 e^{mx}$

Substituting these values of y , y' , y'' in (1), we get

$$(m^2 + am + b)e^{mx} = 0$$

Since $e^{mx} \neq 0$, $y = e^{mx}$ is a solution of (1) if m satisfies the quadratic equation

$$m^2 + am + b = 0 \quad (3)$$

Equation (3) is known as auxiliary equation (A.E.) or characteristic equation of (1).

Observation A.E. (3) is obtained from D.E. (1) by replacing y by 1, y' by m and y'' by m^2 .

The general solution (G.S.) of the homogeneous D.E. (1) is obtained depending on the nature of the two roots of the auxiliary Equation (3) as follows:

Case 1: Two distinct real roots

When the two roots m_1, m_2 of A.E. (3) are real distinct, then $e^{m_1 x}$ and $e^{m_2 x}$ form a linearly independent set of solutions to D.E. (1). By superposition principle, the general solution of (1) is

$$y = c_1 e^{m_1 x} + c_2 e^{m_2 x}$$

where c_1 and c_2 are any two arbitrary constants.

Case 2: Real double (repeated) root

In case of repeated double root, e^{m_1x} and xe^{m_1x} are linearly independent so that the general solution of (1) by linearity principle is

$$y = c_1 e^{mx} + x c_2 e^{mx} = (c_1 + c_2 x) e^{mx}$$

Case 3: Complex conjugate roots.

For complex conjugate roots e^{p+iq} and e^{p-iq} are linearly independent solutions of (1) therefore the general solution of (1) is

$$\begin{aligned} y &= c_1^* e^{(p+iq)x} + c_2^* e^{(p-iq)x} \\ &= c_1^* e^{px} (e^{iqx}) + c_2^* e^{px} e^{-iqx} \\ &= e^{px} [c_1^* (\cos qx + i \sin qx) + c_2^* (\cos qx - i \sin qx)] \\ &= e^{px} [(c_1^* + c_2^*) \cos qx + (c_1^* - c_2^*) i \cdot \sin qx] \\ y &= e^{px} [c_1 \cos qx + c_2 \sin qx] \end{aligned}$$

These results are listed in the following table.

The general solution of (1) in these three cases is obtained as follows:

Case	Nature of the two roots of A.E. (3)	Set of linearly independent solutions of (1)	General solution of (1)
1.	Distinct real roots m_1, m_2	e^{m_1x}, e^{m_2x}	$y = c_1 e^{m_1x} + c_2 e^{m_2x}$
2.	Real double root (two equal roots) (repeated roots) $m = m_1 = m_2$	$e^{mx}, x e^{mx}$	$y = (c_1 + c_2 x) e^{mx}$
3.	Complex conjugate $m_1 = p + iq$ $m_2 = p - iq$	$e^{px} \cos qx,$ $e^{px} \sin qx$	$y = e^{px} \times (c_1 \cos qx + c_2 \sin qx)$

WORKED OUT EXAMPLES

Distinct real roots: second order

Solve the following:

Example 1: $y'' - y' - 12y = 0$

Solution: Rewriting the given D.E. in operator form

$$(D^2 - D - 12)y = 0$$

so that the corresponding auxiliary equation or characteristic equation is obtained by replacing D by m in the given D.E. as $m^2 - m - 12 = 0$.

$m^2 - m - 12 = (m + 3)(m - 4) = 0$. Thus there are two real distinct roots $-3, 4$.

General solution: $y(x) = c_1 e^{-3x} + c_2 e^{4x}$ where c_1 and c_2 are arbitrary constants.

Example 2: $y'' - 3y' + 2y = 0, y(0) = -1, y'(0) = 0$

Solution:

$$\text{A.E.: } m^2 - 3m + 2 = 0$$

$$(m - 2)(m - 1) = 0.$$

$m = 1, 2$ are two real distinct roots

$$\text{G.S.: } y = c_1 e^x + c_2 e^{2x}$$

Particular solution using condition $y(0) = -1$ in the G.S., we get

$$-1 = y(0) = c_1 + c_2 \quad (1)$$

using the condition $y'(0) = 0$ is derivative of G.S. we have

$$\begin{aligned} y' &= c_1 e^x + 2c_2 e^{2x} \\ 0 &= y'(0) = c_1 + 2c_2 \end{aligned} \quad (2)$$

Solving (1) and (2), we get

$$c_1 = -2, c_2 = 1$$

Thus the particular solution is

$$y = -2e^x + e^{2x}$$

EXERCISE

Solve the following:

$$1. \quad y'' - 3y' + 2y = 0$$

$$\text{Ans. } y = c_1 e^x + c_2 e^{2x}$$

$$2. \quad y'' - 5y' + 6y = 0$$

$$\text{Ans. } y = c_1 e^{2x} + c_2 e^{3x}$$

$$3. \quad 4y'' - 12y' + 9y = 0$$

$$\text{Ans. } y = c_1 e^{\frac{x}{2}} + c_2 e^{\frac{5x}{2}}$$

$$4. \quad 2y'' + y' - 6y = 0$$

$$\text{Ans. } y = c_1 e^{\frac{3x}{2}} + c_2 e^{-2x}$$

$$5. \quad y'' + y' - 2y = 0$$

9.4 — HIGHER ENGINEERING MATHEMATICS—III

Ans. $y = c_1 e^{-2x} + c_2 e^x$

6. $y'' - 6y' + 8y = 0, y(0) = 1, y'(0) = 6$

Ans. $y = -e^{2x} + 2e^{4x}$

7. $y'' - y' - 12y = 0, y(0) = 3, y'(0) = 5$

Ans. $y = 2e^{4x} + e^{-3x}$

8. $y'' + y' - 2y = 0, y(0) = 4, y'(0) = -5$

Ans. $y = e^x + 3e^{-2x}$

9. $y'' - 4y' + y = 0$

Ans. $y = c_1 e^{(2+\sqrt{3})x} + c_2 e^{(2-\sqrt{3})x}$

10. $y'' + 2y' - 8 = 0$

Ans. $y = c_1 e^{2x} + c_2 e^{-4x}$.

WORKED OUT EXAMPLES

Equal (or repeated or double) roots:
second order

Solve the following:

Example 1: $y'' + 3y' + 2.25y = 0$

Solution:

A.E.: $m^2 + 3m + 2.25 = 0$.

$(m + \frac{3}{2})^2 = 0$ i.e., $m = -\frac{3}{2}$ is a double (repeated) root.

G.S: $(y = c_1 + c_2 x)e^{-\frac{3x}{2}}$.

Example 2: $y'' - 6y' + 9y = 0, y(0) = 2, y'(0) = 8$

Solution:

A.E.: $m^2 - 6m + 9 = 0$

$(m - 3)^2 = 0$ i.e., $m = 3$ is a double root

G.S: $y = (c_1 + c_2 x)e^{3x}$

using $y(0) = 2$ in G.S, we get $2 = y(0) = c_1$

using $y'(0) = 8$ in $y' = 3e^{3x}(c_1 + c_2 x) + e^{3x} \cdot c_2$
we get

$$8 = 3c_1 + c_2 \quad \therefore c_2 = 2$$

Thus the particular solution is $y = 2(1 + x)e^{3x}$

EXERCISE

Equal (or repeated or double) root: second order

Solve the following:

1. $y'' + 8y' + 16y = 0$

Ans. $y = (c_1 + c_2 x)e^{-4x}$

2. $y'' - 6y' + 9y = 0$

Ans. $y = (c_1 + c_2 x)e^{3x}$

3. $4y'' - 4y' + y = 0$

Ans. $y = (c_1 + c_2 x)e^{\frac{x}{2}}$

4. $y'' - 8y' + 16y = 0$

Ans. $y = (c_1 + c_2 x)e^{4x}$

5. $16y'' - 8y' + y = 0$

Ans. $y = (c_1 + c_2 x)e^{\frac{x}{4}}$

6. $y'' + 6y' + 9y = 0, y(0) = 2, y'(0) = -3$

Ans. $y = (3x + 2)e^{-3x}$

7. $y'' - 4y' + 4y = 0, y(0) = 3, y'(0) = 1$

Ans. $y = (3 - 5x)e^{2x}$

8. $y'' + 4y' + 4y = 0, y(0) = 3, y'(0) = 7$

Ans. $y = (13x + 3)e^{-2x}$

9. $9y'' - 30y' + 25y = 0$

Ans. $y = (c_1 + c_2 x)e^{\frac{5x}{3}}$

10. $y'' + 2ky' + k^2 y = 0$

Ans. $y = (c_1 + c_2 x)e^{-kx}$

WORKED OUT EXAMPLES

Complex conjugate roots: Second order

Solve the following:

Example 1: $y'' + 5y' + 12.5y = 0$.

Solution:

A.E.: $m^2 + 5m + 12.5 = 0$.

So $m = \frac{-5 \pm 5i}{2}$ are the complex conjugate roots.

$$p = -\frac{5}{2}, q = \frac{5}{2},$$

$$\text{G.S.: } y = e^{-\frac{5x}{2}} \left[c_1 \cos \frac{5x}{2} + c_2 \sin \frac{5x}{2} \right]$$

$$\text{Example 2: } y'' - 2y' + 5y = 0, y(0) = -3, y'(0) = 1$$

Solution:

$$\text{A.E.: } m^2 - 2m + 5 = 0.$$

So $m = 1 \pm 2i$ are the complex conjugate roots.

$$p = 1, q = 2,$$

$$\text{G.S.: } y = e^x [c_1 \cos 2x + c_2 \sin 2x]$$

using $y(0) = -3$ in G.S., we get

$$-3 = e^0 [c_1 + 0] \quad \therefore \quad c_1 = -3$$

Differentiating G.S. w.r.t., x

$$y' = e^x [c_1 \cos 2x + c_2 \sin 2x] \\ + e^x [-2c_1 \sin 2x + 2c_2 \cos 2x]$$

using $y'(0) = 1$ in the above equation, we have

$$1 = y'(0) = e^0 [c_1 \cdot 1 + 0] + e^0 [0 + 2c_2 \cdot 1]$$

$$1 = c_1 + 2c_2. \quad \text{Thus } c_2 = 2$$

The required particular solution is

$$y = e^x [-3 \cos 2x + 2 \sin 2x]$$

EXERCISE

Complex conjugate roots: second order

Solve the following:

$$1. \quad y'' + 9y = 0$$

$$\text{Ans. } y = c_1 \sin 3x + c_2 \cos 3x$$

$$2. \quad y'' - 6y' + 25y = 0$$

$$\text{Ans. } y = e^{3x} (c_1 \cos 4x + c_2 \sin 4x)$$

$$3. \quad y'' + 6y' + 11y = 0$$

$$\text{Ans. } y = e^{-3x} (c_1 \sin \sqrt{2}x + c_2 \cos \sqrt{2}x)$$

$$4. \quad y'' - 4y' + 13y = 0$$

$$\text{Ans. } y = e^{2x} (c_1 \sin 3x + c_2 \cos 3x)$$

$$5. \quad y'' - 4y' + 29y = 0, y(0) = 0, y'(0) = 5$$

$$\text{Ans. } y = e^{2x} \sin 5x$$

$$6. \quad y'' + 0.2y' + 4.01y = 0, y(0) = 0, y'(0) = 2$$

$$\text{Ans. } y = e^{-0.1x} \sin 2x$$

$$7. \quad y'' + 6y' + 13y = 0, y(0) = 3, y'(0) = -1$$

$$\text{Ans. } y = e^{-3x} (4 \sin 2x + 3 \cos 2x)$$

$$8. \quad 9y'' + 6y' + 5y = 0, y(0) = 6, y'(0) = 0$$

$$\text{Ans. } y = 3e^{-\frac{x}{3}} \left(\sin \frac{2x}{3} + 2 \cos \frac{2x}{3} \right)$$

$$9. \quad y'' + 2a \cos \alpha y' + a^2 y = 0$$

$$\text{Ans. } y = e^{-ax \cos \alpha} [c_1 \cos (ax \sin \alpha) + c_2 \sin (ax \sin \alpha)]$$

$$10. \quad y'' + y' + y = 0$$

$$\text{Ans. } y = e^{-\frac{x}{2}} \left[c_1 \cos \frac{\sqrt{3}}{2}x + c_2 \sin \frac{\sqrt{3}}{2}x \right]$$

9.4 HIGHER ORDER LINEAR HOMOGENEOUS DIFFERENTIAL EQUATIONS

Analysis considered in 9.3 for second order homogeneous equations with constant coefficients can be extended in a similar way to equations of higher order three or more. Consider the n th order homogeneous equation

$$a_0 \frac{d^n y}{dx^n} + a_1 \frac{d^{n-1} y}{dx^{n-1}} + a_2 \frac{d^{n-2} y}{dx^{n-2}} + \dots \\ + a_{n-1} \frac{dy}{dx} + a_n y = 0 \quad (1)$$

Here $a_0, a_1, a_2, \dots, a_n$ are all constants.

Introducing the notation of differential operator $D \equiv \frac{d}{dx}$ and higher order operators as $D^2 = \frac{d^2}{dx^2}, \dots, D^n = \frac{d^n}{dx^n}$, etc, the given equation can be rewritten with this notation as

$$a_0 D^n y + a_1 D^{n-1} y + a_2 D^{n-2} y + \dots \\ + a_{n-1} D y + a_n y = 0$$

$$\text{or} \quad (a_0 D^n + a_1 D^{n-1} + a_2 D^{n-2} + \dots \\ + a_{n-1} D + a_n) y = 0 \quad (2)$$

$$\text{or} \quad f(D) y = 0 \quad (3)$$

where $f(D) = a_0 D^n + a_1 D^{n-1} + \dots + a_{n-1} D + a_n$ is function of D .

Observation

The auxiliary equation of (1) is obtained by replacing y by 1, y' by m , y'' by $m^2, \dots, y^{(n)}$ by m^n in D.E.

9.6 — HIGHER ENGINEERING MATHEMATICS—III

(1). Thus the A.E.

$$a_0 m^n + a_1 m^{n-1} + a_2 m^{n-2} + \dots + a_{n-1} m + a_n = 0 \quad (4)$$

is an n th degree polynomial in m i.e.,

$$f(m) = 0 \quad (5)$$

The general solution of (1) containing n arbitrary constants is obtained according as the nature of the roots of A.E. (4), as follows:

By synthetic division

$$\begin{array}{r|rrrr} -1 & 1 & -4 & 1 & 6 \\ & & -1 & 5 & -6 \\ \hline & 1 & -5 & 6 & 0 \end{array}$$

We obtain the factorization as

$$(m - (-1))(m^2 - 5m + 6) = 0$$

or

$$(m + 1)(m - 2)(m - 3) = 0$$

Thus there 3 real distinct roots $-1, 2, 3$.

$$\text{G.S.: } y = c_1 e^{-x} + c_2 e^{2x} + c_3 e^{3x}.$$

Case	Nature of the n roots of A.E. (4)	Linearly independent solution of (1)	General solution of (1)
I.	n distinct and real roots $m_1, m_2, m_3, \dots$	$e^{m_1 x}, e^{m_2 x}, e^{m_3 x}, \dots$	$y = c_1 e^{m_1 x} + c_2 e^{m_2 x} + c_3 e^{m_3 x} + \dots$
II.	Two equal and real roots, $n - 2$ distinct roots $m_1, m_1, m_3, m_4, \dots$	$e^{m_1 x}, x e^{m_1 x}, e^{m_3 x}, e^{m_4 x}$	$y = (c_1 + c_2 x) e^{m_1 x} + c_3 e^{m_3 x} + c_4 e^{m_4 x} + \dots$
III.	Three equal real roots, $n - 3$ distinct roots $m_1, m_1, m_1, m_4, m_5, \dots$	$e^{m_1 x}, x e^{m_1 x}, x^2 e^{m_1 x}, e^{m_4 x}, \dots$	$y = (c_1 + c_2 x + c_3 x^2) e^{m_1 x} + c_4 e^{m_4 x} + c_5 e^{m_5 x} + \dots$
IV.	Two complex conjugate roots, $n - 2$ distinct real roots $m_1 = p + iq$ $m_2 = p - iq$ $m_3, m_4, \dots$	$e^{p x} \cos q x, e^{p x} \sin q x, e^{m_3 x}, e^{m_4 x}, \dots$	$y = e^{p x} (c_1 \cos q x + c_2 \sin q x) + c_3 e^{m_3 x} + c_4 e^{m_4 x} + \dots$
V.	Two equal complex conjugate roots, $n - 4$ distinct real roots $m_1 = m_2 = p + iq,$ $m_3 = m_4 = p - iq,$ $m_5, m_6, \dots$	$e^{p x} \cos q x, x e^{p x} \cos q x, e^{p x} \sin q x, x e^{p x} \sin q x, e^{m_5 x}, e^{m_6 x}, \dots$	$y = e^{p x} [(c_1 + c_2 x) \cos q x + (c_3 + c_4 x) \sin q x] + c_5 e^{m_5 x} + \dots$

WORKED OUT EXAMPLES

Distinct real roots: higher order

Solve the following:

Example 1: $y''' - 4y'' + y' + 6y = 0$

Solution:

A.E.: $m^3 - 4m^2 + m + 6 = 0$.

Observe that $m = -1$ is a root of this equation.

Example 2: $y''' - 3y'' - y' + 3y = 0$.

Solution:

A.E.: $m^3 - 3m^2 - m + 3 = 0$.

Observe that $m = 1$ is a root ($1 - 3 - 1 + 3 = 0$).

By synthetic division

$$\begin{array}{r|rrrr} 1 & 1 & -3 & -1 & 3 \\ & & 1 & -2 & -3 \\ \hline & 1 & -2 & -3 & 0 \end{array}$$

We obtain the factorization as

$$\begin{aligned}(m-1)(m^2-2m-3) \\ = (m-1)(m+1)(m-3) = 0\end{aligned}$$

3 real distinct roots $-1, 1, 3$

$$\text{G.S.: } y = c_1 e^{-x} + c_2 e^x + c_3 e^{3x}.$$

Example 3: $4y^{(4)} - 8y''' - 7y'' + 11y' + 6y = 0$

Solution:

$$\text{A.E.: } 4m^4 - 8m^3 - 7m^2 + 11m + 6 = 0.$$

Observe that -1 is a root

$$(4 + 8 - 7 - 11 + 6 = 0)$$

Note also that 2 is a root

$$(64 - 64 - 28 + 22 + 6 = 0)$$

By synthetic division

$$\begin{array}{r|rrrrrr} -1 & 4 & -8 & -7 & 11 & 6 & \\ & & -4 & 12 & -5 & -6 & \\ \hline 2 & 4 & -12 & 5 & 6 & 0 & \\ & & 8 & -8 & -6 & & \\ \hline & 4 & -4 & -3 & 0 & & \end{array}$$

We obtain the factorization as

$$\begin{aligned}(m+1)(m-2)(4m^2-4m-3) = 0 \\ (m+1)(m-2)\left(m+\frac{1}{2}\right)\left(m-\frac{3}{2}\right) = 0\end{aligned}$$

4 distinct real roots, $-\frac{1}{2}, -1, \frac{3}{2}, 2$

$$\text{G.S.: } y = c_1 e^{-\frac{x}{2}} + c_2 e^{-x} + c_3 e^{\frac{3x}{2}} + c_4 e^{2x}.$$

EXERCISE

Higher order: Homogeneous: Distinct roots

Solve the following:

$$1. \quad y''' - 4y'' + y' + 6y = 0$$

$$\text{Ans. } y = c_1 e^{-x} + c_2 e^{2x} + c_3 e^{3x}$$

$$2. \quad y''' - 6y'' + 11y' - 6y = 0$$

$$\text{Ans. } y = c_1 e^x + c_2 e^{2x} + c_3 e^{3x}$$

$$3. \quad y''' - 3y'' - y' + 3y = 0$$

$$\text{Ans. } y = c_1 e^x + c_2 e^{-x} + c_3 e^{3x}$$

$$4. \quad y''' - 6y'' + 11y' - 6y = 0, \quad y(0)=0, \quad y'(0)=0, \\ y''(0)=2$$

$$\text{Ans. } y = e^x - 2e^{2x} + e^{3x}$$

$$5. \quad y''' - 9y'' + 23y' - 15y = 0$$

$$\text{Ans. } y = c_1 e^x + c_2 e^{3x} + c_3 e^{5x}$$

$$6. \quad y''' - 2y'' - 3y' = 0$$

$$\text{Ans. } y = c_1 + c_2 e^{3x} + c_3 e^{-x}$$

WORKED OUT EXAMPLES

Double (repeated) root: higher order

Solve the following:

Example 1: $4y''' + 4y'' + y' = 0$.

Solution:

$$\text{A.E.: } 4m^3 + 4m^2 + m = 0.$$

$$m(4m^2 + 4m + 1) = m\left(m + \frac{1}{2}\right)^2 = 0$$

so $m = 0, -\frac{1}{2}, -\frac{1}{2}$ are the roots of which

$m = -\frac{1}{2}$ is a repeated (double) root.

$$\text{G.S.: } y = c_1 \cdot e^{0 \cdot x} + (c_2 + xc_3)e^{-\frac{x}{2}}$$

Example 2: $y'''' + 6y''' + 9y'' = 0$

Solution:

$$\text{A.E.: } m^4 + 6m^3 + 9m^2 = 0$$

$$m^2(m^2 + 6m + 9) = m^2(m+3)^2 = 0$$

so $m = 0, 0, -3, -3$ are the roots

i.e., $m = 0$ and $m = -3$ each is a double root.

$$\text{G.S.: } y = (c_1 + c_2 x)e^{0 \cdot x} + (c_3 + c_4 x)e^{-3x}.$$

Example 3: $y'''' - y''' = 0$

Solution:

$$\text{A.E.: } m^5 - m^3 = 0$$

$$m^3(m^2 - 1) = 0$$

so $m = 0$ is a triple (repeated 3 times) root and $m = -1, 1$ are distinct real roots.

$$\begin{aligned}\text{G.S.: } y &= c_1 e^{-x} + c_2 e^x + (c_3 + xc_4 + x^2 c_5)e^{0 \cdot x} \\ y &= c_1 e^{-x} + c_2 e^x + (c_3 + xc_4 + x^2 c_5)\end{aligned}$$

9.8 — HIGHER ENGINEERING MATHEMATICS—III

EXERCISE

Higher order: Homogeneous: repeated roots

1. $y''' - 4y'' - 3y' + 18y = 0$

Ans. $y = c_1 + c_2x + c_3x^2 + (c_4 + c_5x)e^x$

8. $y'''' - 3y''' + 2y'' = 0$, $y(0) = 2$, $y'(0) = 0$,
 $y''(0) = 2$, $y'''(0) = 2$

Ans. $y = 2(e^x - x)$.

WORKED OUT EXAMPLES

Complex (conjugate) roots: higher order

Solve the following:

Example: $y^{(4)} + 18y'' + 81y = 0$.

Solution:

A.E.: $m^4 + 18m^2 + 81 = 0$.

$(m^2 + 9)^2 = 0$ so $m^2 = -9$ is a repeated root

$m = \pm 3i$ is repeated (double) root

i.e., $m = +3i, +3i, -3i, -3i$ are the 4 roots.

Solutions are $y_1 = e^{3ix}$, $y_2 = xe^{3ix}$ and $y_3 = e^{-3ix}$
and $y_4 = xe^{-3ix}$.

Thus the G.S. is

$$\begin{aligned} y &= (c_1 + c_2x)e^{3ix} + (c_3 + c_4x)e^{-3ix} \\ &= (c_1 + c_2x)(\cos 3x + i \sin 3x) \\ &\quad + (c_3 + c_4 \cdot x)(\cos 3x - i \sin 3x) \end{aligned}$$

EXERCISE

Higher order: Homogeneous: complex roots

1. $y''' + y'' + 4y' + 4 = 0$

Ans. $y = c_1e^{-x} + c_2 \cos 2x + c_3 \sin 2x$

2. $y''' - y'' + y' - y = 0$

Ans. $y = c_1e^x + c_2 \sin x + c_3 \cos x$

3. $y'''' - 3y''' - 2y'' + 2y' + 12y = 0$

Ans. $y = c_1e^{2x} + c_2e^{3x} + e^{-x}(c_3 \sin x + c_4 \cos x)$

4. $y'''' - 4y''' + 14y'' - 20y' + 25y = 0$

Ans. roots are $1 + 2i, 1 - 2i, 1 + 2i, 1 - 2i$ (each pair of conjugate complex roots is double)

$$y = e^x[(c_1 + c_2x) \sin 2x + (c_3 + c_4x) \cos 2x]$$

or $y = c_1e^x \sin 2x + c_2xe^x \sin 2x + c_3e^x \cos 2x$
 $+ c_4xe^x \cos 2x$

5. $y'''' + 4y = 0$

Ans. roots are $-1 \pm i$ and $1 \pm i$

$$\begin{aligned} y &= e^{-x}(c_1 \cos x + c_2 \sin x) \\ &\quad + e^x(c_3 \cos x + c_4 \sin x) \end{aligned}$$

6. $y'''' + 8y'' + 16y = 0$

Ans. $y = (c_1 + c_2x) \sin 2x + (c_3 + c_4x) \cos 2x$

7. $y'''' + 3y'''' + 3y'' + y = 0$

Ans. $y = (c_1 + c_2x + c_3x^2) \sin x +$
 $(c_4 + c_5x + c_6x^2) \cos x$

8. $y'''' - 2y''' + y = 0$

Ans. $y = (c_1 + c_2x)e^x + e^{-\frac{x}{2}} \left[(c_3 + c_4x) \cos \frac{\sqrt{3}}{2}x \right.$
 $\left. + (c_5 + c_6x) \sin \frac{\sqrt{3}}{2}x \right]$

9.5 NON-HOMOGENEOUS EQUATIONS

Consider the non-homogeneous linear differential equation of n th order with constant coefficients

$$(a_0 D^n + a_1 D^{n-1} + \cdots + a_{n-1} D + a_n)y = F(x) \quad (1)$$

Then

$$(a_0 D^n + a_1 D^{n-1} + \cdots + a_{n-1} D + a_n)y = 0 \quad (2)$$

is the corresponding (or complementary or reduced) homogeneous equation of (1) (obtained by putting the R.H.S. $F(x) = 0$ in D.E. (1)).

A general solution

A general solution of the non-homogeneous equation (1) is a solution of the form

$$y(x) = y_c(x) + y_p(x) \quad (3)$$

$$\text{where } y_c(x) = c_1 y_1(x) + c_2 y_2(x) + \cdots + c_n y_n(x) \quad (4)$$

is the general solution of the corresponding homogeneous Equation (2), containing n arbitrary constants and $y_p(x)$ is any (particular) solution of the non-homogeneous Equation (1) containing no arbitrary constants.

Complementary Function (C.F.): $y_c(x)$

$y_c(x)$ which is the general solution of the reduced homogeneous Equation (2) is more often known as complementary function (C.F.) although it is also called complementary solution or complementary integral.

Particular Integral (P.I.): $y_p(x)$

$y_p(x)$ is more often called as particular integral (also particular solution of the non-homogeneous Equation (1)).

Thus the

General solution = complimentary function
+ particular integral

generally abbreviated as

$$\boxed{\text{G.S.} = \text{C.F.} + \text{P.I.}} \quad (5)$$

Method of Obtaining Particular Integral (P.I.):

Inverse operator: $D^{-1}F(x) = \frac{1}{D}F(x) = \int F(x)dx$.
If $Du(x) = v(x)$ then $u(x) = D^{-1}v(x)$. Here D^{-1} is known as inverse operator of D such that

$$DD^{-1}(F(x)) = F(x) \quad \text{i.e., } DD^{-1} = 1$$

when D is differential operator then D^{-1} also denoted by $\frac{1}{D}$ represents integral operator $\int$. Thus in a similar way $\frac{1}{D^2}$, $\frac{1}{D^3}$, ... etc. denotes integration twice, thrice etc. w.r.t., x .

Equation (1) can now be rewritten as

$$f(D)y = F(x) \quad (6)$$

where

$$f(D) = a_0 D^n + a_1 D^{n-1} + \cdots + a_{n-1} D + a_n \quad (7)$$

is a function of the differential operator D . Then the particular integral (P.I.) of

$$f(D)y = F(x) \quad (6)$$

$$\text{is } y_p = \frac{1}{f(D)}F(x) \quad (8)$$

where $\frac{1}{f(D)}$ is the inverse operator of $f(D)$, such that

$$f(D) \left\{ \frac{1}{f(D)}F(x) \right\} = F(x) = \frac{1}{f(D)} \{f(D)F(x)\}.$$

Book Work: Prove that if

$$(D - a)y = F(x) \quad (9)$$

$$\text{Then } y = \frac{1}{(D - a)}F(x) = e^{ax} \int F(x)e^{-ax} dx \quad (10)$$

Proof: The D.E. $(D - a)y = F(x)$ is a first order linear equation $\frac{dy}{dx} - ay = F(x)$ with I.F. as $e^{\int -a dx} = e^{-ax}$. Then the solution of (9) is

$$ye^{-ax} = \int e^{-ax} \cdot F(x) dx + c$$

Thus a particular solution of (9) (with $C = 0$) is

$$\boxed{y = e^{ax} \int F(x)e^{-ax} dx} \quad (10)$$

Special Case i. When $F(x) = b = \text{constant}$, then

$$(D - a)y = b$$

9.10 — HIGHER ENGINEERING MATHEMATICS—III

Integrating $y e^{-ax} = \int b e^{-ax} dx = \frac{b e^{-ax}}{-a}, a \neq 0$

$$y = \frac{1}{D-a} b = \frac{b}{-a} \quad \text{with } a \neq 0 \quad (11)$$

Special Case ii. If R.H.S. of (8) is $F(x) = e^{ax}$, then (10) reduces to

$$y = e^{ax} \int F(x) e^{-ax} dx = e^{ax} \int e^{ax} e^{-ax} dx$$

$$y = x e^{ax}$$

Thus

$$y_p = \left(\frac{1}{D-a} \right) e^{ax} = x e^{ax} \quad (12)$$

Special Case iii. $(D-a)^r y = F(x) = e^{ax}$ then repeated application of result (ii) above by integrating r times successively, we get

$$y_p = \frac{1}{(D-a)^r} e^{ax} = \frac{x^r}{r!} e^{ax} \quad (13)$$

Using the inverse operator (short-cut) methods, a particular integral y_p of the non-homogeneous D.E.

$$f(D)y = F(x)$$

can be obtained when $F(x)$, the R.H.S. function has the following forms:

- $F(x) = e^{ax+b}$
- $F(x) = \sin(ax+b)$ or $\cos(ax+b)$
- $F(x) = x^m$ or polynomial in x
- $F(x) = e^{ax} v(x)$, exponential shift
- $F(x) = x v(x)$

These and several other useful results of obtaining particular integral are presented in a tabular form at the end of Section 9.5.

Method of Obtaining General Solution of a Non-homogeneous Differential Equations

- Obtain C.F. which is the general solution of the corresponding homogeneous equation.
- P.I. is obtained depending on the nature of the R.H.S. function $F(x)$ using appropriate results listed in the table.

Step III. The G.S.: $y = \text{C.F.} + \text{P.I.}$.

[If initial conditions are specified, the constants in C.F. are evaluated using IC's].

P.I. when $F(x) = e^{ax+b}$

Consider the n th order linear non-homogeneous D.E. with constant coefficients and with R.H.S. function $F(x) = e^{ax+b}$ given by

$$(a_0 D^n + a_1 D^{n-1} + \dots + a_{n-1} D + a_n) y = F(x) = e^{ax+b} \quad (1)$$

or

$$f(D)y = e^{ax+b} \quad (2)$$

where

$$f(D) = a_0 D^n + a_1 D^{n-1} + \dots + a_{n-1} D + a_n \quad (3)$$

We know that $\frac{d}{dx} e^{ax+b} = D e^{ax+b} = a e^{ax+b}$, $D^2 e^{ax+b} = a^2 e^{ax+b}$, $D^3 e^{ax+b} = a^3 e^{ax+b}$, ..., $D^n e^{ax+b} = a^n e^{ax+b}$.

Substituting these values in (3)

$$f(D) e^{ax+b} = (a_0 D^n + a_1 D^{n-1} + \dots + a_{n-1} D + a_n) e^{ax+b}$$

$$= (a_0 a^n + a_1 a^{n-1} + \dots + a_{n-1} a + a_n) e^{ax+b}$$

$$f(D) e^{ax+b} = f(a) e^{ax+b} = e^{ax+b} f(a) \quad (4)$$

where $f(a)$, a constant is obtained, from $f(D)$ by replacing D by ' a '.

Operating on both sides of (4) by $\frac{1}{f(D)}$, we get

$$\frac{1}{f(D)} f(D) e^{ax+b} = \frac{1}{f(D)} f(a) e^{ax+b}$$

$$= f(a) \frac{1}{f(D)} e^{ax+b}$$

$$e^{ax+b} = f(a) \frac{1}{f(D)} e^{ax+b}$$

$$\text{Therefore } \frac{1}{f(D)} e^{ax+b} = \frac{1}{f(a)} e^{ax+b}$$

provided $f(a) \neq 0$.

Result 1: When $f(a) \neq 0$, then the

$$\text{P.I.} = y_p = \frac{1}{f(D)} e^{ax+b} = \frac{1}{f(a)} \cdot e^{ax+b}.$$

Result 2: Suppose $f(a) = 0$

If $f(a) = 0$ then $(m - a)$ is a factor of $f(m)$ so that $(D - a)$ is a factor of $f(D)$ i.e.,

$$f(D) = (D - a)\phi(D)$$

such that $\phi(a) \neq 0$. Then

$$\begin{aligned}\frac{1}{f(D)}e^{ax+b} &= \frac{1}{(D-a)\phi(D)}e^{ax+b} \\ &= \frac{1}{\phi(a)} \frac{1}{D-a}e^{ax} \text{ (from Result I)} \\ &= \frac{1}{\phi(a)} \cdot xe^{ax+b}\end{aligned}$$

Result 3: Suppose $f(D) = (D - a)^r \psi(D)$ with $\psi(a) \neq 0$

Then

$$\begin{aligned}\frac{1}{f(D)}e^{ax+b} &= \frac{1}{(D-a)^r \psi(D)}e^{ax+b} \\ &= \frac{1}{\psi(a)} \frac{1}{(D-a)^r}e^{ax+b} \\ &= \frac{1}{\psi(a)} \cdot \frac{x^r}{r!}e^{ax+b}\end{aligned}$$

WORKED OUT EXAMPLES

P.I. when $F(x) = e^{ax+b}$

Cases: I_a, I_b, I_c, I_d and II_a, II_b, II_c

Solve the following:

Example 1: $(D^2 + 2D + 1)y = 2e^{3x}$

Solution:

C.F.: Here A.E. $m^2 + 2m + 1 = 0$ i.e., $(m + 1)^2 = 0$ so $m = -1$ is a double root. Thus the C.F. is

$$y_c = (c_1 + c_2x)e^{-x}$$

$$\begin{aligned}\text{P.I.: } y_p &= \frac{1}{D^2 + 2D + 1}2e^{3x} \\ &= 2 \cdot \frac{1}{3^2 + 2 \cdot 3 + 1}e^{3x} = \frac{e^{3x}}{8}\end{aligned}$$

Hence

$$\text{G.S.: } y = y_c + y_p = (c_1 + c_2x)e^{-x} + \frac{e^{3x}}{8}.$$

Example 2: $(D^3 - 2D^2 - 5D + 6)y = 2e^x + 4e^{3x} + 7e^{-2x} + 8e^{2x} + 15.$

Solution:

C.F.: Here A.E. is $m^3 - 2m^2 - 5m + 6 = 0$ having roots $m = 1, 3, -2$. Thus the C.F. is

$$y_c = c_1e^x + c_2e^{3x} + c_3e^{-2x}$$

$$\begin{aligned}\text{P.I.: } y_p &= \frac{1}{D^3 - 2D^2 - 5D + 6} \times \\ &\quad \times [(2e^x + 4e^{3x} + 7e^{-2x} + 8e^{2x} + 15)] \\ &= \frac{2}{(D+2)(D-3)(D-1)}e^x \\ &\quad + \frac{4}{(D-1)(D+2)(D-3)}e^{3x} \\ &\quad + \frac{7}{(D-1)(D-3)(D+2)}e^{-2x} \\ &\quad + \frac{8}{D^3 - 2D^2 - 5D + 6}e^{2x} \\ &\quad + \frac{15}{D^3 - 2D^2 - 5D + 6} \cdot 1\end{aligned}$$

Since $m = 1, 3, -2$ are roots of A.E., the 1st, 2nd and 3rd terms in the R.H.S. are evaluated using result I_c whereas the 4th and 5th terms by applying result II_a because $m = 2$ and $m = 0$ are not roots of A.E.

Thus

$$\begin{aligned}y_p &= \frac{2}{-6} \frac{1}{D-1}e^x + \frac{4}{10} \frac{1}{D-3}e^{3x} \\ &\quad + \frac{7}{15} \frac{1}{D+2}e^{-2x} \\ &\quad + \frac{8}{2^3 - 2 \cdot 2^2 - 5 \cdot 2 + 6} \cdot e^{2x} \\ &\quad + \frac{15}{0 - 0 - 0 + 6} \\ \therefore y_p &= -\frac{1}{3}xe^x + \frac{2}{5}xe^{3x} + \frac{7}{15}xe^{-2x} - 2e^{2x} + \frac{15}{6}\end{aligned}$$

Hence G.S.: $y = y_c + y_p$ i.e.,

$$\begin{aligned}y &= c_1e^x + c_2e^{3x} + c_3e^{-2x} - \frac{1}{3}xe^x \\ &\quad + \frac{2}{5}xe^{3x} + \frac{7}{15}xe^{-2x} - 2e^{2x} + \frac{15}{6}\end{aligned}$$

9.12 — HIGHER ENGINEERING MATHEMATICS—III

Example 3: $(D^2 - p^2)y = \sinh px$

Solution:

C.F.: Here A.E. is $m^2 - p^2 = 0$ having $m = \pm p$ as the roots. Thus the C.F. is

$$y_c = c_1 e^{px} + c_2 e^{-px}$$

P.I.: Since p and $-p$ are roots of $m^2 - p^2 = 0$.

Rewriting

$$\begin{aligned} y_p &= \frac{1}{(D^2 - p^2)} \sinh px \\ &= \frac{1}{(D + p)(D - p)} \cdot \sinh px \\ &= \frac{1}{(D + p)(D - p)} \left(\frac{e^{px} - e^{-px}}{2} \right) \\ &= \frac{1}{2} \frac{1}{(D + p)(D - p)} e^{px} \\ &\quad - \frac{1}{2} \frac{1}{(D - p)(D + p)} e^{-px} \\ &= \frac{1}{2} \frac{1}{p + p} \cdot \frac{1}{D - p} e^{px} - \frac{1}{2} \frac{1}{-p - p} \frac{1}{D + p} e^{-px} \end{aligned}$$

Applying result I_c

$$\begin{aligned} &= \frac{1}{2} \frac{1}{2p} x \cdot e^{px} + \frac{1}{2} \frac{1}{2p} x \cdot e^{-px} \\ &= \frac{x}{2p} \left\{ \frac{1}{2} (e^{px} + e^{-px}) \right\} = \frac{x}{2p} \cosh px \end{aligned}$$

Hence G.S.: y

$$y = y_c + y_p = c_1 e^{px} + c_2 e^{-px} + \frac{x}{2p} \cosh px.$$

Example 4: $(D - 2)^3 y = e^{2x}$

Solution:

C.F.: A.E. is $(m - 2)^3 = 0$. So $m = 2$ is root of order 3 i.e., repeated three times. Thus C.F. is

$$y_c = (c_1 + c_2 x + c_3 x^2) e^{2x}$$

$$\text{P.I.: } y_p = \frac{1}{(D - 2)^3} e^{2x}$$

Case II_a cannot be applied since $f(2) = (D - 2)^3$ at $D = 2$ is zero. Using result I_d with $n = 3$

$$y_p = \frac{1}{(D - 2)^3} e^{2x} = \frac{x^3}{3!} e^{2x}$$

Hence G.S.:

$$y = y_c + y_p = (c_1 + c_2 x + c_3 x^2) e^{2x} + \frac{x^3}{6} e^{2x}.$$

EXERCISE

Solve the following:

1. $(D^2 - 5D + 6)y = e^{4x}$

Ans. $y = c_1 e^{2x} + c_2 e^{3x} + \frac{1}{2} e^{4x}$

2. $(D^2 - a^2)y = e^{2x}$

Ans. $y = c_1 e^{ax} + c_2 e^{-ax} + \frac{e^{2x}}{3}$ for $a \neq 2$

$y = c_1 e^{2x} + c_2 e^{-2x} + \frac{1}{4} x e^{2x}$ for $a = 2$

3. $(D^2 + 4)y = e^{3x}$

Ans. $y = (c_1 e^{2ix} + c_2 e^{-2ix}) + \frac{1}{13} e^{3x}$

4. $(D^2 + 2D - 8)y = e^{-3x} + e^{-4x}$

Ans. $y = c_1 e^{2x} + c_2 e^{-4x} - \frac{e^{-3x}}{5} - \frac{x e^{-4x}}{6}$

5. $(D^2 - D + 1)y = \sinh x$

Ans. $y = e^{\frac{x}{2}} \left[c_1 \cos \frac{\sqrt{3}x}{2} + c_2 \sin \frac{\sqrt{3}x}{2} \right] + \frac{1}{6} (3e^x - e^{-x})$

6. $(D^2 + 4D + 5)y = -2 \cosh x$, with $y(0) = 0$, $y'(0) = 1$

Ans. $y = \frac{3}{5} e^{-2x} (\cos x + 3 \sin x) - \frac{e^x}{10} - \frac{e^{-x}}{2}$

7. $(D^2 - 2aD + a^2)y = e^{ax}$

Ans. $y = (c_1 + c_2 x) e^{ax} + \frac{x^2}{2} e^{ax}$

8. $(D^3 + 6D^2 + 9D)y = e^{-3x}$

Ans. $y = c_1 + (c_2 + x c_3) e^{-3x} - \frac{x^2 e^{-3x}}{6}$

9. $(D^3 - 5D^2 + 8D - 4)y = e^{2x} + 2e^x + 3e^{-x}$

Ans. $y = c_1 e^x + c_2 e^{2x} + c_3 x e^{2x} + \frac{1}{2} x^2 e^{2x} + 2x e^x - \frac{e^{-x}}{6}$

10. $(D + 2)(D - 1)^2 y = e^{-2x} + 2 \sinh x$

Ans. $y = c_1 e^{-2x} + (c_2 + c_3 x) e^x + x e^{-2x} + \frac{x^2 e^x}{6} + \frac{e^{-x}}{4}$

11. $(D^3 - 12D + 16)y = (e^x + e^{-2x})^2$

Ans. $y = (c_1 + c_2 x) e^{2x} + c_3 e^{-4x} + \frac{x^2 e^{2x}}{12} + \frac{2e^{-x}}{27} + \frac{x e^{-4x}}{36}$

12. $D(D + 1)^2 y = 12e^{-x}$

Ans. $y = c_1 + (c_2 + xc_3)e^{-x} - 6x^2e^{-x}$

13. $D^2(D-1)^3(D+1)y = e^x$

Ans. $y = (c_1 + c_2x) + (c_3 + c_4x + c_5x^2)e^x + c_6e^{-x} + \frac{x^3e^x}{12}$

14. $y'' + 4y' + 13y = 18e^{-2x}$, $y(0) = 0$,
 $y'(0) = 4$

Ans. $y = e^{-2x} \left(\frac{4}{3} \sin 3x - 2 \cos 3x \right) + 2e^{-2x}$

P.I. When $F(x) = \sin(ax+b)$ or $\cos(ax+b)$

(Case: III_a, III_b, III_c, III_d, III_e, III_f)

Let $\phi(D^2)$ be a rational function of D^2 . Since

$$D \sin(ax+b) = a \cos(ax+b)$$

$$D^2 \sin(ax+b) = -a^2 \sin(ax+b)$$

$$D^3 \sin(ax+b) = -a^3 \cos(ax+b)$$

$$D^4 \sin(ax+b) = a^4 \sin(ax+b) = (-a^2)^2 \sin(ax+b)$$

It follows that

$\phi(D^2) \sin(ax+b) = \phi(-a^2) \sin(ax+b)$ where $\phi(-a^2)$ is obtained by replacing D^2 in $\phi(D^2)$ by “ $-a^2$ ”. Operating with $\frac{1}{\phi(D^2)}$ on both sides

$$\frac{1}{\phi(D^2)} \cdot \phi(D^2) \sin(ax+b) = \frac{1}{\phi(D^2)} \phi(-a^2) \sin(ax+b)$$

$$\sin(ax+b) = \phi(-a^2) \cdot \frac{1}{\phi(D^2)} \sin(ax+b)$$

since $\phi(-a^2)$ is a constant. Thus

$$\frac{1}{\phi(D^2)} \sin(ax+b) = \frac{1}{\phi(-a^2)} \sin(ax+b)$$

provided $\phi(-a^2) \neq 0$. A similar result follows

$$\frac{1}{\phi(D^2)} \cos(ax+b) = \frac{1}{\phi(-a^2)} \cos(ax+b)$$

Note: When $f(D)$ contains terms of odd powers $D, D^3, \dots$ etc. even after application of the above result, multiply by D so as to get even powers of $D^2, D^4, \dots$ etc. interpreting D as differentiation and $\frac{1}{D}$ as integration.

Corollary: If $\phi(-a^2) = 0$ then

$$\phi(D^2) = (D^2 + a^2)\psi(D^2)$$

with $\psi(-a^2) \neq 0$. Thus

$$\begin{aligned} \frac{1}{\phi(D^2)} \sin(ax+b) &= \frac{1}{(D^2 + a^2)\psi(D^2)} \sin(ax+b) \\ &= \frac{1}{\psi(-a^2)} \cdot \frac{1}{D^2 + a^2} \sin(ax+b) \\ &= \frac{1}{\psi(-a^2)} \cdot \left(\frac{-x \cos(ax+b)}{2a} \right) \end{aligned}$$

Similarly,

$$\begin{aligned} \frac{1}{\phi(D^2)} \cos(ax+b) &= \frac{1}{(D^2 + a^2)\psi(D^2)} \cos(ax+b) \\ &= \frac{1}{\psi(-a^2)} \cdot \frac{1}{D^2 + a^2} \cos(ax+b) \\ &= \frac{1}{\psi(-a^2)} \cdot \left(\frac{x \sin(ax+b)}{2a} \right) \end{aligned}$$

WORKED OUT EXAMPLES

Example 1: $(D^2 - 4D - 5)y = e^{2x} + 3 \cos(4x+3)$

Solution: C.F.: The A.E. is $m^2 - 4m - 5 = 0$. The roots are $m = -1, 5$ so that the C.F. is

$$y_c = c_1 e^{-x} + c_2 e^{5x}.$$

$$\begin{aligned} \text{P.I. } y_p &= \frac{1}{D^2 - 4D - 5} [e^{2x} + 3 \cos(4x+3)] \\ &= I_1 + I_2 \end{aligned}$$

$$I_1 = \frac{1}{2^2 - 4 \cdot 2 - 5} e^{2x} = -\frac{1}{9} e^{2x}$$

$$\begin{aligned} I_2 &= \frac{3}{-4^2 - 4D - 5} \cos(4x+3) \\ &= -\frac{3}{4D+21} \cos(4x+3) \end{aligned}$$

Since D^2 terms are not present, we rewrite

$$I_2 = -\frac{3(4D-21)}{(4D+21)(4D-21)} \cdot \cos(4x+3)$$

$$I_2 = \frac{-12D+63}{16D^2-21^2} \cos(4x+3)$$

Replace D^2 by -4^2 . Then

$$\begin{aligned} I_2 &= \frac{-12D+63}{16(-4^2)-21^2} \cdot \cos(4x+3) \\ &= \frac{1}{697} [-12D(\cos(4x+3)) + 63 \cos(4x+3)] \\ &= \frac{-1}{697} [48 \sin(4x+3) + 63 \cos(4x+3)]. \end{aligned}$$

9.14 — HIGHER ENGINEERING MATHEMATICS—III

Example 2: $(D^2 + 4)y = \sin 3x + \cos 2x$.

Solution:

C.F.: Here A.E. is $m^2 + 4 = 0$ having complex roots $m = \pm 2i$. Thus C.F. is

$$\begin{aligned} y_c &= c_1 \cos 2x + c_2 \sin 2x \\ \text{P.I. } y_p &= \frac{1}{D^2 + 4} (\sin 3x + \cos 2x) \\ &= \frac{1}{D^2 + 4} \sin 3x + \frac{1}{D^2 + 4} \cos 2x \\ &= I_1 + I_2 \end{aligned}$$

$$\text{consider } I_1 = \frac{1}{D^2 + 4} \sin 3x$$

Replace D^2 by -3^2 since $f(-a^2) = f(-3^2) \neq 0$

$$I_1 = \frac{1}{-3^2 + 4} \sin 3x = -\frac{1}{5} \sin 3x$$

consider

$$I_2 = \frac{1}{D^2 + 4} \cdot \cos 2x$$

Since $f(-a^2) = f(-2^2) = 0$ we apply result III_e

$$I_2 = \frac{x \sin 2x}{4}$$

$$y_p = I_1 + I_2 = -\frac{1}{5} \sin 3x + \frac{x}{4} \sin 2x$$

$$\text{G.S.: } y = y_c + y_p = c_1 \cos 2x + c_2 \sin 2x$$

$$-\frac{1}{5} \sin 3x + \frac{x}{4} \sin 2x$$

Example 3: $(D^2 + 5D - 6)y = \sin 4x \cdot \sin x$.

Solution:

C.F.: Here A.F. is $m^2 + 5m - 6 = 0$. It has roots $m_1 = 1, -6$. So C.F. is

$$y_c = c_1 e^x + c_2 e^{-6x}$$

$$\begin{aligned} \text{P.I.: } y_p &= \frac{1}{D^2 + 5D - 6} \sin 4x \cdot \sin x \\ &= \frac{1}{D^2 + 5D - 6} \cdot \frac{1}{2} [\cos 3x - \cos 5x] \\ &= \frac{1}{2} [I_1 - I_2] \end{aligned}$$

Consider

$$I_1 = \frac{1}{D^2 + 5D - 6} \cdot \cos 3x$$

Replacing D^2 by -3^2 , we get

$$I_1 = \frac{1}{-3^2 + 5D - 6} \cos 3x = \frac{1}{5(D - 3)} \cos 3x$$

To get D^2 terms in denominator, rewrite as

$$I_1 = \frac{1}{5} \frac{(D + 3)}{(D - 3)(D + 3)} \cdot \cos 3x = \frac{1}{5} \frac{(D + 3)}{D^2 - 3^2} \cos 3x$$

Replacing $D^2 = -3^2$, we get

$$\begin{aligned} I_1 &= \frac{1}{5} \frac{(D + 3)}{-3^2 - 3^2} \cos 3x = -\frac{1}{90} (D + 3)(\cos 3x) \\ &= -\frac{1}{90} [-3 \sin 3x + 3 \cos 3x] = \frac{1}{30} [\sin 3x - \cos 3x] \end{aligned}$$

consider

$$I_2 = \frac{1}{D^2 + 5D - 6} \cdot \cos 5x$$

Replacing D^2 by -5^2 , we get

$$I_2 = \frac{1}{-5^2 + 5D - 6} \cos 5x = \frac{1}{5D - 31} \cos 5x$$

In order to get D^2 terms, we rewrite

$$\begin{aligned} I_2 &= \frac{5D + 31}{(5D - 31)(5D + 31)} \cdot \cos 5x \\ &= \frac{(5D + 31)}{25D^2 - 31^2} \cos 5x \end{aligned}$$

Replacing D^2 by -5^2 , we get

$$\begin{aligned} &= \frac{(5D + 31)}{25(-5)^2 - 31^2} \cos 5x \\ &= -\frac{1}{1586} (5D + 31)(\cos 5x) \\ &= -\frac{1}{1586} [-25 \sin 5x + 31 \cos 5x] \end{aligned}$$

Thus

$$\begin{aligned} y_p &= \frac{1}{2} [I_1 - I_2] = \frac{1}{2} \left[\frac{\sin 3x - \cos 3x}{30} \right. \\ &\quad \left. + \frac{31 \cos 5x - 25 \sin 5x}{1586} \right] \end{aligned}$$

Hence G.S.: $y = y_c + y_p$

Example 4:

$$(D^2 - 4D + 1)y = \cos x \cdot \cos 2x + \sin^2 x$$

Solution:

C.F.: Here A.E. is $m^2 - 4m + 1 = 0$ with real distinct roots $m_1 = 2 + \sqrt{3}$ and $m_2 = 2 - \sqrt{3}$ so that the C.F. is

$$y_c = c_1 e^{(2+\sqrt{3})x} + c_2 e^{(2-\sqrt{3})x}$$

P.I.: Note that

$$\cos x \cdot \cos 2x = \frac{1}{2}(\cos 3x + \cos x)$$

$$\text{and} \quad \sin^2 x = \frac{1}{2}[1 - \cos 2x]$$

so that $\cos x \cdot \cos 4x + \sin^2 x = \frac{1}{2}[\cos 3x + \cos x + 1 - \cos 2x]$

$$\begin{aligned} y_p &= \frac{1}{D^2 - 4D + 1} [\cos x \cdot \cos 4x + \sin^2 x] \\ &= \frac{1}{2} \frac{1}{D^2 - 4D + 1} [\cos 3x + \cos x + 1 - \cos 2x] \\ &= \frac{1}{2} [I_1 + I_2 + I_3 - I_4] \end{aligned}$$

Here

$$I_1 = \frac{1}{D^2 - 4D + 1} \cos 3x$$

Replacing D^2 by -3^2

$$I_1 = \frac{1}{-3^2 - 4D + 1} \cos 3x = \frac{-1}{4} \frac{1}{D + 2} \cos 3x$$

To introduce D^2 terms we rewrite the above as

$$\begin{aligned} I_1 &= -\frac{1}{4} \frac{D - 2}{(D + 2)(D - 2)} \cdot \cos 3x \\ &= -\frac{1}{4} \frac{(D - 2)}{(D^2 - 2^2)} \cos 3x \end{aligned}$$

Replacing D^2 by -3^2 , we get

$$\begin{aligned} I_1 &= -\frac{1}{4} \frac{(D - 2)}{-3^2 - 2^2} \cos 3x = \frac{1}{52} (D - 2) \cos 3x \\ &= \frac{1}{52} [-3 \sin 3x - 2 \cos 3x] \end{aligned}$$

Similarly,

$$\begin{aligned} I_2 &= \frac{1}{D^2 - 4D + 1} \cdot \cos x \\ &= \frac{1}{-1^2 - 4D + 1} \cos x, \quad \because D^2 = -1^2 \\ &= -\frac{1}{4} \frac{1}{D} \cos x = -\frac{1}{4} \int \cos x dx = -\frac{1}{4} \sin x \end{aligned}$$

Also

$$\begin{aligned} I_3 &= \frac{1}{D^2 - 4D + 1} \cdot 1 = \frac{1}{D^2 - 4D + 1} e^{0 \cdot x} \\ &= \frac{1}{0 - 4 \cdot 0 + 1} = \frac{1}{1} = 1 \end{aligned}$$

where D is replaced by $a = 0$

Finally

$$I_4 = \frac{1}{D^2 - 4D + 1} \cdot \cos 2x = \frac{1}{-2^2 - 4D + 1} \cos 2x$$

where D^2 is replaced by -2^2

$$I_4 = -\frac{1}{(4D + 3)} \cos 2x$$

Rewriting this to get D^2 terms we have

$$\begin{aligned} I_4 &= -\frac{(4D - 3)}{(4D + 3)(4D - 3)} \cdot \cos 2x \\ &= -\frac{(4D - 3)}{16D^2 - 3^2} \cos 2x \end{aligned}$$

Now replacing D^2 by -2^2 , we get

$$\begin{aligned} I_4 &= -\frac{(4D - 3)}{16(-2^2) - 3^2} \cos 2x \\ &= \frac{(4D - 3)}{73} \cos 2x \\ &= \frac{1}{73} (4(-2) \sin 2x - 3 \cos 2x) \\ I_4 &= -\frac{1}{73} (8 \sin 2x + 3 \cos 2x) \end{aligned}$$

Thus the P.I.

$$\begin{aligned} y_p &= \frac{1}{2} [I_1 + I_2 + I_3 - I_4] \\ y_p &= \frac{1}{2} \left[-\frac{1}{52} (3 \sin 3x + 2 \cos 3x) - \frac{1}{4} \sin x \right. \\ &\quad \left. + 1 - \frac{1}{73} (8 \sin 2x + 3 \cos 2x) \right] \end{aligned}$$

G.S.: $y = y_c + y_p$

$$\begin{aligned} y &= c_1 e^{(2+\sqrt{3})x} + c_2 e^{(2-\sqrt{3})x} + 1 - \frac{1}{4} \sin x \\ &\quad - \frac{1}{73} (3 \cos 2x + 8 \sin 2x) \\ &\quad - \frac{1}{52} (3 \sin 3x + 2 \cos 3x) \end{aligned}$$

EXERCISE

Solve the following:

1. $(D^4 + 10D^2 + 9)y = \cos(2x + 3)$

Ans. $y = c_1 \cos x + c_2 \sin x + c_3 \cos 3x + c_4 \sin 3x - \frac{1}{15} \cos(2x + 3)$

2. $(D^2 + 2D + 5)y = 6 \sin 2x + 7 \cos 2x$

Ans. $y = e^{-x}(c_1 \sin 2x + c_2 \cos 2x) + 2 \sin 2x - \cos 2x$

3. $(D^3 + D^2 + D + 1)y = \sin 2x + \cos 3x$

Ans. $y = c_1 e^{-x} + c_2 \cos x + c_3 \sin x + \frac{1}{15}(2 \cos 2x - \sin 2x) - \frac{1}{80}(3 \sin 3x + \cos 3x)$

4. $(D^2 + 4)y = \sin x + \sin 2x$

Ans. $y = c_1 \sin 2x + c_2 \cos 2x + \frac{\sin x}{3} - \frac{x \cos 2x}{4}$

5. $(D^2 - 8D + 9)y = 8 \sin 5x$

Ans. $y = c_1 e^{(4+\sqrt{7})x} + c_2 e^{(4-\sqrt{7})x} + \frac{1}{29}(5 \cos 5x - 2 \sin 5x)$

6. $(D^2 + 16)y = e^{-3x} + \cos 4x$

Ans. $y = c_1 \cos 4x + c_2 \sin 4x + \frac{1}{25}e^{-3x} + \frac{x}{8} \sin 4x$

7. $(D^2 - 2D + 2)y = e^x + \cos x$

Ans. $y = e^x(c_1 \cos x + c_2 \sin x) + \left(\frac{\cos x - 2 \sin x}{5}\right)$

8. $(D^2 + 9)y = \cos^2 x$

Ans. $y = c_1 \cos 3x + c_2 \sin 3x + \frac{1}{18} + \frac{1}{10} \cos 2x$

9. $(D^2 + 2D + 1)y = e^{2x} - \cos^2 x$

Ans. $y = (c_1 + c_2)x e^{-x} + \frac{1}{2} + \frac{1}{5}(2 \sin 2x + \cos 2x)$

10. $(D^2 + 1)y = \cos x$

Ans. $y = c_1 \cos x + c_2 \sin x + \sin x \ln \sin x - x \cos x$

11. $(D^2 - 4D + 13)y = 8 \sin 3x$,
 $y(0) = 1, y'(0) = 2$

Ans. $y = \frac{1}{5}[e^{2x}(\sin 3x + 2 \cos 3x) + \sin 3x + 3 \cos 3x]$

12. $(D^4 + 2D^2n^2 + n^4)y = \cos mx$

Ans. $y = (c_1 \cos \eta x + c_2 \sin \eta x)(c_3 + c_4 x) + \frac{1}{\eta^2 - m^2} \cos mx$, with $m \neq \eta$

13. $(D^2 + 4)y = \cos x \cos 3x$

Ans. $y = (c_1 \cos 2x + c_2 \sin 2x) - \frac{1}{24} \cos 4x + \frac{x}{8} \sin 2x$

14. $(2D^2 - 2D + 1)y = \sin 3x \cdot \cos 2x$

Ans. $y = e^{\frac{x}{2}} \left[c_1 \cos \frac{x}{2} + c_2 \sin \frac{x}{2} \right] + \frac{10 \cos 5x - 49 \sin 5x}{5002} + \frac{2 \cos x - \sin x}{10}$

15. $(D^3 + 4D)y = \sin 2x$

Ans. $y = c_1 + c_2 \cos 2x + c_3 \sin 2x - \frac{x}{8} \sin 2x$

P.I. When $F(x) = x^m$, m being a Positive Integer

Case IV: Consider $f(D)y = x^m$ so that

$$\text{P.I.} = y_p = \frac{1}{f(D)} x^m$$

Expanding $\frac{1}{f(D)}$ in ascending power of D , we get

$$y_p = [a_0 + a_1 D + a_2 D^2 + \dots + a_m D^m] x^m$$

since all the terms beyond D^m are omitted as $D^n x^m = 0$ when $n > m$.

This result can be extended when $F(x) = P_m(x)$ a polynomial in x of degree m so that

$$y_p = [a_0 + a_1 D + a_2 D^2 + \dots + a_m D^m][P_m(x)]$$

In particular for

$$(D + a)y = P_m(x)$$

we get

$$\text{P.I.} = y_p = \frac{1}{D + a}[P_m(x)] = \frac{1}{a \left[1 + \frac{D}{a} \right]} P_m(x)$$

$$= \frac{1}{a} \left[1 + \frac{D}{a} \right]^{-1} P_m(x)$$

$$= \frac{1}{a} \left[1 - \frac{D}{a} + \frac{D^2}{a^2} + \dots + (-1)^m \frac{D^m}{a^m} \right] P_m(x)$$

wherein terms of order higher than m are omitted.

WORKED OUT EXAMPLES

Solve the following:

Example 1: $(D^6 - D^4)y = x^2$.

Solution:

C.F.: Here A.E. is $m^6 - m^4 = m^4(m^2 - 1) = 0$.
Thus $m = 0$ is root repeated 4 times and $m \pm 1$ are the other roots. So the C.F. is

$$y_c = (c_1 + c_2x + c_3x^2 + c_4x^3) + c_5e^x + c_6e^{-x}$$

P.I.: Rewriting $(D^6 - D^4)y = D^4(D^2 - 1)y = x^2$ so that

$$y_p = \frac{1}{D^4(D^2 - 1)}x^2 = \frac{1}{D^4} \left[\frac{1}{(D^2 - 1)}x^2 \right]$$

Consider $y_p = \frac{1}{(D^2 - 1)}x^2 = -\frac{1}{(1 - D^2)}x^2$
Expanding in Binomial series

$$\begin{aligned} &= -(1 - D^2)^{-1}x^2 \\ &= -[1 + D^2 + D^4 + D^6 + \dots]x^2 \\ &= -x^2 - D^2x^2 + 0 + 0 \dots = -x^2 - 2 \end{aligned}$$

Thus

$$y_p = \frac{1}{D^4} \left[\frac{1}{(D^2 - 1)}x^2 \right] = \frac{-1}{D^4}[x^2 + 2]$$

Here $\frac{1}{D^4}$ means successive integration 4 times (i.e., integrate w.r.t. x sequentially one after another 4 times).

So

$$\begin{aligned} \frac{1}{D^4}x^2 &= \frac{1}{D^3} \int x^2 dx = \frac{1}{D^3} \frac{x^3}{3} = \frac{1}{D^2} \frac{1}{D} \frac{x^3}{3} \\ &= \frac{1}{D^2} \int \frac{x^3}{3} dx \\ &= \frac{1}{D^2} \frac{x^4}{12} = \frac{1}{D} \frac{1}{D} \frac{x^4}{12} = \frac{1}{D} \int \frac{x^4}{12} dx = \frac{1}{D} \frac{x^5}{60} \\ &= \int \frac{x^5}{60} dx = \frac{x^6}{360} \end{aligned}$$

Similarly,

$$\frac{1}{D^4}[2] = \frac{1}{D^3}2x = \frac{1}{D^2}x^2 = \frac{1}{D} \frac{x^3}{3} = \frac{x^4}{12}$$

Thus

$$y_p = - \left[\frac{x^6}{360} + \frac{x^4}{12} \right].$$

Hence the G.S. $y = y_c + y_p$

$$y = (c_1 + c_2x + c_3x^2 + c_4x^3 + c_5e^x + c_6e^{-x}) - \left[\frac{x^6}{360} + \frac{x^4}{12} \right]$$

Example 2: $(D^2 - 1)y = 2x^4 - 3x + 1$.

Solution:

C.F.: Here A.E. is $m^2 - 1 = 0$ so that $m = \pm 1$ are the two roots. Thus the C.F. is

$$y_c = c_1e^x + c_2e^{-x}$$

$$\begin{aligned} \text{P.I.: } y_p &= \frac{1}{(D^2 - 1)}(2x^4 - 3x + 1) \\ &= -\frac{1}{1 - D^2}(2x^4 - 3x + 1) \\ &= -[1 + D^2 + D^4 + D^6 + \dots][2x^4 - 3x + 1] \\ &= -[1 + D^2 + D^4][2x^4 - 3x + 1] \\ &= -[(2x^4 - 3x + 1) + (24x^2) + 48] \end{aligned}$$

G.S.:

$$y = y_c + y_p = c_1e^x + c_2e^{-x} - [2x^4 + 24x^2 - 3x + 49]$$

Example 3: $(D^3 - 1)y = x^5 + 3x^4 - 2x^3$

Solution:

C.F.: Here A.E. is $m^3 - 1 = 0$ having 3 roots $m = 1, \frac{-1 \pm \sqrt{3}i}{2}$. Thus C.F. y_c is

$$y_c = c_1e^x + e^{-\frac{x}{2}} \left[c_2 \cos \frac{\sqrt{3}}{2}x + c_3 \sin \frac{\sqrt{3}}{2}x \right]$$

$$\begin{aligned} \text{P.I.: } y_p &= \frac{1}{(D^3 - 1)}(x^5 + 3x^4 - 2x^3) \\ &= \frac{-1}{(1 - D^3)}[x^5 + 3x^4 - 2x^3] \\ &= -[1 + D^3 + D^6 + D^9 + \dots][x^5 + 3x^4 - 2x^3] \\ &= -[(x^5 + 3x^4 - 2x^3) + \\ &\quad D^3(x^5 + 3x^4 - 2x^3) + 0 + 0 + \dots] \\ &= -[(x^5 + 3x^4 - 2x^3) + (60x^2 + 72x + 12)] \end{aligned}$$

9.18 — HIGHER ENGINEERING MATHEMATICS—III

Hence G.S.:

$$y = y_c + y_p$$

$$y = c_1 e^x + e^{-\frac{x}{2}} \left[c_2 \cos \frac{\sqrt{3}}{2} x + c_3 \sin \frac{\sqrt{3}}{2} x \right] - [x^5 + 3x^4 - 2x^3 + 60x^2 + 72x + 12]$$

Example 4: $(D^2+2)y = x^3+x^2+e^{-2x}+\cos 3x$.

Solution:

C.F.: Here A.E. is $m^2 + 2 = 0$ with complex roots $m = \pm\sqrt{2}i$ so that the C.F. is

$$y_c = (c_1 \cos \sqrt{2}x + c_2 \sin \sqrt{2}x)$$

P.I.:

$$\begin{aligned} y_p &= \frac{1}{(D^2+2)}(x^3+x^2+e^{-2x}+\cos 3x) \\ &= \frac{1}{(D^2+2)}(x^3+x^2) + \frac{1}{D^2+2}e^{-2x} \\ &\quad + \frac{1}{D^2+2}\cos 3x \\ &= I_1 + I_2 + I_3 \end{aligned}$$

Consider

$$\begin{aligned} I_1 &= \frac{1}{D^2+2}(x^3+x^2) = \frac{1}{2\left(1+\frac{D^2}{2}\right)}(x^3+x^2) \\ &= \frac{1}{2}\left[1 - \frac{D^2}{2} + \frac{D^4}{4} - \dots\right][x^3+x^2] \end{aligned}$$

Since x^3 is the higher degree, omit terms containing D^4 and higher orders. Thus

$$\begin{aligned} I_1 &= \frac{1}{2}\left[1 - \frac{D^2}{2}\right][x^3+x^2] \\ &= \frac{1}{2}\left[x^3+x^2 - \frac{1}{2}(6x+2)\right] \\ I_1 &= \frac{1}{2}[x^3+x^2-3x-1] \end{aligned}$$

Consider $I_2 = \frac{1}{D^2+2}e^{-2x}$.

Replacing D by -2 , we get

$$I_2 = \frac{1}{(-2)^2+2}e^{-2x} = \frac{1}{6}e^{-2x}$$

Consider

$$I_3 = \frac{1}{D^2+2}\cos 3x$$

Replacing D^2 by -3^2 , we get

$$I_3 = \frac{1}{-3^2+2}\cos 3x = -\frac{1}{7}\cos 3x$$

Thus

$$y_p = \frac{1}{2}[x^3+x^2-3x-1] + \frac{1}{6}e^{-2x} - \frac{1}{7}\cos 3x$$

G.S.:

$$y = y_c + y_p$$

$$y = (c_1 \cos \sqrt{2}x + c_2 \sin \sqrt{2}x)$$

$$+ \frac{1}{2}(x^3+x^2-3x-1) + \frac{1}{6}e^{-2x} - \frac{1}{7}\cos 3x$$

EXERCISE

Solve the following:

1. $(D^2+3D+2)y = x^3+x^2$

Ans. $y = c_1 e^{-x} + c_2 e^{-2x} + \frac{x^3}{2} - \frac{7x^2}{4} + \frac{15x}{4} - \frac{31}{8}$

2. $(D^3-D)y = 1+x^5$

Ans. $y = c_1 + c_2 e^x + c_3 e^{-x} - (x + 60x^2 + 5x^4 + \frac{x^6}{6})$

3. $(D^4+D^3+D^2)y = 5x^2$

Ans. $y = (c_1 + c_2 x)$

$$+ e^{\frac{-x}{2}} \left[c_3 \cos \frac{\sqrt{3}}{2} x + c_4 \sin \frac{\sqrt{3}}{2} x \right]$$

$$+ \frac{5}{12}x^4 - \frac{5}{3}x^3 + 10x - 10$$

4. $(2D^2+2D+3)y = x^2+2x-1$

Ans. $y = e^{-\frac{x}{2}} \left[c_1 \cos \frac{\sqrt{5}}{2} x + c_2 \sin \frac{\sqrt{5}}{2} x \right] + \frac{x^2}{3} + \frac{2x}{9} - \frac{25}{27}$

5. $(D^2+D+1)y = x^3$.

Ans. $y = e^{\frac{-x}{2}} \left[c_1 \cos \frac{\sqrt{3}}{2} x + c_2 \sin \frac{\sqrt{3}}{2} x \right] + x^3 - 3x^2 + 6.$

6. $(D^2+4D+4)y = x^2+2x$ with $y(0) = 0$, $y'(0) = 0$.

$$\text{Ans. } y = -\frac{3}{8}(1+2x)e^{-2x} + \frac{1}{8}(2x^2+3)$$

$$7. (D^3 - 2D + 4)y = x^4 + 3x^2 - 5x + 2$$

$$\text{Ans. } y = c_1 e^{-2x} + e^x (c_2 \cos x + c_3 \sin x) + \frac{x^4}{4} + \frac{x^3}{2} + \frac{3x^2}{2} - \frac{5x}{4} - \frac{7}{8}$$

$$8. (D^4 + 2D^3 - 3D^2)y = x^2 + 3e^{2x} + 4 \sin x$$

$$\text{Ans. } y = c_1 + c_2 x + c_3 e^x + c_4 e^{-3x} - \frac{x^2}{108}(3x^2 + 8x + 28) + \frac{3}{20}e^{2x} + \frac{2}{5}(\cos x + 2 \sin x)$$

$$9. (D^2 + 3D + 2)y = e^{-x} + x^2 + \cos x$$

$$\text{Ans. } y = c_1 e^{-x} + c_2 e^{-2x} - e^{-x} + \frac{2x^2 - 6x + 7}{4} + \frac{1}{10}(\cos x + 3 \sin x)$$

$$10. (D + 1)^2 y = e^{-x} + x^2$$

$$\text{Ans. } y = (c_1 + c_2 x)e^{-x} + \frac{1}{2} \frac{x^2}{2} e^{-x} + x^2 - 4x + 6$$

$$11. (D^3 - D^2 - 6D)y = 1 + x^2$$

$$\text{Ans. } y = c_1 + c_2 e^{-2x} + c_3 e^{3x} - \frac{1}{6} \left(\frac{23x}{18} - \frac{x^2}{6} + \frac{x^3}{3} \right)$$

$$12. (D^3 - D)y = 2x + 1 + 4 \cos x + 2e^x$$

$$\text{Ans. } y = c_1 + c_2 e^x + c_3 e^{-x} + x e^x - (x^2 + x) - 2 \sin x.$$

Exponential Shift

(Case: V)

Book Work: Prove that

$$\frac{1}{f(D)} e^{ax} V(x) = e^{ax} \frac{1}{f(D+a)} V(x)$$

where $V(x)$ is any function of x and $f(D+a)$ is obtained by replacing D by $D+a$ in $f(D)$.

Proof: Let u be a function of x , then

$$\frac{d}{dx} (e^{ax} u(x)) = D(e^{ax} u(x)) = a e^{ax} u + e^{ax} Du$$

$$D(e^{ax} u) = e^{ax} (au + Du) = e^{ax} (D+a)u$$

Differentiating once more w.r.t. x

$$D^2(e^{ax} u) = D[e^{ax} (D+a)u]$$

$$= a e^{ax} (D+a)u + e^{ax} [D^2 + aD]u$$

$$D^2(e^{ax} u) = e^{ax} [D^2 u + 2aDu + a^2 u] = e^{ax} [D+a]^2 u$$

By mathematical induction

$$D^r(e^{ax} u) = e^{ax} (D+a)^r u$$

Thus substituting these values

$$f(D)(e^{ax} u) = e^{ax} f(D+a)(u) \quad (1)$$

Put

$$f(D+a)(u(x)) = V(x) \quad (2)$$

Then

$$u(x) = \frac{1}{f(D+a)} V(x) \quad (3)$$

Substituting (3) in (1)

$$f(D) \left(e^{ax} \frac{1}{f(D+a)} V(x) \right) = e^{ax} V(x) \quad (4)$$

operating with $\frac{1}{f(D)}$ on both sides of (4), we have

$$\frac{1}{f(D)} \cdot f(D) \cdot \left(e^{ax} \frac{1}{f(D+a)} V(x) \right) = \frac{1}{f(D)} \{e^{ax} V(x)\} \quad (5)$$

Thus

$$\frac{1}{f(D)} \{e^{ax} V(x)\} = e^{ax} \frac{1}{f(D+a)} V(x)$$

WORKED OUT EXAMPLES

Solve the following:

Example 1: $(D^2 - 4D + 3)y = e^x \cos 2x + \cos 3x$.

Solution:

C.F. Here A.E. is $m^2 - 4m + 3 = 0$ with roots $m = 1, 3$ so that the C.F. is $y_c = c_1 e^x + c_2 e^{3x}$

P.I.:

$$\begin{aligned} y_p &= \frac{1}{D^2 - 4D + 3} (e^x \cos 2x + \cos 3x) \\ &= \frac{1}{D^2 - 4D + 3} (e^x \cos 2x) \\ &\quad + \frac{1}{D^2 - 4D + 3} (\cos 3x) = I_1 + I_2 \end{aligned}$$

Applying shift result to I_1 replace D by

$D+a = D+1$, we get

$$\begin{aligned} I_1 &= \frac{1}{D^2 - 4D + 3} (e^x \cos 2x) \\ &= \frac{e^x}{(D+1)^2 - 4(D+1) + 3} \cdot \cos 2x \\ I_1 &= \frac{e^x}{D^2 - 2D} \cos 2x \end{aligned}$$

9.20 — HIGHER ENGINEERING MATHEMATICS—III

Replacing D^2 by -2^2 we have

$$I_1 = \frac{e^x}{-2^2 - 2D} \cos 2x = \frac{-e^x}{2} \frac{1}{D+2} \cos 2x$$

In order to get D^2 terms we rewrite the above as

$$\begin{aligned} &= -\frac{e^x}{2} \cdot \frac{D-2}{(D+2)(D-2)} \cos 2x \\ &= -\frac{e^x}{2} \frac{D-2}{D^2-2^2} \cdot \cos 2x \end{aligned}$$

Replace D^2 by -2^2 then

$$\begin{aligned} I_1 &= -\frac{e^x}{2} \frac{(D-2)}{-2^2-2^2} \cos 2x = \frac{e^x}{16} (D-2)(\cos 2x) \\ &= \frac{e^x}{16} [-2 \sin 2x - 2 \cos 2x] \\ &= -\frac{e^x}{8} [\sin 2x + \cos 2x] \end{aligned}$$

Consider

$$I_2 = \frac{1}{D^2 - 4D + 3} \cdot \cos 3x$$

Replacing D^2 by -3^2 , we get

$$I_2 = \frac{1}{-3^2 - 4D + 3} \cos 3x = -\frac{1}{2(2D+3)} \cos 3x$$

Rewrite this to get D^2 terms as

$$\begin{aligned} I_2 &= -\frac{1}{2} \frac{2D-3}{(2D+3)(2D-3)} \cdot \cos 3x \\ &= -\frac{1}{2} \frac{(2D-3)}{(4D^2-3^2)} \cos 3x \end{aligned}$$

Replace D^2 by -3^2 then

$$\begin{aligned} I_2 &= -\frac{1}{2} \frac{2D-3}{4(-3^2)-3^2} \cos 3x = \frac{1}{90} (2D-3)(\cos 3x) \\ I_2 &= \frac{1}{90} [-6 \sin 3x - 3 \cos 3x] \\ &= -\frac{1}{30} [2 \sin 3x + \cos 3x] \end{aligned}$$

Thus

$$\begin{aligned} y_p &= I_1 + I_2 \\ &= -\frac{e^x}{8} [\sin 2x + \cos 2x] - \frac{1}{30} [2 \sin 3x + \cos 3x] \end{aligned}$$

Hence G.S.:

$$y = y_c + y_p$$

i.e.,

$$\begin{aligned} y &= c_1 e^x + c_2 e^{3x} - \frac{e^x}{8} [\sin 2x + \cos 2x] \\ &\quad - \frac{1}{30} [2 \sin 3x + \cos 3x]. \end{aligned}$$

Example 2: $(D^2 + 2)y = x^2 e^{3x} + e^x \cos 2x$

Solution:

C.F.: Here the A.E. is $m^2 + 2 = 0$ with roots $m = \pm \sqrt{2}i$ so that the C.F. is

$$y_c = (c_1 \cos \sqrt{2}x + c_2 \sin \sqrt{2}x)$$

$$\begin{aligned} \text{P.I.: } y_p &= \frac{1}{D^2 + 2} [x^2 e^{3x} + e^x \cdot \cos 2x] \\ &= \frac{1}{D^2 + 2} [e^{3x} \cdot x^2] + \frac{1}{D^2 + 2} [e^x \cdot \cos 2x] \\ &= I_1 + I_2 \end{aligned}$$

Applying shift result with $a = 3$ replace D by $D + 3$ in I_1 .

Then

$$\begin{aligned} I_1 &= \frac{1}{D^2 + 2} [e^{3x} \cdot x^2] = \frac{e^{3x}}{(D+3)^2 + 2} [x^2] \\ &= \frac{e^{3x}}{D^2 + 6D + 11} x^2 \\ &= \frac{e^{3x}}{11 \left[1 + \frac{D^2 + 6D}{11} \right]} \cdot x^2 \end{aligned}$$

Expanding in powers of $\frac{D^2 + 6D}{11}$, we get

$$\begin{aligned} I_1 &= \frac{e^{3x}}{11} \left[1 - \left(\frac{D^2 + 6D}{11} \right) + \left(\frac{D^2 + 6D}{11} \right)^2 \right. \\ &\quad \left. - \left(\frac{D^2 + 6D}{11} \right)^3 + \dots \right] x^2 \end{aligned}$$

Since x^2 is the highest power, discard terms of D^3 and higher orders. Then

$$\begin{aligned} I_1 &= \frac{e^{3x}}{11} \left[1 + \left(-\frac{D^2}{11} - \frac{6D}{11} \right) + \left(\frac{36}{11^2} D^2 \right) \right] x^2 \\ &= \frac{e^{3x}}{11} \left[x^2 - \frac{12x}{11} + \frac{50}{121} \right] \end{aligned}$$

Consider

$$I_2 = \frac{1}{D^2 + 2} e^x \cos 2x$$

Applying shift result, replace D by $D + 1$ in the above then

$$I_2 = \frac{e^x}{(D+1)^2 + 2} \cdot \cos 2x = \frac{e^x}{D^2 + 2D + 3} \cos 2x$$

Replace D^2 by -2^2 , we get

$$I_2 = \frac{e^x}{-2^2 + 2D + 3} \cos 2x = \frac{e^x}{2} \frac{1}{2D - 1} \cos 2x$$

To have D^2 terms, rewrite the above as

$$\begin{aligned} I_2 &= e^x \cdot \frac{2D + 1}{(2D - 1)(2D + 1)} \cos 2x \\ &= \frac{e^x(2D + 1)}{4D^2 - 1^2} \cos 2x \end{aligned}$$

Replace D^2 by -2^2 , we get

$$I_2 = \frac{e^x(2D + 1)}{4 \cdot (-2^2) - 1^2} \cos 2x = \frac{e^x(2D + 1)}{-17} \cos 2x$$

$$I_2 = -\frac{e^x}{17} [-4 \sin 2x + \cos 2x]$$

Thus $y_p = I_1 + I_2 = \frac{e^{3x}}{11} \left[x^2 - \frac{12x}{11} + \frac{50}{121} \right] + \frac{e^x}{17} [4 \sin 2x - \cos 2x]$

Hence G.S.: $y = y_c + y_p$

$$\begin{aligned} y &= [c_1 \cos \sqrt{2}x + c_2 \sin \sqrt{2}x] + \frac{e^{3x}}{11} \\ &\quad \times \left[x^2 - \frac{12x}{11} + \frac{50}{121} \right] + \frac{e^x}{17} [4 \sin 2x - \cos 2x] \end{aligned}$$

EXERCISE

Solve the following:

1. $(D^2 - 4D + 3)y = 2xe^{3x} + 3e^x \cos 2x$

Ans. $y = c_1 e^x + c_2 e^{3x} + \frac{e^{3x}}{2}(x^2 - x) - \frac{3e^x}{8}(\cos 2x + \sin 2x)$

2. $(D^2 + 5D + 6)y = e^{-2x}(\sec^2 x)(1 + 2 \tan x)$

Ans. $y = c_1 e^{-2x} + c_2 e^{-3x} + e^{-2x} \tan x$

3. $(D^2 + 4)y = e^x \sin^2 x$

Ans. $y = c_1 \cos 2x + c_2 \sin 2x + \frac{e^x}{2} \left[\frac{1}{5} - \frac{1}{17}(4 \sin 2x + \cos 2x) \right]$

4. $(D^2 + 4D + 3)y = e^{-x} \sin x + x$

Ans. $y = c_1 e^x + c_2 e^{-3x} + \frac{1}{16} e^x (2x^2 - x) - \frac{1}{27}(9x^3 + 18x^2 + 42x + 40)$

5. $(D^4 - 1)y = \cos x \cdot \cosh x$

Ans. $y = c_1 e^x + c_2 e^{-x} + c_3 \cos x + c_4 \cos x - \frac{1}{5} \cos x \cdot \cosh x$

6. $(D^2 - 4D + 4)y = e^{2x} \cos^2 x,$

Ans. $y = (c_1 + c_2 x)e^{2x} + e^{2x} \left(\frac{x^2}{4} - \frac{1}{8} \cos 2x \right)$

7. $(D^2 + 4D + 5)y = e^{-2x}(1 + \cos x)$

Ans. $y = e^{-2x} (c_1 \cos x + c_2 \sin x + 1 + \frac{x}{2} \sin x)$

8. $(D^2 - 6D + 13)y = 8e^{3x} \sin 2x$

Ans. $y = e^{3x}(c_1 \cos 2x + c_2 \sin 2x - 2x \cos 2x)$

9. $(D^2 - 4)y = x \sinh x$

Ans. $y = c_1 e^{2x} + c_2 e^{-2x} - \frac{x}{2} \sinh x - \frac{2}{9} \cosh x$

10. $(D^3 - 2D + 4)y = e^x \sin x$

Ans. $y = c_1 e^{-2x} + (c_2 \cos x + c_3 \sin x)e^x + (3 \sin x + \cos x) \frac{x e^x}{20}$

11. $(D^2 - 2D + 1)y = x^2 e^{3x}$

Ans. $y = (c_1 + c_2 x)e^x + (2x^2 - 4x + 3) \frac{e^{3x}}{8}$

P.I. When $F(x) = xV(x)$

(Case: VI)

Book Work: Prove that

$$\frac{1}{f(D)} \{xV(x)\} = x \frac{1}{f(D)} V(x) - \frac{f'(D)}{\{f(D)\}^2} V(x)$$

where $V(x)$ is any function of x and $f'(D)$ is the derivative of $f(D)$ w.r.t. D .

Proof: Let $z = xU(x)$ where U is any function of x .

Then $Dz = xDU + U$

$$D^2 z = D(xDU + U) = xD^2 U + DU + DU$$

$$D^2 z = xD^2 U + 2DU$$

$$D^3 z = D(xD^2 U + 2DU) = xD^3 U + 3DU$$

By mathematical induction

$$D^r z = xD^r U + rD^{r-1}U = xD^r U + \left(\frac{d}{dD} D^r \right) U$$

9.22 — HIGHER ENGINEERING MATHEMATICS—III

Substituting these values in $f(D)$, we get

$$f(D)(xU) = xf(D)U + \left(\frac{d}{dD}f(D)\right)U \quad (1)$$

Put $f(D)U = V(x)$ (2)

Then $U = \frac{1}{f(D)}V$ (3)

Substituting U from (3) in (1)

$$f(D)\left[x \cdot \frac{1}{f(D)}V\right] = xf(D) \cdot \frac{1}{f(D)}V + \left[\frac{d}{dD}f(D)\right]\left[\frac{1}{f(D)}V\right]$$

Rearranging the terms

$$xV = f(D)\left[x \frac{1}{f(D)}V\right] - f'(D) \cdot \frac{1}{f(D)}V \quad (4)$$

Operating with $\frac{1}{f(D)}$ on both sides of (4), we get

$$\frac{1}{f(D)}\{xV\} = \frac{1}{f(D)}f(D)\left[x \frac{1}{f(D)}V\right] - \frac{1}{f(D)}f'(D)\frac{1}{f(D)}V$$

Rewriting

$$\frac{1}{f(D)}\{xV\} = x \frac{1}{f(D)}V - \frac{f'(D)}{\{f(D)\}^2}V$$

$$\frac{1}{f(D)}\{xV\} = \left[x \frac{1}{f(D)} - \frac{f'(D)}{\{f(D)\}^2}\right]V$$

WORKED OUT EXAMPLES

Solve the following:

Example 1: $(D^2 - 2D + 1)y = xe^x \sin x$

Solution:

C.F.: Here $m^2 - 2m + 1 = 0$ is the A.E. with $m = 1$ as a double root so that the C.F. y_c is

$$y_c = (c_1 + c_2x)e^x$$

P.I.: $y_p = \frac{1}{(D^2 - 2D + 1)}x(e^x \sin x)$

$$= \frac{1}{(D - 1)^2}e^x(x \sin x)$$

using shift result with $a = 1$ so that D is replaced by $D + 1$, we get

$$y_p = \frac{e^x}{[(D + 1) - 1]^2}(x \sin x) = \frac{e^x}{D^2}x \sin x$$

Applying result VI

$$\frac{1}{D^2}x(\sin x) = x \cdot \frac{1}{D^2} \sin x - \frac{2D}{D^4} \sin x \quad (5)$$

$$= x(-\sin x) - 2 \cos x \quad (6)$$

Thus $y_p = e^x[-x \sin x - 2 \cos x]$ (7)

Hence G.S.: $y = y_c + y_p$

$$y = (c_1 + c_2x)e^x - e^x(x \sin x + 2 \cos x)$$

Example 2: $(D^2 - 1)y = x^2 \cos x$

Solution:

C.F.: Here A.E. is $m^2 - 1 = 0$ with $m = \pm 1$ as the roots so that the C.F. is

$$y_c = c_1e^x + c_2e^{-x}$$

P.I.:

$$y_p = \frac{1}{(D^2 - 1)} \cdot x^2 \cos x = \frac{1}{D^2 - 1}x \cdot (x \cos x)$$

Applying result VI

$$y_p = \frac{x}{D^2 - 1}(x \cos x) - \frac{2D}{(D^2 - 1)^2} \cdot x \cos x = I_1 - 2I_2$$

Consider

$$I_1 = \frac{x}{D^2 - 1}(x \cos x)$$

Applying result VI once again

$$I_1 = x \cdot \left[x \cdot \frac{1}{D^2 - 1} \cos x - \frac{2D}{(D^2 - 1)^2} \cos x \right]$$

Replacing D^2 by -1^2 in the denominator

$$I_1 = x^2 \cdot \frac{1}{-1^2 - 1} \cos x - \frac{x2D}{(-1^2 - 1)^2} \cos x$$

$$= -\frac{x^2 \cos x}{2} + \frac{x \sin x}{2}$$

Consider

$$I_2 = \frac{D}{(D^2 - 1)^2}x \cos x, \text{ applying VI}$$

$$= D \left[\frac{x}{(D^2 - 1)^2} \cdot \cos x - \frac{2(D^2 - 1) \cdot 2D}{(D^2 - 1)^4} \cos x \right]$$

Replacing D^2 by -1^2 in the denominator

$$\begin{aligned} I_2 &= D \left[\frac{x}{(-1^2 - 1)^2} \cos x - \frac{4D}{(-1^2 - 1)^3} \cos x \right] \\ &= \frac{1}{4} D[x \cos x] + \frac{1}{2} D^2(\cos x) \\ &= \frac{1}{4} [\cos x - x \sin x] - \frac{1}{2} \cos x \end{aligned}$$

Thus

$$\begin{aligned} y_p &= I_1 - 2I_2 = \frac{1}{2} [-x^2 \cos x + x \sin x] \\ &\quad - \frac{1}{2} [\cos x - x \sin x] + \cos x \\ &= \left(\frac{1 - x^2}{2} \right) \cos x + x \sin x \end{aligned}$$

$$\text{Ans. } y = c_1 e^x + c_2 e^{-x} + x \sin x + \frac{(1-x^2)\cos x}{2}$$

Example 3: $(D^2 - 1)y = x \sin x + x^2 e^x$

Solution:

C.F.: Here A.E. is $m^2 - 1 = 0$ with $m = \pm 1$ as roots so that the C.F. $y_c = c_1 e^x + c_2 e^{-x}$.

$$\text{P.I.: } y_p = \frac{1}{D^2 - 1} x \sin x + \frac{1}{D^2 - 1} x^2 e^x = I_1 + I_2$$

Applying result VI for I_1 , we get

$$\begin{aligned} I_1 &= \frac{1}{D^2 - 1} x \sin x \\ &= \frac{x}{D^2 - 1} \sin x - \frac{2D}{(D^2 - 1)^2} \sin x \end{aligned}$$

Replacing D^2 by -1^2 in the denominator

$$\begin{aligned} I_1 &= \frac{x}{-1^2 - 1} \sin x - \frac{2}{(-1^2 - 1)^2} \cdot D \sin x \\ &= -\frac{x \sin x}{2} - \frac{\cos x}{2} \\ I_1 &= -\frac{1}{2} (x \sin x + \cos x) \end{aligned}$$

Applying result VI to I_2 , we have

$$\begin{aligned} I_2 &= \frac{1}{D^2 - 1} x^2 e^x \\ &= x \cdot \frac{1}{D^2 - 1} (x e^x) - \frac{2D}{(D^2 - 1)^2} (x e^x) \end{aligned}$$

Applying result VI once again to each of the two terms in the R.H.S., we get

$$\begin{aligned} I_2 &= x \left[x \frac{1}{D^2 - 1} e^x - \frac{2D}{(D^2 - 1)} e^x \right] \\ &\quad - 2D \left[x \frac{1}{(D^2 - 1)^2} e^x - \frac{2(D^2 - 1)2D}{(D^2 - 1)^4} e^x \right] \\ &= \left[x^2 \frac{1}{(D + 1)(D - 1)} e^x - \frac{2xD}{(D + 1)(D - 1)^2} e^x \right] \\ &\quad - 2D \left[x \frac{1}{(D + 1)^2(D - 1)^2} e^x \right. \\ &\quad \left. - \frac{4D}{(D + 1)^3(D - 1)^3} e^x \right] \end{aligned}$$

Replacing D by 1, we get

$$\begin{aligned} &= \left[x^2 \frac{1}{2(D - 1)} e^x - \frac{2xD}{4(D - 1)^2} e^x \right] \\ &\quad - 2D \left[\frac{x}{4(D - 1)^2} e^x - \frac{4}{8(D - 1)^3} e^x \right]. \end{aligned}$$

Applying result I_c, I_d

$$\begin{aligned} I_2 &= \frac{x^2}{2} x e^x - \frac{x}{e} D \cdot \left(\frac{x^2 e^x}{2!} \right) \\ &\quad - 2D \left[\frac{x}{4} \cdot \frac{x^2 e^x}{2!} - \frac{1}{2} D \frac{x^3 e^x}{3!} \right] \\ &= \frac{x^3 e^x}{2} - \frac{x}{4} [x^2 e^x + 2x e^x] - \frac{1}{4} [x^3 e^x + 3x^2 e^x] \\ &\quad + \frac{1}{6} [x^3 e^x + 6x^2 e^x + 6x e^x] \\ &= x e^x \left[\frac{x^2}{2} - \frac{x^2}{4} - \frac{x}{2} - \frac{x^2}{4} - \frac{3}{4} x + \frac{1}{6} x^2 + x + 1 \right] \\ I_2 &= x e^x \left[\frac{x^2}{6} - \frac{x}{4} + 1 \right] = \frac{x e^x}{12} [2x^2 - 3x + 12] \end{aligned}$$

$$\begin{aligned} y_p &= I_1 + I_2 = -\frac{1}{2} (x \sin x + \cos x) \\ &\quad + \frac{x e^x}{12} (2x^2 - 3x + 12) \end{aligned}$$

Thus G.S.: $y = y_c + y_p$

$$\begin{aligned} y &= c_1 e^x + c_2 e^{-x} - \frac{1}{2} (x \sin x + \cos x) \\ &\quad + \frac{x e^x}{12} (2x^2 - 3x + 12) \end{aligned}$$

EXERCISE

Solve the following:

1. $(D^2 + 3D + 2)y = x \sin 2x$

Ans. $y = c_1 e^{-x} + c_2 e^{-2x} - \frac{(30x-7)}{200} \cos 2x - \left(\frac{5x-12}{100}\right) \sin 2x$

2. $(D^2 + 2D + 1)y = x \cos x$

Ans. $y = (c_1 + c_2 x)e^{-x} + \frac{x}{2} \sin x + \frac{1}{2}(\cos x - \sin x)$

3. $(D^2 - 1)y = x^2 \sin 3x$

Ans. $y = c_1 e^x + c_2 e^{-x} - \frac{x^2}{10} \cdot \sin 3x - \frac{3x}{25} \cos 3x + \frac{13}{250} \sin 3x$

4. $(D^3 - 3D^2 - 6D + 8)y = x e^{-3x}$

Ans. $y = c_1 e^x + c_2 e^{4x} + c_3 e^{-2x} - \frac{e^{-3x}}{784}(28x + 39)$

5. $(D^2 - 1)y = x \sin x + e^x(1 + x^2)$

Ans. $y_1 = c_1 e^x + c_2 e^{-x} - \frac{1}{2}(x \sin x + \cos x) + \frac{e^x}{2} \left(\frac{x^3}{3} - \frac{x^2}{2} + \frac{3x}{2} - \frac{3}{4} \right)$

6. $(D^2 + 4)y = x \sin^2 x$

Ans. $y = c_1 \cos 2x + c_2 \sin 2x + \frac{x}{8} - \frac{x \cos 2x + 2x^2 \sin 2x}{32}$

7. $(D^2 + 1)y = x^2 e^{2x} + x \cos x$

Ans. $y = (c_1 \cos x + c_2 \sin x) + \frac{e^{2x}}{5} \left[x^2 - \frac{8}{5}x + \frac{22}{25} \right] + \left(\frac{x^2}{4} - \frac{1}{8} \right) \sin x + \frac{x}{4} \cos x$

8. $(D^4 - 2D^3 - 3D^2 + 4D + 4)y = x^2 e^x$

Ans. $y_1 = (c_1 + c_2 x)e^{-x} + (c_3 + c_4 x)e^{2x} + \frac{e^x}{4} \left(x^2 - 2x - \frac{3}{2} \right)$

9. $(D^2 - 5D + 6)y = x e^{4x}$

Ans. $y = c_1 e^{2x} + c_2 e^{3x} + e^{4x} \frac{(2x-3)}{4}$

10. $(D^2 + a^2)y = \sec ax$

Ans. $y = c_1 \cos ax + c_2 \sin ax + \frac{x}{a} \sin ax + \frac{1}{a^2} \cos ax \cdot \log(\cos ax)$

Table of Particular Integrals

Inverse operator (short) methods to find particular integral of (6) when R.H.S. $F(x)$ is of the form

Case	Form of $F(x)$	Particular Integral (P.I.): y_p	Subject to the condition that	Remarks/ observation
I_a	Any function of x	$y_p = \frac{1}{D-a} F(x) = e^{ax} \int F(x) e^{-ax} dx$	$c = 0$	Substitute $F(x)$ and integrate w.r.t., x
I_b	$F(x) = b = \text{constant}$	$y_p = \frac{1}{D-a} b = -\frac{b}{a}$	$a \neq 0$	
I_c	$F(x) = e^{ax}$	$y_p = \frac{1}{D-a} e^{ax} = x e^{ax}$		
I_d	$F(x) = e^{ax}$	$y_p = \frac{1}{(D-a)^n} e^{ax} = \frac{x^n}{n!} e^{ax}$		Repeated factor n times
I_e	Any function of x	If $f(D) = (D - a_1)(D - a_2) \cdots (D - a_n)$ Resolving into partial fractions $y_p = \frac{1}{f(D)} F(x) = \left(\frac{A_1}{D-a_1} + \frac{A_2}{D-a_2} + \cdots + \frac{A_n}{D-a_n} \right) F(x)$ Applying result I_a $y_p = A_1 e^{a_1 x} \int F(x) e^{-a_1 x} dx + \cdots + A_n e^{a_n x} \int F(x) e^{-a_n x} dx$		Most general case Resolve $F(D)$ into factors Resolve $\frac{1}{f(D)}$ into partial fractions Apply result I_a to each term
Π_a	e^{ax+b}	$y_p = \frac{1}{f(D)} e^{ax+b} = \frac{1}{f(a)} e^{ax+b}$	$f(a) \neq 0$	Replace D by 'a' in $f(D)$
Π_b	Constant $= b = b e^{0x}$ with $a = 0$	$y_p = \frac{1}{f(D)} b = \frac{b}{f(0)}$	$f(0) \neq 0$	Replace D by zero in $f(D)$
Π_c	e^{ax+b}	$y_p = \frac{1}{f(D)} e^{ax+b} = \frac{1}{(D-a)^n g(D)} e^{ax+b}$ $= \frac{1}{g(a)} \frac{1}{(D-a)^n} e^{ax+b}$ $y_p = \frac{1}{g(a)} \frac{x^n}{n!} e^{ax+b}$	$g(a) \neq 0$	Replace D by 'a' in $g(D)$ and apply result of I_d

(Contd.)

(Continued)

Case	Form of $F(x)$	Particular Integral (P.I.): y_p	Subject to the condition that	Remarks/observation
III _a	$\sin(ax + b)$	$y_p = \frac{1}{f(D^2)} \sin(ax + b)$ $= \frac{1}{f(-a^2)} \sin(ax + b)$	$f(-a^2) \neq 0$	Replace D^2 by $-a^2$ in $f(D)$ when terms of $D, D^3, \dots$ are present,
III _b	$\cos(ax + b)$	$y_p = \frac{1}{f(D^2)} \cos(ax + b)$ $= \frac{1}{f(-a^2)} \cos(ax + b)$	$f(-a^2) \neq 0$	Multiply by D in order to get $D^2, D^4, \dots$, etc. terms. Then replace D^2 by $-a^2$, etc.
III _c	$\sin(ax + b)$	$y_p = \frac{1}{D^2 + a^2} \sin(ax + b)$ $= -\frac{x \cos(ax + b)}{(2a)}$	$a \neq 0$	$\sin$ is replaced by $\cos$ and multiplied by $-\frac{x}{2a}$
III _d	$\sin(ax + b)$	$y_p = \frac{1}{(D^2 + a^2)^n} \sin(ax + b)$ $= \frac{x^n}{(2a)^n n!} \sin(ax - n\frac{\pi}{2})$	$a \neq 0$	
III _e	$\cos(ax + b)$	$y_p = \frac{1}{D^2 + a^2} \cos(ax + b)$ $= \frac{x \sin(ax + b)}{2a}$	$a \neq 0$	$\cos$ is replaced by $\sin$ and multiplied by $\frac{x}{2a}$
III _f	$\cos(ax + b)$	$y_p = \frac{1}{(D^2 + a^2)^n} \cos(ax + b)$ $= \frac{x^n}{(2a)^n} \frac{1}{n!} \cos(ax - \frac{n\pi}{2})$	$a \neq 0$	
IV	x^m	$y_p = \frac{1}{f(D)} x^m = [f(D)]^{-1} x^m$ $y_p = [a_0 + a_1 D + a_2 D^2 + \dots + a_m D^m] x^m$	$a_0 \neq 0$	Expand $[f(D)]^{-1}$ is ascending powers of D and delete all terms beyond D^m (since $D^n x^m = 0$ when $n > m$)
V	$e^{ax} V(x)$	$y_p = \frac{1}{f(D)} e^{ax} V(x) = e^{ax} \frac{1}{f(D+a)} V(x)$ (Exponential shift)	$f(D+a) \neq 0$	Replace D by $D+a$ in $f(D)$. Then evaluate $\frac{1}{f(D+a)} V(x)$ by the above methods
VI	$x V(x)$	$y_p = \frac{1}{f(D)} x V(x)$ $= x \frac{1}{f(D)} V(x) - \frac{f'(D)}{[f(D)]^2} V(x)$		

9.6 DIFFERENTIAL EQUATIONS WITH VARIABLE COEFFICIENTS: REDUCIBLE TO EQUATIONS WITH CONSTANT COEFFICIENTS

Special Case A: Euler or Cauchy or Euler-Cauchy or Cauchy-Euler Differential Equation or Equi-dimensional equation

The equation of n th order is of the form

$$(a_0 x^n D^n + a_1 x^{n-1} D^{n-1} + \dots + a_{n-1} x D + a_n) y = F(x) \quad (1)$$

where $a_0, a_1, a_2, \dots, a_n$ are all constants

and $F(x)$ is a function of x

By the substitution

$$x = e^t \quad (2)$$

the Euler Equation (1) can be transformed into a linear D.E. with constant coefficients with t as the independent variable, which can be solved by the methods described in the earlier Sections 9.4 and 9.5.

From (2), $t = \ln x$ and $\frac{dx}{dt} = e^t$ so that

$$\frac{dy}{dx} = \frac{dy}{dt} \frac{dt}{dx} = e^{-t} \frac{dy}{dt} = \frac{1}{x} \frac{dy}{dt} \quad (3)$$

Introducing $\mathcal{D} \equiv \frac{d}{dt}$, we have

$$\frac{dy}{dx} = Dy = \frac{1}{x} \frac{dy}{dt} = \frac{1}{x} \mathcal{D}y \quad (4)$$

or $x Dy = \mathcal{D}y$

Similarly, differentiating (3) once more w.r.t. x , we

get

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{d}{dx} \left[e^{-t} \frac{dy}{dt} \right] = \frac{d}{dt} \left[e^{-t} \frac{dy}{dt} \right] \frac{dt}{dx} \\ &= e^{-t} \left[e^{-t} \frac{d^2y}{dt^2} - e^{-t} \frac{dy}{dt} \right] = e^{-2t} \left[\frac{d^2y}{dt^2} - \frac{dy}{dt} \right]\end{aligned}$$

Thus

$$\frac{d^2y}{dx^2} = D^2y = e^{-2t} [D^2y - Dy] = \frac{1}{x^2} [D^2y - Dy]$$

Thus

$$x^2 D^2y = (D^2 - D)y = D(D-1)y \quad (5)$$

Similarly, differentiating again, we get

$$x^3 D^3 = D^3 - 3D^2 + 2D = D(D-1)(D-2) \quad (6)$$

$$\begin{aligned}x^4 D^4 &= D^4 - 6D^3 + 11D^2 - 6D \\ &= D(D-1)(D-2)(D-3)\end{aligned} \quad (7)$$

and by mathematical induction

$$x^r D^r = D(D-1)(D-2) \dots (D-(r-1)) \quad (8)$$

Method of solving Cauchy-Euler equation

- I. Put $x = e^t$ and use (4), (5), (6), etc. to transform Euler equation to D.E. with constant coefficients.
- II. Solve this D.E. with t as the independent variable by methods described in Sections 9.3 to 9.5.
- III. Replace t by $\ln x$ in the solution obtained in step II.

The second order equation

$$ax^2y'' + bxy' + cy = Q(x)$$

reduces to

$$a \left(\frac{d^2y}{dt^2} - \frac{dy}{dt} \right) + b \left(\frac{dy}{dt} \right) + cy = Q^*(t)$$

$$aD^2y + (b-a)Dy + cy = Q^*(t)$$

where $Q^*(t)$ is $Q(x)$ with x replaced by e^t .

WORKED OUT EXAMPLES

Solve the following:

Example 1: $x^2y'' - 3xy' + 3y = 0$ with $y(1) = 0, y'(1) = -2$

Solution: Substituting (2), (3), (4), (5) in the given D.E., we get

$$\left(\frac{d^2y}{dt^2} - \frac{dy}{dt} \right) - 3 \frac{dy}{dt} + 3y = 0$$

$$\text{or } \frac{d^2y}{dt^2} - 4 \frac{dy}{dt} + 3y = 0$$

This is 2nd order D.E. whose A.E. is

$$m^2 - 4m + 3 = 0$$

The roots are $m = 1, 3$

$$\text{G.S.} \quad y(t) = c_1 e^t + c_2 e^{3t}$$

$$y(x) = c_1 x + c_2 x^3$$

$$\text{Since } 0 = y(1) = c_1 + c_2$$

$$-2 = y'(1) = c_1 + 3c_2$$

$$c_1 = -c_2 \text{ so that } c_2 = -1 \text{ thus } c_1 = 1$$

Hence the particular solution

$$y = x - x^3$$

Example 2: $x^3 \frac{d^3y}{dx^3} + 3x^2 \frac{d^2y}{dx^2} + x \frac{dy}{dx} + y = x + \ln x$

Solution: Substituting (2), (4), (5), (6) in the given D.E., we get

$$D(D-1)(D-2)y + 3D(D-1)y + Dy + y = e^t + t$$

$$\text{or } D^3y + y = e^t + t$$

C.F.: The A.E. is $m^3 + 1 = 0$ having roots

$$m = -1, \frac{1 \pm \sqrt{3}i}{2} \text{ so that the C.F. } y_c \text{ is}$$

$$y_c = c_1 e^{-t} + e^{\frac{t}{2}} \left(c_2 \cos \frac{\sqrt{3}}{2} t + c_3 \sin \frac{\sqrt{3}}{2} t \right)$$

$$\text{P.I.: } y_p = \frac{1}{D^3 + 1} \{e^t + t\} = \frac{1}{D^3 + 1} e^t + \frac{1}{D^3 + 1} t$$

$$= \frac{1}{1^3 + 1} e^t + \{1 - D^3 + D^6 + \dots\} t$$

$$= \frac{e^t}{2} + t - 0 + 0 + \dots$$

G.S: $y = y_c + y_p$

$$y = c_1 e^{-t} + e^{\frac{t}{2}} \left(c_2 \cos \frac{\sqrt{3}}{2} t + c_3 \sin \frac{\sqrt{3}}{2} t \right) + \frac{e^t}{2} + t$$

Replacing t by $\ln x$

$$y(x) = \frac{c_1}{x} + \sqrt{x} \left(c_2 \cos \frac{\sqrt{3}}{2} \ln x + c_3 \sin \frac{\sqrt{3}}{2} \ln x \right) + \frac{x}{2} + \ln x.$$

Example 3: $x^2 \frac{d^2 y}{dx^2} - 3x \frac{dy}{dx} + 5y = x^2 \sin(\log x)$

Solution: Using (2), (3), (4), (5) the D.E. reduces to

$$\left(\frac{d^2 y}{dt^2} - \frac{dy}{dt} \right) - 3 \left(\frac{dy}{dt} \right) + 5y + e^{2t} \sin t$$

$$\frac{d^2 y}{dt^2} - 4 \frac{dy}{dt} + 5y = e^{2t} \sin t$$

C.F.: Here A.E. is $m^2 - 4m + 5 = 0$ having roots $m = 2 \pm i$ so that the C.F. y_c is

$$y_c = e^{2t} (c_1 \cos t + c_2 \sin t)$$

P.I.
$$y_p = \frac{1}{\mathcal{D}^2 - 4\mathcal{D} + 5} e^{2t} \sin t$$

Using shift result replace $\mathcal{D}$ by $\mathcal{D} + 2$

$$y_p = \frac{e^{2t}}{(\mathcal{D} + 2)^2 - 4(\mathcal{D} + 2) + 5} \sin t$$

$$y_p = \frac{e^{2t}}{\mathcal{D}^2 + 1} \sin t$$

Using result III_c

$$= e^{2t} \left(\frac{-t \cdot \cos t}{2} \right)$$

G.S.: $y = y_c + y_p$

$$y(t) = e^{2t} (c_1 \cos t + c_2 \sin t) - \frac{t e^{2t}}{2} \cos t$$

Replacing t by $\ln x$

$$y(x) = x^2 (c_1 \cos(\log x) + c_2 \sin(\log x)) - \log x \cdot \frac{x^2}{2} \cdot \cos(\log x)$$

EXERCISE

Solve the following:

1. $x^2 y'' + 3 \cdot 5xy' + y = 0$

Ans. $y = c_1 x^{-\frac{1}{2}} + c_2 x^{-2}$

2. $x^2 y'' - 3xy' + 3y = 0$

Ans. $c_1 x^3 + c_2 x^2$

3. $4x^2 y'' - 4xy' + 3y = 0$

Ans. $y = c_1 x^{\frac{1}{2}} + c_2 x^{\frac{3}{2}}$

4. $9x^2 y'' + 3xy' + y = 0$

Ans. $y = (c_1 + c_2 \ln x)x^{\frac{1}{3}}$

5. $x^3 y''' - 3x^2 y'' + 6xy' - 6y = 0$

Ans. $y = c_1 x + c_2 x^2 + c_3 x^3$

6. $x^3 y''' - x^2 y'' - 6xy' + 18y = 0$

Ans. $y = (c_1 + c_2 \ln x)x^3 + c_3 x^{-2}$

7. $x^2 y'' - 2xy' + 2y = 4x^3$

Ans. $y = c_1 x^2 + c_2 x + 2x^3$

8. $x^2 y'' - xy' + 4y = \cos \ln x + x \sin \ln x$

Ans. $y = c_1 \cdot x \cdot \cos(\sqrt{3} \ln x) + c_2 x \sin(\sqrt{3} \ln x) + \frac{1}{13} (3 \cos \ln x - 2 \sin \ln x) + \frac{1}{2} x \cdot \sin \ln x$

9. $x^2 y'' + 4xy' + 2y = e^x$

Ans. $y = c_1 x^{-1} + c_2 x^{-2} + x^{-2} e^x$

10. $x^2 y'' - 4xy' + 6y = 4x - 6$

Ans. $y = c_1 x^2 + c_2 x^3 + 2x - 1$

11. $x^2 y'' - 2xy' - 10y = 0$ with $y(1) = 5$, $y'(1) = 4$

Ans. $y = \frac{3}{x^2} + 2x^5$

12. $x^2 y'' - 4xy' + 4y = 4x^2 - 6x^3$, $y(2) = 4$, $y'(2) = -1$

Ans. $y = \frac{5x}{3} - 2x^2 + 3x^3 - \frac{23x^4}{24}$

13. $x^2 y'' - 2xy' + 2y = \ln^2 x - \ln x^2$

Ans. $y = c_1 x + c_2 x^2 + \frac{1}{2} (\ln^2 x + \ln x) + \frac{1}{4}$

9.28 — HIGHER ENGINEERING MATHEMATICS—III

$$14. x^3 y''' - 8x^2 y'' + 28xy' - 40y = -\frac{9}{x}$$

$$\text{Ans. } y = c_1 x^2 + c_2 x^4 + c_3 x^5 + \frac{x^{-1}}{10}$$

$$15. x^3 y''' + 2x^2 y'' = x + \sin(\ln x)$$

$$\text{Ans. } y = c_1 + c_2 x + c_3 \ln x + x \ln x + \frac{1}{2}(\cos \ln x + \sin \ln x)$$

$$16. x^2 y'' + 5xy' + 4y = x^2 + 16(\ln x)^2$$

$$\text{Ans. } y = c_1 x^{-2} + c_2 x^{-2} \ln x + \frac{x^2}{16} + 4(\ln x)^2 - 8 \ln x + 6$$

$$17. x^2 y'' + 3xy' + y = \frac{1}{(1-x)^2}$$

$$\text{Ans. } y = \left(\frac{1}{x}\right)(c_1 + c_2 \ln x) + \frac{1}{x} \ln \frac{x}{1-x}.$$

Special Case B:

Legendre Linear Equation

The Equation of n th order is of the form

$$[a_0(ax+b)^n D^n + a_1(ax+b)^{n-1} D^{n-1} + \dots + a_{n-1}(ax+b)D + a_n]y = F(x) \quad (1)$$

where $a, b, a_0, a_1, a_2, \dots, a_{n-1}, a_n$ are all constants. This Equation (1) can be reduced to (Cauchy-Euler equation) and then to a linear differential equation with constant coefficients by the transformation

$$ax + b = e^t \quad (2)$$

$$\text{Solving for } x = \frac{e^t - b}{a} \quad (3)$$

Differentiating (2) w.r.t. 't', we have

$$a \frac{dx}{dt} = e^t \quad (4)$$

Now

$$\frac{dy}{dx} = \frac{dy}{dt} \cdot \frac{dt}{dx} = ae^{-t} \frac{dy}{dt} = \frac{a}{e^t} \frac{dy}{dx}$$

$$(ax+b)Dy = aDy \quad (5)$$

Differentiating again w.r.t., x

$$\frac{d^2 y}{dx^2} = \frac{d}{dx} \left(\frac{dy}{dx} \right) = \frac{d}{dt} \left(\frac{dy}{dx} \right) \frac{dt}{dx}$$

$$= ae^{-t} \cdot \frac{d}{dt} \left(ae^{-t} \frac{dy}{dt} \right)$$

$$\frac{d^2 y}{dx^2} = a^2 e^{-2t} \left[\frac{d^2 y}{dt^2} - \frac{dy}{dt} \right]$$

$$(ax+b)^2 D^2 y = a^2 [D^2 - D]y \quad (6)$$

$$\text{Similarly } (ax+b)^3 D^3 y = a^3 [D^3 - 3D^2 + 2D]y \quad (7)$$

Method of Solving Legendre Equation

I. Identify a and b . Using the substitution $ax + b = e^t$, and (3), (4), (5), (6), (7), etc., the given Legendre equation reduces to D.E. with constant coefficients.

II. Solve D.E. obtained in I with t as independent variable, by standard methods described in Section. 9.3 to 9.5

III. Replace t by $\ln(ax+b)$ in the solution obtained in II.

Note: The second order equation

$$a_0(ax+b)^2 y'' + b_0(ax+b)y' + c_0 y = Q(x)$$

reduces to

$$a_0 a^2 (D^2 - D)y + b_0 a D y + C_0 y = Q^*(t)$$

or

$$a_0 a^2 D^2 y + (b_0 a - a_0 a^2) D y + C_0 y = Q^*(t)$$

WORKED OUT EXAMPLES

Solve the following:

$$\text{Example: } (2x+5)^2 y'' - 6(2x+5)y' + 8y = 6x$$

Solution:

Here $a_0 = 1, b_0 = -6, c_0 = 8, Q(x) = 6x, a = 2, b = 5$. Replace $2x + 5 = e^t$ and use (3), (4), (5) (6) in the given Legendre D.E. which then reduces to a linear equation

$$4 \left[\frac{d^2 y}{dt^2} - \frac{dy}{dt} \right] - 12 \frac{dy}{dt} + 8y = 3(e^t - 5)$$

$$\frac{d^2 y}{dt^2} - 4 \frac{dy}{dt} + 2y = \frac{1}{4}(3e^t - 15)$$

C.F.: The A.E. is $m^2 - 4m + 2 = 0$ with roots $m = 2 \pm \sqrt{2}$ so that the C.F. y_c is

$$y_c = c_1 e^{(2+\sqrt{2})t} + c_2 e^{(2-\sqrt{2})t}$$

$$\begin{aligned}
 \text{P.I.: } y_p &= \frac{1}{D^2 - 4D + 2} \cdot \frac{1}{4}(3e^t - 15) \\
 &= \frac{3}{4} \frac{1}{D^2 - 4D + 2} e^t - \frac{15}{4} \frac{1}{D^2 - 4D + 2} \cdot 1 \\
 &= \frac{3}{4} \frac{1}{1 - 4 + 2} e^t - \frac{15}{4} \frac{1}{0 - 0 + 2} \\
 &= -\frac{3}{4} e^t - \frac{15}{8}
 \end{aligned}$$

Then G.S.: $y = y_c + y_p$

$$y = c_1 e^{(2+\sqrt{2})t} + c_2 e^{(2-\sqrt{2})t} - \frac{3}{4} e^t - \frac{15}{8}.$$

Replacing t by $\ln(2x + 5)$, we get

$$\begin{aligned}
 y(x) &= c_1 (2x + 5)^{2+\sqrt{2}} + c_2 (2x + 5)^{2-\sqrt{2}} \\
 &\quad - \frac{3}{4} (2x + 5) - \frac{15}{8}.
 \end{aligned}$$

EXERCISE

Solve the following:

1. $(x + 2)^2 y'' + 3(x + 2)y' - 3y = 0$

Ans. $y = c_1(x + 2) + c_2(x + 2)^{-3}$

2. $(2x + 1)^2 y'' - 2(2x + 1)y' + 4y = 0$

Ans. $y = c_1(2x + 1) + c_2(2x + 1) + \ln(2x + 1)$

3. $(x + 1)^2 y'' - 3(x + 1)y' + 4y = x^2 + x + 1$

Ans. $y = (c_1 + c_2 \ln x)x^2 + \frac{(\ln x)^2}{2}x^2 - x + \frac{1}{4}$

4. $(3x + 2)^2 y'' + 3(3x + 2)y' - 36y = 3x^2 + 4x + 1$

Ans. $y = c_1(3x + 2)^2 + c_2(3x + 2)^{-2} + \frac{1}{108}[(3x + 2)^2 \ln(3x + 2) + 1]$

5. $(x + 1)^2 y'' + (x + 1)y' - y = \ln(x + 1)^2 + x - 1$

Ans. $y = c_1(x + 1) + c_2(x + 1)^{-1} - \ln(x + 1)^2 + \frac{1}{2}(x + 1) \ln(x + 1) + 2$

6. $(1 + x)^2 y'' + (1 + x)y' + y = 2 \sin[\log(1 + x)]$

Ans. $y = c_1 \cos[\log(1 + x)] + c_2 \sin[\log(1 + x)] - \log(1 + x) \cdot \cos x$

7. $(1 + 4x)^2 y'' + (1 + 4x)y' + 4y = 8(1 + 4x)^2$

Ans. $y = c_1(1 + 4x)^a + c_2(1 + 4x)^b + \frac{8}{41}(1 + 4x)^2$ with $a = 6 + 2\sqrt{5}$, $b = 6 - 2\sqrt{5}$

8. $(2x + 3)^2 y'' + (2x + 3)y' - 2y = 24x^2$

Ans. $y = c_1 u^{-\frac{1}{2}} + c_2 u + \frac{3}{5}u^2 - 6u \ln(u) - 27$ with $u = 2x + 3$

9. $(x + 1)^3 y'' + 3(x + 1)^2 y' + (x + 1)y = 6 \ln(x + 1)$

Ans. $y(x + 1) = c_1 + c_2 \ln(x + 1) + \ln 3(x + 1)$

10. $(x - 2)^2 y'' - 3(x - 2)y' + 4y = x$

Ans. $y = (x - 2)^2 \cdot [c_1 + c_2 \ln(x - 2)] + x - \frac{3}{2}.$

9.7 METHOD OF VARIATION OF PARAMETERS

Method of variation of parameters enables to find the general solution of any linear non-homogeneous D.E. of second order even (with variable coefficients also) provided its complimentary function is given (known). The particular integral of the non-homogeneous equation is obtained by varying the parameters i.e., by replacing the arbitrary constants in the C.F. by variable functions.

Consider a linear non-homogeneous second order D.E. with variable coefficients

$$y'' + P(x)y' + Q(x)y = R(x) \quad (1)$$

Suppose the complimentary functions y_c of (1) is given as

$$y_c = c_1 y_1(x) + c_2 y_2(x) \quad (2)$$

In method of variation of parameters the arbitrary constants c_1 and c_2 in (2) are replaced by two unknown functions $u_1(x)$ and $u_2(x)$

Thus the particular integral y_p of (1) is

$$y_p = u_1(x)y_1(x) + u_2(x)y_2(x) \quad (3)$$

9.30 — HIGHER ENGINEERING MATHEMATICS—III

where

$$u_1(x) = - \int \frac{R(x)y_2(x)}{W} dx \quad (4)$$

$$u_2(x) = \int \frac{R(x)y_1(x)}{W} dx \quad (5)$$

Here $W = \text{Wronskian of } y_1, y_2 = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$

$$= y_1 y_2' - y_1' y_2 \neq 0 \quad (6)$$

Hence the required general solution of (1) is

$$y = y_c + y_p$$

where y_c and y_p are given by (2) and (3).

Method of Obtaining a Particular Integral of (1) by Variation of Parameters

I. Obtain the complimentary function y_c of (1) as

$$y_c = c_1 y_1(x) + c_2 y_2(x)$$

II. Calculate Wronskian w by (6)

Identify $R(x)$, $y_1(x)$, $y_2(x)$

Determine $u_1(x)$ and $u_2(x)$ by (4) and (5).

Particular integral

$$y_p = u_1(x)y_1(x) + u_2(x)y_2(x).$$

Note: There is another powerful “method of undetermined coefficients” which is not discussed here.

WORKED OUT EXAMPLES

Solve the following D.E. by variation of parameters method:

Example 1: $(D^2 - 1)y = 2(1 - e^{-2x})^{-\frac{1}{2}}$

Solution: C.F.: Here A.E. is $m^2 - 1 = 0$ with, $m = \pm 1$ as the roots so that the C.F. y_c is

$$y_c = c_1 e^x + c_2 e^{-x}$$

So $y_1 = e^x$ and $y_2 = e^{-x}$ form two independent solutions to the corresponding homogeneous equation.

$$\begin{aligned} \text{Wronskian } w &= y_1 y_2' - y_2 y_1' = \\ &= e^x (-e^{-x}) - e^{-x} e^x = -2 \end{aligned}$$

Assume the particular solution y_p as

$$y_p = u_1(x)y_1(x) + u_2(x)y_2(x)$$

where

$$u_1(x) = - \int \frac{f y_2}{w} dx = - \int \frac{2}{(1 - e^{-2x})^{\frac{1}{2}}} \cdot \frac{e^{-x}}{-2} dx$$

Here $f(x) = \text{R.H.S. of the given equation} = \frac{2}{(1 - e^{-2x})^{\frac{1}{2}}}$

$$\text{So } u_1 = \int \frac{e^{-x} dx}{(1 - e^{-2x})^{\frac{1}{2}}}$$

$$\text{Put } e^{-x} = t, -e^{-x} dx = dt$$

$$\text{Thus } u_1 = \int \frac{dt}{\sqrt{1 - t^2}} = -\sin^{-1}(t) = -\sin^{-1}(e^{-x})$$

Similarly

$$\begin{aligned} u_2 &= \int \frac{f y_1 dx}{w} = \int \frac{2}{\sqrt{1 - e^{-2x}}} \cdot \frac{e^x}{-2} dx \\ &= - \int \frac{e^x dx}{\sqrt{1 - e^{-2x}}} = - \int \frac{e^{2x} dx}{\sqrt{e^{2x} - 1}} \end{aligned}$$

$$\text{Put } e^{2x} = t, 2e^{2x} dx = dt$$

$$\begin{aligned} \text{So } u_2 &= -\frac{1}{2} \int \frac{dt}{\sqrt{t - 1}} = -\frac{1}{2} \frac{(t - 1)^{\frac{1}{2}}}{\frac{1}{2}} \\ &= -(t - 1)^{\frac{1}{2}} = -(e^{2x} - 1)^{\frac{1}{2}} \\ y_p &= -\sin^{-1}(e^{-x})e^x - (e^{2x} - 1)^{\frac{1}{2}} \cdot e^x \end{aligned}$$

Hence G.S.: $y = y_c + y_p$ so that

$$y = c_1 e^x + c_2 e^{-x} - e^x \cdot \sin^{-1}(e^{-x}) - (e^{2x} - 1)^{\frac{1}{2}} e^{-x}$$

Example 2: $(D^2 + 1)y = \operatorname{cosec} x \cdot \cot x$.

Solution:

C.F.: Here A.E. is $m^2 + 1 = 0$ with complex roots $m = \pm i$ so that the C.F. y_c is

$$y_c = c_1 \cos x + c_2 \sin x$$

Take $y_1 = \cos x$ and $y_2 = \sin x$. They form the system of independent solutions. The Wronskian

$$w = y_1 y_2' - y_2 y_1' = \cos x \cdot \cos x - \sin x \cdot (-\sin x) = 1$$

Assume that the particular integral y_p of the form

$$y_p = u_1(x)y_1(x) + u_2(x)y_2(x)$$

where $u_1 = -\int \frac{fy_2}{w} dx$.

Here $f = \operatorname{cosec} x \cdot \cot x$

$$\text{Thus } u_1 = -\int \frac{\operatorname{cosec} x \cdot \cot x \cdot \sin x}{1} dx = -\ln |\sin x|$$

Similarly,

$$\begin{aligned} u_2 &= \int \frac{fy_1}{w} dx = \int \frac{\operatorname{cosec} x \cdot \cot x \cdot \cos x}{1} dx \\ &= \int \cot^2 x dx = -\cot x - x \end{aligned}$$

Hence

$$y_p = -\ln |\sin x| \cdot \cos x - (x + \cot x) \sin x$$

Thus G.S.: $y = y_c + y_p$ is

$$\begin{aligned} y &= c_1 \cos x + c_2 \sin x - \cos x \cdot \ln |\sin x| \\ &\quad - x \sin x - \sin x \cdot \cot x \end{aligned}$$

Example 3: $(D^2 + 2D + 1)y = e^{-x} \ln x$

Solution:

C.F.: Here A.E. is $m^2 + 2m + 1 = 0$ with $m = -1$ as the double root so that the C.F. y_c is

$$y_c = (c_1 + c_2 x)e^{-x}.$$

Take $y_1 = e^{-x}$ and $y_2 = xe^{-x}$ as the fundamental system. Now the Wronskian w is

$$\begin{aligned} w &= y_1 y_2' - y_2 y_1' = e^{-x}(e^{-x} - xe^{-x}) \\ &\quad - (xe^{-x})(-e^{-x}) = e^{-2x} \end{aligned}$$

Assume the P.I. y_p as

$$y_p = u_1(x)y_1(x) + u_2(x)y_2(x)$$

where $u_1 = -\int \frac{fy_2}{w} dx$ with $f = e^{-x} \cdot \ln x$

$$u_1 = -\int \frac{e^{-x} \cdot \ln x \cdot xe^{-x}}{e^{-2x}} dx$$

$$= -\int x \cdot \ln x \cdot dx$$

$$u_1 = \frac{x^2}{2} \left[\frac{1}{2} - \ln x \right]$$

Also

$$\begin{aligned} u_2 &= \int \frac{fy_1}{w} dx = \int \frac{e^{-x} \ln x \cdot e^{-x}}{e^{-2x}} dx \\ &= \int \ln x dx = x \ln x - x \end{aligned}$$

Thus $y_p = \frac{x^2}{2} \left[\frac{1}{2} - \ln x \right] e^{-x} + e^{-2x} [x \ln x - x]$.
Hence G.S.: $y = y_c + y_p$

$$\begin{aligned} y &= c_1 e^{-x} + c_2 x e^{-x} + \frac{x^2}{2} \left(\frac{1}{2} - \ln x \right) e^{-x} \\ &\quad + e^{-2x} (x \cdot \ln x - x) \end{aligned}$$

EXERCISE

Solve the following D.E. by the method of variation of parameters:

1. $(D^2 + 1)y = \csc x$

Ans. $y = c_1 \cos x + c_2 \sin x - x \cos x + \sin x \ln |\sin x|$

2. $(D^2 - 2D + 1)y = x^{\frac{3}{2}} e^x$

Ans. $y = [c_1 + c_2 x + \frac{4}{35} x^{\frac{7}{2}}] e^x$

3. $(D^2 - 1)y = e^{-2x} \cdot \sin(e^{-x})$

Ans. $y = c_1 e^x + c_2 e^{-x} - e^x \cos(e^{-x}) - \sin(e^{-x})$

4. $(D^2 - 3D + 2)y = \frac{1}{1+e^{-x}}$

Ans. $y = c_1 e^x + c_2 e^{2x} + e^x \cdot \ln(1 + e^{-x}) + e^{2x} [\ln(1 + e^{-x}) - e^{-x}]$

5. $(D^2 - 6D + 9)y = \frac{e^{3x}}{x^2}$

Ans. $y = c_1 e^{3x} + c_2 x e^{3x} - e^{3x} \ln x$

6. $(D^2 - 2D)y = e^x \sin x$

Ans. $y = c_1 + c_2 e^{2x} - \frac{e^x}{2} \sin x$

7. $(D^3 + D)y = \csc x$

Ans. $y = c_1 + c_2 \cos x + c_3 \sin x - \ln |\cot x| - \cos x \ln |\sin x| - x \sin x$

8. $(D^2 - 2D + 2)y = e^x \tan x$

Ans. $y = e^x (c_1 \cos x + c_2 \sin x) - e^x \cdot \cos x \log(\sec x + \tan x)$

9. $(D^2 + 3D + 2)y = e^x + x^2$

9.32 — HIGHER ENGINEERING MATHEMATICS—III

Ans. $y = c_1 e^{-x} + c_2 e^{-2x} + \frac{e^x}{6} + \left(\frac{x^2}{2} - \frac{3x}{2} + \frac{7}{4} \right)$

10. $(D^2 + a^2)y = x \cos ax$

Ans.
$$c_1 \cos ax + c_2 \sin ax + \frac{\cos ax}{2a} \\ \times \left[\frac{\sin 2ax}{4a^2} - \frac{x \cos 2ax}{2a} \right] + \frac{\sin ax}{2a} \\ \times \left[\frac{x^2}{2} + \frac{x \sin 2ax}{2a} - \frac{\cos 2ax}{4a^2} \right]$$

11. $(D^2 + 1)y = \log \cos x$

Ans. $y = c_1 \cos x + c_2 \sin x + (\log \cos x - 1) + \sin x \cdot \log (\sec x + \tan x)$

12. $(D^2 + 4)y = 4 \sec^2 2x$

Ans. $y = c_1 \cos 2x + c_2 \sin 2x - 1 + \sin 2x \cdot \ln (\sec 2x + \tan 2x)$

13. $(D^2 + 3D + 2)y = \frac{1}{1+e^x}$

Ans. $y = c_1 e^{-x} + c_2 e^{-2x} + (e^{-x} + e^{-2x}) \log(1 + e^x)$

14. $(D^2 - 1)y = e^{-x} \sin e^{-x} + \cos e^{-x}$

Ans. $y = c_1 e^x + c_2 e^{-x} - e^x \sin e^{-x}$

15. $(D^2 + 1)y = x \cos 2x$

Ans. $y = c_1 \cos x + c_2 \sin x - \frac{x}{2} \cos 2x + \frac{4}{9} \sin 2x$

16. $(D^2 - 3D + 2)y = x e^x + 2x$

Ans. $c_1 e^x + c_2 e^{2x} - \frac{x^2}{2} e^x - x e^{-x} + x + \frac{3}{2}$

9.8 THE METHOD OF UNDETERMINED COEFFICIENTS

The particular integral of an n th order linear non-homogeneous D.E. with constant coefficients

$$(a_0 D^n + a_1 D^{n-1} + \dots + a_{n-1} D + a_n)y = F(x) \quad (1)$$

can be determined by the method of undetermined coefficients, provided the R.H.S. function $F(x)$ in (1) is an exponential function, polynomial in x , cosine, sine or sums or products of such functions. The derivatives of such functions $F(x)$ have a form similar to $F(x)$ itself and are finite in number. Although the class of such functions $F(x)$ is quite restricted,

they include functions of frequent occurrence. This method is relatively simple. The particular integral y_p of (1) is assumed in a form similar to the R.H.S. function $F(x)$ and involving undetermined (unknown) coefficients which are then determined by substitution of y_p in D.E. (1). The advantage of this method is that for a wrong choice of y_p , or with few terms leads to contradiction, while choice of too many terms makes superfluous coefficients zero. Thus this method is self correcting. However, this method fails when $F(x) = \sec x, \tan x$ etc. since the number of new terms obtained by differentiation is infinite. Table 9.4 gives the form (choice) of P.I. y_p for a specific $F(x)$.

Procedure:

Let $m_1, m_2, \dots, m_n$ be the roots of auxiliary equation $f(m) = 0$ where $f(D)y = F(x)$ is the given D.E. Here $f(D) = a_0 D^n + a_1 D^{n-1} + a_2 D^{n-2} + \dots + a_{n-1} D + a_n$. Let $S = \{y_1(x), y_2(x), \dots, y_n(x)\}$ be the set of n linearly independent solutions of the homogeneous equation $f(D)y = 0$ corresponding to the n roots $m_1, m_2, \dots, m_n$. Then the complementary function y_c is given by $y_c = c_1 y_1 + c_2 y_2 + \dots + c_n y_n$.

To find the particular integral by the method of undetermined coefficients

I. Straight case

If the R.H.S. function $F(x)$ is **not** a member of the solution set, then choose P.I. y_p from the above table depending on the nature of $F(x)$.

Example: $(D^2 - 3D + 2)y = 4e^{3x}$ has A.E.: $m^2 - 3m + 2 = 0$ with roots $m_1 = 1, m_2 = 2$ and set of L.I. solutions, $S = \{e^x, e^{2x}\}$. C.F. is $y_c = c_1 e^x + c_2 e^{2x}$.

Since the R.H.S. e^{3x} is **not** a member of the solution set, choose P.I. y_p as ce^{3x} . Substituting y_p in the given D.E., we determine the unknown coefficient c as: $9ce^{3x} - 3 \cdot 3ce^{3x} + 2ce^{3x} = 4e^{3x} \therefore 2c = 4$ or $c = 2$, So $y_p = 2e^{3x}$. (Check: $y_p = \frac{4}{D^2 - 3D + 2} e^{3x} = \frac{4}{9 - 3 \cdot 3 + 2} e^{3x} = 2e^{3x}$).

Table 9.4

S. No.	R.H.S. function $F(x)$	Choice of particular integral y_p
1.	ke^{ax}	ce^{ax}
2.	$k \sin(ax + b)$ or $k \cos(ax + b)$	$\left\{ \begin{array}{l} c_1 \sin(ax + b) + c_2 \cos(ax + b) \end{array} \right.$
3.	$ke^{ax} \sin(bx + d)$ or $ke^{ax} \cos(bx + d)$	$\left\{ \begin{array}{l} c_1 e^{ax} \sin(bx + d) + c_2 e^{ax} \cos(bx + d) \end{array} \right.$
4.	kx^n where $n = 0, 1, 2, \dots$	$c_0 + c_1x + c_2x^2 + \dots + c_{n-1}x^{n-1} + c_nx^n$
5.	$kx^n e^{ax}$ for $n = 0, 1, 2, \dots$	$e^{ax} \{c_0 + c_1x + c_2x^2 + \dots + c_{n-1}x^{n-1} + c_nx^n\}$
6.	$kx^n \sin(ax + b)$ or $kx^n \cos(ax + b)$	$\left\{ \begin{array}{l} a_0 \sin(ax + b) + b_0 \cos(ax + b) + \\ + a_1 \cdot x \cdot \sin(ax + b) + b_1 \cdot x \cdot \cos(ax + b) + \\ + a_2 x^2 \sin(ax + b) + b_2 x^2 \cos(ax + b) + \\ \text{-----} \\ + a_n x^n \sin(ax + b) + b_n x^n \cos(ax + b) \end{array} \right.$
7.	$kx^n e^{dx} \sin(ax + b)$ or $kx^n e^{dx} \cos(ax + b)$	$\left\{ \begin{array}{l} e^{dx} \left\{ a_0 \sin(ax + b) + b_0 \cos(ax + b) + \right. \\ + a_1 x \sin(ax + b) + b_1 x \cdot \cos(ax + b) + \\ \text{-----} \\ \left. + a_n x^n \sin(ax + b) + b_n x^n \cos(ax + b) \right\} \end{array} \right.$

Here $k, a, b, d, c, c_1, c_2, \dots, c_n, a_0, b_0, a_1, b_1, \dots, a_n, b_n$ are all constants and n is a positive integer i.e., $n = 0, 1, 2, 3, \dots$

II. Sum case

When the R.H.S. $F(x)$ is a combination (sum) of the functions in column 1 of the table, then P.I. is chosen as a combination of the corresponding functions in second column and proceed as in straight case I.

Note: Here also as in case I, the terms of R.H.S. $F(x)$ are *not* members of the solution set S .

Example: $(D^3 - 2D^2 + D - 2)y = 5 \cos 2x - 6x^2$

A.E.: $m^3 - 2m^2 + m - 2 = 0, (m - 2)(m^2 + 1) = 0$

i.e., $m = 2, \pm i, S = \{e^{2x}, \cos x, \sin x\}$;

C.F.: $y_c = c_1 e^{2x} + c_2 \cos x + c_3 \sin x$.

Choose $y_p = A \cos 2x + B \sin 2x + Cx^2 + Dx + E$.

Substitute y_p in D.E. and solve for A, B, C, D, E .

$(8A \sin 2x - 8B \cos 2x) - 2(-4A \cos 2x - 4B \sin 2x + 2C) +$

$+ (-2A \sin 2x + 2B \cos 2x + 2Cx + D) -$

$- 2(A \cos 2x + B \sin 2x + Cx^2 + Dx + E) = 5 \cos 2x - 6x^2$.

Equating coefficients of:

x^2 : $-2C = -6 \therefore C = 3$

x : $2C - 2D = 0 \therefore D = C = 3$

const: $-4C + D - 2E = 0 \therefore E = -\frac{3C}{2} = -\frac{9}{2}$

$\cos 2x$: $6A - 6B = 5$
 $\sin 2x$: $A + B = 0 \quad \left\{ \begin{array}{l} A = -B = \frac{5}{12} \end{array} \right.$

Required P.I. y_p is

$y_p = \frac{5}{12} \cos 2x - \frac{5}{12} \sin 2x + 3x^2 + 3x - \frac{9}{2}$.

III. Modified case

When any term of $F(x)$ is a *member* of the solution set S , then the method fails if we choose y_p from the table. In such cases, the choice from the table should be modified as follows:

A. If a term u of $F(x)$ is also a term of the complementary function (i.e., $u \in S =$ solution set)

9.34 — HIGHER ENGINEERING MATHEMATICS—III

then the choice from the table corresponding to u should be multiplied by

- a. x if u corresponds to a simple root of C.F.
- b. x^2 if u corresponds to a double root C.F.
- c. x^s if u corresponds to a s -fold root of C.F.

Example: $(D - 2)^3 y = 6e^{2x}$; A.E.: $m = 2, 2, 2$,
 $S = \{e^{2x}, xe^{2x}, x^2e^{2x}\}$ C.F.: $y_c = c_1e^{2x} + c_2xe^{2x} + c_3x^2e^{2x}$. But e^{2x} on R.H.S. $\in S$ i.e., e^{2x} is a term of the C.F. So the choice of Ae^{2x} should be multiplied by x^3 . Thus the modified choice of P.I. is $x^3 Ae^{2x}$.

B. Suppose $x^r u$ is a term of $F(x)$ and u is a term of C.F. corresponding to an s -fold root then the choice from the table corresponding to $x^r u$ should be multiplied by x^s .

Example: $(D - 3)^4(D + 4)y = x^3e^{3x} + 6x^2$
 Normal choice from the table would have been

$$y_p^* = (Ax^3e^{3x} + Bx^2e^{3x} + Cxe^{3x} + De^{3x}) + (Ex^2 + Fx + G).$$

But e^{3x} is a term of the C.F. and $m = 3$ is 4th order root. Here

$$y_c = c_1e^{3x} + c_2xe^{3x} + c_3x^2e^{3x} + c_4x^3e^{3x}.$$

So the modified (corrected) choice of P.I. in this case is

$$y_p = x^4(Ax^3e^{3x} + Bx^2e^{3x} + Cxe^{3x} + De^{3x}) + (Ex^2 + Fx + G).$$

WORKED OUT EXAMPLES

Straight case

Solve the following examples by the method of undetermined coefficients.

Example 1: $y'' - 3y' + 2y = 4x^2$.

Solution: A.E.: $m^2 - 3m + 2 = 0$, $m = 1, 2$.

C.F.: $y_c = c_1e^x + c_2e^{2x}$.

P.I.: R.H.S. $F(x) = kx^n$ ($n = 2$) so choose from the table P.I. as $y_p = Ax^2 + Bx + C$

Differentiating $y_p' = 2Ax + B$, $y_p'' = 2A$.

Substituting in the given D.E.

$$2A - 3(2Ax + B) + 2(Ax^2 + Bx + C) = 4x^2$$

Equating the coefficients of like powers of x :

$$x^2 : 2A = 4 \quad \therefore A = 2$$

$$x : -6A + 2B = 0 \quad \therefore B = 6$$

$$x^0 : 2A - 3B + 2C = 0 \quad \therefore C = 7$$

Required P.I. by the method of undetermined coefficients is

$$y_p = 2x^2 + 6x + 7$$

G.S.: $y = y_c + y_p = c_1e^x + c_2e^{2x} + 2x^2 + 6x + 7$.

Example 2: $y'' + 6y' + 5y = 2e^x + 10e^{5x}$.

Solution: A.E.: $m^2 + 6m + 5 = 0$, $m = -1, -5$

C.F.: $y_c = c_1e^{-x} + c_2e^{-5x}$

P.I.: Choose $y_p = Ae^x + Be^{5x}$

$$y_p' = Ae^x + 5Be^{5x}, y_p'' = Ae^x + 25Be^{5x}$$

$$(Ae^x + 25Be^{5x}) + 6(Ae^x + 5Be^{5x}) + 5(Ae^x + Be^{5x}) = 2e^x + 10e^{5x}.$$

Equating the coefficients of e^x and e^{5x} :

$$e^x : A + 6A + 5A = 2 \quad \therefore A = \frac{1}{6}$$

$$e^{5x} : 25B + 30B + 5B = 10, B = \frac{1}{6}$$

$$y_p = \frac{1}{6}e^x + \frac{1}{6}e^{5x}$$

$$y = y_c + y_p = c_1e^{-x} + c_2e^{-5x} + \frac{1}{6}(e^x + e^{5x}).$$

Example 3: $y'' + 2y' + 4y = 13 \cos(4x - 2)$.

Solution: A.E.: $m^2 + 2m + 4 = 0$, $m = -1 \pm \sqrt{3}i$

$y_c = e^{-x}[c_1 \cos \sqrt{3}x + c_2 \sin \sqrt{3}x]$

P.I.: Choose $y_p = A \cos(4x - 2) + B \sin(4x - 2)$

$$y_p' = -4A \sin(4x - 2) + 4B \cos(4x - 2)$$

$$y_p'' = -16A \cos(4x - 2) - 16B \sin(4x - 2)$$

$$[-16A \cos(4x - 2) - 16B \sin(4x - 2)] +$$

$$+2[-4A \sin(4x - 2) + 4B \cos(4x - 2)] +$$

$$+4[A \cos(4x - 2) + B \sin(4x - 2)] = 13 \cos(4x - 2)$$

Equating coefficients of $\cos(4x - 2)$ and $\sin(4x - 2)$,
 $-16A + 8B + 4A = 13$, $-16B - 8A + 4B = 0$.

Solving $A = -\frac{3}{4}$, $B = \frac{1}{2}$, so

$$y_p = -\frac{3}{4} \cos(4x - 2) + \frac{1}{2} \sin(4x - 2)$$

$$y = y_c + y_p = e^{-x} [c_1 \cos \sqrt{3}x + c_2 \sin \sqrt{3}x] - \frac{3}{4} \cos(4x - 2) + \frac{1}{2} \sin(4x - 2).$$

Example 4: $y'' - y = e^x \sin 2x$.

Solution: A.E.: $m^2 - 1 = 0$, $m = \pm 1$

C.F.: $y_c = c_1 e^x + c_2 e^{-x}$

P.I.: Choose $y_p = Ae^x \sin 2x + Be^x \cos 2x$

$$y'_p = 2Ae^x \cos 2x + Ae^x \sin 2x + Be^x \cos 2x - 2Be^x \sin 2x$$

$$y'' = (A - 2B)(e^x \sin 2x + 2e^x \cos 2x) + (2A + B)(e^x \cos 2x - 2e^x \sin 2x)$$

Substituting in D.E.

$$[2(A - 2B) + (2A + B)]e^x \cos 2x + [A - 2B - 2(2A + B)]e^x \sin 2x - [Ae^x \sin 2x + Be^x \cos 2x] = e^x \sin 2x.$$

Equating the coefficients of

$$e^x \sin 2x : A - 2B - 4A - 2B - A = 1 \quad \text{or} \quad A + B = -\frac{1}{4}$$

$$e^x \cos 2x : 2A - 4B + 2A + B - B = 0 \quad \text{or} \quad A - B = 0$$

Solving $A = B = -\frac{1}{8}$

$$y_p = -\frac{1}{8}(e^x)(\sin 2x + \cos 2x).$$

$$y = y_c + y_p = c_1 e^x + c_2 e^{-x} - \frac{1}{8} e^x (\sin 2x + \cos 2x).$$

Sum case

Example 5: $y'' - 9y = x^3 + e^{2x} - \sin 3x$.

Solution: $m^2 - 9 = 0$, $m = \pm 3$,

C.F.: $y_c = c_1 e^{-3x} + c_2 e^{3x}$

P.I.: Choose $y_p = Ax^3 + Bx^2 + Cx + D + Ee^{2x} + F \sin 3x + G \cos 3x$

$$y'_p = 3Ax^2 + 2Bx + C + 2Ee^{2x} + 3F \cos 3x - 3G \sin 3x$$

$$y''_p = 6Ax + 2B + 4Ee^{2x} - 9F \sin 3x - 9G \cos 3x.$$

Substituting

$$(6Ax + 2B + 4Ee^{2x} - 9F \sin 3x - 9G \cos 3x) - 9(Ax^3 + Bx^2 + Cx + D + Ee^{2x} + F \sin 3x + G \cos 3x) = x^3 + e^{2x} - \sin 3x.$$

Equating the coefficients of:

$$x^3 : -9A = 1, \quad A = -\frac{1}{9}$$

$$x^2 : -9B = 0 \quad \therefore B = 0$$

$$x : 6A - 9C = 0 \quad \therefore C = -\frac{2}{27}$$

$$x^0 : 2B - 9D = 0 \quad \therefore D = 0$$

$$e^{2x} : 4E - 9E = 1 \quad \therefore E = -\frac{1}{5}$$

$$\sin 3x : -9F - 9F = -1 \quad \therefore F = \frac{1}{18}$$

$$\cos 3x : -9G - 9G = 0 \quad \therefore G = 0$$

$$y_p = -\frac{1}{9}x^3 - \frac{2}{27}x - \frac{1}{5}e^{2x} + \frac{1}{18} \sin 3x.$$

$$y = y_c + y_p = c_1 e^{-3x} + c_2 e^{3x} - \frac{1}{9}x^3 - \frac{2}{27}x - \frac{1}{5}e^{2x} + \frac{1}{18} \sin 3x.$$

Modified case

Example 6: $y''' + y' = 2x^2 + e^{2x} + 4 \sin x$.

Solution: A.E. is $m^3 + m = 0$ or $m = 0, \pm i$

C.F.: $y_c = c_1 + c_2 \sin x + c_3 \cos x$.

Normally as per the table one would have assumed the P.I. as,

$$y_p = Ax^2 + Bx + C + De^{2x} + E \sin x + F \cos x.$$

But note that $\sin x$, a term in R.H.S. function, is a term in the C.F. i.e., member of solution set $S = \{1, \sin x, \cos x\}$. Therefore the corresponding terms in y_p should be multiplied by x . Also note that the term x^2 in R.H.S. also corresponds to a term in C.F. Thus the modified (correct) choice of P.I. y_p is

$$y_p = x(Ax^2 + Bx + C) + De^{2x} + x(E \sin x + F \cos x)$$

$$y_p = (Ax^3 + Bx^2 + Cx) + De^{2x} + Ex \sin x + Fx \cos x$$

$$y'_p = 3Ax^2 + 2Bx + C + 2De^{2x} + E \sin x +$$

$$+ Ex \cos x + F \cos x - Fx \sin x$$

$$y''_p = 6Ax + 2B + 4De^{2x} + 2E \cos x - Ex \sin x -$$

$$- 2F \sin x - Fx \cos x$$

$$y'''_p = 6A + 8De^{2x} - 3E \sin x - Ex \cos x - 3F \cos x + Fx \sin x.$$

9.36 — HIGHER ENGINEERING MATHEMATICS—III

Substituting in D.E.

$$(6A + 8De^{2x} - 3E \sin x - Ex \cos x - 3F \cos x + Fx \sin x) + (3Ax^2 + 2Bx + C + 2De^{2x} + E \sin x + Ex \cos x + F \cos x - Fx \sin x) = 2x^2 + e^{2x} + 4 \sin x.$$

Equating the coefficients of

$$x^2 : 3A = 2 \quad \therefore A = \frac{2}{3}$$

$$x : 2B = 0 \quad \therefore B = 0$$

$$x^0 : 6A + C = 0 \quad \therefore C = -6A = -6 \cdot \frac{2}{3} = -4$$

$$e^{2x} : 8D + 2D = 1 \quad \therefore D = \frac{1}{10}$$

$$\sin x : -3E + E = 4 \quad \therefore E = -2$$

$$\cos x : -3F + F = 0 \quad \therefore F = 0$$

$$x \cos x : -E + E = 0 \quad \therefore E = 0$$

$$x \sin x : F + F = 0 \quad \therefore F = 0$$

$$y_p = \frac{2}{3}x^3 - 4x + \frac{1}{10}e^{2x} - 2x \sin x.$$

Example 7: $(D^2 + 9)y = x^2 \cos 3x$.

Solution: A.E.: $m^2 + 9 = 0, m = \pm 3i$

C.F.: $y_c = c_1 \cos 3x + c_2 \sin 3x$.

In the normal case, the choice of P.I. from table is

$$y_p = Ax^2 \cos 3x + Bx^2 \sin 3x + Cx \cos 3x + Dx \sin 3x + E \cos 3x + F \sin 3x.$$

But in the R.H.S. expression $F(x) = x^2 \cos 3x$, the term $\cos 3x$ is also a term (part) of the C.F. corresponding to a root of multiplicity one i.e., $\cos 3x$ is a member of the solution set. So the modified (corrected) choice of P.I. is

$$y_p = x \left[Ax^2 \cos 3x + Bx^2 \sin 3x + Cx \cos 3x + Dx \sin 3x + E \cos 3x + F \sin 3x \right].$$

Note that $H \cos 3x + K \sin 3x$ is *not* included in the P.I. y_p , because these terms are already present in the C.F. (and therefore are superfluous i.e., even if we take these two terms in y_p , finally coefficients H and K will become zero). So

$$y_p = Ax^3 \cos 3x + Bx^3 \sin 3x + Cx^2 \cos 3x + Dx^2 \sin 3x + Ex \cos 3x + Fx \sin 3x.$$

Differentiating twice

$$y'_p = 3Ax^2 \cos 3x - 3Ax^3 \sin 3x + 3Bx^2 \sin 3x - 3Bx^3 \cos 3x + 2Cx \cos 3x - 3Cx^2 \sin 3x + 2Dx \sin 3x - 3Dx^2 \cos 3x + E \cos 3x - 3Ex \sin 3x + F \sin 3x - 3Fx \cos 3x. \quad \text{or}$$

$$y'_p = (3Ax^2 - 3Bx^3 + 2Cx - 3Dx^2 + E - 3Fx) \cos 3x + (-3Ax^3 + 3Bx^2 - 3Cx^2 + 2Dx - 3Ex + F) \sin 3x$$

$$y''_p = (6Ax - 9Bx^2 + 2C - 6Dx + 0 - 3F) \cos 3x - 3(3Ax^2 - 3Bx^3 + 2Cx - 3Dx^2 + E - 3Fx) \sin 3x + 3(-3Ax^3 + 3Bx^2 - 3Cx^2 + 2Dx - 3Ex + F) \cos 3x + (-9Ax^2 + 6Bx - 6Cx + 2D - 3E) \sin 3x.$$

Substituting in D.E. and equating the coefficients on both sides of

$$x^2 \cos 3x : 9B + 9B - 9C + 9C = 1 \quad \therefore B = \frac{1}{18}$$

$$x^2 \sin 3x : -9A - 9A - 9D + 9D = 0 \quad \therefore A = 0$$

$$x^3 \cos 3x : -9A + 9A = 0$$

$$x^3 \sin 3x : -9B + 9B = 0$$

$$x \cos 3x : 6A + 6D + 6D - 9E + 9E = 0 \quad \therefore D = 0$$

$$x \sin 3x : 6B - 6C - 6C - 9F + 9F = 0,$$

$$B - 2C = 0, C = \frac{1}{36}$$

$$\cos 3x : 2C + 3F + 3F = 0, F = \frac{1}{3}C = \frac{1}{108}$$

$$\sin 3x : 2D - 3E - 3E = 0 \quad \therefore E = 0$$

$$y_p = \frac{1}{18}x^3 \sin 3x + \frac{1}{36}x^2 \cos 3x + \frac{1}{108}x \sin 3x.$$

Example 8: $(D - 2)^3 y = 17e^{2x}$.

Solution: C.F.: A.E. is $m - 2 = 0, m = 2, 2, 2$. So $y_c = (c_1 + c_2x + c_3x^2)e^{2x}$. The choice of P.I. y_p as Ae^{2x} is not sufficient, since the term e^{2x} in the R.H.S. of D.E. is a term of the C.F. corresponding to a root of multiplicity $m = 3$. So the modified choice of P.I. y_p is

$$y_p = x^3(Ae^{2x}) = Ax^3e^{2x}$$

Differentiating,

$$y'_p = (3x^2 + 2x^3)Ae^{2x}$$

$$y''_p = (x + 2x^2 + \frac{4}{6}x^3)6Ae^{2x}$$

$$y'''_p = (1 + 6x + 6x^2 + \frac{8}{6}x^3)6Ae^{2x}.$$

Substituting in $(D^3 - 6D^2 + 12D - 8)y = 17e^{2x}$ we get

$$6Ae^{2x}(1 + 6x + 6x^2 + \frac{8}{6}x^3) - 36(x + 2x^2 + \frac{4}{6}x^3)Ae^{2x} + 12Ae^{2x}(3x^2 + 2x^3) - 8Ae^{2x}(x^3) = 17e^{2x}.$$

Equating the coefficients on both sides of

$$e^{2x} : 6A = 17, \quad \text{so} \quad A = \frac{17}{6};$$

$$x : 36A - 36A = 0, \quad x^2 : 36A - 72A + 36A = 0,$$

$$x^3 : 8A - 24A + 24A - 8A = 0. \quad \text{Thus}$$

$$y_p = \frac{17}{6}x^3e^{2x}$$

Thus

$$y = y_c + y_p = (c_1 + c_2x + c_3x^2)e^{2x} + \frac{17}{6}x^3e^{2x}.$$

[Note that the P.I. can be obtained in a simpler way by operator method, where

$$y_p = \frac{1}{(D-2)^3}(17e^{2x}) = 17 \cdot \frac{x^3}{3!}e^{2x} = \frac{17}{6}x^3e^{2x}].$$

EXERCISE

Method of undetermined coefficients

Solve the following D.E. by the method of undetermined coefficients. (Here G.S. = $y = y_c + y_p$, where y_c is the complementary function and y_p is the particular integral.)

Straight and sum cases:

1. $y'' - 2y' - 3y = 2e^{4x}$

Ans. $y_c = c_1e^{3x} + c_2e^{-x}, y_p = \frac{2}{5}e^{4x}$

2. $y'' + 2y' + 5y = 6 \sin 2x + 7 \cos 2x$

Ans. $y_c = e^{-x}[c_1 \cos 2x + c_2 \sin 2x],$
 $y_p = 2 \sin 2x - \cos 2x$

3. $y'' - 2y' = e^x \sin x$

Ans. $y_c = c_1 + c_2e^{2x}, y_p = -\frac{1}{2}e^x \sin x$

4. $y'' + y' - 2y = 2x - 40 \cos 2x$

Ans. $y_c = c_1e^x + c_2e^{-2x}, y_p = -\frac{1}{2} - x + 6 \cos 2x - 2 \sin 2x$

5. $y'' - 2y' + 3y = x^3 + \sin x$

Ans. $y_c = e^x(c_1 \cos \sqrt{2}x + c_2 \sin \sqrt{2}x)$

$$y_p = \frac{1}{3}x^3 + \frac{2}{3}x^2 + \frac{2}{9}x - \frac{8}{29} + \frac{1}{4}(\sin x + \cos x)$$

6. $y'' + 4y = 8x^2$

Ans. $y_c = c_1 \cos 2x + c_2 \sin 2x, y_p = 2x^2 - 1$

7. $y'' + 2y' + 5y = 1.25e^{0.5x} + 40 \cos 4x - 55 \sin 4x$, with $y(0) = 0.2$ and $y'(0) = 60.1$

Ans. $y_c = e^{-x}(c_1 \cos 2x + c_2 \sin 2x)$

$$y_p = 0.2e^{0.5x} + 5 \sin 4x$$

particular solution satisfying initial conditions

$$y = 20e^{-x} \sin 2x + 0.2e^{0.5x} + 5 \sin 4x.$$

8. $y'' + 2y' + 4y = 2x^2 + 3e^{-x}$

Ans. $y_c = e^{-x}(c_1 \cos \sqrt{3}x + c_2 \sin \sqrt{3}x)$

$$y_p = \frac{x^2}{2} - \frac{x}{2} + e^{-x}$$

9. $y'' - y = e^{3x} \cos 2x - e^{2x} \sin 3x$

Ans. $y_c = c_1e^x + c_2e^{-x}$

$$y_p = \frac{1}{30}e^{2x}(2 \cos 3x + \sin 3x) + \frac{1}{40}e^{3x}(\cos 2x + 3 \sin 2x)$$

10. $y'' - 9y = x + e^{2x} - \sin 2x$

Ans. $y_c = c_1e^{3x} + c_2e^{-3x}$

$$y_p = -\frac{x}{9} - \frac{e^{2x}}{5} + \frac{1}{13} \sin 2x$$

Modified case

11. $y'' + y' - 6y = 10e^{2x} - 18e^{3x} - 6x - 11$

Ans. $y_c = c_1e^{-3x} + c_2e^{2x}$

$$y_p = 2xe^{2x} - 3e^{3x} + x + 2$$

Hint: Choose $y_p = x(Ae^{2x}) + Be^{3x} + Cx + D$.

12. $y''' + 2y'' - y' - 2y = e^x + x^2$

Ans. $y_c = c_1 e^x + c_2 e^{-x} + c_3 e^{-2x}$

$$y_p = -\frac{x^2}{2} + \frac{x}{2} - \frac{5}{4} + \frac{1}{6} x e^x$$

Hint: Choose $y_p = x(Ae^x) + Bx^2 + Cx + D$.

13. $y'' - 3y' + 2y = e^x$

Ans. $y_c = c_1 e^x + c_2 e^{2x}$

$$y_p = -x e^x$$

Hint: Choose $y_p = x(Ae^x)$.

14. $y'' + y = \sin x$

Ans. $y_c = c_1 \cos x + c_2 \sin x$

$$y_p = -\frac{1}{2} x \sin x$$

Hint: Choose $y_p = x(A \cos x + B \sin x)$.

15. $y'' - 4y' + 4y = x^3 e^{2x} + x e^{2x}$

Ans. $y_c = c_1 e^{2x} + c_2 x e^{2x}$

$$y_p = \frac{1}{20} x^5 e^{2x} + \frac{1}{6} x^3 e^{2x}$$

Hint: Choose $y_p = x^2(Ax^3 e^{2x} + Bx^2 e^{2x} + Cx e^{2x} + D e^{2x})$.

16. $y'' - 3y' + 2y = 2x^2 + e^x + 2x e^x + 4e^{3x}$

Ans. $y_c = c_1 e^x + c_2 e^{2x}$

$$y_p = x^2 + 3x + \frac{7}{2} + 2e^{3x} - x^2 e^x - 3x e^x$$

Hint: Choose $y_p = (Ax^2 + Bx + C) + x(Dx e^x + E e^x) + F e^{3x}$.

17. $y'''' + y'' = 3x^2 + 4 \sin x - 2 \cos x$

Ans. $y_c = c_1 + c_2 x + c_3 \sin x + c_4 \cos x$

$$y_p = \frac{x^4}{4} - 3x^2 + x \sin x + 2x \cos x$$

Hint: Choose $y_p = x^2(Ax^2 + Bx + C) + x(D \sin x + E \cos x)$.

18. $y'' + 2y = x^2 \sin 2x$

Ans. $y_c = c_1 \cos 2x + c_2 \sin 2x$

$$y_p = -\frac{1}{12} x^3 \cos 2x + \frac{1}{16} x^2 \sin 2x + \frac{1}{32} x \cos 2x$$

Hint: Choose $y_p = x(Ax^2 \cos 2x + Bx^2 \sin 2x + Cx \cos 2x + Dx \sin 2x + E \cos 2x + F \sin 2x)$.

19. $y''' - y' = 4e^{-x} + 3e^{2x}$ with initial conditions $y(0) = 0, y'(0) = -1, y''(0) = 2$

Ans. $y_c = c_1 + c_2 e^x + c_3 e^{-x}$

$$y_p = 2x e^{-x} + \frac{1}{2} e^{2x}$$

particular solution obtained by using initial conditions $y = -\frac{9}{2} + 4e^{-x} + 2x e^{-x} + \frac{1}{2} e^{2x}$

Hint: Choose $y_p = x(Ae^{-x}) + Be^{2x}$.

20. $y''' - y'' - 4y' + 4y = 2x^2 - 4x - 1 + 2x^2 e^{2x} + 5x e^{2x} + e^{2x}$

Ans. $y_c = c_1 e^x + c_2 e^{2x} + c_3 e^{-2x}$

$$y_p = \frac{x^2}{2} + \frac{1}{6} x^3 e^{2x}$$

Hint: Choose $y_p = (Ax^2 + Bx + C) + x(Dx^2 e^{2x} + Ex e^{2x} + F e^{2x})$.

9.9 SYSTEM OF SIMULTANEOUS LINEAR D.E. WITH CONSTANT COEFFICIENTS

In several applied mathematics problems, there are more than one dependent variables, each of which is a function of one independent variable, usually say time t . The formulation of such problems leads to a system (or a family) of simultaneous linear D.E. with constant coefficients. Such a system can be solved by the method of elimination, Laplace transform method, method using matrices and short-cut operator methods. Here only the method of elimination is considered.

Note: The number of simultaneous equations in the system = number of dependent variables.

Method of Elimination

Consider a system of 2 O.D.E. in 2 dependent variables x and y and one independent variable t given by

$$f_1(D)x + g_1(D)y = h_1(t) \quad (1)$$

$$f_2(D)x + g_2(D)y = h_2(t)$$

where f_1, f_2, g_1, g_2 , are all functions of the differential operator $D = \frac{d}{dt}$.

- I. Eliminate y from the given system, resulting in a D.E. exclusively in x alone.
- II. Solve this D.E. for x .
- III. Substituting x (obtained in step II) in a similar manner obtain a D.E. only in y .
- IV. Solve the D.E. obtained in III for y .

Note 1: When the system consists of n O.D.E. in n dependent variables, repeat the above procedure for each of the n dependent variables.

Note 2: In the elimination process in step I, D may be treated as if it is a (ordinary) variable.

Note 3: The number of independent arbitrary constants appearing in the general solution of the system of D.E. (1) is equal to the degree of D in the coefficient determinant

$$\Delta = \begin{vmatrix} f_1(D) & g_1(D) \\ f_2(D) & g_2(D) \end{vmatrix}$$

provided $\Delta \neq 0$.

Note 4: If $\Delta = 0$, the system (1) is dependent.

WORKED OUT EXAMPLES

Solve the following:

Example 1: Solve

$$\frac{dx}{dt} = 3x + 8y \quad (1)$$

$$\frac{dy}{dt} = -x - 3y \quad (2)$$

$$\text{with } x(0) = 6, y(0) = -2 \quad (3)$$

Solution: Solving (2) for x , we get

$$x = -3y - \frac{dy}{dt} \quad (4)$$

Differentiating (4) w.r.t. 't', we have

$$\frac{dx}{dt} = -3\frac{dy}{dt} - \frac{d^2y}{dt^2} \quad (5)$$

Substituting (4) and (5) in (1), we obtain

$$\frac{d^2y}{dt^2} - y = 0$$

whose general solution is

$$y(t) = c_1 e^t - c_2 e^{-t} \quad (6)$$

Substituting (6) in (4) we get

$$x(t) = -4c_1 e^t - 2c_2 e^{-t} \quad (7)$$

Thus the general solution of the given system of Equations (1) and (2) is given by (6) and (7).

We use the initial conditions (3) to determine c_1 and c_2

$$6 = -4c_1 - 2c_2$$

$$-2 = c_1 + c_2$$

solving we find $c_1 = -1, c_2 = -1$.

Substituting these values in (6) and (7), we get the particular solution

$$x = 4e^t + 2e^{-t}, y = -e^t - e^{-t}$$

Example 2:

$$(D^2 + D + 1)x + (D^2 + 1)y = e^t \quad (1)$$

$$(D^2 + D)x + D^2 y = e^{-t} \quad (2)$$

Solution: To find x , eliminate y from (1) and (2), by multiplying (1) by D^2 and (2) by $(D^2 + 1)$ and subtracting

$$\begin{aligned} (D^2 + D + 1)D^2 x - (D^2 + D)(D^2 + 1)x \\ = D^2(e^t) - (D^2 + 1)e^{-t} \end{aligned}$$

$$\begin{aligned} [D^4 + D^3 + D^2 - (D^4 + D^3 + D^2 + D)]x \\ = e^t - e^{-t} - e^{-t} - Dx = e^t - 2e^{-t} \end{aligned}$$

Integrating w.r.t. 't', we get

$$x(t) = -e^t - 2e^{-t} + c_1 \quad (3)$$

To find y , substitute (3) in (2)

$$(D^2 + D)(-e^t - 2e^{-t} + c_1) + D^2 y = e^{-t}$$

$$-e^{+t} - 2e^{-t} + 0 - e^t + 2e^{-t} + 0 + D^2 y = e^{-t}$$

$$D^2 y = 2e^t + e^t$$

9.40 — HIGHER ENGINEERING MATHEMATICS—III

Integrating w.r.t. 't', we get

$$Dy = 2e^t - e^{-t} + c_2$$

Integrating once more w.r.t. 't', we get

$$y(t) = 2e^t + e^t + c_2t + c_3. \quad (4)$$

Since $\begin{vmatrix} D^2+D+1 & D^2+1 \\ D^2+D & D^2 \end{vmatrix} = -D$ of degree 1 in D , there

should be only one arbitrary constant.

Substituting (3) and (4) in (2), we get

$$\begin{aligned} (D^2 + D)(-e^t - 2e^{-t} + c_1) \\ + D^2(2e^t + e^{-t} + c_2t + c_3) &= e^{-t} \\ (-e^t - 2e^{-t} - e^t + 2e^{-t}) \\ + (2e^t + e^{-t} + 0 + 0) &= -e^{-t} \end{aligned}$$

Equation (2) satisfied.

So substitute x and y from (3) and (4) in (1)

$$\begin{aligned} (D^2 + D + 1)(-e^t - 2e^{-t} + c_1) \\ + (D^2 + 1)(2e^t + e^{-t} + c_2t + c_3) &= e^t \\ [-e^t - 2e^{-t} - e^t + 2e^{-t} + (-e^t - 2e^{-t} + c_1)] \\ + [2e^t + e^{-t} + 0 + 0 + (2e^t + e^{-t} + c_2t + c_3)] &= e^t \end{aligned}$$

i.e., $c_1 + c_2t + c_3 = 0 \therefore c_2t + c_3 = -c_1$. Thus the G.S. of the system with one arbitrary constant c_1

$$\begin{aligned} x(t) &= -e^t - 2e^{-t} + c_1 \\ y(t) &= 2e^t + e^{-t} - c_1 \end{aligned}$$

EXERCISE

Solve the following:

$$1. \frac{dx}{dt} = y + 1, \frac{dy}{dt} = x + 1$$

$$\text{Ans. } x = c_1 e^t + c_2 e^{-t} - 1$$

$$y = c_1 e^t - c_2 e^{-t} - 1$$

$$2. \frac{dx}{dt} = 2y - 1, \frac{dy}{dt} = 1 + 2x$$

$$\text{Ans. } x(t) = c_1 e^{2t} + c_2 e^{-2t} - \frac{1}{2}$$

$$y(t) = c_1 e^{2t} - c_2 e^{-2t} + \frac{1}{2}$$

$$3. \frac{dx}{dt} - 3x - 6y = t^2, \frac{dy}{dt} + \frac{dx}{dt} - 3y = e^t$$

$$\text{Ans. } x(t) = c_3 \cos 3t + c_4 \sin 3t + \frac{3}{5} e^t$$

$$-\frac{t^2}{3} + \frac{2t}{9} + \frac{2}{27}$$

$$y(t) = \left(\frac{1}{2} c_4 - \frac{1}{2} c_3 \right) \cos 3t$$

$$+ \left(\frac{-c_3}{2} - \frac{c_4}{2} \right) \sin 3t - \frac{e^t}{5} - \frac{2t}{9}$$

$$4. (D + 6)y - Dx = 0$$

$$(3 - D)x - 2Dy = 0$$

$$\text{with } x = 2, y = 3 \text{ at } t = 0$$

$$\text{Ans. } x = 4e^{2t} - 2e^{-3t}$$

$$y = e^{2t} + 2e^{-3t}$$

$$5. (D + 5)x + (D + 3)y = e^{-t}$$

$$(2D + 1)x + (D + 1)y = 3$$

$$\text{Ans. } x(t) = -\frac{2}{3} c_1 e^t - \frac{c_2}{3} e^{-2t} - 9$$

$$y(t) = c_1 e^t + c_2 e^{-2t} + \frac{15}{2} + \frac{e^{-t}}{2}$$

$$6. (D + 1)x + 2y = 1$$

$$2x + (D - 2)y = t$$

$$\text{Ans. } x = c_1 e^{3t} + 2c_2 e^{-2t} + \frac{t}{3} + \frac{4}{9}$$

$$y = -2c_1 e^{3t} + c_2 e^{-2t} - \frac{2t}{3} + \frac{1}{9}$$

$$7. (D - 3)x + 2(D + 2)y = 2 \sin t$$

$$2(D + 1)x + (D - 1)y = \cos t$$

$$\text{Ans. } x = c_1 e^{-5t} + c_2 e^{-\frac{t}{3}} + \frac{8 \sin t + \cos t}{65}$$

$$y = -\frac{4}{3} c_1 e^{-5t} + c_2 e^{-\frac{t}{3}} + \frac{61 \sin t - 33 \cos t}{130}$$

$$8. (D + 2)x + (D - 1)y = -\sin t$$

$$(D - 3)x + (D + 2)y = 4 \cos t$$

$$\text{Ans. } x = \frac{3}{5}c_1 e^{-\frac{t}{8}} + \frac{2}{5}\sin t - \frac{1}{5}\cos t$$

$$y = c_1 e^{-\frac{t}{8}} + \sin t + \cos t$$

$$9. \quad Dx - (D + 1)y = -e^t$$

$$x + (D - 1)y = e^{2t}$$

$$\text{Ans. } x = (c_1 - c_2)\cos t + (c_1 + c_2)\sin t + \frac{3e^{2t}}{5}$$

$$y = c_1 \cos t + c_2 \sin t + 2\frac{e^{2t}}{5} + \frac{e^t}{2}$$

$$10. \quad (D^2 + 4)x - 3Dy = 0$$

$$3Dx + (D^2 + 4)y = 0$$

$$\text{Ans. } x = c_1 \cos 4t + c_2 \sin 4t + c_3 \cos t + c_4 \sin t$$

$$y = c_2 \cos 4t - c_1 \sin 4t - c_4 \cos t + c_3 \sin t$$

$$11. \quad D^2y = x - 2$$

$$D^2x = y + 2$$

$$\text{Ans. } x = c_1 \sin t + c_2 \cos t + c_3 e^t + c_4 e^{-t} + 2$$

$$y = -c_1 \sin t - c_2 \cos t + c_3 e^t + c_4 e^{-t} - 2$$

$$12. \quad (D + 1)x + (D - 1)y = e^t$$

$$(D^2 + D + 1)x + (D^2 - D + 1)y = t^2$$

$$\text{Ans. } x = \frac{t^2}{2} - t + \frac{e^t}{2}$$

$$y = \frac{t^2}{2} + t - \frac{3e^t}{2}$$

$$13. \quad D^2x + 2Dy + 8x = 32t$$

$$D^2y + 3Dx - 2y = 60e^{-t}$$

$$\text{with } x(0) = 6, x^1(0) = 8,$$

$$y(0) = -24, y^1(0) = 0$$

$$\text{Ans. } x = 12 \cos 2t + 2e^{-2t} - 8e^{-t} + 4t$$

$$y = -12 \sin 2t + 6e^{-2t} - 36e^{-t} + 6$$

$$14. \quad 2D^2x + 3Dy - 4 = 0$$

$$2D^2y - 3Dx = 0$$

$$\text{with } x = y = Dx = Dy = 0 \text{ at } t = 0$$

$$\text{Ans. } x = \frac{8}{9}(1 - \cos \frac{3}{2}t)$$

$$y = \frac{4}{3}t - \frac{8}{9}\sin \frac{3}{2}t$$

9.10 METHOD OF REDUCTION OF ORDER*

Suppose $y_1(x)$ is known non-trivial solution of the second order homogeneous linear equation

$$a_0(x)\frac{d^2y}{dx^2} + a_1(x)\frac{dy}{dx} + a_2(x)y = 0 \quad (1)$$

Then the second linearly independent non-trivial solution $y_2(x)$ of (1) can be obtained by the *method of reduction of order*. This method makes use of a transformation of the form

$$y_2(x) = y_1(x)v(x) \quad (2)$$

which reduces the second order equation (1) to a first order differential equation which is then integrate for the unknown function $v(x)$.

Rewrite (1) in the standard form

$$\frac{d^2y}{dx^2} + P(x)\frac{dy}{dx} + Q(x)y = 0 \quad (3)$$

where $P(x) = \frac{a_1(x)}{a_0(x)}$, $Q(x) = \frac{a_2(x)}{a_0(x)}$ with $a_0(x) \neq 0$. Differentiating (2) w.r.t. x , we get

$$\frac{dy_2}{dx} = \frac{dy_1}{dx} \cdot v(x) + y_1(x)\frac{dv}{dx} \quad (4)$$

$$\frac{d^2y_2}{dx^2} = \frac{d^2y_1}{dx^2}v(x) + 2\frac{dy_1}{dx} \cdot \frac{dv}{dx} + y_1\frac{d^2v}{dx^2} \quad (5)$$

Substituting (2), (4), (5) in (3), we obtain

$$\left[y_1 \frac{d^2v}{dx^2} + 2\frac{dy_1}{dx} \cdot \frac{dv}{dx} + v \frac{d^2y_1}{dx^2} \right] + P(x) \left[y_1 \frac{dv}{dx} + \frac{dy_1}{dx}v \right] + Q(x)y_1v(x) = 0$$

Rewriting

$$y_1 \frac{d^2v}{dx^2} + \left[P(x)y_1 + 2\frac{dy_1}{dx} \right] \frac{dv}{dx} + v(x) \left[\frac{d^2y_1}{dx^2} + P(x)\frac{dy_1}{dx} + Q(x)y_1 \right] = 0$$

* Credited to Joseph Louis Lagrange (1736-1813).

9.42 — HIGHER ENGINEERING MATHEMATICS—III

Since $y_1(x)$ is a (known) solution of (1), the last term in the above equation becomes zero. Now introducing $\omega = \frac{dv}{dx}$, the above equation reduces to a first order linear differential equation in the new dependent variable ω , given by

$$\frac{d\omega}{dx} + \left[P(x) + 2 \frac{y_1'}{y_1} \right] \omega = 0 \quad (6)$$

Separating the variables and integrating, we get

$$\frac{d\omega}{\omega} + 2 \frac{dy_1}{y_1} + P(x)dx = 0$$

or

$$\ln |\omega| + \ln y_1^2 = - \int P(x)dx + \ln |c|$$

Then

$$\boxed{\omega(x) = \frac{c}{y_1^2} e^{-\int P(x)dx}} \quad (7)$$

Choosing, $c = 1$

$$\omega(x) = \frac{dv}{dx} = \frac{1}{y_1^2} e^{-\int P dx}$$

On integration

$$v(x) = \int \frac{1}{y_1^2} e^{-\int P dx} dx$$

Thus we obtain the required second solution $y_2(x)$ as

$$\boxed{y_2(x) = y_1(x)v(x) = y_1(x) \int \frac{1}{y_1^2} e^{-\int P(x)dx} \cdot dx} \quad (8)$$

It can easily be verified that $y_1(x)$ and $y_2(x)$ are linearly independent since

$$\begin{aligned} \omega(y_1, y_2) &= \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix} = \begin{vmatrix} y_1 & y_1 v \\ y_1' & y_1' v + y_1 v' \end{vmatrix} = y_1^2 v' \\ &= e^{\int -P dx} \neq 0 \end{aligned}$$

Hence y_1, y_2 form the basis for D.E. (1) and the general solution of (1) is given by

$$y(x) = c_1 y_1(x) + c_2 y_2(x)$$

Note: This method of reduction of order is useful only when *one* solution is *known*.

WORKED OUT EXAMPLES

Example 1: Verify that $y = e^{2x}$ is a solution of $(2x + 1)y'' - 4(x + 1)y' + 4y = 0$. Hence find the general solution.

Solution: Differentiating $y' = 2e^{2x}$, $y'' = 4e^{2x}$. Substituting y, y', y'' in the given D.E., we get

$$(2x + 1)4e^{2x} - 4(x + 1)2e^{2x} + 4e^{2x} = 0$$

or $[8x + 4 - 8x - 8 + 4]e^{2x} = 0$ or $0 = 0$

Thus $y_1 = e^{2x}$ is a solution. To obtain a second linearly independent solution, by the method of reduction of order, assume

$$y_2(x) = y_1(x)v(x)$$

The given D.E. in the standard form is

$$y'' - \frac{4(x + 1)}{(2x + 1)}y' + \frac{4}{(2x + 1)}y = 0$$

So $P(x) = -\frac{4(x+1)}{(2x+1)}$. Then

$$\omega(x) = \frac{1}{y_1^2} e^{-\int P dx}$$

Now

$$\begin{aligned} \int -P dx &= - \int -\frac{4(x + 1)}{(2x + 1)} dx \\ &= \int \left(\frac{4x + 2}{2x + 1} + \frac{2}{2x + 1} \right) dx \\ &= 2x + \ln(2x + 1) \end{aligned}$$

Then

$$\begin{aligned} \omega &= \frac{1}{(e^{2x})^2} e^{2x + \ln(2x+1)} = \frac{e^{2x}}{(e^{2x})^2} \cdot (2x + 1) \\ \omega(x) &= \frac{2x + 1}{e^{2x}} \end{aligned}$$

Now $v(x) = \int \omega(x)dx = \int \frac{2x+1}{e^{2x}} dx$

Integrating by parts

$$v(x) = (2x + 1) \frac{e^{-2x}}{-2} - 2 \cdot \frac{e^{-2x}}{4}$$

The required second solution

$$y_2(x) = y_1(x)v(x) = e^{2x} \left[-\frac{2x+1}{2} \cdot \frac{1}{e^{2x}} - \frac{1}{2} \frac{1}{e^{2x}} \right] \\ = -x - 1 = -(x+1)$$

Then the general solution is

$$y(x) = c_1 y_1(x) + c_2 y_2(x) = c_1 e^{2x} + c_2(x+1)$$

Example 2: Obtain the basis for the equation $\sin^2 x \cdot \frac{d^2 y}{dx^2} - 2y = 0$ if $y_1(x) = \cot x$ is a solution. Also write the general solution.

Solution: In the standard form the equation is

$$\frac{d^2 y}{dx^2} - 2(\operatorname{cosec}^2 x)y = 0$$

So $P(x) = 0$. The $e^{-\int P dx} = e^0 = 1$.

Now $\omega(x) = \frac{1}{y_1^2} e^{-\int P dx} = \frac{1}{\cot^2 x} \cdot 1 = \tan^2 x$

So $v(x) = \int \omega(x) dx = \int \tan^2 x dx$

$$= \int (\sec^2 x - 1) dx = [\tan x - x]$$

Then $y_2(x) = y_1(x)v(x) = \cot x[\tan x - x]$
 $= 1 - x \cot x$.

The basis consisting of the two linearly independent solutions is $\{y_1, y_2\} = \{\cot x, 1 - x \cot x\}$. The general solution is

$$y(x) = c_1 y_1(x) + c_2 y_2(x) = c_1 \cot x + c_2[1 - x \cot x]$$

EXERCISE

Determine a linearly independent solution by reduction of order given y_1 as a solution, for the following differential equations.

1. $(x^2 + 1)y'' - 2xy' + 2y = 0, y_1(x) = x$

Ans. $y_2(x) = x^2 - 1$

Hint: $\omega(x) = \left(\frac{x^2+1}{x^2}\right), v(x) = x - \frac{1}{x}$

2. $x^2 y'' - 4xy' + 4y = 0, y_1 = x$

Ans. $y_2 = x^4$

Hint: $P(x) = \frac{-4}{x}, \quad \omega(x) = \frac{1}{x^2} \cdot x^4 = x^2,$
 $v(x) = \frac{x^3}{3}$

3. $x^2 y'' - xy' + y = 0, y_1 = x$

Ans. $y_2 = x \cdot \ln x$

Hint: $P(x) = -\frac{1}{x}, \omega(x) = \frac{1}{x^2} \cdot x,$
 $v(x) = x \int \frac{dx}{x}$

4. $y'' - y' = 0, y_1 = e^x$

Ans. $y_2 = e^x$

5. $x^2 y'' - 5xy' + 9y = 0, y_1 = x^3$

Ans. $y_2 = x^3 \ln x$

Hint: $\omega(x) = \frac{1}{x^6} \cdot e^{\int \frac{5dx}{x}} = \frac{x^5}{x^6} = \frac{1}{x}, \quad v(x) = \int \frac{dx}{x} = \ln x.$

6. $x^2 y'' + xy' + (x^2 - \frac{1}{4})y = 0, y_1 = \frac{\cos x}{\sqrt{x}}$

Ans. $y_2(x) = \frac{\sin x}{\sqrt{x}}$

Hint: $\omega(x) = \sec^2 x, \quad v(x) = \int \sec^2 x \cdot dx = \tan x$

7. $xy'' - (2x - 1)y' + (x - 1)y = 0, y_1 = e^x$

Ans. $y_2 = e^x \ln x$

8. $y'' - 4xy' + (4x^2 - 2)y = 0, y_1 = e^{x^2}$

Ans. $y_2 = xe^{x^2}$

9.11 HIGHER ORDER LINEAR EQUATIONS WITH VARIABLE COEFFICIENTS

No general procedure exists for solving second and higher order linear equations with variable coefficients. However by transformations, some types of second - (or higher) - order differential equations can be reduced to first (or lower) - order equations which can be solved by earlier methods. We consider the following types.

I. Equation of the Form $\frac{d^n y}{dx^n} = f(x)$

Integrating this exact equation directly, we get an equation of lower $(n - 1)$ degree as

$$\frac{d^{n-1} y}{dx^{n-1}} = \int f(x) dx + c_1 = g(x) + c_1$$

which is also exact.

9.44 — HIGHER ENGINEERING MATHEMATICS—III

By integrating directly again we have

$$\begin{aligned}\frac{d^{n-2}y}{dx^{n-2}} &= \int (g(x) + c_1)dx + c_2 \\ &= \int g(x)dx + c_1(x) + c_2\end{aligned}$$

The solution is obtained by repeated direct integration.

II. Equation of the form $\frac{d^2y}{dx^2} = f(y)$

This equation becomes exact by multiplying both the sides with $2\frac{dy}{dx}$. Then

$$2\frac{dy}{dx} \cdot \frac{d^2y}{dx^2} = f(y)\frac{dy}{dx}$$

or

$$\frac{d}{dx} \left(\frac{dy}{dx} \right)^2 = 2f(y)\frac{dy}{dx}$$

Integrating w.r.t. x , we get

$$\left(\frac{dy}{dx} \right)^2 = 2 \int f(y)dy + c_1 = g(y) + c_1$$

Since the variables are separable

$$\frac{dy}{\sqrt{g(y) + c_1}} = dx$$

which on integration yields the required solution as

$$\int \frac{dy}{\sqrt{g(y) + c_1}} = x + c_2$$

III. Equation not Explicitly Containing the Unknown Dependent Variable y

When the dependent variable y is absent, the equation takes the form

$$F \left(\frac{d^n y}{dx^n}, \frac{d^{n-1}y}{dx^{n-1}}, \dots, \frac{dy}{dx}, x \right) = 0$$

The order of this equation can be reduced by one with the substitution $\frac{dy}{dx} = p$, $\frac{d^2y}{dx^2} = \frac{dp}{dx} \dots \frac{d^n y}{dx^n} = \frac{d^{n-1}p}{dx^{n-1}}$. Then the reduced equation with p as the dependent variable is solved. In general a substitution of the form $\frac{d^m y}{dx^m} = q$ will reduce the order of the equation

by m . Thus the substitution $\frac{dy}{dx} = p$ reduces a second order equation to a first order equation in p as a function of x . The equation

$$\frac{d^2y}{dx^2} = f \left(x, \frac{dy}{dx} \right)$$

reduces to a first order equation

$$\frac{dp}{dx} = f(x, p)$$

which on integration gives

$$p = p(x, c_1)$$

Since $\frac{dy}{dx} = p = p(x, c_1)$, the general solution is obtained as

$$y = \int p(x, c_1)dx + c_2$$

IV. Equation not Explicitly Containing the Independent Variable x

In the equation of the form

$$F \left(\frac{d^n y}{dx^n}, \frac{d^{n-1}y}{dx^{n-1}}, \dots, \frac{dy}{dx}, y \right) = 0$$

The substitution $\frac{dy}{dx} = p$ reduces it by order one. Considering p as a function of y (and not of x as before), we have

$$\frac{d^2y}{dx^2} = \frac{dp}{dx} = \frac{dp}{dy} \frac{dy}{dx} = p \frac{dp}{dy}$$

Similarly

$$\begin{aligned}\frac{d^3y}{dx^3} &= \frac{d}{dy} \left(\frac{d^2y}{dx^2} \right) \frac{dy}{dx} = \frac{d}{dy} \left(p \frac{dp}{dy} \right) p \\ &= p^2 \frac{d^2p}{dy^2} + p \left(\frac{dp}{dy} \right)^2\end{aligned}$$

The equation

$$\frac{d^2y}{dx^2} = f \left(y, \frac{dy}{dx} \right)$$

takes the form

$$p \frac{dp}{dy} = f(y, p)$$

which on integration w.r.t. y yields

$$p = p(y, c_1)$$

or
$$\frac{dy}{dx} = p(y, c_1)$$

Separating the variables

$$\frac{dy}{p(y, c_1)} = dx$$

which on integration gives the general solution

$$\phi(x, y, c_1, c_2) = 0$$

V. Solution by Change of Independent Variable

Assume a relation $z = z(x)$ then $\frac{dy}{dx} = \frac{dy}{dz} \cdot \frac{dz}{dx}$. Now

$$\begin{aligned} \frac{d^2y}{dx^2} &= \frac{d}{dx} \left(\frac{dy}{dz} \frac{dz}{dx} \right) = \frac{d}{dx} \left(\frac{dy}{dz} \right) \frac{dz}{dx} + \frac{dy}{dz} \cdot \frac{d^2z}{dx^2} \\ &= \frac{d}{dz} \left(\frac{dy}{dz} \right) \frac{dz}{dx} \cdot \frac{dz}{dx} + \frac{dy}{dz} \cdot \frac{d^2z}{dx^2} \end{aligned}$$

$$\frac{d^2y}{dx^2} = \frac{d^2y}{dz^2} \left(\frac{dz}{dx} \right)^2 + \frac{dy}{dz} \cdot \frac{d^2z}{dx^2}$$

with the above relation the D.E.

$$\frac{d^2y}{dx^2} + P(x) \frac{dy}{dx} + Q(x)y = R(x)$$

gets transformed to a D.E. in the independent variable z as

$$\left(\frac{d^2y}{dz^2} \cdot \left(\frac{dz}{dx} \right)^2 + \frac{dy}{dz} \cdot \frac{d^2z}{dx^2} \right) + P(x) \cdot \frac{dy}{dz} \cdot \frac{dz}{dx} + Q(x)y = R(x)$$

or
$$\frac{d^2y}{dz^2} + P_1(x) \frac{dy}{dz} + Q_1(x)y = R_1(x)$$

where $P_1(x) = \frac{\frac{d^2z}{dx^2} + P \frac{dz}{dx}}{S^*}$ and $Q_1(x) = \frac{Q(x)}{S^*}$, $R_1(x) = \frac{R(x)}{S^*}$, $S^* = \left(\frac{dz}{dx} \right)^2$

Here P_1 , Q_1 , R_1 will be converted to functions of z by eliminating x using the relation $z = z(x)$. Now choose

$$\left(\frac{dz}{dx} \right)^2 = Q(x)$$

To get real functions, the sign before $Q(x)$ is chosen as positive always. Integrating

$$z = \int Q(x) dx = z(x)$$

omitting the constant of integration. Now calculate P_1 , Q_1 , R_1 with this $z = z(x)$. When P , Q , R turns out to be constants (or zero), the new equation in z can be solved for $y(z)$. By replacing z in terms of x , the required solution $y(x)$ is obtained.

WORKED OUT EXAMPLES

I.
$$\frac{d^n y}{dx^n} = f(x)$$

Example 1: Solve $\frac{d^3 y}{dx^3} = \log x$

Solution: Integrating w.r.t. x , we get

$$\frac{d^2 y}{dx^2} = \int \log x dx + c_1 = x \ln x - x + c_1$$

Integrating again wrt x , we have

$$\begin{aligned} \frac{dy}{dx} &= \int x \ln x dx - \frac{x^2}{2} + c_1 x + c_2 \\ &= \frac{x^2}{2} \ln x - \frac{x^2}{4} - \frac{x^2}{2} + c_1 x + c_2 \end{aligned}$$

Integrating again,

$$\begin{aligned} y(x) &= \frac{1}{2} \int x^2 \ln x dx - \frac{3}{4} \frac{x^3}{3} + c_1 \frac{x^2}{2} + c_2 x + c_3 \\ y &= \frac{1}{2} \left[\frac{x^3}{3} \ln x - \frac{x^3}{9} \right] - \frac{1}{4} x^3 + \frac{c_1}{2} x^2 + c_2 x + c_3 \\ 36y &= 6x^3 \ln x - 11x^3 + c_1^* x^2 + c_2^* x + c_3^* \end{aligned}$$

II.
$$\frac{d^n y}{dx^n} = f(y)$$

Example 2: Solve $y^3 y'' = a$ with $y = 1$, $y' = 0$ at $x = 0$

Solution: Multiplying both sides by $2y'$, we have

$$2y' y'' = 2y' \cdot a \cdot y^{-3}$$

9.46 — HIGHER ENGINEERING MATHEMATICS—III

$$\frac{d}{dx}(y')^2 = 2ay^{-3} \frac{dy}{dx}$$

Integrating w.r.t. x

$$(y')^2 = 2a \frac{y^{-2}}{-2} + c_1$$

At $x = 0$, $y = 1$, $y' = 0$ so $0 = -a + c_1 \therefore c_1 = a$
Then

$$(y')^2 = \left(a - \frac{a}{y^2}\right) \text{ or } y' = \sqrt{\frac{a(y^2 - 1)}{y^2}}$$

Separating the variables

$$\frac{y \, dy}{\sqrt{a}\sqrt{y^2 - 1}} = dx$$

Integrating

$$\frac{1}{2\sqrt{a}} \frac{\sqrt{(y^2 - 1)}}{\frac{1}{2}} = x + c_2$$

when $x = 0$, $y = 1$ so $0 = 0 + c_2 \therefore c_2 = 0$
Thus $(y^2 - 1) = ax^2$

III. Equation not explicitly containing y

Example 3: Solve $x^2 \frac{d^3 y}{dx^3} - 4x \frac{d^2 y}{dx^2} + 6 \frac{dy}{dx} = 4$

Solution: Put $\frac{dy}{dx} = p$, then $\frac{d^2 y}{dx^2} = \frac{dp}{dx}$, $\frac{d^3 y}{dx^3} = \frac{d^2 p}{dx^2}$.
With these substitution, the given D.E. reduces to a second order D.E. in the dependent variable p with variable coefficients given by

$$x^2 \frac{d^2 p}{dx^2} - 4x \frac{dp}{dx} + 6p = 4$$

This is Euler-Cauchy equation. So put $x = e^t$ then $\mathcal{D}(\mathcal{D} - 1)p - 4\mathcal{D}p + 6p = 4$ where $\mathcal{D} = \frac{d}{dt}$.

$$\text{or } \frac{d^2 p}{dt^2} - 5 \frac{dp}{dt} + 6p = 4$$

The auxiliary equation is $m^2 - 5m + 6 = 0$ with real distinct roots $m = 2, 3$. So the complementary function is

$$p_c(t) = c_1 e^{2t} + c_2 e^{3t}$$

particular integral

$$p_p(t) = \frac{1}{\mathcal{D}^2 - 5\mathcal{D} + 6} 4 = \frac{4}{6} = \frac{2}{3}$$

The general solution is

$$p(t) = c_1 e^{2t} + c_2 e^{3t} + \frac{2}{3}$$

$$\text{or } \frac{dy}{dx} = c_1 x^2 + c_2 x^3 + \frac{2}{3}$$

Integrating w.r.t. x

$$y(x) = c_1 \frac{x^3}{3} + c_2 \frac{x^4}{4} + \frac{2}{3}x + c_3$$

IV. Equations not explicitly containing x

Example 4: Solve. $y(1 - \ln y) \frac{d^2 y}{dx^2} + (1 + \ln y) \left(\frac{dy}{dx}\right)^2 = 0$

Solution: Put $\frac{dy}{dx} = p$. Then $\frac{d^2 y}{dx^2} = \frac{d}{dx}(p) = \frac{dp}{dy} \cdot \frac{dy}{dx}$
ie, $\frac{d^2 y}{dx^2} = p \frac{dp}{dy}$. Here we consider p as a function of y with these substitutions, the given equation reduces to

$$y(1 - \ln y)p \frac{dp}{dy} + (1 + \ln y)p^2 = 0$$

Separating the variables

$$\frac{dp}{p} + \frac{(1 + \ln y)}{y(1 - \ln y)} dy = 0$$

Introducing $t = \ln y$, we have $dt = \frac{dy}{y}$, so

$$\frac{dp}{p} + \frac{(1 + t)}{(1 - t)} \cdot dt = 0$$

$$\text{or } \frac{dp}{p} - \left[1 + \frac{2}{t-1}\right] dt = 0$$

$$\text{Integrating } \ln p - t - 2 \ln(t - 1) = c_1$$

$$\text{or } p = c_2(t - 1)^2 e^t$$

$$\text{i.e., } \frac{dy}{dx} = c_2(\ln y - 1)^2 e^{\ln y}$$

Separating the variables

$$\frac{dy}{y(\ln y - 1)^2} = c_2 dx$$

$$\text{or } c_2 dx = \frac{dt}{(t-1)^2} \quad \text{where } t = \ln y$$

Integrating

$$c_2 x + c_3 = -\frac{1}{t - 1}$$

The general solution is

$$(1 - \ln y)(c_2 x + c_3) = 1$$

V. Change of independent variable

Example 5: Solve $\frac{d^2 y}{dx^2} + \tan x \frac{dy}{dx} + y \cos^2 x = 0$

Solution: $P(x) = \tan x$, $Q(x) = \cos^2 x$. The transformation $z = f(x)$ is so chosen that $P_1 = \frac{d^2 z}{dx^2} + P \frac{dz}{dx} = 0$ or with $u = \frac{dz}{dx}$,

$$\frac{du}{dx} + u \cdot \tan x = 0$$

Integrating $\ln u = \ln \cos x + c_1$ or $u = c_2 \cos x$. Since $u = \frac{dz}{dx} = c_2 \cos x$ we have $z(x) = c_2 \sin x$

Now $Q_1 = \frac{Q}{u^2} = \frac{\cos^2 x}{(c_2 \cos x)^2} = \frac{1}{c_2^2}$

Then the transformed equation with z as the new independent variable is

$$\frac{d^2 y}{dz^2} + P_1 \frac{dy}{dz} + Q_1 y = 0$$

$$\text{or } \frac{d^2 y}{dz^2} + 0 + \frac{1}{c_2^2} y = 0$$

Integrating $y(z) = A \cos\left(\frac{z}{c_2}\right) + B \sin\left(\frac{z}{c_2}\right)$
or $y(x) = A \cos(\sin x) + B \sin(\sin x)$

Example 6: Solve $y'' - y' \cot x - y \sin^2 x = \cos x - \cos^3 x$

Solution: The equation in the standard form has $P(x) = -\cot x$, $Q(x) = -\sin^2 x$, $R(x) = \cos x - \cos^3 x$. Choose the new independent variable z such that

$S^* = \left(\frac{dz}{dx}\right)^2 = \sin^2 x$ or $\frac{dz}{dx} = \sin x$. On integration, $z(x) = -\cos x$. With this z , the given equation reduces to $\frac{d^2 y}{dz^2} + p_1 \frac{dy}{dz} + Q_1 y = R_1$ where

$$P_1 = \frac{\frac{d^2 z}{dx^2} + P \frac{dz}{dx}}{S^*} = \frac{\cos x - \cot x \cdot \sin x}{\sin^2 x} = 0$$

$$Q_1 = \frac{Q}{S^*} = \frac{-\sin^2 x}{\sin^2 x} = -1$$

and

$$R_1 = \frac{R}{S^*} = \frac{\cos x - \cos^3 x}{\sin^2 x} = \frac{\cos x(1 - \cos^2 x)}{\sin^2 x} = \cos x$$

Thus the D.E. with z as the independent variable is

$$\frac{d^2 y}{dz^2} + 0 - 1 \cdot y = \cos x = -z$$

The complementary function is $y = c_1 e^z + c_2 e^{-z}$ and particular integral $y = \frac{1}{D^2 - 1}(-z) = +\frac{1}{(1 - D^2)}z = +[1 + D^2 - D^4 + \dots]z = +z$. Thus the general solution is

$$y(z) = c_1 e^z + c_2 e^{-z} + z \text{ or } y(x) = c_1 e^{-\cos x} + c_2 e^{\cos x} - \cos x$$

EXERCISE

I. $\frac{d^n y}{dx^n} = f(x)$

Solve

1. $y''' = x e^x$

Ans. $y = x e^x - 3 e^x + \frac{1}{2} c_1 x^2 + c_2 x + c_3$

2. $y'' = x^2 \sin^2 x$

Ans. $y = -x^2 \sin x - 4x \cos x + 6 \sin x + c_1 x + c_2$

3. $y''' = x + \ln x$

Ans. $y = \frac{x^4}{24} + \frac{x^3}{6} \ln x - \frac{11}{35} x^3 + c_1 x^2 + c_2 x + c_3$

4. $y''' = \sin^2 x$

Ans. $y = \frac{x^3}{12} + \frac{\sin 2x}{16} + \frac{c_1 x^2}{2} + c_2 x + c_3$

5. $y^{(n)} = x^m$

Ans. $y = \frac{m!}{(m+n)!} x^{m+n} + c_1 x^{n-1} + c_2 x^{n-2} + \dots + c_n$

6. $x^2 y'' = \ln x$

Ans. $y = -\frac{1}{2}(\ln x)^2 + \ln x - c_1 x + c_2$

II. $\frac{d^2 y}{dx^2} = f(y)$

Solve

7. $y'' = \sec^2 y \cdot \tan y$ with $y = 0$ and $y' = 1$ when $x = 0$

Ans. $x + c_2 = \frac{1}{\sqrt{c_1-1}} \sin^{-1} \left\{ \sin y \sqrt{\frac{c_1-1}{c_1}} \right\}$,
 $c_1 = 1, c_2 = 0$, so $y = \sin^{-1} x$.

8. $y'' = 2(y^3 + y)$ with $y = 0, y' = 1$ when $x = 0$

Ans. $y = \tan x$

9. $y'' = e^{-2y}$

Ans. $c_1 e^y = \cosh (c_1 x + c_2)$

10. $\sin^3 y \cdot y'' = \cos y$

Ans. $\sqrt{1+c_1} \cdot \sin (x+c_2) + \sqrt{\frac{1+c_1}{c_1}} \cos y = 0$

11. $y'' = 3\sqrt{y}$ with $y = 1, y' = 2$ when $x = 0$

Ans. $x = 2(y^{\frac{1}{4}} - 1)$

12. $y'' + a^2 y^{-2} = 0$

Ans. $\sqrt{c_1 y^2 + y} - \sqrt{2ac_1} x + c_2 = \frac{1}{\sqrt{c_1}} \ln \left\{ \sqrt{(c_1 y + 1)} + \sqrt{c_1 y} \right\}$

III. $\frac{d^2 y}{dx^2} = f \left(x, \frac{dy}{dx} \right)$

Solve

13. Catenary: $ay'' = \sqrt{1 + (y')^2}$ with $y = a$ and $y' = 0$ at $x = 0$

Ans. $y = a \cosh \left(\frac{x}{a} \right)$,

Hint: $a \frac{dp}{dx} = \sqrt{1 + p^2}$, $p = \sinh \left(\frac{x}{a} + c_1 \right)$,
 $c_1 = c_2 = 0$

14. $(1 - x^2)y'' - xy' - 2 = 0$

Ans. $y = (\sin^{-1} x)^2 + c_1 \sin^{-1} x + c_2$

15. $y'' + y' + (y')^3 = 0$

Ans. $y = -\sin^{-1}(c_1 e^{-x}) + c_2$

16. $xy'' - \sqrt{1 + (y')^2} = 0$

Ans. $2y = c_1 \frac{x^2}{2} - \frac{1}{c_1} \ln x + c_2$

17. $y'''' \cdot y''' = 1$

Ans. $y = \frac{8\sqrt{2}}{105}(x + c_1)^{7/2} + \frac{1}{2}c_2 x^2 + c_3 x + c_4$

18. $y'''' - \cot x \cdot y''' = 0$

Ans. $y = c_1 \cos x + c_2 x^2 + c_3 x + c_4$

IV. $\frac{d^2 y}{dx^2} = f \left(y, \frac{dy}{dx} \right)$

19. $3y'' = y^{-5/3}$

Ans. $x + c_2 = \pm \frac{1}{c_1^{2/3}} \sqrt{c_1 y^{2/3} - 1} (c_1 y^{2/3} + 2)$

20. $yy'' - (y')^2 = y^2 \ln y$

Ans. $\ln y = \sqrt{c_1} \cdot \sinh (x + c_2)$

21. $yy'' + y'(y' - 2y) = 0$

Ans. $y^2 + c_1 = c_2 e^{2x}$

22. $2yy'' - (y')^2 - 1 = 0$

Ans. $a^2(x + b)^2 = 4(ay - 1)$

23. $yy'' - 2(y')^2 - y^2 = 0$

Ans. $\sqrt{c_1} \cdot y \cdot \cos (x + c_2) = 1$

V. Change of Independent Variable

24. $(1 + x^2)y'' + 2x(1 + x^2)y' + 4y = 0$

Ans. $y(1 + x^2) = c_1(1 - x^2) + 2c_2 x$

25. $\sin^2 x y'' + \sin x \cdot \cos x y' + 4y = 0$

Ans. $y = c_1 \cos (2 \log \tan \frac{x}{2}) + c_2 \sin (2 \log \tan \frac{x}{2})$

26. $\cos x y'' + y' \sin x - 2y \cos^3 x = 2 \cos^5 x$

Ans. $y = c_1 e^z + c_2 e^{-z}$ where $z = \sqrt{2} \sin x$

27. $xy'' - y' + 4x^3 y = x^5$

Ans. $y = c_1 \cos x^2 + c_2 \sin x^2 + \frac{x^2}{4}$

28. $xy'' - y' - 4x^3 y = 8x^3 \sin x^2$

Ans. $y = c_1 x^2 + c_2 e^{-x^2} - \sin x^2$

29. $xy'' + (4x^2 - 1)y' + 4x^3 y = 2x^3$

Ans. $y = e^{-x^2} (c_1 \cos x^2 + c_2 \sin x^2) + \frac{1}{2}$

30. $y'' + (3 \sin x - \cot x)y' + 2y \sin^2 x = \sin^2 x \cdot e^{-\cos x}$

Ans. $y = c_1 e^{\cos x} + c_2 e^{2 \cos x} + \frac{1}{6} e^{-\cos x}$

9.12 SIMPLE HARMONIC MOTION

A particle is said to be in simple harmonic motion if the acceleration of the particle is proportional to its displacement i.e.,

$$\frac{d^2 x}{dt^2} = -\omega^2 x$$

or $\ddot{x} + \omega^2 x = 0$

(1)

where $x(t)$ is the displacement of the particle at any time t , from a fixed reference point O . The general solution of the second order linear homogeneous D.E. (1), known as harmonic D.E., is

$$x(t) = c_1 \cos \omega t + c_2 \sin \omega t \quad (2)$$

Introducing $c_1 = A \sin \phi_0$, $c_2 = A \cos \phi_0$, so that $A = \sqrt{c_1^2 + c_2^2}$ and $\tan \phi_0 = \frac{c_1}{c_2}$, (2) can be written as $x(t) = A \sin(\omega t + \phi_0)$. (3)

Fig. 9.1

Suppose the particle starts from rest from the point R which is at a distance ' b ' from O , then the initial conditions are $x = b$, $\dot{x} = 0$ at $t = 0$.

From (2)

$$b = x(0) = c_1 \cdot 1 + c_2 \cdot 0 \quad \therefore c_1 = b$$

Differentiating (2), the velocity of the particle is

$$v = \frac{dx}{dt} = \omega(-b \sin \omega t + c_2 \cos \omega t)$$

Using the second initial condition

$$0 = \dot{x}(0) = \omega(-b \cdot 0 + c_2 \cdot 1) \quad \therefore c_2 = 0$$

Thus the displacement x and velocity v are given respectively by

$$\boxed{x(t) = b \cos \omega t} \quad (4)$$

and

$$v = \frac{dx}{dt} = -b\omega \sin \omega t = -\omega \sqrt{b^2 - x^2} \quad (5)$$

Thus the particle oscillates between the two extremities R and Q where the velocity is zero. The velocity of the particle attains maximum at origin O . The oscillations (motion) are called *harmonic*. The integral curves are sine curves. *Amplitude* of the simple harmonic motion is the constant A , which is the maximum displacement of particle from origin (equilibrium position).

Periodic time or *period of oscillation* is the time for a complete oscillation and is given by $\frac{2\pi}{\omega}$. Note that x and $\dot{x}$ given by (4) and (5), involving $\cos$ and $\sin$, are periodic functions of period $\frac{2\pi}{\omega}$ i.e., $x(t + \frac{2\pi}{\omega}) = x(t)$. The part of the curve between P and Q represents one period of the motion.

Fig. 9.2

Frequency is the number of oscillations per second during the time 2π and is given by $\frac{1}{\text{periodic time}} = \frac{\omega}{2\pi}$.

Here ϕ_0 is the initial phase.

The power of modeling is seen by the equation (1) which also represents the motion of a particle with constant angular velocity along a circle, also the free undamped vertical motion of a mass-spring system and also the motion of the bob of a simple pendulum in a vertical plane.

WORKED OUT EXAMPLES

Example 1: Compute the time required for a particle, in simple harmonic motion with amplitude 20 cm and periodic time 4 seconds, in passing between two points which are at distances 15 cm and 5 cm from the origin O .

Solution: Here $b = 20$, $4 = \frac{2\pi}{\omega}$ or $\omega = \frac{2\pi}{4} = \frac{\pi}{2}$

Then $x(t) = b \cos \omega t = 20 \cos \frac{\pi t}{2}$

When $t = t_1$, given $x = x_1 = 5$

When $t = t_2$, given $x = x_2 = 15$

Fig. 9.3

Thus $5 = x_1 = 20 \cos \frac{\pi t_1}{2}$ and $15 = x_2 = 20 \cos \frac{\pi t_2}{2}$.

Then $\frac{\pi t_2}{2} - \frac{\pi t_1}{2} = \cos^{-1} \frac{15}{20} - \cos^{-1} \frac{5}{20}$ or the time

9.50 — HIGHER ENGINEERING MATHEMATICS—III

taken by particle in passing between x_1 , and x_1 is given by

$$t_2 - t_1 = \frac{2}{\pi} \left[\cos^{-1} \frac{3}{4} - \cos^{-1} \frac{1}{4} \right]$$

Example 2: A particle of mass m moves in a straight line under the action of force mn^2x which is always directed towards a fixed point O on the line. Determine the displacement $x(t)$ if the resistance to the motion is $2\lambda mnv$ given that initially $x = 0, \dot{x} = x_0$. Here $0 < \lambda < 1$.

Solution: The D.E. describing this simple harmonic motion is

$$m\ddot{x} = -2\lambda mn\dot{x} - mn^2x$$

$$\text{or } \frac{d^2x}{dt^2} + 2\lambda n \frac{dx}{dt} + n^2x = 0$$

The auxiliary equation is

$$r^2 + 2\lambda nr + n^2 = 0$$

$$\text{with roots } r = \frac{-2\lambda n \pm \sqrt{4\lambda^2 n^2 - 4n^2}}{2}$$

$$r = -\lambda n \pm n\sqrt{1 - \lambda^2}i$$

The general solution is

$$x(t) = e^{-\lambda nt} [c_1 \cos n\omega t + c_2 \sin n\omega t]$$

where $\omega = \sqrt{1 - \lambda^2}$. Using the initial condition

$$0 = x(0) = c_1 \cdot 1 + c_2 \cdot 0 \quad \therefore c_1 = 0$$

Differentiating $x(t)$ w.r.t. 't'

$$\dot{x} = -\lambda ne^{-\lambda nt} [c_1 \cos n\omega t + c_2 \sin n\omega t]$$

$$+ e^{-\lambda nt} [-c_1 n\omega \sin n\omega t + c_2 n\omega \cos n\omega t]$$

Since at $t = 0, \dot{x} = x_0$, we have

$$x_0 = \dot{x} = -\lambda n[0 + 0] + [0 + c_2 n\omega \cdot 1]$$

$$\therefore c_2 = \frac{x_0}{n\omega}$$

Then the displacement $x(t)$ is given by

$$x(t) = e^{-\lambda nt} \cdot \frac{x_0}{n\omega} \cdot \sin n\omega t$$

$$\text{with } \omega = \sqrt{1 - \lambda^2}$$

EXERCISE

- Find the time of a complete oscillation in a simple harmonic motion if $x = x_1, x = x_2$, and $x = x_3$ when $t = 1, t = 2, t = 3$ seconds respectively.

$$\text{Ans. } 2\pi/\theta \text{ where } \cos \theta = \frac{x_1 + x_3}{2x_2}$$

$$\text{Hint: } x(t) = b \cos \omega t, \quad x_1 = b \cos \omega, \\ x_2 = b \cos 2\omega, \quad x_3 = b \cos 3\omega, \quad \frac{x_1 + x_3}{2x_2} = \frac{\cos \omega + \cos 3\omega}{2 \cos 2\omega} = \cos \omega$$

- Determine the equation of motion of a particle of mass m attached to one end of stretched elastic horizontal string whose other end is fixed. Find the displacement x of the particle if $x = x_0, \dot{x} = 0$ when $t = 0$.

$$\text{Ans. } \ddot{x} + \frac{g}{e}x = \frac{gL}{e} \text{ where } L \text{ is the natural length of the string, } e \text{ is the elongation due to weight } mg. \\ x(t) = (x_0 - L) \cos \omega t + L \text{ where } \omega = \sqrt{\frac{g}{e}}.$$

$$\text{Hint: G.S.: } x(t) = c_1 \cos \omega t + c_2 \sin \omega t + L.$$

- Find the period of a particle of mass m , in simple harmonic motion, attached to the middle point of an elastic string (of natural length $2a$) stretched between two points Q and R which are $4a$ apart.

$$\text{Ans. Period } 2\pi/\omega \text{ where } \omega^2 = 2\lambda/am \text{ where } \lambda \text{ is the modulus.}$$

9.13 MASS-SPRING MECHANICAL SYSTEM

Airplanes, bridges, ships, machines, cars etc. are vibrating mechanical systems. The simplest mechanical system is the mass-spring system which consists of a coil spring of natural length L , suspended vertically from a fixed point support (such as a ceiling or beam). A constant mass ' m ' attached to the lower end of the spring, stretches the spring to a length $(L + e)$ and comes to rest which is known as the static equilibrium position. Here $e > 0$ is the static deflection due to the hanging the mass on the spring. Now the mass is set in motion either by pushing or pulling

the mass from equilibrium position and/or by imparting a non-zero velocity (downward or upward) to the mass (in the equilibrium position). Since the motion takes place in the vertical direction, we consider the downward direction as positive. In order to determine the displacement $x(t)$ of the mass from the static equilibrium position, we use Newton's second law and Hooke's law. The mass m is subjected to the following forces:

- (a) a gravitational force mg acting downwards.
- (b) a spring restoring force $-k(x(t) + e)$ due to displacement of the spring from rest (equilibrium) position.
- (c) a frictional (or damping or resistance) force of the medium, opposing the motion and of magnitude $-c\dot{x}(t)$.
- (d) an external force $F(t)$.

The differential equation (D.E.) describing the motion of the mass is obtained by Newton's second law as

$$m\ddot{x}(t) = mg - k(x(t) + e) - c\dot{x}(t) + F(t)$$

Here $k > 0$ is known spring constant or stiffness of the spring, $c \geq 0$ is known as damping constant, g is gravitational constant. Since the force on the mass exerted by the spring must be equal and opposite to

the gravitational force on the mass, we have $ke = mg$. Thus the D.E. modeling the motion of mass is

$$m\ddot{x}(t) + c\dot{x}(t) + kx(t) = F(t)$$

which is a second order linear non-homogenous equation with constant coefficients. The displacement (or motion) of the mass at any time t is $x(t)$ which is the solution of D.E. (1). Let us consider three important cases of D.E. (1) referred to as free motion, damped motion and forced motion.

Free, Undamped Oscillations of a Spring

In the absence of external force ($F(t) = 0$) and neglecting the damping force ($c = 0$), D.E. (1) reduce to

$$m\ddot{x} + kx = 0 \quad (2)$$

which is the *harmonic oscillator equation*. Putting $\omega^2 = \frac{k}{m}$, the equation (2) takes the form

$$\ddot{x} + \omega^2 x = 0$$

whose general solution is sinusoidal given by

$$x(t) = c_1 \cos \omega t + c_2 \sin \omega t \quad (3)$$

Introducing $c_1 = A \cos \phi$, $c_2 = -A \sin \phi$, equation (3) can be rewritten as

$$x = A \cos \phi \cos \omega t - A \sin \phi \sin \omega t = A \cos (\omega t + \phi)$$

i.e. $x(t) = A \cos(\omega t + \phi)$ (4)

where $A = \sqrt{c_1^2 + c_2^2}$, $\tan \phi = -\frac{c_2}{c_1}$. The constant A is called the *amplitude* of the motion and gives the maximum (positive) displacement of the mass from its equilibrium position. Thus the free, undamped motion of the mass is a simple harmonic motion, which is periodic. The *period* of motion is the time interval between two successive maxima and is given by

$$T = \frac{2\pi}{\omega} = 2\pi \sqrt{\frac{m}{k}}$$

The *natural frequency* (or simply frequency) of the motion (or harmonic oscillator) is the reciprocal

Fig. 9.4 Forced damped mass-spring system

of the period, which gives the number of oscillations/second. Thus the natural frequency is the undamped frequency (i.e. frequency of the system with out damping)

Free, Damped Motion of a Mass

Every system has some damping, otherwise the system continues to move forever. Damping force opposes oscillations. Damping not only decreases the amplitude but also alters the natural frequency of the system. With external force absent ($F(t) = 0$) and damping present ($c \neq 0$), the D.E. (1) takes the form

$$m\ddot{x} + c\dot{x} + kx = 0 \quad (5)$$

whose auxiliary equation is

$$r^2 + 2br + \omega^2 = 0 \quad (6)$$

Here $2b = \frac{c}{m}$ and $\omega^2 = \frac{k}{m}$. The roots of (6) are

$$r = \frac{-2b \pm \sqrt{4b^2 - 4\omega^2}}{2} = -b \pm \sqrt{b^2 - \omega^2} \quad (7)$$

The motion of mass depends on the damping through the nature of the discriminant $b^2 - \omega^2$.

Case (i) $b^2 - \omega^2 > 0$ i.e., $c^2 > 4mk$

Since $b > \omega$, the roots $r_1 = -b + \sqrt{b^2 - \omega^2}$ and $r_2 = -b - \sqrt{b^2 - \omega^2}$ are distinct, real negative numbers. The general solution is

$$x(t) = c_1 e^{r_1 t} + c_2 e^{r_2 t} \quad (8)$$

which tends to zero as $t \rightarrow \infty$. Thus the damping is so great that no oscillations can occur. The motion (or system) is said to be *over critically damped* (or simply *overdamped*).

Case (ii) $b^2 - \omega^2 = 0$ or $b = \omega$. Here both the roots are equal, real negative number $-b$. The general solution is

$$x(t) = (c_1 + c_2 t)e^{-bt} \quad (9)$$

which tends to zero as $t \rightarrow \infty$. Thus the damping is just enough to prevent oscillations so that the motion is no longer oscillatory. In this case the motion is said to be *critically damped*.

In both cases (i) and (ii) the displacement $x(t)$ is asymptotic and approaches zero (the equilibrium position) as $t \rightarrow \infty$.

Case (iii) when $b < \omega$ then $b^2 - \omega^2 < 0$ so the roots of the auxiliary equation (7) are complex conjugate given by $-b \pm \sqrt{\omega^2 - b^2} i$. The general solution is

$$x(t) = e^{-bt} [c_1 \cos \sqrt{\omega^2 - b^2} t + c_2 \sin \sqrt{\omega^2 - b^2} t] \quad (10)$$

which can be written in the alternative form

$$x(t) = Ae^{-bt} [\cos \left(\left(\sqrt{\omega^2 - b^2} \right) \cdot t + \phi \right)] \quad (11)$$

Here $A = \sqrt{c_1^2 + c_2^2}$ and $\phi = \tan^{-1} \left(-\frac{c_1}{c_2} \right)$.

Since $A > 0$ and $b > 0$ the first factor is in (11). The *time-varying amplitude* or the *damping factor* $Ae^{-bt} \rightarrow 0$ monotonically as $t \rightarrow \infty$. The other factor $\cos \left(\left(\sqrt{\omega^2 - b^2} \right) \cdot t + \phi \right)$ in (11) is periodic, oscillatory representing simple harmonic motion.

Fig. 9.5

The solution (11) which is the product of these two factors is a damped oscillatory motion in which the oscillations die (damped) out. Resonance never occurs in this case since the frequency of the free damped system $\frac{\sqrt{\omega^2 - b^2}}{2\pi} = \frac{1}{2\pi} \sqrt{\frac{k}{m} - \frac{c^2}{4m^2}}$ is less than the natural frequency $\frac{1}{2\pi} \sqrt{\frac{k}{m}}$ of the corresponding undamped system. In this case the motion is said to be *underdamped*. The free underdamped solutions given by (10) or (11) are also known as *damped harmonic motion*.

Forced Oscillations

In the presence of an external force $F(t)$, also known as *input* or *driving force*, the solutions of D.E. (1) are known as *output* or *response* of the system to the external force. In this case, the oscillations are said to be forced oscillations, which are of two types damped forced oscillations and undamped forced oscillations.

Case (i): Damped forced oscillations

The D.E. in this case is

$$m\ddot{x} + c\dot{x} + kx = F(t) \quad (1)$$

Suppose the external impressed forces $F(t)$ is a periodic sinusoidal force with amplitude F_1 and circular frequency β of the form

$$F(t) = F_1 \cos \beta t, \quad (F_1 > 0; \beta > 0)$$

Then D.E. (1) takes the form

$$m\ddot{x} + c\dot{x} + kx = F_1 \cos \beta t$$

or $\ddot{x} + 2b\dot{x} + \omega^2 x = E_1 \cos \beta t \quad (12)$

where $2b = \frac{c}{m}$, $\omega^2 = \frac{k}{m}$, $E_1 = \frac{F_1}{m}$. Assume that $b < \omega$. Then the complementary function of (12) is

$$x_c = Ae^{-bt} \cos \left(\left(\sqrt{\omega^2 - b^2} \right) \cdot t + \phi \right) \quad (13)$$

which approaches zero as $t \rightarrow \infty$. The particular integral of (12) is

$$\begin{aligned} x_p &= \frac{1}{D^2 + 2bD + \omega^2} E_1 \cos \beta t \\ &= \frac{E_1}{\omega^2 - \beta^2 + 2bD} \cos \beta t \\ &= \frac{E_1[\omega^2 - \beta^2 - 2bD]}{(\omega^2 - \beta^2)^2 - 4b^2 D^2} \cos \beta t \\ &= \frac{E_1[\omega^2 - \beta^2 - 2bD] \cos \beta t}{(\omega^2 - \beta^2)^2 + 4b^2 \beta^2} \\ x_p &= \frac{E_1}{(\omega^2 - \beta^2) + 4b^2 \beta^2} [(\omega^2 - \beta^2)^2 \cos \beta t + 2b\beta \sin \beta t] \end{aligned}$$

Put $\cos \theta = \frac{\omega^2 - \beta^2}{(\omega^2 - \beta^2) + 4b^2 \beta^2}$, $\sin \theta = \frac{2b\beta}{(\omega^2 - \beta^2) + 4b^2 \beta^2}$

Then x_p can be written in the phase angle form as

$$x_p = E_1 \cdot \cos (\beta t - \theta) \quad (14)$$

The general solution is

$$x(t) = x_c + x_p \quad (15)$$

where x_c and x_p are respectively given by (13) and (14). The first terms x_c in (15) given by

$Ae^{-bt} \cos \left(\left(\sqrt{\omega^2 - b^2} \right) t + \phi \right)$ known as *transient term*, tends to zero as $t \rightarrow \infty$ and represents the damped oscillations that would be the entire motion of the corresponding free motion (i.e. when external force $F_1 \cos \omega t$ was absent). The second term x_p in (15) given by (14), known as *steady-state* term represents a simple harmonic motions of period, $\frac{2\pi}{\beta}$ which results from the presence of the external force $F(t)$ whose period is also $\frac{2\pi}{\beta}$. Hence after a sufficiently long time, the output corresponding to a purely sinusoidal input will be practically a harmonic oscillation whose frequency is that of the input.

Case (ii): Undamped forced oscillations: Resonance

In the undamped case $c = 0$ and D.E. (1) takes the form

$$m\ddot{x} + kx = F(t) = F_1 \cos \beta t$$

$$\text{or } \ddot{x} + \omega^2 x = E_1 \cos \beta t \quad (16)$$

where $\omega^2 = \frac{k}{m}$, $E_1 = \frac{F_1}{m}$ and ω , E_1 , β are positive constants. The complementary function of (16) is

$$x_c = c_1 \cos \omega t + c_2 \sin \omega t \quad (17)$$

Thus every free solution (17) of D.E. (16) is periodic with frequency ω . The frequency of the driving force in (16) is of frequency β . Now we study the nature of solution of D.E. (16).

When $\omega = \beta$: In this case the particular integral of D.E. (16), which is the forced solution, is

$$x_p = \frac{1}{D^2 + \omega^2} E_1 \cos \beta t = \frac{E_1}{2\omega} t \cdot \sin \beta t \quad (18)$$

Thus when $\omega = \beta$, the general solution of D.E. (16) is $x = x_c + x_p$ or

$$x = c_1 \cos \omega t + c_2 \sin \omega t + \frac{E_1}{2\omega} \cdot t \cdot \sin \beta t \quad (19)$$

The forced solution (the particular integral (18)) grows with time and becomes larger and larger (because of the presence of 't'). Thus in an undamped system if $\omega = \beta$ i.e., the frequency β of external force matches (equals) with the natural frequency

9.54 — HIGHER ENGINEERING MATHEMATICS—III

ω . The phenomenon of unbounded oscillations occurs, which is known as *resonance*. In resonance, for a bounded input the system responds with an unbounded output. Thus resonance, the phenomenon of excitation of large oscillation, is undesirable because the system may get destroyed due to these unwanted large vibrations.

Forced solution x_p (18) in the case of resonance

Fig. 9.6

WORKED OUT EXAMPLES

Free, undamped oscillations:

Example 1: An 8 lb weight is placed at one end of a spring suspended from the ceiling. The weight is raised to 5 inches above the equilibrium position and left free. Assuming the spring constant 12 lb/ft, find the equation of motion, displacement function $x(t)$, amplitude, period, frequency and maximum velocity.

Solution: $\frac{w}{g}\ddot{x} = -kx$. Here $\omega = 8$, $g = 32$, $k = 12$. The equation of motion is $\frac{8}{32}\ddot{x} + 12x = 0$ or

$$\frac{d^2x}{dt^2} + 48x = 0$$

The auxiliary equation $r^2 + 48 = 0$ has two complex conjugate roots given by $r = \pm 4\sqrt{3}i$. The displacement function $x(t)$ is

$$x(t) = C_1 \cos \omega t + C_2 \sin \omega t$$

where $\omega = 4\sqrt{3}$. The given initial conditions are $x = -5$ inches $= -\frac{5}{12}$ ft and $\dot{x} = 0$ at $t = 0$. Using $x = -\frac{5}{12}$ at $t = 0$, we get $-\frac{5}{12} = x(0) = C_1 \cdot 1 + C_2 \cdot 0 \therefore C_1 = -\frac{5}{12}$.

Differentiating $x(t)$ w.r.t. ' t ' we get

$$\dot{x} = -C_1\omega \sin \omega t + C_2\omega \cos \omega t$$

Using $\dot{x} = 0$ at $t = 0$, we get

$$0 = \dot{x} = -C_1\omega \cdot 0 + C_2\omega \cdot 1 \quad \therefore C_2 = 0$$

$$x(t) = -\frac{5}{12} \cos 4\sqrt{3}t = \frac{5}{12} \sin \left(4\sqrt{3}t - \frac{\pi}{2} \right)$$

Amplitude is $\frac{5}{12}$ feet

$$\text{Period } T = \frac{2\pi}{\omega} = \frac{2\pi}{4\sqrt{3}} = \frac{\pi\sqrt{3}}{6} \text{ sec}$$

$$\text{Frequency : } f = \frac{6}{\pi\sqrt{3}} \text{ cycles/sec}$$

$$\text{Maximum velocity: } \omega \cdot (\text{Amplitude}) = (4\sqrt{3}) \left(\frac{5}{12} \right) = \frac{5}{\sqrt{3}} \text{ ft/sec}^2.$$

Free, Damped Oscillation

Example 2: A 2 lb weight suspended from one end of a spring stretches it to 6 inches. A velocity of 5 ft/sec² upwards is imparted to the weight at its equilibrium position. Suppose a damping force βv acts on the weight. Here $0 < \beta < 1$ and $v = \dot{x} =$ velocity. (a) Determine the position and velocity of the weight at any time (b) Express the displacement function $x(t)$ in the amplitude-phase form. (c) Find the amplitude, period, frequency, maximum velocity (d) Determine the values of β for which the system is critically damped, over damped or oscillatory. (e) Discuss the case for $\beta = 0.6$.

Solution: Since a 2 lb weight stretches to $\frac{1}{2}$ feet, from Hookes law, we get

$2 = k \cdot \frac{1}{2}$ or $k = 4$ is spring constant. Then the D.E. of motion is

$$\frac{w}{g}\ddot{x} + \beta\dot{x} + kx = 0$$

$$\text{or } \frac{2}{32}\ddot{x} + \beta\dot{x} + 4x = 0$$

$$\frac{d^2x}{dt^2} + 16\beta\frac{dx}{dt} + 64x = 0$$

The auxiliary equation is

$$r^2 + 16\beta + 64 = 0$$

$$\text{with roots } r = \frac{-16\beta \pm \sqrt{256\beta^2 - 256}}{2}$$

$$= 8(-\beta \pm \sqrt{\beta^2 - 1})$$

$$r = 8(-\beta \pm \sqrt{1 - \beta^2}i) = 8(-\beta \pm \alpha i) \text{ where } \alpha = \sqrt{1 - \beta^2}$$

The general solution is

$$x(t) = e^{-8\beta t} [c_1 \cos 8\alpha t + c_2 \sin 8\alpha t]$$

Using the initial condition $x = 0$ at $t = 0$,

$$0 = 1 \cdot [c_1 \cdot 1 + c_2 \cdot 0] \quad \therefore c_1 = 0$$

Differentiating $x(t)$ w.r.t. 't', we get

$$\dot{x} = -8\beta e^{-8\beta t} [c_1 \cos 8\alpha t + c_2 \sin 8\alpha t]$$

$$+ e^{-8\beta t} [-c_1 8\alpha \sin 8\alpha t + c_2 8\alpha \cos 8\alpha t]$$

Initially $\dot{x} = -5$ so at $t = 0$,

$$-5 = \dot{x} = -8\beta \cdot 1 [c_1 \cdot 1 + c_2 \cdot 0] + 1 \cdot [-c_1 \cdot 8\alpha \cdot 0 +$$

$$+ c_2 \cdot 8\alpha \cdot 1]$$

$$\therefore c_2 = \frac{-5}{8\alpha}$$

(a) Thus the displacement function is

$$x(t) = e^{-8\beta t} \left(\frac{-5}{8\alpha} \right) \sin 8\alpha t$$

and velocity downward positive is

$$v = \dot{x} = \frac{-5}{8\alpha} e^{-8\beta t} [-8\beta \sin 8\alpha t + 8\alpha \cos 8\alpha t]$$

$$\dot{x} = \frac{5}{\alpha} e^{-\beta t} [-\alpha \cos 8\alpha t + 8\beta \sin 8\alpha t]$$

(b) Rewriting $x(t)$ as

$$x(t) = \frac{5}{8\alpha} e^{-8\beta t} \sin (8\alpha t + \pi)$$

which is in the amplitude-phase form

(c) Amplitude: $A(t) = \frac{5}{8\alpha} e^{-8\beta t}$

$$\text{Period: } T = \frac{2\pi}{\omega} = \frac{2\pi}{8\alpha} = \frac{\pi}{4\alpha}$$

$$\text{Frequency: } f = \frac{1}{T} = \frac{4\alpha}{\pi}$$

$$\text{Maximum velocity: } \omega \cdot A = 8\alpha \left(\frac{5}{8\alpha} e^{-8\beta t} \right)$$

$$= 5e^{-8\beta t}$$

(d) If the discriminant of the auxiliary equations

$$\beta^2 \geq 0$$

accordingly the system is said to be over or critically or under damped. Thus the given (mass-spring) system is

(i) over damped if $\beta^2 > 1$

(ii) critically damped if $\beta^2 = 1$

(iii) under damped if $\beta^2 < 1$ (i.e., oscillatory)

(e) If $\beta = 0.6$ then

$$x(t) = \frac{-5}{6.4} e^{-4.8t} \sin 6.4t$$

$$v(t) = e^{-4.8t} [3.75 \sin 6.4t - 5 \cos 6.4t]$$

$$\text{Amplitude: } \frac{5}{6.4} e^{-4.8t}$$

$$\text{Period: } \frac{\pi}{3.2}$$

$$\text{Frequency: } \frac{3.2}{\pi}$$

Since $\beta^2 = 0.36 < 1$, the system is damped i.e., it is oscillatory

Forced Damped Oscillations

Example 3: A 16 lb weight is suspended from a spring having a constant 5 lb/ft. Assume that an external force given by $24 \sin 10t$ and a damping force $4v$ are acting on the spring. Initially the weight is at rest at its equilibrium position.

(a) Find the position of the weight at any time.

(b) Indicate the transient and steady-state solutions

(c) Find the amplitude, period and frequency of the steady-state solution

(d) Determine the velocity of the weight at any time.

Solution: The D.E. is

$$\frac{\omega}{g} \ddot{x} = -c\dot{x} - kx + F(t)$$

$$\text{or } \frac{16}{32} \ddot{x} + 4\dot{x} + 5x = 24 \sin 10t$$

$$\text{or } \frac{d^2x}{dt^2} + 8\frac{dx}{dt} + 10x = 48 \sin 10t$$

which is a second order linear non-homogeneous D.E. with constant coefficients. Its auxiliary equation is

$$r^2 + 8r + 10 = 0 \quad \text{or} \quad r = \frac{-8 \pm \sqrt{64 - 40}}{2}$$

so two real distinct roots $r_1 = -4 - \sqrt{6}$, $r_2 = -4 + \sqrt{6}$. Then the complementary function is

$$x_c(t) = c_1 e^{r_1 t} + c_2 e^{r_2 t}$$

9.56 — HIGHER ENGINEERING MATHEMATICS—III

Now the particular integral is

$$\begin{aligned}x_p &= \frac{1}{D^2 + 8D + 10} 48 \sin 10t = \frac{48}{-100 + 8D + 10} \sin 10t \\&= \frac{48(8D + 90)}{(8D + 90)(8D - 90)} \sin 10t = \frac{48(8D + 90)}{64D^2 - 8100} \sin 10t \\&= \frac{48[80 \cos 10t + 90 \sin 10t]}{64(-100) - 8100} \\x_p &= \frac{-48}{1450} (8 \cos 10t + 9 \sin 10t)\end{aligned}$$

The position of weight at any time is

$$x(t) = c_1 e^{r_1 t} + c_2 e^{r_2 t} - \frac{48}{1450} (8 \cos 10t + 9 \sin 10t).$$

Use the initial condition: $x = 0$ at $t = 0$

$$0 = x(0) = c_1 + c_2 - \frac{48}{1450} (8) \quad \therefore c_1 + c_2 = \frac{384}{1450}$$

Differentiating $x(t)$ w.r.t. ' t ', we get

$$\dot{x}(t) = r_1 c_1 e^{r_1 t} + r_2 c_2 e^{r_2 t} - \frac{48}{1450} [-80 \sin 10t + 90 \cos 10t]$$

Use the initial condition: $\dot{x} = 0$ at $t = 0$.

$$\begin{aligned}0 &= \dot{x}(0) = r_1 c_1 + r_2 c_2 - \frac{48 \times 9}{145} \\(-4 - \sqrt{6})c_1 + (-4 + \sqrt{6})c_2 &= \frac{-432}{145}\end{aligned}$$

Solving for c_1 and c_2 , we get the required solution as

$$(a) \quad x(t) = 0.96e^{-1.56t} - 0.695e^{-6.45t} - 0.298 \sin 10t - 0.265 \cos 10t$$

(b) Transient solution is

$$0.960 e^{-1.56t} - 0.695 e^{-6.45t}$$

Steady-state solution is

$$\begin{aligned}-0.298 \sin 10t - 0.265 \cos 10t \\= 0.397 \sin(10t + 3.87)\end{aligned}$$

(c) Steady-state part:

Amplitude = 0.397 feet

Period = $\frac{2\pi}{\omega} = \frac{2\pi}{10} = \frac{\pi}{5}$ sec

Frequency = $\frac{5}{\pi}$ cycles/sec.

(d) The velocity of the weight at any time is

$$\begin{aligned}\dot{x}(t) &= -1.5e^{-1.56t} + 4.483 e^{-6.45t} - 2.98 \cos 10t + \\&\quad + 2.65 \sin 10t\end{aligned}$$

Resonance : Forces Undamped Oscillations

Example 4: A 32 lb weight is suspended from a spring having constant 4 lb/ft. Prove that the motion is one of resonance if a force $16 \sin 2t$ is applied and damping force is negligible. Assume that initially the weight is at rest in the equilibrium position.

Solution: The D.E. describing this phenomena is

$$\frac{32}{32} \ddot{x} + 4x = 16 \sin 2t$$

The roots of the auxiliary equation $r^2 + 4 = 0$ are complex conjugate $\pm 2i$. The complementary function is

$$x_c(t) = c_1 \cos 2t + c_2 \sin 2t$$

The particular integral is

$$x_p = \frac{1}{D^2 + 4} 16 \sin 2t = \frac{-16 \cdot t \cdot \cos 2t}{2 \cdot 2} = -4t \cos 2t$$

. Then the general solution is

$$x(t) = c_1 \cos 2t + c_2 \sin 2t - 4t \cos 2t$$

Using $x = 0$ at $t = 0$

$$0 = x(0) = c_1 \cdot 1 + c_2 \cdot 0 - 0 \quad \therefore c_1 = 0$$

Differentiating $x(t)$ w.r.t. ' t ', we get

$$\dot{x} = 2c_2 \cos 2t - 4 \cos 2t + 8t \sin 2t$$

Using $\dot{x} = 0$ at $t = 0$

$$0 = \dot{x}(0) = 2c_2 \cdot 1 - 4 \cdot 1 + 0 \quad \therefore c_2 = 2$$

The position of weight at any time is

$$x(t) = 2 \sin 2t - 4t \cos 2t = \sqrt{2^2 + 4t^2} \sin(2t - \phi)$$

and its velocity is

$$\dot{x} = 4 \cos 2t - 4 \cos 2t + 8t \sin 2t = 8t \sin 2t$$

Frequency of the external force is $\frac{2}{2\pi} = \frac{1}{\pi}$ cycles/sec. Natural frequency (of the free undamped)

system is $\frac{2}{2\pi} = \frac{1}{\pi}$ cycles/sec. Therefore *resonance* occurs in the system because the frequency of the external force equals to the natural frequency of the system.

EXERCISE

Free Undamped Oscillations

1. An 8 lb weight is placed at the lower end of a coil spring suspended from the ceiling. The weight comes to rest in its equilibrium position, thereby stretching the spring 6 inches. The weight is then pulled down 3 inches below its equilibrium position and released at $t = 0$ with an initial velocity of 1 ft/sec directed downward. Neglecting air resistance of the medium and assuming that no external forces are present, determine the amplitude, period and frequency of the resulting motion.

Ans. Amplitude $\frac{\sqrt{5}}{8} \approx 0.280$ ft, period $= \frac{2\pi}{8} = \frac{\pi}{4}$ sec.

Frequency: $\frac{4}{\pi}$ oscillations/sec.

Hint: $\frac{8}{32}\ddot{x} + 16x = 0$, $x(0) = \frac{1}{4}$, $\dot{x} = 1$ roots $\pm 8i$, $x(t) = c_1 \cos 8t + c_2 \sin 8t$, $c_1 = \frac{1}{8}$, $c_2 = \frac{1}{4}$, $x = \frac{\sqrt{5}}{8} \cos(8t + \phi)$

2. Determine the displacement of a body of weight 10 kg attached to a spring given that 20 kg weight will stretch the spring to 10 cm. Find the maximum velocity and period of oscillations

Ans. $x(t) = 0.2 \cos 14t$, Max. velocity $= 14(0.2) = 2.8$ m/sec.

period: $\frac{2\pi}{14} = 0.45$ sec

Hint Spring constant $k = 200$ kg/m; Tension $= k(0.05 + x)$, $\frac{\omega}{g}\ddot{x} = \omega - T$, $\frac{10}{9.8}\ddot{x} = 10 - (10 + 200x)$ or $\ddot{x} + 14^2x = 0$.

3. A spring is such that it would be stretched to 6 inches by 12 lb weight. If the weight is pulled down 4 inches below the equilibrium point and given an upward velocity of 2 feet/sec, determine the motion of the weight assuming no damping. Find also the amplitude and period.

Ans: $x(t) = \frac{1}{3} \cos 8t - \frac{1}{4} \sin 8t$

Hint: $k = 24$ lb/ft, $\frac{12}{32}\ddot{x} + 24x = 0$, amplitude $= \frac{5}{12}$, Period: $\frac{\pi}{4}$

4. A 6 lb weight stretches a spring 6 inches. If the weight is pulled 4 inches below the equilibrium position, find the motion of weight. Find the amplitude, period, frequency and position, velocity and acceleration of the weight $\frac{1}{2}$ sec after it has been released.

Ans: $x = \frac{1}{3} \cos 8t$, Amplitude $\frac{1}{3}$ ft, period: $\frac{2\pi}{8} = \frac{\pi}{4}$ sec, frequency: $\frac{8}{2\pi} = \frac{4}{\pi}$ cycles/sec; At $t = \frac{1}{2}$ sec, $x = -0.219$, $\dot{x} = 2.01$, $\ddot{x} = 14.0$

Hint: $k = 12$, $\ddot{x} + 64x = 0$

5. An 8 lb weight is placed on a spring with spring constant $k = 12$ lb/ft. Find the motion amplitude, period and frequency if the weight is raised 5 inches and then thrust upward with velocity 5 ft/sec.

Ans: $x(t) = \frac{5}{12} \cos 4\sqrt{3}t + \frac{5\sqrt{3}}{12} \sin 4\sqrt{3}t$, Amplitude: $5/6$, Period $\pi/2\sqrt{3}$, Frequency $= 2\sqrt{3}/\pi$

Hint: $\ddot{x} + 48x = 0$, $x(0) = -\frac{5}{12}$, $\dot{x}(0) = -5$.

Free Damped Oscillations

6. A 32 lb weight is suspended from a coil spring stretches the spring to 2 ft. The weight is then pulled down 6 inches from the equilibrium position and released at $t = 0$. Find the motion of the weight and determine the nature of motion if the resistance of the medium is

(a) $4\dot{x}$, (b) $8\dot{x}$, (c) $10\dot{x}$.

Ans: $x(t) = e^{-2t}(c_1 \sin 2\sqrt{3}t + c_2 \cos 2\sqrt{3}t)$, $c_1 = \sqrt{3}/6$, $c_2 = \frac{1}{2}$,

$x = \frac{\sqrt{3}}{3}e^{-2t} \cos(2\sqrt{3}t - \frac{\pi}{6})$. Motion is damped oscillatory with period $2\pi/(2\sqrt{3})$; with damping factor $e^{-2t}/\sqrt{3}$.

Hint: $\ddot{x} + 4\dot{x} + 16x = 0$, $x(0) = \frac{1}{2}$, $\dot{x}(0) = 0$, roots $-2 \pm 2\sqrt{3}$

(b) $x(t) = (c_1 + c_2t)e^{-4t}$, $c_1 = \frac{1}{2}$, $c_2 = 2$, Motion is critically damped, and $x \rightarrow 0$ as $t \rightarrow \infty$

Hint: $\ddot{x} + 8\dot{x} + 16x = 0$, roots: $-4, -4$

9.58 — HIGHER ENGINEERING MATHEMATICS—III

(c) $x(t) = \frac{2}{3}e^{-2t} - \frac{1}{6}e^{-8t}$, overdamped case

Hint: $\ddot{x} + 10\dot{x} + 16x = 0$, roots: $-2, -8$

7. A 3 lb weight on a spring stretches it to 6 inches. Suppose a damping force βv is present ($\beta > 0$). Show that the motion is (a) critically damped if $\beta = 1.5$ (b) overdamped if $\beta > 1.5$ (c) oscillatory if $\beta < 1.5$

Hint: $\ddot{x} + \frac{32}{3}\beta\dot{x} + 64x = 0$

8. A weight of 980 gm is attached to a spring with spring constant $k = 20$ gm/cm. The resistance is $\frac{1}{4}v$. Find the motion of weight if it pulled down $\frac{1}{4}$ cm below its equilibrium position and then released. Also find the time it takes the damping factor to drop to $\frac{1}{10}$ of its initial value.

Ans: $x(t) = e^{-0.05t} [0.25 \cos(4.5)t + 0.003 \sin(4.5)t]$, time $t = 46$ sec.

Hint: $10\ddot{x} + \dot{x} + 200x = 0$, roots $-0.05 \pm 4.5i$ $x(0) = \frac{1}{4}$ cm, $\dot{x}(0) = 0$, damping factor = $re^{-0.05t}$. Here r is constant of proportionality. At time t , damping factor = $\frac{1}{10}r$ or $\frac{1}{10}r = re^{-0.05t}$ or $e^{t/20} = 10$.

9. A 2 lb weight is pulled 6 inches below its equilibrium position and then released. Assuming a spring constant $k = 16$, damping force $2\dot{x}$. Determine whether the motion is overdamped or critically damped.

Ans: Critically damped

Hint: $\ddot{x} + 32\dot{x} + 256x = 0$, roots: $-16, -16$. $x(t) = e^{-16t}(c_1 + c_2t)$, $x = 6$ inches and $\dot{x} = 0$ at $t = 0$, $c_1 = \frac{1}{2}$, $c_2 = 8$.

Forced Oscillations

10. If weight $\omega = 16$ lb, spring constant $k = 10$ lb/ft, damping force $2\dot{x}$, external force $F(t)$ is $5 \cos 2t$, find the motion of the weight given $x(0) = \dot{x}(0) = 0$. Write the transient and steady-state solutions. Describe the nature of these solutions.

Ans: $x(t) = e^{-2t} \left[-\frac{3}{8} \sin 4t - \frac{1}{2} \cos 4t \right] + \frac{1}{2} \cos 2t + \frac{1}{4} \sin 2t$.

Transient solution: $\frac{5e^{-2t}}{8} \cos(4t - 0.64)$,

representing a damped oscillatory motion, steady-state solution: $\frac{\sqrt{5}}{4} \cos(2t - 0.46)$, representing a simple harmonic motion with amplitude $\frac{\sqrt{5}}{4}$ and period π .

Hint: $\ddot{x} + 4\dot{x} + 20x = 10 \cos 2t$, $x(0) = \dot{x}(0) = 0$. $x(t) = \frac{5e^{-2t}}{8} \cos(4t - \phi) + \frac{\sqrt{5}}{4} \cos(2t - \theta)$ with $\tan \theta = \frac{1}{2}$, $\tan \phi = \frac{3}{4}$.

11. Determine the transient and steady-state solutions of mechanical system with weight $w = 6$ lb, stiffness constant $k = 12$, damping force $1.5\dot{x}$, external force $24 \cos 8t$ and initial conditions $x = \frac{1}{3}$ ft, $\dot{x} = 0$.

Ans: Transient: $\frac{e^{-4t}}{9} (3 \cos 4\sqrt{3}t - 11\sqrt{3} \sin 4\sqrt{3}t)$. Steady-state $2 \sin 8t$.

Hint: $\ddot{x} + 8\dot{x} + 64x = 128 \cos 8t$, root: $-4 \pm 4\sqrt{3}i$.

Find the steady-state and transient oscillations of the mechanical system corresponding to the following D.E.

12. $\ddot{x} + 3\dot{x} + 2x = 10 \sin t$

Ans: $\sin t - 3 \cos t$, $c_1 e^{-2t} + c_2 e^{-t}$

13. $\ddot{x} + 2\dot{x} + 2x = \sin 2t - 2 \cos 2t$, $x(0) = \dot{x}(0) = 0$

Ans: $-0.5 \sin 2t; e^{-t} \sin t$

Resonance: Forced Undamped Oscillations

14. If a weight 6 lbs hangs from a spring with constant $k = 12$ and no damping force exists, find the motion of weight when an external force $3 \cos 8t$ acts. Initially $x = 0$ and $\dot{x} = 0$. Determine whether resonance occurs.

Ans: $x(t) = t \sin 8t$, resonance occurs.

Hint: $\ddot{x} + 64x = 16 \cos 8t$, solution is $x(t) = c_1 \cos 8t + c_2 \sin 8t + t \sin 8t$, use I.C., $c_1 = c_2 = 0$.

15. A 64 lb weight is attached to the lower end of a coil spring with spring constant 18 lb/ft. An external force $3 \cos \omega t$ is applied to the system. If the weight is pulled down to 6 inches below its

equilibrium position and released from rest at $t = 0$, (a) Assuming a damping force $4\dot{x}$ determine the resonance frequency of the resulting motion (b) If there is no damping, determine the value of ω that gives rise to undamped resonance

Ans: (a) resonance frequency $\frac{1}{2\pi} \sqrt{\frac{18}{2} - \frac{1}{2} \left(\frac{16}{4}\right)} \approx 0.42$ cycles/sec. Thus resonance occurs when $\omega = \sqrt{7} \approx 2.65$. (b) $C =$ damping constant $= 0$, thus undamped resonance occurs when $\omega = 3$.

Hint: (a) $2\ddot{x} + 4\dot{x} + 18x = 3 \cos \omega t$
 (b) $\ddot{x} + 9x = \frac{3}{2} \cos \omega t$, C.F. : $x_c = c_1 \sin 3t + c_2 \cos 3t$ with natural frequency $\frac{3}{2\pi}$. Initial conditions $x(0) = \frac{1}{2}$, $\dot{x}(0) = 0$, then $x(t) = \frac{1}{2} \cos 3t + \frac{1}{4}t \sin 3t$.

16. Determine forced solutions if resonance occurs in a mechanical system consisting of a weight ω attached to a spring with stiffness constant $k = 24$ lb/ft and an applied external force $2 \cos 2t$. What should be the value of the weight w in this case?

Ans: Forced solution: $\frac{1}{12}t \sin 2t$; weight $w = 6$ g.

Hint: $\omega\ddot{x} + 24gx = 2g \cos 2t$, since resonance occurs, period of free oscillations $\frac{2\pi}{\omega} =$ period of forced oscillations π so $\sqrt{\left(\frac{24g}{\omega}\right)} = \pi$
 $w = 6$ g.

17. Determine whether resonance occurs in a system consisting of a weight 32 lb attached to a spring with constant $k = 4$ lb/ft and external force $16 \sin 2t$ and no damping force present. Initially $x = \frac{1}{2}$ and $\dot{x} = -4$.

Ans: Resonance occurs

Hint: $\ddot{x} + 4x = 16 \sin 2t$, $x(t) = \frac{1}{2} \cos 2t - 4t \cos 2t$. Natural frequency of system $= \frac{2}{2\pi}$ and frequency of the forcing function $= \frac{2}{2\pi}$.

9.14 RLC-CIRCUIT

An RLC-series circuit consists of a resistor, a conductor, a capacitor and an emf as shown in the figure.

Fig. 9.7

Using the Kirchhoff's law, the sum of the voltage drops across the three elements inductor, resistor and capacitance equal to the external source E . Thus the RLC-circuit is modeled by

$$L \frac{dI}{dt} + RI + \frac{1}{C}Q = E(t) \quad (1)$$

which contains two dependent variable Q and I . Since $I = \frac{dQ}{dt}$, the above equation can be written as

$$L \frac{d^2Q}{dt^2} + R \frac{dQ}{dt} + \frac{1}{C}Q = E(t) \quad (2)$$

which contains only one dependent variable Q . Differentiating (1) w.r.t. ' t ', we obtain

$$L \frac{d^2I}{dt^2} + R \frac{dI}{dt} + \frac{1}{C}I = \frac{dE}{dt} \quad (3)$$

which contains only one dependent variable I . Thus the charge Q and current I at any time in the RLC circuit are obtained as solutions of (2) and (3) which are both linear 2nd order non homogeneous ordinary differential equations. The equation (3) is used more often, since current $I(t)$ is more important than charge $Q(t)$, in most of the practical problems. The RLC-circuit reduces to an RL-circuit in absence of capacitor and to RC-circuit when no inductor is present.

Example 1: Determine the current $I(t)$ in an RLC-circuit with (a) emf $E(t) = E_0 \cos \omega t$ (b) emf $E(t) = E_0 \sin \omega t$.

Solution: The differential equation representing the RLC-circuit with I as the dependent variable is given

9.60 — HIGHER ENGINEERING MATHEMATICS—III

by

$$L \frac{d^2 I}{dt^2} + R \frac{dI}{dt} + \frac{1}{C} I = \frac{dE}{dt} \quad (3)$$

Since $e^{i\theta} = \cos \theta + i \sin \theta$, consider $E(t) = E_0 e^{i\omega t} = E_0 (\cos \omega t + i \sin \omega t)$

so that both the problems (a) and (b) can be solved simultaneously by using the complex form for emf $E(t)$. Thus

$$L \frac{d^2 I}{dt^2} + R \frac{dI}{dt} + \frac{1}{C} I = E_0 \cdot \omega i e^{i\omega t} \quad (4)$$

The general solution of (4) = Complimentary function (C.F.) + particular integral (P.I.). Complementary Function : I_C

The auxiliary equation is

$$Lm^2 + Rm + \frac{1}{C} = 0$$

$$m^2 + \frac{R}{L}m + \frac{1}{LC} = 0$$

With two distinct roots

$$m_{1,2} = \frac{-\frac{R}{L} \pm \sqrt{\left(\frac{R}{L}\right)^2 - 4 \cdot \frac{1}{LC}}}{2}$$

$$m_{1,2} = -\frac{R}{2L} \pm \frac{1}{2L} \sqrt{R^2 - \frac{4L}{C}} \quad (5)$$

$$m_1 = -a + b$$

and $m_2 = -a - b$ where $b = \frac{1}{2L} \sqrt{R^2 - \frac{4L}{C}}$, $a = \frac{R}{2L}$

The complimentary function I_C is given by

$$I_C = c_1 e^{m_1 t} + c_2 e^{m_2 t} \quad (6)$$

Particular Integral: I_p

Assume the particular solution of (3) as

$$I_p = A e^{i\omega t} \quad (7)$$

where A is an undetermined constant obtained by substituting (7) in (3). Then

$$L(i\omega)^2 A e^{i\omega t} + Ri\omega A e^{i\omega t} + \frac{1}{C} A e^{i\omega t} = iE_0 \omega e^{i\omega t}$$

or $(-\omega^2 L + i\omega R + \frac{1}{C}) A e^{i\omega t} = E_0 \omega i e^{i\omega t}$. Then

$$A = \frac{E_0 \omega i}{(-\omega^2 L + \frac{1}{C}) + i\omega R}$$

$$= \frac{E_0 i}{-(\omega L - \frac{1}{\omega C}) + iR}$$

The particular solution i.e., $\text{Re}(I_p)$. Thus when $E = E_0 \cos \omega t$, the steady-state solution is

$$I_p = \frac{E_0}{\sqrt{R^2 + S^2}} \cdot \cos(\omega t - \delta) \quad (10)$$

Similarly when $E = E_0 \sin \omega t$, the steady-state solution is the imaginary part of I_p , namely,

$$I_p = \frac{E_0}{\sqrt{R^2 + S^2}} \sin(\omega t - \delta) \quad (11)$$

Complex number $z = R + is$ is known as the *complex impedance*. Its magnitude $\sqrt{R^2 + S^2}$ is known as simply *impedance* R . The real part of z is *resistance* while S , the imaginary part of z is called the *reactance* and $\frac{1}{z}$ is called the *admittance*.

Put $S = \omega L - \frac{1}{\omega C}$ Then

$$A = \frac{E_0 i}{-S + iR} = \frac{E_0}{R + iS}$$

Then $I_p = A e^{i\omega t} = \frac{E_0}{R + iS} e^{i\omega t} \quad (8)$

Here S is known as *reactance* of the circuit. When $S = 0$, the amplitude of I is greatest and the circuit is in resonance.

Using the polar form of a complex number

$$a + ib = r e^{i\theta} = \sqrt{a^2 + b^2} e^{i\theta}$$

where $r = \sqrt{a^2 + b^2}$ and $\theta = \tan^{-1} \frac{b}{a}$, we can write I_p as

$$I_p = \frac{E_0}{\sqrt{R^2 + S^2}} e^{i\omega t} = \frac{E_0}{\sqrt{R^2 + S^2}} e^{i(\omega t - \delta)}$$

$$I_p = \frac{E_0 [\cos(\omega t - \delta) + i \sin(\omega t - \delta)]}{\sqrt{R^2 + S^2}} \quad (9)$$

where $\tan \delta = \frac{S}{R}$. The quantity $\sqrt{R^2 + S^2}$ is known as impedance of the circuit.

For an impressed voltage $E(t) = E_0 \cos \omega t = \text{Real part of } (E_0 e^{i\omega t}) = \text{Re}(E_0 e^{i\omega t})$, the steady-state current in the RLC-circuit is given by the real part. Since $R > 0$, the transient solution

$$I_C = c_1 e^{m_1 t} + c_2 e^{m_2 t} \rightarrow 0$$

as $t \rightarrow \infty$. Thus after long time, the out put will be a harmonic oscillation given by either (10) or (11) as the case may be.

RLC-circuit

WORKED OUT EXAMPLES

Example 1: A circuit consists of an inductance of 0.05 henrys, a resistance of 5 ohms and a condensor of capacitance 4×10^{-4} farad. If $Q = I = 0$ when $t = 0$, find $Q(t)$ and $I(t)$ when (a) there is a constant emf of 110 volts (b) there is an alternating emf $200 \cos 100t$. (c) Find the steady-state solution in (b).

Solution:

(a) Here $L = 0.05$,

$$R = 5, C = 4 \times 10^{-4}, E = 110$$

The differential equation of the RLC-circuit

$$L \frac{d^2 Q}{dt^2} + R \frac{dQ}{dt} + \frac{Q}{C} = E(t)$$

now takes the form

$$0.05 \frac{d^2 Q}{dt^2} + 5 \frac{dQ}{dt} + \frac{Q}{4 \times 10^{-4}} = 110$$

$$\text{or } \frac{d^2 Q}{dt^2} + 100 \frac{dQ}{dt} + 50000 Q = 2200$$

Fig. 9.8

C.F.: A.E.: $m^2 + 100m + 50,000 = 0$ with roots

$$m = -50 \pm 50\sqrt{19}i$$

Complementary function

$$Q_F = e^{-50t} (A \cos 50\sqrt{19}t + B \sin 50\sqrt{19}t)$$

Particular integral:

$$Q_P = \frac{1}{D^2 + 100D + 50,000} 2200 = \frac{2200}{50,000} = \frac{11}{250}$$

The general solution is $Q = Q_C + Q_F$,

$$Q = e^{-50t} (A \cos \omega t + B \sin \omega t) + \frac{11}{250}$$

where $\omega = 50\sqrt{19}$. Since $Q = 0$ at $t = 0$, we have

$$0 = A + \frac{11}{250} \quad \text{or} \quad A = -\frac{11}{250}$$

Now differentiating Q w.r.t. 't', get

$$I(t) = \frac{dQ}{dt} = e^{-50t} [-\omega A \sin \omega t + B \omega \cos \omega t]$$

$$-50 e^{-50t} (A \cos \omega t + B \sin \omega t)$$

Since $I = 0$ at $t = 0$, we have

$$0 = B\omega - 50A \quad \text{or} \quad B = \frac{50A}{\omega}$$

i.e., $B = \frac{50}{50\sqrt{19}} \cdot \left(-\frac{11}{250}\right) = -\frac{11\sqrt{19}}{4750}$. Thus

$$Q(t) = e^{-50t} \left(-\frac{11}{250} \cos 50\sqrt{19}t - \frac{11\sqrt{19}}{4750} \sin 50\sqrt{19}t \right) + \frac{11}{250}$$

and

$$I(t) = e^{-50t} [(B\omega - 50A) \cos \omega t + (-\omega A - 50B) \sin \omega t]$$

$$I(t) = \frac{44}{\sqrt{19}} e^{-50t} \sin 50\sqrt{19}t$$

(b) When $E(t) = 200 \cos 100t$; the equation is

$$\frac{d^2 Q}{dt^2} + 100 \frac{dQ}{dt} + 50,000 Q = 40,000 \cos 100t$$

for which the complementary is same as in the above case (a).

The particular integral Q_P is

$$Q_P = \frac{1}{D^2 + 100D + 50,000} 40,000 \cos 100t$$

9.62 — HIGHER ENGINEERING MATHEMATICS—III

$$= \frac{40,000}{-10,000 + 100D + 50,000} \cdot \cos 100t$$

$$= \frac{40(D + 400)}{(D - 400)(D + 400)} \cos 100t$$

$$= \frac{40(D + 400)}{-10,000 - 1,60,000} \cos 100t$$

$$= \frac{-4}{17000} [-100 \sin 100t - 400 \cos 100t]$$

$$Q_p = \frac{4 \sin 100t + 16 \cos 100t}{170}$$

Thus

$$Q(t) = e^{-50t} \left(-\frac{16}{170} \cos \omega t - \frac{12\sqrt{19}}{1615} \sin \omega t \right) + \frac{4}{170} (4 \cos 100t + \sin 100t)$$

Differentiating Q w.r.t. ' t ', we get

$$I(t) = e^{-50t} \left(-\frac{40}{17} \cos \omega t + \frac{1640}{323} \sqrt{19} \cdot \sin \omega t \right) + \frac{40}{17} (\cos 100t - 4 \sin 100t)$$

$$\text{where } \omega = 50\sqrt{19}$$

- (c) The steady-state solutions are obtained in the limiting case as $t \rightarrow \infty$. Taking $t \rightarrow \infty$, we get the steady-state solutions as

$$Q(t) = \frac{4}{170} (4 \cos 100t + \sin 100t)$$

and

$$I(t) = \frac{40}{17} (\cos 100t - 4 \sin 100t)$$

RLC-circuits

EXERCISE

- Determine the charge on the capacitor at any time $t > 0$ in a circuit in series having an emf given by $E(t) = 100 \sin 60t$ V, a resistor of 2Ω , an inductor of 0.1 H and a capacitor of

$\frac{1}{260}$ farads if the initial current and initial charge on the capacitor are both zero. Find the steady-state solution.

$$\text{Ans. } Q(t) = \frac{6e^{-10t}}{61} (6 \sin 50t + 5 \cos 50t) - \frac{5}{\sqrt{61}} (5 \sin 60t + 6 \cos 60t)$$

$$\text{or } Q(t) = \frac{6\sqrt{61}}{61} e^{-10t} \cos(50t - \phi)$$

$$-\frac{5\sqrt{61}}{61} \cos(60t - \theta) \text{ where } \cos \phi = 5/\sqrt{61}, \sin \phi = 6/\sqrt{61}, \cos \theta = 6/\sqrt{61}, \sin \theta = 5/\sqrt{61}.$$

$$\text{Steady-state solution: } Q(t) = -\frac{5}{61} (5 \sin 60t + 6 \cos 60t)$$

Hint: $\frac{d^2Q}{dt^2} + 20\frac{dQ}{dt} + 2600Q = 1000 \sin 60t$, roots of A.E.: $r^2 + 20r + 2600$ are $-10 \pm 50i$; use $Q(0) = I(0) = 0$

- Assuming $Q = I = 0$ at $t = 0$, in an RLC-circuit having a source of voltage $E(t) = 155 \sin 377t$, $R = 100 \Omega$, $L = 0.1$ henry, $C = 10^{-3}$ farad, determine the current at any instant of time.

$$\text{Ans. } I(t) = -0.042 e^{-10t} + 0.526 e^{-990t} - 0.484 \cos 377t + 1.380 \sin 377t.$$

Hint: $0.1 \frac{d^2I}{dt^2} + 100 \frac{dI}{dt} + 1000I = (155)(377 \cos 377t)$ A.E.: $0.1r^2 + 100r + 1000 = 0$ has roots $r_1 = -10$, $r_2 = -990$

- An electric circuit consists of an inductance of 0.1 henry, a resistance of 20 ohms and a condenser of capacitance 25 micro farads (one micro = 10^{-6}). Find the charge Q and the current I at any time t , with the following initial conditions (a) $Q = 0.05$ coulomb, $I = \frac{dQ}{dt} = 0$ when $t = 0$ (b) $Q = 0.05$, $I = -0.2$ ampere when $t = 0$ (c) what will be Q and I after a long time?

$$\text{Ans. (a) } Q(t) = e^{-100t} (0.05 \cos 624.5t + 0.008 \sin 624.5t)$$

$$I(t) = -0.32 e^{-100t} \sin 624.5t$$

$$\text{(b) } Q = e^{-100t} (0.05 \cos 624.5t + 0.0077 \sin 624.5t)$$

$$I = e^{-100t} (-0.2 \cos 624.5t - 32.0 \sin 624.5t)$$

(c) Q and $I \rightarrow 0$ as $t \rightarrow \infty$ since both solution are transient containing e^{-t} .

Hint: $\ddot{Q} + 200 \dot{Q} + 400,000 Q = 0$.

4. Determine Q and I in an RLC-circuit with $L = 0.05$ H, $R = 20 \Omega$, $C = 100$ micro F, emf $E = 100$ V. With $Q = 0$, $I = 0$ at $t = 0$.

Ans. $Q = e^{-200t} (-0.01 \cos 400t - 0.005 \sin 400t) + 0.01$, $I = 5e^{-200t} \sin 400t$

Hint: $\ddot{Q} + 400 \dot{Q} + 200,000 Q = 2000$

5. (a) Solve the above problem 4 when emf $E(t) = 100 \cos 200t$ (b) Find the steady-state solutions.

Ans. $Q = e^{-200t} [-0.01 \cos 400t - 0.0075 \sin 400t] + 0.01 \cos 200t + 0.005 \sin 200t$

$$I = e^{-200t} [-\cos 400t + 5.5 \sin 400t] - 2 \sin 200t + \cos 200t$$

(b) Steady-state solutions are obtained by taking limit as $t \rightarrow \infty$. They are

$$Q = 0.01 \cos 200t + 0.005 \sin 200t$$

$$I = \cos 200t - 2 \sin 200t$$

Hint: $\ddot{Q} + 400 \dot{Q} + 200,000 Q = 2000 \cos 200t$

6. (a) Determine Q and I in the RLC-circuit with $L = 0.5$ H, $R = 6 \Omega$, $C = 0.02$ F, $E(t) = 24 \sin 10t$ and initial conditions $Q = I = 0$ at $t = 0$ (b) state the steady-state and transient solutions.

Ans. (a) $Q = \frac{e^{-6t}}{10} [4 \cos 8t + 3 \sin 8t] - \frac{2}{5} \cos 10t$

$$I = \frac{e^{-6t}}{10} [-32 \sin 8t + 24 \cos 8t] - \frac{6}{10} e^{-6t} [4 \cos 8t + 3 \sin 8t] + 4 \sin 10t$$

(b) Transient solutions of Q and I are

$$Q_{tr} = \frac{e^{-6t}}{10} [4 \cos 8t + 3 \sin 8t]$$

$$I_{tr} = \frac{e^{-6t}}{10} [-50 \sin 8t]$$

Steady-state solutions of Q_s and I_s are $Q_s = -\frac{2}{5} \cos 10t$, $I_s = 4 \sin 10t$

7. (a) Find Q and I in the RLC-circuit with $L = 2$, $R = 4$, $C = 0.05$, $E = 100$ and $Q(0) = \dot{Q}(0) = 0$. (b) Find the steady-state solutions.

Ans. (a) $Q(t) = 5 - \frac{5}{3} e^{-t} (3 \cos 3t + \sin 3t)$

$$I(t) = \frac{5}{3} e^{-t} (3 \cos 3t + \sin 3t) - \frac{5}{3} e^{-t} (3 \cos 3t - 9 \sin 3t)$$

(b) Steady-state solutions: as $t \rightarrow \infty$, $Q = 5$, $I = 0$.

8. Find $I(t)$ in the RLC-circuit with $E(t) = 100 \sin 200t$ V, $R = 40 \Omega$, $L = 0.25$ H, $C = 4 \times 10^{-4}$ F and $I(0) = 0$ and $Q(0) = 0.01$.

Ans. $I(t) = e^{-80t} (-4.588 \sin 60t + 1.247 \cos 60t) - 1.247 \cos 200t + 1.331 \sin 200t$

9.15 SIMPLE PENDULUM

A simple pendulum consists of a mass m (the bob) at the end of a straight wire of variable length $L(t)$ where t is the time. It is assumed that the mass of the wire is negligible compared to the mass of the bob.

Fig. 9.9

The pendulum is suspended from a fixed point of support O . The bob is free to move in a vertical plane due to force of gravity and given external force $F(t)$. Let θ be the angle which the wire OP makes with the vertical OX at time t , positive when measured

9.64 — HIGHER ENGINEERING MATHEMATICS—III

counterclockwise. The equation of angular motion $\theta(t)$ will be obtained by modeling using Newton's second law.

Assume that the moving pendulum experiences a viscous damping force $\bar{f}$ proportional to its linear velocity and opposing the motion. The other forces acting on the bob are the tension of the wire $\bar{T}$, gravity and a given external force $F(t)$. The tangential and normal components of the force of gravity mg are $-mg \sin \theta$ and $mg \cos \theta$. Let $\hat{r}$ and $\hat{\theta}$ be unit vectors, where $\hat{\theta}$ points in the direction of increasing θ . Then

$$\bar{v} = \frac{d}{dt}(L\hat{r}) = L\dot{\theta}\hat{\theta} + \frac{dL}{dt}\hat{r}$$

$$\bar{a} = \frac{d}{dt}\left[L\dot{\theta}\hat{\theta} + \frac{dL}{dt}\hat{r}\right]$$

$$\bar{a} = L\ddot{\theta}\hat{\theta} + \frac{dL}{dt}\dot{\theta}\hat{\theta} + \frac{d^2L}{dt^2}\hat{r} + \frac{dL}{dt}\frac{d\hat{r}}{dt} - L\dot{\theta}^2\hat{r}$$

Using Newton's second law we get two equations (along $\bar{r}$ and along $\hat{\theta}$)

$$-mL\dot{\theta}^2 + \frac{d^2L}{dt^2} = -T + mg \cos \theta$$

$$mL\ddot{\theta} = -\frac{2dL}{dt}\dot{\theta} - cL\dot{\theta} - mg \sin \theta + F(t)$$

Here c is the damping constant.

Thus the equation of the angular motion $\theta(t)$ of the forced damped simple pendulum with driving force $F(t)$ and of variable length $L(t)$ is given by

$$mL\ddot{\theta} + (2m\dot{L} + cL)\dot{\theta} + mg \sin \theta = F(t) \quad (1)$$

Assumptions:

1. When the length of the pendulum is *not* variable but fixed, then equation (1) reduces to

$$mL\ddot{\theta} + cL\dot{\theta} + mg \sin \theta = F(t) \quad (2)$$

2. Free undamped nonlinear equation of pendulum (with $c = 0$, $F(t) = 0$) is

$$mL\ddot{\theta} = -mg \sin \theta$$

$$L \frac{d^2\theta}{dt^2} = -g \sin \theta$$

Multiplying both sides by $2\frac{d\theta}{dt}$ on both sides

$$2\frac{d\theta}{dt} \cdot L \cdot \frac{d^2\theta}{dt^2} = -2g \cdot \sin \theta \frac{d\theta}{dt}$$

$$L \frac{d}{dt} \left(\frac{d\theta}{dt} \right)^2 = 2g \frac{d}{dt} (\cos \theta)$$

Integrating

$$L \left(\frac{d\theta}{dt} \right)^2 = 2g \cos \theta + c_1 \quad (3)$$

$$\frac{d\theta}{\sqrt{2g \cos \theta + c_1}} = \pm \frac{dt}{\sqrt{L}} \quad (4)$$

This integral (4) cannot be expressed in terms of elementary functions.

When the maximum displacement is α , then the angular velocity $\dot{\theta} = 0$. Put $\theta = \alpha$ and $\dot{\theta} = 0$ in (3).

Then $LO = 2g \cos \alpha + c_1 \therefore c_1 = -2g \cos \alpha$

Substituting c_1 in (3), we get

$$L\dot{\theta}^2 = 2g \cos \theta - 2g \cos \alpha$$

$$\text{or } \dot{\theta}^2 = \frac{2g}{L} (\cos \theta - \cos \alpha)$$

Since $\cos A = 1 - 2 \sin^2 \frac{A}{2}$, we can rewrite

$$\dot{\theta}^2 = \frac{4g}{L} \left(\sin^2 \frac{\alpha}{2} - \sin^2 \frac{\theta}{2} \right)$$

Change the variable of integration from θ to ϕ by the substitution

$$\sin \frac{\theta}{2} = \sin \frac{\alpha}{2} \cdot \sin \phi \quad (6)$$

and integrating w.r.t. ' t ', we get

$$t = \sqrt{\frac{L}{g}} \int_0^\phi \frac{d\phi}{\sqrt{1 - k^2 \sin^2 \phi}}, \text{ where } k^2 = \sin^2 \frac{\alpha}{2}.$$

This integral (6) is known as an elliptic integral of the first kind.

3. Equation (2) is non-linear second order non-homogeneous differential equation (with constant coefficients) with non-linearity arising through the term ' $\sin \theta$ '. Since

$$\sin \theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} \dots$$

for sufficiently small θ , the term $\sin \theta$ can be replaced by θ . Thus we get an approximate *linearized pendulum equation* with damping as

$$mL\ddot{\theta} + cL\dot{\theta} + mg\theta = F(t) \quad (7)$$

4. Free damped motion of the pendulum is obtained from (7) with $F(t) = 0$ as

$$mL\ddot{\theta} + cL\dot{\theta} + mg\theta = 0 \quad (8)$$

or
$$\frac{d^2\theta}{dt^2} + \frac{c}{m} \frac{d\theta}{dt} + \frac{g}{L}\theta = 0$$

This is second order linear homogeneous equation with auxiliary equation

$$\lambda^2 + \frac{c}{m}\lambda + \frac{g}{L} = 0$$

Its roots are $\lambda = -\frac{c}{m} \pm \sqrt{\frac{c^2}{m^2} - \frac{4g}{L}}$

Case (i) When $\frac{c}{m} > \frac{2g}{L}$ then the roots λ_1 and λ_2 are real and distinct. In this case the general solution is

$$\theta(t) = c_1 e^{\lambda_1 t} + c_2 e^{\lambda_2 t}$$

Case (ii) when $\frac{c}{m} = \frac{2g}{L}$, the roots are real and equal then the solution is

$$\theta(t) = (c_1 + t c_2) \cdot e^{\lambda t}$$

Case (iii) When $\frac{c}{m} < \frac{2g}{L}$ the roots are complex conjugate then the complete solution is

$$\theta(t) = e^{-kt} \cdot \left[c_1 \cos \sqrt{\omega^2 - k^2} t + c_2 \sin \sqrt{\omega^2 - k^2} t \right] \quad (9)$$

Here $k = \frac{c}{m}$, $\omega = \frac{2g}{L}$. Thus the pendulum motion is oscillatory with period $\frac{2\pi}{\sqrt{\omega^2 - k^2}}$ when $k < \omega$

5. Free undamped linear equation is obtained from (7) with $F(t) = 0$ and $c = 0$

$$mL\ddot{\theta} + mg\theta = 0$$

or
$$\frac{d^2\theta}{dt^2} + \frac{g}{L}\theta = 0 \quad (10)$$

The roots of the auxiliary equation are

$$\lambda^2 + \frac{g}{L} = 0 \quad \text{or} \quad \lambda = \pm \sqrt{\frac{g}{L}} i$$

The general solution of (10) is

$$\theta(t) = c_1 \cos \sqrt{\frac{g}{L}} t + c_2 \sin \sqrt{\frac{g}{L}} t \quad (11)$$

Thus the motion of the bob is simple harmonic and the time of an oscillation is $2\pi \sqrt{\frac{L}{g}}$. Observe that the period $2\pi \sqrt{\frac{L}{g}}$ is independent of the initial displacement. A beat or a swing of a pendulum is the movement of the bob from one end to the other constituting half an oscillation. Thus the time for one beat is $\pi \sqrt{\frac{L}{g}}$. Suppose a pendulum of length L makes n beats in time T , then

T = time of n beats = $n \cdot$ time for one beat

$$T = n \cdot \pi \sqrt{\frac{L}{g}}$$

or

$$n = \frac{T}{\pi} \sqrt{\frac{g}{L}}$$

Now taking log and differentiating both sides

$$\frac{dn}{n} = \frac{1}{2} \left(\frac{dg}{g} - \frac{dL}{L} \right) \quad (12)$$

Thus the gain or loss of oscillations of a pendulum due to change in g or L can be determined from (12).

Case (i) If L = constant and g is a variable, then

$$\frac{dn}{n} = \frac{1}{2} \frac{dg}{g}$$

Case (ii) : If g = constant and L is a variable, then

$$\frac{dn}{n} = -\frac{dL}{2L}$$

WORKED OUT EXAMPLES

Example 1: If a clock, loses 5 seconds/day, determine the alteration required in the length of the pendulum in order that the clock keeps correct time.

Solution: Since 24 hours = $24 \times 60 \times 60 = 86400$ seconds, a seconds pendulum beats 86400

9.66 — HIGHER ENGINEERING MATHEMATICS—III

times a day. As the clock loses 5 seconds/day

$$\frac{n + dn}{n} = \frac{86400 - 5}{86400}$$

$$\text{or } \frac{dn}{n} = \frac{86395}{86400} - 1$$

Assuming g as constant we have

$$\frac{86395}{86400} - 1 = \frac{dn}{n} = -\frac{dL}{2L}$$

$$\text{or } \frac{dL}{L} = +2 \left(1 - \frac{86395}{86400}\right) = \frac{10}{86400} = \frac{1}{8640}$$

i.e., $dL = \frac{1}{8640} L$. So the length of the pendulum be shortened by $\frac{1}{8640}$ of its original length.

Example 2: Find the angular motion $\theta(t)$ of a forced undamped pendulum whose equation is given by $\ddot{\theta} + \omega_0^2 \theta = F_0 \sin kt$ where ω_0 and F_0 are constants; if $x = \dot{x} = 0$ at $t = 0$.

Solution: The roots of the auxiliary equation are $\lambda^2 + \omega_0^2 = 0$ or $\lambda = \pm \omega_0 i$. The complementary function $\theta_c(t) = c_1 \cos \omega_0 t + c_2 \sin \omega_0 t$. The particular integral

$$\theta_p = \frac{F_0}{D^2 + \omega_0^2} \sin kt = F_0 \cdot \left(\frac{-t}{2\omega_0}\right) \cdot \cos \omega_0 t \text{ when } k = \omega_0.$$

Then the general solution is

$$\theta(t) = \theta_c(t) + \theta_p(t)$$

$$\theta(t) = c_1 \cos \omega_0 t + c_2 \sin \omega_0 t - \frac{F_0 t}{2\omega_0} \cos \omega_0 t$$

$$\text{At } t = 0, 0 = \theta(0) = c_1 + 0 - 0 \therefore c_1 = 0$$

Differentiating θ w.r.t. t

$$\dot{\theta} = -\omega_0 c_1 \sin \omega_0 t + c_2 \omega_0 \cos \omega_0 t - \frac{F_0}{2\omega_0} \cos \omega_0 t + \frac{F_0 t}{2} \sin \omega_0 t$$

$$\text{At } t = 0, 0 = \dot{\theta}(0) = 0 + c_2 \omega_0 - \frac{F_0}{2\omega_0} + 0$$

$$\therefore c_2 = \frac{F_0}{2\omega_0^2}$$

The required solution is $\theta(t) = \frac{F_0}{2\omega_0^2} \sin \omega_0 t - \frac{F_0 t}{2\omega_0} \cos \omega_0 t$.

$$\theta(t) = \frac{F_0}{2\omega_0^2} (\sin \omega_0 t - t \omega_0 \cdot \cos \omega_0 t)$$

EXERCISE

1. Determine the change in gravity g in order to correct a clock with a seconds pendulum which is losing 10 seconds/day at a place where $g = 32 \text{ ft/sec}^2$.

Ans. g must be increased by 0.0074 ft/sec^2

$$\text{Hint: } \frac{dn}{n} = \left(\frac{86400-10}{86400}\right) = \frac{dg}{2g} \text{ or } dg = \left(1 - \frac{1}{4320}\right) 32 = 31.9925$$

2. Compare the acceleration due to gravity at two places if a seconds pendulum gains 10 seconds/day at one place and loses 10 seconds/day at another place.

Ans. 4321/4319

3. If the length of a pendulum is increased in the ratio 900:901, determine how many seconds a clock would lose/day.

Ans. Clock loses 48 seconds/day

$$\text{Hint: } \frac{L+dL}{dL} = \frac{901}{900}, \frac{dn}{n} = \frac{-dl}{2l} = \frac{-1}{1800}, dn = \frac{-86400}{1800} = -48$$

4. If a simple undamped linearized undriven pendulum is 8 feet long and swings with an amplitude of 1 rad, compute (a) The angular velocity of the pendulum at its lowest point (b) its acceleration at the ends of its paths.

Ans. $\pm 2 \text{ rad/sec}$ (b) $\pm 4 \text{ rad sec}^2$

Chapter 10

Series Solutions

INTRODUCTION

In the earlier Chapter 9, methods of obtaining solutions to second and higher order linear non-homogeneous differential equations with constant coefficients were studied.

Euler-Cauchy and Legendre equations, two special cases of differential equations with variable coefficients were also considered earlier, in 9.5.

In general, the solutions to differential equations with variable coefficients such as Bessel's equation, Legendre's equation and hypergeometric equation can *not* be expressed as finite linear combination of known elementary functions. However in such cases solutions can be obtained in the form of infinite power series. In this chapter, two methods *power series* method and an extension of the power series method the *Frobenius* method* (*generalized power series* method) are considered for solving differential equations with variable coefficients.

We consider the important concept of orthogonality and the process of Gram-Schmidt orthogonalization. Finally we also study the Sturm-Liouville problems.

10.1 CLASSIFICATION OF SINGULARITIES

Consider a homogeneous linear second order differential equation with variable coefficients:

$$a_0(x)\frac{d^2y}{dx^2} + a_1(x)\frac{dy}{dx} + a_2(x)y = 0 \quad (1)$$

Assuming $a_0(x) \neq 0$, the above equation is written in the standard (normalized) form as

$$\frac{d^2y}{dx^2} + P(x)\frac{dy}{dx} + Q(x)y = 0 \quad (2)$$

where $P(x) = \frac{a_1(x)}{a_0(x)}$ and $Q(x) = \frac{a_2(x)}{a_0(x)}$

Analytic

A function $f(x)$ is said to be analytic at x_0 if $f(x)$ has Taylor's series expansion about x_0 given by

$$\sum_{n=0}^{\infty} \frac{f^{(n)}(x_0)}{n!} (x - x_0)^n$$

exists and converges to $f(x)$ for all x in some open interval including x_0 .

If a function $f(x)$ is not analytic at x_0 then it is said to be **singular** at x_0 .

Regular or Ordinary Point (O.P.)

A point x_0 is said to be a regular or ordinary point of the differential equation (2), equivalently (1), if *both* $P(x)$ and $Q(x)$ are analytic at x_0 .

Singular Point

A point x_0 is said to be a singular point of (2) if either of $P(x)$ or $Q(x)$ or both are *not* analytic at x_0 .

Singular points are classified as regular singular point and irregular point as follows:

*Ferdinand Georgy Frobenius (1849-1917) German mathematician.

10.2 — HIGHER ENGINEERING MATHEMATICS—III

Regular Singular Point (RSP)

A singular point x_0 of differential equation (2) is called a *regular singular point* if both $(x - x_0)P(x)$ and $(x - x_0)^2 Q(x)$ are analytic at x_0 . On the other hand, if either $(x - x_0)P(x)$ or $(x - x_0)^2 Q(x)$ or both are *not* analytic at x_0 , then x_0 is called an *irregular singular point* (ISP).

WORKED OUT EXAMPLES

Example 1: $y'' + (x^2 + 1)y' + (x^3 + 2x^2 + 3x)y = 0$. Since $P(x) = x^2 + 1$ and $Q(x) = x^3 + 2x^2 + 3x$ are polynomials, are *both* analytic everywhere, any point x is an ordinary or regular point of the given differential equation.

Example 2: $(1 - x^2)y'' + 2y' - 3y = 0$. Standard form: $y'' + \frac{2}{1-x^2}y' - \frac{3}{1-x^2}y = 0$. Since both $P(x) = \frac{2}{1-x^2}$ and $Q(x) = -\frac{3}{1-x^2}$ are not analytic at $x = \pm 1$, the given DE has two singular points at $x = +1$ and $x = -1$. Further since $(x - 1)P(x) = (x - 1) \cdot \frac{2}{(1-x^2)} = \frac{2}{1+x}$ is analytic at $x = 1$ and $(x - 1)^2 Q(x) = (x - 1)^2 \cdot \frac{(-3)}{(1-x^2)} = +\frac{3(x-1)}{(x+1)}$ is analytic at $x = 1$.

Therefore $x = 1$ is a regular singular point. Similarly since both $(x + 1)P(x)$ and $(x + 1)^2 Q(x)$ are analytic at $x = -1$, the point $x = -1$ is also a regular singular point.

Example 3: $x^3(x - 1)y'' + 2(x - 1)y' + 5xy = 0$. Here $P(x) = \frac{2(x-1)}{x^3(x-1)} = \frac{2}{x^3}$ and $Q(x) = \frac{5}{x^2(x-1)}$. $x = 0$ and $x = 1$ are singular points. Further $x = 0$ is an irregular singular point since $x \cdot P(x) = \frac{2 \cdot (x-1)}{x^2(x-1)}$ is *not* analytic (although $x^2 Q(x) = \frac{5}{x-1}$ is analytic at $x = 0$). (Note *both* must be analytic). However $x = 1$ is a regular singular point since *both* $(x - 1)P(x) = \frac{2(x-1)}{x^3}$ and $(x - 1)^2 Q(x) = \frac{5(x-1)}{x^2}$ are analytic at $x = 1$.

EXERCISE

Locate and classify the ordinary points (OP), regular singular point (RSP) and irregular singular point (ISP) of the following differential equations

- $x^2(x^2 - 4)y'' + 2x^3y' + 3y = 0$

Ans. $x = 0, \pm 2$ are regular singular points (R.S.P.)
No I.S.P. All points, except $x = 0, \pm 2$ are O.P.'s.

- $(x^2 + 1)(x - 4)^3 y'' + (x - 4)^2 y' + y = 0$

Ans. $x = \pm i$ are RSP, $x = 4$ is ISP. All other points are O.P.'s

- $e^x y'' + 2y' - xy = 0$

Ans. No singular points. Any point is a OP

- $x^2 y'' + y' + y = 0$

Ans. $x = 0$ is I.S.P.

- $x(x - 1)^3 y'' + 2(x - 1)^3 + 3y = 0$

Ans. Except $x = 0, x = 1$, all other points are OP
 $x = 0$ is RSP, $x = 1$ is ISP

- $y'' + (x^3 + x^2 + 1)y' - 3(x^2 - 4x - 2)y = 0$

Ans. No singular points. Any point is OP

- $(x - 1)xy'' + x^2 y' + y = 0$

Ans. $x = 0, 1$ are S.P. all other points are O.P.s
 $x = 0$ is RSP, $x = 1$ is also RSP.

- $x^2(x - 2)y'' + 2(x - 2)y' + (x + 1)y = 0$

Ans. $x = 0, 2$ are S.P., $x = 0$ is ISP, $x = 2$ is RSP, all other points O.P.

- $x(x - 1)^2(x + 2)y'' + x^2 y' - (x^3 + 2x - 1)y = 0$

Ans. $x = 0$, RSP, $x = 1$ is ISP, $x = -2$ is RSP. All other points O.P.

- $x^4(x^2 + 1)(x - 1)^2 y'' + 4x^3(x - 1)y' + (x + 1)y = 0$

Ans. $x = \pm i, 1$ are RSP; $x = 0$ is ISP.

- $(x^4 - 2x^3 + x^2)y'' + 2(x - 1)y' + x^2 y = 0$

Ans. $x = 1$ is RSP, $x = 0$ is ISP

10.2 POWER SERIES SOLUTION

An expression of the form $c_0 + c_1(x - x_0) + c_2(x - x_0)^2 + \dots + c_n(x - x_0)^n + \dots$

or in the summation form

$$\sum_{n=0}^{\infty} c_n(x - x_0)^n \quad (3)$$

is known as a *power series* of the variable x in powers of $(x - x_0)$ (or about the point x_0). The constants $c_0, c_1, c_2, \dots, c_n, \dots$ are known as the *coefficients* and x_0 is known as the *centre* (of expansion) of the power series (1). Since n takes only positive integral values, the power series (1) does *not* contain negative or fractional powers. So power series (1) contains only positive powers.

Theorem: If x_0 is a regular (or ordinary) point of differential equation (2), then a general solution of (2) is obtained as a linear combination of two linearly independent power series solutions of the form

$$\sum_{n=0}^{\infty} c_n (x - x_0)^n \quad (3)$$

and these power series both converge in some interval $|x - x_0| < R$ (with $R > 0$).

Power Series Method:

Step I: Assume that $y = \sum_{n=0}^{\infty} c_n (x - x_0)^n$ (4) be the solution (2).

Step II: Substitute, y, y', y'' obtained by differentiating (4) termwise, in (2). Collect the coefficients of like powers of $(x - x_0)$. This converts the differential equation (2) into the form

$$k_0 + k_1(x - x_0) + k_2(x - x_0)^2 + \dots = 0 \quad (5)$$

Here $k_i (i = 0, 1, 2, 3, \dots)$ are functions of certain coefficients c_n .

Step III: If (4) is solution of (2), all k_i 's must be zero. Solve $k_0 = 0, k_1 = 0, k_2 = 0 \dots$ for the unknown coefficients c_n 's.

Generally this leads to a *recurrence relation* between c_n 's, which helps to determine unknown coefficients in terms of the other known coefficients.

Thus c_n 's are determined by equating to zero each power of $(x - x_0)$ in (5).

Step IV: Substitution of these c_n 's in (4) gives the required power series solution of (2).

WORKED OUT EXAMPLES

Example 1: Find a power series solution in powers of x of the differential equation

$$x(x+1)y' - (2x+1)y = 0$$

Solution: Assume that $y = \sum_{n=0}^{\infty} c_n x^n$ is a power series solution in power of x (i.e., about $x_0 = 0$). Differentiating y w.r.t. x we get.

$$y' = \sum_{n=0}^{\infty} n c_n x^{n-1}$$

Substituting y and y' in the given equation, we get

$$\begin{aligned} x(x+1) \sum_{n=0}^{\infty} n c_n x^{n-1} - (2x+1) \sum_{n=0}^{\infty} c_n x^n &= 0. \\ \sum_{n=0}^{\infty} n c_n x^{n+1} + \sum_{n=0}^{\infty} n c_n x^n - 2 \cdot \sum_{n=0}^{\infty} c_n x^{n+1} - \sum_{n=0}^{\infty} c_n x^n &= 0. \end{aligned}$$

$$\text{or } \sum_{n=0}^{\infty} (n-2) c_n x^{n+1} + \sum_{n=0}^{\infty} (n-1) c_n x^n = 0$$

Rewrite the first summation in the LHS so that x in each of the summations in LHS will have the common exponent n . Put $n+1 = m$, then $\sum_{m=1}^{\infty} (m-3) c_{m-1} x^m$, since $n = m-1$. But m is a dummy variable. So the first summation may be written as $\sum_{n=1}^{\infty} (n-3) c_{n-1} x^n$. Thus the given D.E. takes the form

$$\sum_{n=1}^{\infty} (n-3) c_{n-1} x^n + \sum_{n=0}^{\infty} (n-1) c_n x^n = 0$$

Although x has the same exponent in the two summations, the range of the summations are different. The common range is from 1 to ∞ . Expanding the second summation for $n = 0$ (that do not belong to the common range 1 to ∞) we can rewrite the above equation as

$$\sum_{n=1}^{\infty} [(n-3) c_{n-1} + (n-1) c_n] x^n - c_0 \cdot x^0 = 0$$

Equating to zero, the coefficients of $x^n: n = 0 : x^0$: coefficient of x^0 is c_0 equated to zero. Thus $c_0 = 0$. $n \geq 1 : x^n : (n-3) c_{n-1} + (n-1) c_n = 0$

10.4 — HIGHER ENGINEERING MATHEMATICS—III

or $(n-1)c_n = -(n-3)c_{n-1}$ for $n \geq 1$

For $n = 1$, $0 \cdot c_1 = 2c_0 = 2 \cdot 0 = 0$.

Thus c_1 is arbitrary (can take any value).

For $n = 2$, $c_2 = c_1$

For $n = 3$, $2c_3 = 0 \quad \therefore c_3 = 0$

For $n > 3$, $c_n = 0$ because of the presence of the factor $(n-3)$.

For example $n = 4$, $3c_4 = -4c_3 = 0$ since $c_3 = 0$.

For $n = 5$, $4c_5 = -2c_4 = 0$ since $c_4 = 0$ and so on.

Thus $c_0 = 0$, $c_1 = c_2$ and $c_n = 0$ for $n \geq 3$. Then the power series solution reduces to the form $y = c_1x + c_2x^2 = c_1(x + x^2)$

since $c_1 = c_2$.

Example 2: Using power series method solve $(1-x^2)y'' - 2xy' + 2y = 0$ (which is a particular case of Legendre's equation with $n = 1$).

Solution: Assume $y = \sum_{n=0}^{\infty} c_n x^n$. Differentiating,

$y' = \sum_{n=0}^{\infty} n c_n x^{n-1}$, $y'' = \sum_{n=0}^{\infty} n(n-1) c_n x^{n-2}$. Substituting in the given equation

$$(1-x^2) \sum_{n=0}^{\infty} n(n-1) c_n x^{n-2} - 2x \sum_{n=0}^{\infty} n c_n x^{n-1} + 2 \sum_{n=0}^{\infty} c_n x^n = 0$$

$$\text{or} \quad \sum_{n=2}^{\infty} n(n-1) c_n x^{n-2} - \sum_{n=0}^{\infty} [n(n-1) + 2n - 2] c_n x^n = 0$$

since for $n = 0$ and $n = 1$ the first two terms in the first summation vanish.

Put $m = n - 2$ so that the first summation can be written as

$$\sum_{n=0}^{\infty} (n+2)(n+1) c_{n+2} x^n - \sum_{n=0}^{\infty} (n^2 + n - 2) c_n x^n = 0$$

Equating to zero the coefficient of x^n ,

$$(n+2)(n+1) c_{n+2} = (n+2)(n-1) c_n$$

$$\text{or} \quad (n+1) c_{n+2} = (n-1) c_n.$$

For $n = 0$, $c_2 = -c_0$

For $n = 1$, $2c_3 = 0 \cdot c_1$ (because of the presence of the factor $(n-1)$). So c_1 is arbitrary and *all* the coefficients with odd suffix will be zero i.e. $c_3 = c_5 = c_7 = c_9 = \dots = 0$ (because $4c_5 = 2c_3 = 0$ etc.).

For even suffix coefficients

$$c_{2m+2} = \frac{(2m-1)}{(2m+1)} c_{2m} \quad \text{for } m = 0, 1, 2, \dots$$

For $m = 0$, $c_2 = -c_0$, for $m = 1$, $c_4 = \frac{1}{3} c_2 = -\frac{1}{3} c_0$, for $m = 2$, $c_6 = \frac{3}{5} c_4 = \frac{3}{5} \cdot \left(-\frac{1}{3}\right) c_0 = -\frac{1}{5} c_0$ etc.

Thus the required power series solution involving two arbitrary constants is

$$y = c_0 + c_1x + c_2x^2 + 0 + c_4x^4 + 0 + c_6x^6 + 0 + c_8x^8 + \dots$$

$$y = c_1x + c_0 \left[1 - x^2 - \frac{1}{3}x^4 - \frac{1}{5}x^6 - \frac{1}{7}x^8 \dots \right]$$

Note: Except $x \pm 1$, all other points are regular points of the given DE.

Example 3: Solve the initial value problem $xy'' + y' + 2y = 0$ with $y(1) = 2$, $y'(1) = 4$.

Solution: Since the initial conditions are prescribed at $x = 1$, we obtain a power series solution in powers of $(x-1)$ of the form

$$y = \sum_{n=0}^{\infty} c_n (x-1)^n$$

The procedure is simplified by introducing $t = x - 1$. In this case the initial value problem transforms to solution of the differential equation

$$(t+1) \frac{d^2y}{dt^2} + \frac{dy}{dt} + 2y = 0 \quad (1)$$

with $y(t=0) = 2$ and $y'(t=0) = 4$. So assume the power series solution of the form

$$y(t) = \sum_{n=0}^{\infty} c_n t^n \quad (2)$$

Substituting (2) in (1), we get

$$(t+1) \sum_{n=2}^{\infty} n(n-1) c_n t^{n-2} + \sum_{n=1}^{\infty} n c_n t^{n-1}$$

$$\begin{aligned}
 &+ 2 \cdot \sum_{n=0}^{\infty} c_n t^n = 0. \\
 &\sum_{n=2}^{\infty} n(n-1)c_n t^{n-1} + \sum_{n=2}^{\infty} n(n-1)c_n t^{n-2} \\
 &+ \sum_{n=1}^{\infty} n c_n t^{n-1} + 2 \sum_{n=0}^{\infty} c_n t^n = 0
 \end{aligned}$$

To have a common exponent n for t put $n-1 = m$ in first summation, put $n-2 = m$ in second and put $n-1 = m$ in third summation. Then the above equation takes the form

$$\begin{aligned}
 &\sum_{n=1}^{\infty} (n+1)n c_{n+1} t^n + \sum_{n=0}^{\infty} (n+2)(n+1)c_{n+2} t^n \\
 &+ \sum_{n=0}^{\infty} (n+1)c_{n+1} t^n + 2 \sum_{n=0}^{\infty} c_n t^n = 0
 \end{aligned}$$

Thus the recurrence relation is obtained by equating to zero the coefficient of t^n as

$$(n+1)^2 c_{n+1} + (n+1)(n+2)c_{n+2} + 2c_n = 0$$

For $n \geq 0$. Solving

$$c_{n+2} = \frac{-[2c_n + (n+1)^2 c_{n+1}]}{(n+1)(n+2)}, \text{ for } n \geq 0$$

$$\text{For } n = 0, c_2 = \frac{-[2c_0 + c_1]}{2}$$

$$\text{For } n = 1, c_3 = \frac{-[2c_1 + 4c_2]}{6} = \frac{2}{3}c_0$$

$$\text{For } n = 2, c_4 = \frac{-[2c_2 + 9c_3]}{12}$$

$$\text{For } n = 3, c_5 = \frac{-[2c_3 + 16c_4]}{20} \text{ etc.}$$

Substituting these coefficients c'_n in (2), we get

$$y(t) = c_0 + c_1 t + c_2 t^2 + c_3 t^3 + c_4 t^4 + c_5 t^5 + \dots \quad (3)$$

Using the initial condition $y(t=0) = 2$, we have

$$2 = y(0) = c_0. \quad \therefore \quad c_0 = 2.$$

Differentiating (3) w.r.t. ' t ', we get

$$y'(t) = c_1 + 2c_2 t + 3c_3 t^2 + \dots$$

Using the second initial condition $y'(t=0) = 4$, we get

$$4 = y'(0) = c_1 \quad \therefore \quad c_1 = 4$$

with $c_0 = 2$, $c_1 = 4$, we get $c_2 = -4$, $c_3 = \frac{4}{3}$, $c_4 = -\frac{1}{3}$, $c_5 = \frac{-2}{15}$ etc. Substituting these values

$$y(t) = 2 + 4t - 4t^2 + \frac{4}{3}t^3 - \frac{1}{3}t^4 + \frac{2}{15}t^5 + \dots$$

Replacing t by $x-1$, we get the required power series solution in powers of $(x-1)$ as

$$\begin{aligned}
 y(x) &= 2 + 4(x-1) - 4(x-1)^2 + \frac{4}{3}(x-1)^3 - \\
 &\quad - \frac{1}{3}(x-1)^4 + \frac{2}{15}(x-1)^5 + \dots
 \end{aligned}$$

EXERCISE

Obtain power series solution in powers of x for the following differential equations (1 to 9)

$$1. \quad y' = ky$$

$$\text{Ans. } y = c_0 e^{kx}$$

Hint: Recurrence relation (RR): $c_n = \frac{k^n}{n!} c_0$

$$2. \quad (1-x^2)y' - y = 0$$

$$\text{Ans. } y = c_0 \left[1 + x + \frac{x^2}{2} + \frac{x^3}{2} + \frac{3}{8}x^4 + \frac{11}{40}x^5 + \dots \right]$$

Hint: RR: $c_{n+1} = \frac{(n-1)c_{n-1} + c_n}{n+1}$ for $n \geq 1$, $c_1 = c_0$

$$3. \quad xy' - (x+2)y - 2x^2 - 2x = 0$$

$$\text{Ans. } y = 2x + c_2 x^2 e^x$$

Hint: RR: $c_n = \frac{c_{n-1}}{n-2}$ for $n > 2$, $c_0 = 0$, $c_1 = 2$, c_2 arbitrary constant.

$$4. \quad y' - 2xy = 0$$

$$\text{Ans. } y = c_0 e^{x^2}$$

Hint: $c_1 = c_3 = c_5 = \dots = 0$, $c_2 = c_0$, $c_4 = \frac{c_2}{2}$, $c_6 = \frac{c_0}{3!}$ etc.

10.6 — HIGHER ENGINEERING MATHEMATICS—III

5. $y'' - 3y' + 2y = 0$

Ans. $y = c_0 + c_1x + \left(\frac{3}{2}c_1 - c_0\right)x^2 + \left(\frac{7}{6}c_1 - c_0\right)x^3 + \dots$
 put $c_0 = A + B$, $c_1 = A + 2B$, then $y = Ae^x + Be^{2x}$

Hint: RR: $c_{m+2} = \frac{3(m+1)c_{m+1} - 2c_m}{(m+1)(m+2)}$, $m \geq 0$

6. $y'' - xy' + y = 0$

Ans. $y = c_1x + c_0 \left[1 - \frac{1}{2!}x^2 - \frac{1}{4!}x^4 - \frac{3}{6!}x^6 - \frac{3 \cdot 5}{8!}x^8 + \dots \right]$

Hint: c_1 arbitrary, $c_3 = c_5 = c_7 = \dots = 0$.
 RR: $c_{2m+2} = \frac{(2m-1)}{2(m+1)(2m+1)}c_{2m}$, for $m = 0, 1, 2, \dots$

7. $y'' + y = 0$

Ans. $y = c_0 \cos x + c_1 \sin x$

8. $y'' + xy' + (x^2 + 2)y = 0$

Ans. $y = c_0 \left(1 - x^2 + \frac{1}{4}x^4 + \dots \right) + c_1 \left(x - \frac{1}{2}x^3 + \frac{3}{40}x^5 + \dots \right)$

Hint: RR: $c_{n+2} = -\frac{(n+2)c_n + c_{n-2}}{(n+1)(n+2)}$ for $n \geq 2$,
 $c_2 = -c_0$, $c_3 = -\frac{1}{2}c_1$, c_0, c_1 arbitrary

9. $(x^2 - 1)y'' + 3xy' + xy = 0$, $y(0) = 4$, $y'(0) = 6$

Ans. $y = 4 + 6x + \frac{11}{3}x^3 + \frac{1}{2}x^4 + \frac{11}{4}x^5 + \dots$

Hint: $y = c_0 \left(1 + \frac{1}{6}x^3 + \frac{1}{8}x^5 + \dots \right) + c_1 \left(x + \frac{1}{2}x^3 + \frac{1}{12}x^4 + \frac{3}{8}x^5 + \dots \right)$

RR: $c_{n+2} = \frac{n(n+2)c_n + c_{n-1}}{(n+1)(n+2)}$ for $n \geq 2$,
 $c_2 = 0$, c_1, c_0 arbitrary.

10. Solve $y'' = y$ in power series in power of $(x - 1)$.

Ans. $y = c_0 \cosh(x - 1) + c_1 \sinh(x - 1)$.

Hint: $c_{n+2} = \frac{c_n}{(n+1)(n+2)}$, c_0, c_1 arbitrary.

Put $x - 1 = t$, $y = c_0 \left(1 + \frac{1}{2!}t^2 + \frac{1}{4!}t^4 + \dots \right) + c_1 \left(t + \frac{t^3}{3!} + \frac{t^5}{5!} + \dots \right)$

11. Obtain power series solution about $x = 1$ for equation $y'' + (x - 1)^2y' - 4(x - 1)y = 0$.

Ans. $y = c_0 \sum_{n=0}^{\infty} \frac{4(-1)^n(x-1)^{3n}}{3^n(3n-1)(3n-4)n!} + c_1(x-1) + \frac{1}{4}(x-1)^4c_1$.

Hint: c_0, c_1 arbitrary,

$c_{3k} = (-1)^k \frac{[(-4)(-1)(2)\dots(3k-1)]}{(3 \cdot 6 \cdot 9 \dots 3k)(2 \cdot 5 \cdot 8 \dots (3k-1))} c_0$

12. Determine power series solution with centre at $x = -3$ for $y'' - 2(x + 3)y' - 3y = 0$

Ans. $y = c_0 \left[1 + \sum_{n=1}^{\infty} \frac{3 \cdot 7 \cdot 11 \dots (4n-1)}{(2n)!} (x+3)^{2n} \right] + c_1 \left[(x+3) + \sum_{n=1}^{\infty} \frac{5 \cdot 9 \cdot 13 \dots (4n+1)}{(2n+1)!} (x+3)^{2n+1} \right]$

13. Solve $y'' + xy = 0$ in power series about $x = 0$.

Ans. $y = c_0 \left(1 - \frac{x^3}{3!} + \frac{4x^6}{6!} - \frac{2 \cdot 8}{7!}x^9 + \dots \right) + c_1 \left(x - \frac{2x^4}{4!} + \frac{10x^7}{7!} + \dots \right)$

Hint: RR: $c_{n+2} = \frac{-c_{n-1}}{(n+2)(n+1)}$, $c_2 = 0$

14. Solve the initial value problem $(x - 1)y'' + xy' + y = 0$, $y(0) = 2$, $y'(0) = -1$

Ans. $y = 2 - x + x^2 + \frac{x^4}{4} + \frac{3x^5}{20}$

Hint: $y = c_0 \left(1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{5x^4}{24} + \frac{19x^5}{120} + \dots \right) + c_1 \left(x + \frac{x^3}{3} + \frac{x^4}{6} + \frac{x^5}{6} + \dots \right)$

$c_2 = \frac{c_0}{2}$, RR: $c_n = \frac{(n-2)c_{n-1} + c_{n-2}}{n}$ for $n \geq 3$, c_0 arbitrary.

15. Solve the initial value problem $(x - 1)y'' + y' + 2(x - 1)y = 0$, $y(4) = 5$, $y'(4) = 0$.

Ans. $y(x) = 5 \left[1 - (x - 4)^2 + \frac{1}{9}(x - 4)^3 + \frac{5}{36}(x - 4)^4 + \dots \right]$

Hint: $y(x) = c_0 \left[1 - (x - 4)^2 + \frac{1}{9}(x - 4)^3 + \frac{5}{36}(x - 4)^4 + \dots \right] + c_1 [(x - 4)]$

$-\frac{1}{6}(x - 4)^2 - \frac{8}{27}(x - 4)^3 + \frac{5}{108}(x - 4)^4 + \dots$

RR: $c_{n+2} = -\frac{n+1}{3(n+2)}c_{n+1} - \frac{2}{(n+1)(n+2)}c_n - \frac{2c_{n-1}}{3(n+2)(n+1)}$ for $n = 0, 1, 2, \dots$. Here c_0, c_1 are arbitrary.

10.3 FROBENIUS METHOD

In 10.2 a power series solution $\sum_{n=0}^{\infty} c_n(x - x_0)^n$ was obtained for differential equation *only* when x_0 is an ordinary (or regular) point. Solution near regular singular point x_0 can be obtained by an extension of the power series method known as *Frobenius method* (or *generalized power series method*). In this method we consider a series of the form

$$|x - x_0|^r \sum_{n=0}^{\infty} c_n(x - x_0)^n \quad (1)$$

known as *Frobenius series*. Here r is an unknown (real or complex) constant to be determined.

Theorem: Let x_0 be a regular singular point of the differential equation

$$\frac{d^2 y}{dx^2} + P(x) \frac{dy}{dx} + Q(x)y = 0 \quad (2)$$

Then (2) has at least one nontrivial solution of the form

$$y = |x - x_0|^r \sum_{n=0}^{\infty} c_n(x - x_0)^n \quad (3)$$

which is convergent (valid) in some deleted interval about x_0 , $0 < |x - x_0| < R$ (with $R > 0$).

Note: In the following analysis, for simplicity, we consider the interval as $0 < (x - x_0) < R$. Solutions valid in the interval $-R < (x - x_0) < 0$, can be obtained simply by replacing $(x - x_0)$ by $-(x - x_0)$.

Frobenius Method

Step I. Assume a solution of the form

$$y = (x - x_0)^r \sum_{n=0}^{\infty} c_n(x - x_0)^n \quad (4)$$

for the differential equation (2) with x_0 as a regular singular point. The series (4) is valid in $0 < x - x_0 < R$. Here the exponent r is chosen so that $c_0 \neq 0$, which simply means that the highest possible power of x is factored out.

Step II. Differentiate (4) obtaining

$$\frac{dy}{dx} = \sum_{n=0}^{\infty} (n + r)c_n(x - x_0)^{n+r-1} \quad (5)$$

and

$$\frac{d^2 y}{dx^2} = \sum_{n=0}^{\infty} (n + r)(n + r - 1)c_n(x - x_0)^{n+r-2} \quad (6)$$

Substitute (4), (5), (6) is the differential equation (2). Collecting the coefficients of like powers of $(x - x_0)$, equation (2) takes the form

$$K_0(x - x_0)^{r+k} + K_1(x - x_0)^{r+k+1} + K_2(x - x_0)^{r+k+2} + \dots = 0$$

Here the coefficients K_i , for $i = 0, 1, 2, \dots$, are functions of the exponent r and the constant coefficients c_n . Also k is an integer.

Step III. Since (4) is assumed to be the solution of (2), we must have

$$K_0 = K_1 = K_2 = \dots = 0$$

Here K_0 is the coefficient of the *lowest* power $r + k$ of $(x - x_0)$. The equation $K_0 = 0$ is a quadratic equation in r , known as the *indicial equation* of the differential equation (2). The roots r_1 and r_2 of the indicial equation are known as the *exponents* of (2) and are the only possible values for the constant r in the assumed solution (4). Generally r_1 is taken as the *larger* root so that $r_1 > r_2$ (or $\text{Re}(r_1) > \text{Re}(r_2)$ in the case of complex conjugate roots).

Step IV. Now that r is known, solving the equations $K_1 = 0$, $K_2 = 0$, $K_3 = 0 \dots$, we determine completely the unknown constant coefficients c_n 's.

Step V. Let $y_1(x)$ and $y_2(x)$ be the two nontrivial linearly independent solutions of the differential equation (2). Then the general solution of (2) is $y(x) = Ay_1(x) + By_2(x)$, where A and B are arbitrary constants. Then with the known exponent r and the known coefficients c_n 's, $y_1(x)$, one of the two solution of (2) is of the form (4). The form of the second (other) solution $y_2(x)$ may be similar to (4) (with different r and different coefficients) or may contain a logarithmic term. The form of $y_2(x)$ will

10.8 — HIGHER ENGINEERING MATHEMATICS—III

be indicated by the indicial equation. There are three cases:

Case 1. Distinct roots not differing by an integer 1, 2, 3, ...

Suppose $r_1 - r_2 \neq N$, where N is a non-negative integer (i.e. $r_1 - r_2 \neq 0, 1, 2, 3, \dots$). Then

$$y_1(x) = |x - x_0|^{r_1} \sum_{n=0}^{\infty} c_n(x - x_0)^n \quad (7)$$

$$\text{and } y_2(x) = |x - x_0|^{r_2} \sum_{n=0}^{\infty} b_n(x - x_0)^n \quad (8)$$

Here $c_0 \neq 0, b_0 \neq 0$.

Case 2. Roots differing by an integer 1, 2, 3, ...

Suppose $r_1 - r_2 = N$ where N is a positive integer. Then

$$y_1(x) = |x - x_0|^{r_1} \sum_{n=0}^{\infty} c_n(x - x_0)^n \quad (7)$$

and

$$y_2(x) = |x - x_0|^{r_2} \sum_{n=0}^{\infty} b_n(x - x_0)^n + A^* y_1(x) \ln |x - x_0| \quad (9)$$

Here $c_0 \neq 0, b_0 \neq 0$ and the constant A^* may or may not be zero.

Case 3. Double root: $r_1 = r_2$

Suppose $r_1 - r_2 = 0$. Then

$$y_1(x) = |x - x_0|^{r_1} \sum_{n=0}^{\infty} c_n(x - x_0)^n \quad (7)$$

with $c_0 \neq 0$ and

$$y_2(x) = |x - x_0|^{r_1+1} \sum_{n=0}^{\infty} b_n(x - x_0)^n + y_1(x) \ln |x - x_0| \quad (10)$$

Note 1: Series solutions in (7), (8), (9), (10) are convergent in some deleted interval $0 < |x - x_0| < R$.

Note 2: If $r_1 - r_2 = N$, where $N = 1, 2, 3, \dots$ sometimes it is possible to obtain the general solution using the *smaller root alone*, without bothering to find explicitly the solution corresponding to the larger root.

Note 3: In case 2, $r_1 - r_2 = N$ where $N = 1, 2, 3, \dots$, the second solution $y_2(x)$ may or may not contain the logarithmic term $A^* y_1(x) \ln |x - x_0|$. In some cases A^* is zero, so y_2 is same as (8).

Note 4: In case 3, $r_1 - r_2 = 0$ (double root), $y_2(x)$ always contain the logarithmic term $y_1(x) \ln |x - x_0|$ and is *never* of the simple form (8).

Note 5: In case 2: roots differing by an integer in the logarithmic case, take the first solution $y_1(x, r)$, then the second solution is $\frac{\partial y_1(x, r)}{\partial r}$ i.e., derivative of $y_1(x, r)$ partially w.r.t. the exponent r . Then taking r as the *smaller* root r_2 , we get the two linearly independent solutions $y_1(x, r_2)$ and $\frac{\partial y_1}{\partial r}(x, r_2)$. Here the second solution y_2 contains the logarithmic term.

Note 6: In both cases 2 and 3, the second solution containing logarithmic term can be obtained by reduction of order.

WORKED OUT EXAMPLES

Case 1. Roots not differencing by an integer

Example 1: Find the general solution of

$$8x^2 y'' + 10xy' - (1+x)y = 0$$

Solution: The given equation in the standard form

$$y'' + \frac{10}{8x} y' - \frac{(1+x)}{8x^2} y = 0$$

So $x = 0$ is a regular singular point since $xP(x) = x \frac{10}{8x} = \frac{10}{8}$ and $x^2 Q(x) = x^2 \frac{(1+x)}{8x^2} = \frac{(1+x)}{8}$ are both analytic at the point $x = 0$. To obtain the solutions about a regular singular point $x_0 = 0$ we use the Frobenius method. Assume the solution of the given DE as

$$y = (x - 0)^r \sum_{n=0}^{\infty} c_n x^n = \sum_{n=0}^{\infty} c_n x^{n+r}$$

Differentiating y w.r.t. x twice, we get

$$y' = \sum_{n=0}^{\infty} (n+r)c_n x^{n+r-1}$$

and

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1)c_n x^{n+r-2}$$

Substituting y , y' , y'' in the given DE:

$$\begin{aligned} 8x^2 \sum_{n=0}^{\infty} (n+r)(n+r-1)c_n x^{n+r-2} \\ + 10x \sum_{n=0}^{\infty} (n+r)c_n x^{n+r-1} \\ - (1+x) \sum_{n=0}^{\infty} c_n x^{n+r} = 0 \end{aligned}$$

or

$$\sum_{n=0}^{\infty} [8(n+r)(n+r-1) + 10(n+r) - 1]c_n x^{n+r} - \sum_{n=0}^{\infty} c_n x^{n+r+1} = 0$$

Equating to zero the coefficient of lowest power $n+r$ of x i.e. $0+r$ of x or x^r , we get

$$[8(0+r)(0+r-1) + 10(0+r) - 1]c_0 = 0$$

Since it is assumed that $c_0 \neq 0$

$$8r^2 + 2r - 1 = 0$$

which is the required indicial equation with roots $r_{1,2} = \frac{-2 \pm 6}{16}$ or $r_1 = \frac{1}{4}$ and $r_2 = -\frac{1}{2}$. Here r_1, r_2 are real, distinct and $r_1 - r_2 = \frac{1}{4} - (-\frac{1}{2}) = \frac{3}{4} \neq N$ where N is an integer $0, 1, 2, 3, \dots$. The present problem is case 1. To obtain the recurrence relation the last summation in above equation is rewritten. Then

$$\begin{aligned} \sum \{8(n+r)(n+r-1) + 10(n+r) - 1\}c_n \\ - c_{n-1}x^{n+r} = 0 \end{aligned}$$

Thus the recurrence relation is

$$[8(n+r)^2 + 2(n+r) - 1]c_n = c_{n-1}$$

To obtain $y_1(x)$, put $r = \frac{1}{4}$. Then the recurrence relation reduces to

$$\left[8\left(n + \frac{1}{4}\right)^2 + 2\left(n + \frac{1}{4}\right) - 1 \right] c_n = c_{n-1}$$

or

$$c_n = \frac{1}{2n(4n+3)} c_{n-1}$$

For $n = 1$, $c_1 = \frac{1}{2 \cdot 1 \cdot (7)} \cdot c_0$

$n = 2$, $c_2 = \frac{1}{2 \cdot 2 \cdot (11)} c_1$

$n = 3$, $c_3 = \frac{1}{2 \cdot 3 \cdot (15)} c_2$

$n = n-1$, $c_{n-1} = \frac{1}{2(n-1)(4n-1)} c_{n-2}$

$n = n$, $c_n = \frac{1}{2n(4n+3)} c_{n-1}$

Then multiplying these, we can express c_n in terms of c_0 :

$$\begin{aligned} c_1 \cdot c_2 \cdot c_3 \dots c_{n-1} \cdot c_n &= \frac{c_0}{2 \cdot 1 \cdot 7} \cdot \frac{c_1}{2 \cdot 2 \cdot 11} \cdot \frac{c_2}{2 \cdot 3 \cdot 15} \dots \times \\ &\times \dots \frac{c_{n-2}}{2(n-1)(4n-1)} \cdot \frac{c_{n-1}}{2n(4n+3)} \end{aligned}$$

Thus $c_n = \frac{c_0}{2^n \cdot n! \cdot 7 \cdot 11 \cdot 15 \dots (4n-1)(4n+3)}$

Hence the first solution

$$y_1(x) = \sum_{n=0}^{\infty} c_n x^{n+\frac{1}{4}} = c_0 x^{\frac{1}{4}} + \sum_{n=1}^{\infty} c_n x^{n+\frac{1}{4}}$$

$$y_1(x) = c_0 x^{1/4} + c_0 \sum_{n=1}^{\infty} \frac{x^{n+\frac{1}{4}}}{2^n \cdot n! \cdot 7 \cdot 11 \dots (4n-1)(4n+3)}$$

Generally, c_0 is assumed to be equal to 1. In a similar way, to obtain the second solution $y_2(x)$, put $r = -\frac{1}{2}$ in the recurrence relation which then reduces to

$$c_n = \frac{c_{n-1}}{2n(4n-3)}$$

Then $c_1 \cdot c_2 \cdot c_3 \dots c_{n-1} \cdot c_n = \frac{c_0}{2 \cdot 1} \cdot \frac{c_1}{4 \cdot 5} \times$
 $\times \dots \frac{c_2}{6 \cdot 9} \dots \frac{c_{n-2}}{(2n-2)(4n-7)} \cdot \frac{c_{n-1}}{2n(4n-3)}$

$$c_n = \left[\frac{1}{2} \cdot \frac{1}{4} \cdot \frac{1}{6} \dots \frac{1}{2(n-1)} \cdot \frac{1}{2n} \right] \left[\frac{1}{1} \cdot \frac{1}{5} \cdot \frac{1}{9} \dots \frac{1}{4n-7} \cdot \frac{1}{4n-3} \right] c_0$$

$$c_n = \frac{1}{2^n \cdot n! \cdot 1 \cdot 5 \cdot 9 \dots (4n-3)} c_0$$

Choose $c_0 = 1$. Then

$$y_2(x) = \sum_{n=0}^{\infty} c_n x^{n-\frac{1}{2}} = c_0 x^{-\frac{1}{2}} + \sum_{n=1}^{\infty} c_n x^{n-\frac{1}{2}}$$

$$y_2(x) = x^{-\frac{1}{2}} + \sum_{n=1}^{\infty} \frac{x^{n-\frac{1}{2}}}{2^n \cdot n! \cdot 1 \cdot 5 \cdot 9 \dots (4n-3)}$$

10.10 — HIGHER ENGINEERING MATHEMATICS—III

The required general solution is

$$y(x) = Ay_1(x) + By_2(x)$$

Case 2: Roots differing by an integer: Non-logarithmic case

Example 2: Using method of Frobenius, obtain series solution in power of x for $x(1+x)y'' + (x+5)y' - 4y = 0$

Solution: Here $x = 0$ is a regular singular point of the given differential equation (DE). Assume the solution in the form

$$y = \sum_{r=0}^{\infty} c_n x^{n+r}$$

Substituting y , y' and y'' in DE, we get

$$\begin{aligned} x(1+x) \sum_{n=0}^{\infty} (n+r)(n+r-1)c_n x^{n+r-2} \\ + (x+5) \sum_{n=0}^{\infty} (n+r)c_n x^{n+r-1} - 4 \sum_{n=0}^{\infty} c_n x^{n+r} = 0 \\ \text{or} \quad \sum_{n=0}^{\infty} (n+r)(n+r-1)c_n x^{n+r-1} + \\ + \sum_{n=0}^{\infty} (n+r)(n+r-1)c_n x^{n+r} + \sum_{n=0}^{\infty} (n+r)c_n x^{n+r} + \\ + 5 \sum_{n=0}^{\infty} (n+r)c_n x^{n+r-1} - 4 \sum_{n=0}^{\infty} c_n x^{n+r} = 0 \end{aligned}$$

The indicial equation is obtained by equating to zero the coefficient of lowest power $r-1$ of x namely (from first and fourth summations).

$r(r-1) + 5r = 0$ or $r(r+4) = 0$ i.e., $r = 0, -4$
The roots $r_1 = 0$ and $r_2 = -4$ are real, distinct and differ by an integer i.e., $r_1 - r_2 = 0 - (-4) = 4$. To obtain the recurrence relation, the indices in the second, third and fifth summations are shifted to $n-1$ so we get

$$\begin{aligned} \sum_{n=0}^{\infty} [(n+r)(n+r-1) + 5(n+r)]c_n x^{n+r-1} + \\ + \sum_{n=1}^{\infty} [(n-1+r)(n+r-2) + \\ (n+r-1) - 4]c_{n-1} \cdot x^{n+r-1} = 0 \end{aligned}$$

The required recurrence relation is $[(n+r)(n+r-1) + 5(n+r)]c_n + [(n+r-1)(n+r-2) + (n+r-1) - 4]c_{n-1} = 0$ valid for $n \geq 1$.

Start with the smaller root $r_2 = -4$ (with a hope that (!) both the two linearly independent solutions $y_1(x)$ and $y_2(x)$ are obtained in this case itself). With $r = -4$, the recurrence relation reduces to $[(n-4)(n-5) + 5(n-4)]c_n + [(n-5)(n-6) + (n-5) - 4]c_{n-1} = 0$

or $n(n-4)c_n = -(n-7)(n-3)c_{n-1}$ for $n \geq 1$.

Now, for $n = 1$, $c_1 = -\frac{(-6)(-2)}{1(-3)}c_0 = 4c_0$

For $n = 2$, $c_2 = -\frac{(-5)(-1)}{2(-2)}c_1 = \frac{5}{4}c_1 = 5c_0$

For $n = 3$, $c_3 = 0$ because of the presence of $(n-3)$ factor in the recurrence relation.

For $n = 4$,

$$4 \cdot 0 \cdot c_4 = -(-3)(4-3)c_3 = 0$$

Therefore c_4 is arbitrary since for any c_4 the above equation is satisfied.

For $n = 5$, $c_5 = \frac{4}{5}c_4$

For $n = 6$, $c_6 = \frac{1}{5}c_4$

For $n = 7$, $c_7 = 0 \cdot c_6 = 0$ (because of $(n-7)$)

Therefore $c_n = 0$ for $n \geq 7$ (since $c_7 = 0$) i.e., $c_8, c_9, c_{10}, c_{11} \dots$ are all zero.

Thus we had two arbitrary constant's c_0 and c_4 . The solution is

$$y_2(x) = \sum_{n=0}^{\infty} c_0 x^{n+r} = \sum_{n=0}^{\infty} c_0 x^{n-4}$$

Substituting the coefficients $c_1 = 4c_0$, $c_2 = 5c_0$, $c_3 = 0$, $c_5 = \frac{4}{5}c_4$, $c_6 = \frac{1}{5}c_4$, $c_7 = c_8 = c_9 = \dots = 0$ we get

$$\begin{aligned} y_2(x) = c_0 x^{-4} + c_1 x^{-3} + c_2 x^{-2} + c_3 x^{-1} + c_4 + \\ c_5 x + c_6 x^2 + c_7 x^3 + c_8 x^4 + c_9 x^5 + \dots \end{aligned}$$

$$\begin{aligned} y_2(x) = c_0(x^{-4} + 4x^{-3} + 5x^{-2}) \\ + c_4 \left(1 + \frac{4}{5}x + \frac{1}{5}x^2\right) \end{aligned}$$

or $y_2(x) = c_0 x^{-4}(1 + 4x + 5x^2) + c_4 x^0(1 + \frac{4}{5}x + \frac{1}{5}x^2)$

Indeed $y_2(x)$ itself is the required general solution containing two arbitrary constants c_0 and c_4 .

Verification: Suppose we investigate the solution for the larger root $r_1 = 0$. Then the recurrence relation becomes

$$c_n = \frac{-(n-3)(n+1)}{n(n+4)}c_{n-1} \quad \text{for } n \geq 1$$

Now for $n = 1$, $c_1 = \frac{4}{5}c_0$

for $n = 2$, $c_2 = \frac{1}{4}c_1 = \frac{1}{5}c_0$

for $n = 3$, $c_3 = 0$

for $n > 3$, $c_n = 0$ i.e., $c_4 = c_5 = c_6 = \dots = 0$

Then the solution corresponding to the larger indicial root $r_1 = 0$ is

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} c_n x^{n+r} = \sum_{n=0}^{\infty} c_n x^n \\ &= c_0 + c_1 x + c_2 x^2 + c_3 x^3 + c_4 x^4 + \dots \\ &= c_0 + \frac{4}{5}c_0 x + \frac{1}{5}c_0 x^2 + 0 + 0 + 0 + \dots \\ y_1(x) &= c_0 \left(1 + \frac{4}{5}x + \frac{1}{5}x^2 \right) \end{aligned}$$

This solution $y_1(x)$ is *already* contained in (a part of) the solution $y_2(x)$ (see note 2 on page 10.8).

Case 3: Roots differing by an integer: Logarithmic case

Example 3: Determine two linearly independent solutions about $x = 0$ for

$$4x^2 y'' + 2x(2-x)y' - (1+3x)y = 0$$

Solution: $x = 0$ is a regular singular point. Assume

$y = \sum_{n=0}^{\infty} c_n x^{n+r}$ to be the series solution. Substituting y, y', y'' the equation becomes

$$\begin{aligned} 4 \sum_{n=0}^{\infty} (n+r)(n+r-1)c_n x^{n+r} + 4 \sum_{n=0}^{\infty} (n+r)c_n x^{n+r} \\ - 2 \sum_{n=0}^{\infty} (n+r)c_n x^{n+r+1} - \sum_{n=0}^{\infty} c_n x^{n+r} \\ - 3 \sum_{n=0}^{\infty} c_n x^{n+r+1} = 0 \end{aligned}$$

Equating to zero the coefficient of the lowest power x^r (from 1st, 2nd, 4th summations), we get

$$4(r)(r-1) + 4(r) - 1 = 0$$

$$4r^2 - \frac{1}{2} = 0 \text{ or } r = +\frac{1}{2}, -\frac{1}{2}$$

Here $r_1 = \frac{1}{2}$, $r_2 = -\frac{1}{2}$ so $r_1 - r_2 = \frac{1}{2} - (-\frac{1}{2}) = 1$.

Thus the difference is a non-zero positive integer. From the larger root $r_1 = \frac{1}{2}$, only one solution can be obtained. From the smaller root, $r_2 = -\frac{1}{2}$, two solutions can be obtained. Rewriting

$$\begin{aligned} \sum_{n=0}^{\infty} [4(n+r)(n+r-1) + 4(n+r) - 1]c_n x^{n+r} \\ - \sum_{n=1}^{\infty} [2(n+r-1) + 3]c_{n-1} x^{n+r} = 0 \end{aligned}$$

The indicial equation is

$$[4(n+r)^2 - 1]c_n = [2(n+r) + 1]c_{n-1}$$

$$\text{or } c_n = \frac{c_{n-1}}{2r+2n-1} \text{ for } n \geq 1$$

Now for $n = 1$, $c_1 = \frac{c_0}{2r+1}$

$n = 2$, $c_2 = \frac{c_1}{2r+3}$

$n = 3$, $c_3 = \frac{c_2}{2r+5}$

$$n = n-1, c_{n-1} = \frac{c_{n-2}}{2r+2n-3}$$

$$n = n, c_n = \frac{c_{n-1}}{2r+2n-1}$$

$$c_1 \cdot c_2 \cdot c_3 \dots c_{n-1} \cdot c_n = \frac{c_0}{2r+1} \cdot \frac{c_1}{2r+3} \times$$

$$\times \frac{c_2}{2r+5} \dots \frac{c_{n-2}}{2r+2n-3} \cdot \frac{c_{n-1}}{2r+2n-1}$$

$$\therefore c_n = \frac{c_0}{(2r+1)(2r+3)(2r+5)\dots(2r+2n-3)(2r+2n-1)}$$

for $n \geq 1$. With this c_n , the solution takes the form

$$y = \sum_{n=0}^{\infty} c_n x^{n+r}$$

$$y(x, r) = c_0 \sum_{n=0}^{\infty} \frac{x^{n+r}}{(2r+1)(2r+3)(2r+5)\dots(2r+2n-3)(2r+2n-1)}.$$

Since the factor $(2r+1)$ in the denominator vanishes for the value of the smaller root $r_2 = -\frac{1}{2}$, expand the series for $n = 0, 1$ and choose $c_0 = (2r+1)$ so that $c_1 = 1$.

$$\begin{aligned} y(x, r) &= (2r+1)x^r + 1 \cdot x^{r+1} + \\ &+ \sum_{n=2}^{\infty} \frac{x^{n+r}}{(2r+3)(2r+5)\dots(2r+2n-1)} \end{aligned}$$

Here $c_n = \frac{c_1}{(2r+3)(2r+5)\dots(2r+2n-1)}$ for $n \geq 2$

The two linearly independent solutions are given by $y(x, r)$ at $r_2 = -\frac{1}{2}$ and $\frac{\partial y(x, r)}{\partial r}$ at $r_2 = -\frac{1}{2}$. Differen-

10.12 — HIGHER ENGINEERING MATHEMATICS—III

tiating y partially w.r.t. r we get

$$\begin{aligned}\frac{\partial y(x, r)}{\partial r} &= 2x^r + (2r+1)x^r \ln x + x^{r+1} \ln x + \\ &+ \sum_{n=2}^{\infty} \frac{x^{n+r} \cdot \ln x}{(2r+3)(2r+5) \cdots (2r+2n-1)} + \\ &+ \sum_{n=2}^{\infty} x^{n+r} \frac{\partial}{\partial r} \left[\frac{1}{(2r+3)(2r+5) \cdots (2r+2n-1)} \right]\end{aligned}$$

For $u(x) = u_1(x)u_2(x) \cdots u_n(x)$, then

$$\frac{du}{dx} = u(x) \left[\frac{du_1}{u_1} + \frac{du_2}{u_2} + \cdots + \frac{du_n}{u_n} \right]$$

Using this result

$$\begin{aligned}&\frac{d}{dr} [(2r+3)^{-1}(2r+5)^{-1} \cdots (2r+2n-1)^{-1}] \\ &= \frac{1}{(2r+3)(2r+5) \cdots (2r+2n-1)} \left[\frac{-(2r+3)^{-2} \cdot 2}{(2r+3)^{-1}} - \frac{(2r+5)^{-2} \cdot 2}{(2r+5)^{-1}} \right. \\ &\quad \left. \cdots - \frac{(2r+2n-1)^{-2} \cdot 2}{(2r+2n-1)^{-1}} \right] \\ &= \frac{-2}{(2r+3)(2r+5) \cdots (2r+2n-1)} \times \\ &\quad \times \left[\frac{1}{2r+3} + \frac{1}{2r+5} + \cdots + \frac{1}{2r+2n-1} \right]\end{aligned}$$

Substituting this value

$$\begin{aligned}\frac{\partial y(x, r)}{\partial r} &= y(x, r) \cdot \ln x + 2x^r - \\ &- \sum_{n=2}^{\infty} \frac{2 \cdot x^{n+r}}{(2r+3) \cdots (2r+2n-1)} \left[\frac{1}{2r+3} + \cdots + \frac{1}{2r+2n-1} \right]\end{aligned}$$

Now the required two linearly independent solutions are given by $y_1(x) = y(x, r)$ at $r = -\frac{1}{2}$

$$\begin{aligned}&= y \left(x, r = -\frac{1}{2} \right) \\ &= 0 \cdot x^{-\frac{1}{2}} + x^{-\frac{1}{2}+1} + \sum_{n=2}^{\infty} \frac{x^{n-\frac{1}{2}}}{2 \cdot 4 \cdot 6 \cdots 2(n-1)} \\ &= x^{\frac{1}{2}} + \sum_{n=2}^{\infty} \frac{x^{n-\frac{1}{2}}}{2^{n-1}(n-1)!} \\ &y_1(x) = \sum_{n=1}^{\infty} \frac{x^{n-\frac{1}{2}}}{2^{n-1}(n-1)!}\end{aligned}$$

The second solution $y_2(x)$ is given by $y_2(x) = \frac{\partial y(x, r)}{\partial r}$ at $r = -\frac{1}{2}$

$$= y_1(x) \cdot \ln x + 2x^{-\frac{1}{2}} -$$

$$\begin{aligned}&- \sum_{n=2}^{\infty} \frac{2 \cdot x^{n-\frac{1}{2}}}{2 \cdot 4 \cdot 6 \cdots 2(n-1)} \left[\frac{1}{2} + \frac{1}{4} + \cdots + \frac{1}{2(n-1)} \right] \\ &= y_1(x) \ln x + 2x^{-\frac{1}{2}} - \sum_{n=2}^{\infty} \frac{2 \cdot x^{n-\frac{1}{2}}}{2^{n-1} \cdot (n-1)!} \cdot \frac{1}{2} H_{n-1}\end{aligned}$$

where $H_{n-1} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n-1}$ is the partial sum of the harmonic series. Hence the second solution is

$$y_2(x) = y_1(x) \ln x + 2x^{-\frac{1}{2}} - \sum_{n=2}^{\infty} \frac{H_{n-1}}{2^{n-1}} \frac{x^{n-\frac{1}{2}}}{(n-1)!}$$

Case 4. Double root:

Example 4: Using method of Frobenius obtain two linearly independent solutions about $x = 0$ for $x^2 y'' + x(x-1)y' + (1-x)y = 0$

Solution: Here $x_0 = 0$ is a regular singular point of the given DE. Assume the solution in the form

$$y = \sum_{n=0}^{\infty} c_n x^{n+r}$$

Substituting y, y', y'' in DE, we get

$$\begin{aligned}&\sum_0^{\infty} (n+r)(n+r-1)c_n x^{n+r} + \sum (n+r)c_n x^{n+r+1} - \\ &- \sum (n+r)c_n x^{n+r} + \sum c_n x^{n+r} - \sum c_n x^{n+r+1} = 0\end{aligned}$$

The indicial equation is (with $n = 0$ from 1st, 3rd and 4th summations)

$$r(r-1) - r + 1 = 0 \quad \text{or} \quad (r-1)^2 = 0$$

Thus the indicial roots are equal $r_1 = r_2 = 1$. The recurrence relation for $n \geq 1$ is $[(n+r)(n+r-1) - (n+r) + 1]c_n + [(n+r-1) - 1]c_{n-1} = 0$. Put $r = 1$. Then the recurrence relation takes the form

$$c_n = -\frac{(n-1)}{n^2} c_{n-1} \quad \text{for } n \geq 1$$

Now $c_n = 0$ for $n \geq 1$ because of the factor $(n-1)$. Thus $c_1 = c_2 = c_3 = c_4 = \cdots = 0$. So the first solution is

$$y_1(x) = \sum_{n=0}^{\infty} c_n x^{n+1} = c_0 x$$

Choosing $c_0 = 1$, $y_1(x) = x$.

The second solution $y_2(x)$ is obtained by reduction of order. The standard form of the given DE is

$$y'' + \frac{x(x-1)}{x^2}y' + \frac{(1-x)}{x^2}y = 0$$

So $p(x) = \frac{x-1}{x}$. Assume the linearly independent solution $y_2 = uy_1$ where $u = \int \frac{1}{y_1^2} e^{-\int p dx} dx$.

Here $e^{-\int p dx} = e^{-\int (1-\frac{1}{x}) dx} = e^{\ln x - x} = xe^{-x} = \frac{x}{e^x}$. Then

$$\begin{aligned} u &= \int \frac{1}{x^2} \cdot \frac{x}{e^x} dx = \int \frac{dx}{xe^x} \\ &= \int \frac{1}{x} e^{-x} dx = \int \frac{1}{x} \cdot \sum_{n=0}^{\infty} \frac{(-x)^n}{n!} dx \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \int x^{n-1} dx \\ u &= \int \frac{dx}{x} + \sum_{n=1}^{\infty} \frac{(-1)^n}{n!} \int x^{n-1} dx \\ u &= \ln x + \sum_{n=1}^{\infty} \frac{(-1)^n}{n!} \cdot \frac{x^n}{n} \end{aligned}$$

Now the second solution is

$$\begin{aligned} y_2 &= uy_1 = ux = \left[\ln x + \sum_{n=1}^{\infty} \frac{(-1)^n}{n!} \frac{x^n}{n} \right] x \\ y_2 &= x \ln x + \sum_{n=1}^{\infty} \frac{(-1)^n}{n! \cdot n} \cdot x^{n+1} \end{aligned}$$

Case 5: Double root: solution in powers of $(x - x_0)$

Example 5: Using Frobenius method, obtain series solution about $x = 2$ for $x(x-2)y'' + 2(x-1)y' - 2y = 0$.

Solution: $x = 2$ is a regular singular point of the given DE. Put $x - 2 = t$. Then $x = t + 2$, $dx = dt$. So the given DE in t takes the form

$$(t+2)t \frac{d^2y}{dt^2} + 2(t+1) \frac{dy}{dt} - 2y = 0 \quad (1)$$

Now assume a solution of the form

$$y(t) = \sum_{n=0}^{\infty} c_n t^{n+r} \quad (2)$$

Substituting y , $\frac{dy}{dt}$, $\frac{d^2y}{dt^2}$ in (1), we get

$$\begin{aligned} &(t+2)t \sum_{n=0}^{\infty} (n+r)(n+r-1)c_n t^{n+r-2} + \\ &+ 2(t+1) \sum_{n=0}^{\infty} (n+r)c_n t^{n+r-1} - 2 \sum_{n=0}^{\infty} c_n t^{n+r} = 0 \end{aligned}$$

or

$$\begin{aligned} &\sum_{n=0}^{\infty} (n+r)(n+r-1)c_n t^{n+r} + \\ &+ 2 \sum_{n=0}^{\infty} (n+r)(n+r-1)c_n t^{n+r-1} + \\ &+ 2 \sum_{n=0}^{\infty} (n+r)c_n t^{n+r} + 2 \sum_{n=0}^{\infty} (n+r)c_n t^{n+r-1} - \\ &- 2 \sum_{n=0}^{\infty} c_n t^{n+r} = 0 \end{aligned}$$

Indicial equation is obtained by equating to zero the coefficient of lowest power of t namely t^{r-1} at $(n = 0)$

i.e., $2r(r-1) + 2r = 0$ or $r^2 = 0$ or $r = 0, 0$ roots are equal. To obtain the recurrence relation shift the index of first, third and fourth summations. Then

$$\begin{aligned} &[(n+r-1)(n+r-2) + 2(n+r-1) - 2]c_{n-1} \\ &+ 2[(n+r)(n+r-1) + 2(n+r)]c_n = 0 \end{aligned}$$

or

$$c_n = -\frac{[(n+r)^2 - (n+r) - 2]}{2(n+r)^2} c_{n-1}, \text{ for } n \geq 1$$

Take $r = 0$. Then

$$\begin{aligned} c_n &= -\frac{(n^2 - n - 2)}{2n^2} c_{n-1} \\ c_n &= -\frac{(n-2)(n+1)}{2n^2} c_{n-1} \text{ for } n \geq 1 \end{aligned}$$

For $n = 1$, $c_1 = c_0$,

For $n = 2$, $c_2 = 0$ so $c_3 = c_4 = c_5 = c_6 \cdots = 0$.

Thus the first solution is

$$y_1(t) = \sum_{n=0}^{\infty} c_n t^{n+0} = c_0 + c_1 t = c_0 + c_0 t$$

10.14 — HIGHER ENGINEERING MATHEMATICS—III

or $y_1(x) = c_0(1 + (x - 2))$

The second solution y_2 is obtained by reduction of order. Rewriting the given DE in standard form

$$\frac{d^2y}{dt^2} + \frac{2(t+1)}{t(t+2)} \frac{dy}{dt} - \frac{2}{t(t+2)}y = 0$$

Here $P(t) = \frac{2(t+1)}{t(t+2)}$. So

$$\begin{aligned} e^{-\int P(t)dt} &= e^{-\int \frac{dt}{t} + \frac{dt}{t+2}} \\ &= e^{-\ln(t)(t+2)} = \frac{1}{t(t+2)} \end{aligned}$$

since $\frac{2(t+1)}{t(t+2)} = \frac{A}{t} + \frac{B}{t+2} = \frac{1}{t} + \frac{1}{t+2}$.
The second solution is

$$y_2(t) = y_1 U$$

where $U = \int \frac{1}{y_1^2} e^{-\int P(t)dt} dt$.

Now

$$U = \int \frac{1}{(1+t)^2} \cdot \frac{1}{t(t+2)} dt$$

By partial fractions

$$\begin{aligned} \frac{1}{t(t+2)(t+1)^2} &= \frac{A}{t} + \frac{B}{t+2} + \frac{C}{t+1} + \frac{D}{(t+1)^2} \\ &= \frac{1}{2}t - \frac{1}{2} \frac{1}{t+2} + 0 - \frac{1}{(t+1)^2} \end{aligned}$$

So

$$\begin{aligned} U &= \int \frac{1}{2} \frac{dt}{t} - \frac{1}{2} \int \frac{dt}{t+2} - \int \frac{dt}{(t+1)^2} \\ &= \frac{1}{2} \ln \left(\frac{t}{t+2} \right) + \frac{1}{(t+1)} \end{aligned}$$

Then

$$\begin{aligned} y_2 &= y_1 U = (1+t) \left[\frac{1}{2} \ln \left(\frac{t}{t+2} \right) + \frac{1}{t+1} \right] \\ y_2(t) &= 1 + \frac{1}{2}(t+1) \cdot \ln \left(\frac{t}{t+2} \right) \end{aligned}$$

or

$$y_2(x) = 1 + \frac{1}{2}(x-1) \ln \left(\frac{x-2}{x} \right).$$

EXERCISE

Using Frobenius method, obtain two linearly independent solutions about $x_0 = 0$, for the following differential equations.

Distinct roots not differing by an integer

1. $2x^2y'' - xy' + (x-5)y = 0$

Ans. $y = c_1x^{5/2} \left(1 - \frac{1}{9}x + \frac{1}{198}x^2 - \frac{1}{7722}x^3 + \dots \right) + c_2x^{-1} \left(1 + \frac{1}{5}x + \frac{1}{30}x^2 + \frac{1}{90}x^3 + \dots \right)$
 $= c_1y_1 + c_2y_2$

Hint: Indicial equation: $2r^2 - 3r - 5 = 0$,
 $r_1 = \frac{5}{2}, r_2 = -1$

RR: $[2(n+r)(n+r-1) - (n+r) - 5]c_n + c_{n-1} = 0$ for $n \geq 1$.

For $r_1 = \frac{5}{2}$, $c_n = \frac{c_{n-1}}{n(2n+7)}$, for $r = -1$, $c_n = \frac{c_{n-1}}{n(2n-7)}$.

2. $2xy'' + (1+x)y' - 2y = 0$

Ans. $y_1 = x^{\frac{1}{2}} + \sum_{n=1}^{\infty} \frac{(-1)^n 3x^{n+\frac{1}{2}}}{2^n n! (2n-3)(2n-1)(2n+1)}$ and
 $y_2 = 1 + 2x + \frac{1}{3}x^2$

Hint: Indicial equation: $r(2r-1) = 0$, $r_1 = \frac{1}{2}, r_2 = 0$

RR: $(n+r)(2n+2r-1)c_n + (n+r-3)c_{n-1} = 0$

For $r_1 = \frac{1}{2}$, $c_n = \frac{(-1)^n 3c_0}{2^n n! (2n-3)(2n-1)(2n+1)}$

For $r_1 = 0$, $b_n = \frac{-(n-3)b_{n-1}}{n(2n-1)}$

3. $2x^2y'' + xy' + (x^2-3)y = 0$

Ans. $y_1 = c_0x^{3/2} \left(1 - \frac{1}{18}x^2 + \frac{1}{936}x^4 - \dots \right)$, $y_2(x) = c_0x^{-1} \left(1 + \frac{1}{2}x^2 - \frac{1}{24}x^4 + \dots \right)$

Hint: Indicial equation: $2r^2 - r - 3 = 0$,
 $r_1 = \frac{3}{2}, r_2 = -1$

RR: $[2(n+r)(n+r-1) + (n+r) - 3]c_n + c_{n-2} = 0$.

For $r_1 = \frac{3}{2}$, $c_n = \frac{c_{n-2}}{n(2n+5)}$,

For $r = -1$, $c_n = \frac{c_{n-2}}{n(2n-5)}$

4. $2x(x-1)y'' + 3(x-1)y' - y = 0$

Ans. $y_1 = c_0 - c_0 \sum_{n=1}^{\infty} \frac{1}{4n^2-1} x^n$, $y_2 = c_0(1-x)x^{-\frac{1}{2}}$

Hint: $r_1 = 0$, $r_2 = -\frac{1}{2}$, RR: $(2n+2r+1)c_n = (2n+2r-3)c_{n-1}$ for $r_1 = 0$, $c_n = \frac{2n-3}{2n+1}c_{n-1}$, for $r_2 = 0$, $c_n = \frac{(n-2)}{n}c_{n-1}$, and $c_n = 0$ for $n \geq 2$.

5. $2xy'' + 5(1+2x)y' + 5y = 0$

Ans. $y_1 = 1 + \sum_{n=1}^{\infty} \frac{3(-5)^n x^n}{n!(2n+1)(2n+3)}$,
 $y_2 = x^{-3/2} - 10x^{-1/2}$

Hint: $r_1 = 0$, $r_2 = -\frac{3}{2}$, RR: $(n+r)(2(n+r)+3)c_n = -5(2(n+r)-1)c_{n-1}$, for $r_1 = 0$, $c_n = \frac{-5(2n-1)}{n(2n+3)}c_{n-1}$

For $r = -\frac{3}{2}$, $c_n = \frac{-10(n-2)}{2n(n-\frac{3}{2})}c_{n-1}$, $c_n = 0$, for $n \geq 2$

6. $4xy'' + 2y' + y = 0$

Ans. $y_1 = c_0 \left(-\frac{x}{2!} + \frac{x^2}{4!} - \frac{x^3}{6!} + \cdots \right) = c_0 \cos \sqrt{x}$
 $y_2 = c_0(x^{1/2}) \cdot \left(1 - \frac{x}{3!} + \frac{x^2}{5!} + \cdots \right) = c_0 \cdot \sin \sqrt{x}$

Hint: $r_1 = \frac{1}{2}$, $r_2 = 0$

RR: $2(r+n)(2r+2n-1)c_n + c_{n-1} = 0$ for $n > 1$.

For $r_2 = 0$, $c_n = \frac{-1}{2n(2n-1)} \cdot c_{n-1}$

For $r_1 = \frac{1}{2}$, $c_n = -\frac{1}{2n(2n+1)}c_{n-1}$

Difference of roots a positive integer: Non-Logarithmic Case

7. $x^2y'' - xy' - (x^2 + \frac{5}{4})y = 0$

Ans. $y_1 = x^{5/2} \left[1 + \sum_{n=1}^{\infty} \frac{x^{2n}}{[2 \cdot 4 \cdot 6 \cdots 2n][5 \cdot 7 \cdot 9 \cdots (2n+3)]} \right]$
 $y_2 = x^{-1/2} \left[1 - \frac{x^2}{2} - \frac{x^4}{2 \cdot 4} \right.$
 $\left. - \sum_{n=3}^{\infty} \frac{x^{2n}}{[2 \cdot 4 \cdot 6 \cdots 2n][3 \cdot 5 \cdot 7 \cdots (2n-3)]} \right]$

Hint: $r_1 = \frac{5}{2}$, $r_2 = -\frac{1}{2}$,

RR: $[(n+r)(n+r-1) - (n+r) - \frac{5}{4}]c_n - c_{n-2} = 0$, for $n \geq 2$

For $r_1 = \frac{5}{2}$, $c_n = \frac{c_{n-2}}{n(n+3)}$, for $r_2 = -\frac{1}{2}$, $c_n = \frac{c_{n-2}}{n(n-3)}$

8. $xy'' - (4+x)y' + 2y = 0$

Ans. $y_1 = c_0 \left(1 + \frac{1}{2}x + \frac{1}{12}x^2 \right)$
 $y_2 = c_5 \left(x^5 + \sum_{n=6}^{\infty} \frac{60x^n}{(n-5)!(n-1)(n-2)} \right)$

Hint: $r_1 = 5$, $r_2 = 0$

RR: $(n+r)(n+r-5)c_n - (n+r-3)c_{n-1} = 0$

For $r_2 = 0$, $n(n-5)c_n - (n-3)c_{n-1} = 0$, c_0 and c_5 are arbitrary, for $n > 5$, $c_n = \frac{(n-3)(c_{n-1})}{n(n-5)}$.

9. $x^2y'' + 2x(x-2)y' + 2(2-3x)y = 0$

Ans. $y_1 = c_0(x-2x^2+2x^3)$
 $y_2 = c_3 \left[x^4 + \sum_{n=4}^{\infty} \frac{(-2)^{n-3}}{n!} 6 \cdot x^{n+1} \right]$

Hint: $r_1 = 4$, $r_2 = 1$. For $r_2 = 1$, $c_n = \frac{-2}{n}c_{n-1}$. For $r_1 = 4$, $c_n = \frac{-2}{n+3}c_{n-1}$.

10. $x(1+x)y'' + (x+5)y' - 4y = 0$ about $x = -1$

Ans. $y = c_0[1 + (x+1) + \frac{1}{2}(x+1)^2]$
 $+ \frac{c_5}{12} \left[\sum_{n=5}^{\infty} (n-4)(n-3)(n+1)(x+1)^n \right]$

11. $(1-x^2)y'' + 2xy' + y = 0$

Ans. $y_1 = c_0 \left(1 - \frac{x^2}{2} + \frac{x^4}{8} + \cdots \right)$
 $y_2 = c_1 \left(x - \frac{x^3}{5} + \frac{x^5}{40} \cdots \right)$

Hint: $r_1 = 1$, $r_2 = 0$

RR: $(r+n+1)(r+n)c_{n+1} = [(r+n)^2 - 5(r+n) + 3]c_{n-1}$

For $r_2 = 0$, $c_{n+1} = \frac{n^2-5n+3}{n(n+1)}c_{n-1}$, c_0 and c_1 are arbitrary.

Difference of roots a positive integer: Logarithmic case

12. $x^2y'' + (x^2-3x)y' + 3y = 0$

Ans. $y_1 = c_2x^3e^{-x}$
 $y_2 = \left(-\frac{x}{2} - \frac{x^2}{2} + \frac{3}{4}x^3 - \frac{1}{4}x^4 + \cdots \right)$
 $+ \frac{1}{2}x^3e^{-x} \ln x$

Hint: $r_1 = 3$, $r_2 = 1$

RR: $[(n+r)(n+r-1) - 3(n+r)]c_n + (n+r-1)c_{n-1} = 0$, $n \geq 1$

For $r_1 = 3$, $c_n = \frac{c_{n-1}}{n}$, $n \geq 1$. For $r_2 = 1$, solution involves logarithm, obtained by reduction of order.

13. $x^2y'' + x(1-x)y' - (1+3x)y = 0$

Ans. $y_1 = -3x - \sum_{n=3}^{\infty} \frac{(n+1)x^{n-1}}{(n-2)!}$

$$y_2 = y_1 \ln x + x^{-1} - 2 - \sum_{n=0}^{\infty} \left[\frac{1-(n+3)H_n}{n!} \right] x^{n+1}$$

Here H_n = partial sum of Harmonic series

$$H_n = \left[1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \dots + \frac{1}{n} \right]$$

Hint: $r_1 = 1, r_2 = -1$,

RR: $(n+r+1)(n+r-1)c_n =$

$(n+r+2)c_{n-1}$

$$\text{For } n \geq 1, c_n = \frac{(n+r+2)c_0}{(r+2)[r(r+1)\dots(r+n-1)]}$$

First solution

$$y_1 = y(x, r) = (r+1)x^r + \frac{(r+1)(r+3)x^{1+r}}{r(r+2)} + \frac{(r+4)x^{2+r}}{r(r+2)} + \sum_{n=3}^{\infty} \frac{(n+r+2)x^{n+r}}{(r+2)r[(r+2)(r+3)\dots(r+n-1)]}$$

Second solution $y_2 = \frac{\partial y(x, r)}{\partial r} \Big|_{r=-1}$.

$$14. (x^2 - x)y'' - xy' + y = 0$$

$$\text{Ans. } y_1 = x, y_2 = x \ln x + 1$$

Hint: $r_1 = 1, r_2 = 0$,

RR: $(n+r-1)c_n - (n+r+1)(n+r)c_{n+1} = 0$

$$\text{For } r_1 = 1, c_{n+1} = \frac{n^2}{(n+2)(n+1)} c_n$$

Second solution by reduction of order.

$$15. xy'' - 3y' + xy = 0$$

$$\text{Ans. } y_1 = -\frac{1}{2 \cdot 2 \cdot 4} x^4 + \frac{x^6}{2 \cdot 2 \cdot 2 \cdot 4 \cdot 6} - \frac{x^8}{2 \cdot 2 \cdot 2 \cdot 4 \cdot 2 \cdot 6 \cdot 8} + \dots$$

$$y_2 = y_1 \ln x + 1 + \frac{1}{2^2} x^2 + \frac{1}{2^5 2!} x^4 - \frac{1}{2^6 3! 1!} \left(1 + \frac{1}{2} + \frac{1}{3} \right) x^6 + \dots$$

Hint: $r_1 = 4, r_2 = 0$

RR: $(n+r)(n+r-4)c_n = -c_{n-2}$, for $n \geq 2$

Second solution by $\frac{\partial y}{\partial r}$ with $r = 0$ where

$$\bar{y}(x, r) = x^r \left[r - \frac{rx^2}{(2+r)(r-2)} + \frac{x^4}{(r-2)(r+2)(r+4)} - \frac{x^6}{(r-2)(r+2)^2(r+4)(r+6)} + \dots \right]$$

$$16. (x - x^2)y'' - (1 + 3x)y' - y = 0$$

$$\text{Ans. } y_1 = c_0[-2x^2 - 6x^3 + \dots]$$

$$y_2 = y_1 \log x + c_0[1 - x - 5x^2 - 11x^3 + \dots]$$

Hint: $r_1 = 2, r_2 = 0$, First solution $y(x, r)$ at $r = 0$

$$y(x, r) = c_0 x^r \left[r + \frac{r(r+1)}{r-1} x + \frac{(r+1)(r+2)}{r-1} x^2 + \frac{(r+1)(r+2)(r+3)}{(r-1)(r+1)} x^3 + \dots \right]$$

Second solution is $\frac{\partial y(x, r)}{\partial r}$ at $r = 0$.

Equal roots (double root)

$$17. x(x-1)y'' + (3x-1)y' + y = 0$$

(special case of Hypergeometric equation)

$$\text{Ans. } y_1 = \frac{1}{1-x}, y_2 = \frac{\ln x}{1-x}$$

Hint: $r_1 = r_2 = 0$, RR: $c_{n+1} = c_n$. So $c_0 = c_1 = c_2 = \dots = 1$, second solution by reduction of order

$$18. x^2 y'' + 3xy' + (1-2x)y = 0$$

$$\text{Ans. } y_1 = x^{-1} + \sum_{n=1}^{\infty} \frac{2^n x^{n-1}}{(n!)^2}$$

$$y_2 = y_1 \cdot \ln x - \sum_{n=1}^{\infty} \frac{2^{n+1} \cdot H_n \cdot x^{n-1}}{(n!)^2}$$

Hint: $r_1 = r_2 = -1$

RR: $(n+r+1)^2 c_n - 2c_{n-1} = 0$ for $n \geq 1$. Also for $n \geq 1, c_n = \frac{2^n c_0}{[(r+2)(r+3)\dots(r+n+1)]^2} = c_n(r)$

First solution $y(x, r) = x^r + \sum_{n=1}^{\infty} c_n(r) \cdot x^{n+r}$ at $r = -1$

Second solution $\frac{\partial y(x, r)}{\partial r}$ at $r = -1$

$$19. x^2 y'' - x(1+x)y' + y = 0$$

$$\text{Ans. } y_1 = c_0 x e^x, y_2 = c_0 x e^x \ln x - c_0 x \left[x - \frac{3}{4} x^2 + \frac{11}{6^2} x^3 + \dots \right]$$

Hint: $r_1 = r_2 = 1$

RR: $c_n = \frac{c_{n-1}}{(n+r-1)}$ for $n \geq 1$. Also $c_n = \frac{c_0}{r(r+1)(r+2)\dots(r+n-1)} = c_n(r)$

First solution

$$y_1 = c_0 x^r \left[1 + \frac{x}{r} + \frac{x^2}{r(r+1)} + \frac{x^3}{r(r+1)(r+2)} + \dots \right] \text{ at } r = 1.$$

Second solution is $y_2(x) = \frac{\partial y_1(x, r)}{\partial r}$ at $r = 1$ or second solution by reduction of order.

$$20. (x - x^2)y'' + (1 - x)y' - y = 0$$

$$\text{Ans. } y_1 = c_0 \left(1 + x + \frac{1}{2} x^2 + \frac{1}{2} \cdot \frac{5}{9} x^3 + \dots \right)$$

$$y_2 = c_0 \log x \cdot \left(1 + x + \frac{1}{2} x^2 + \frac{1}{2} \cdot \frac{5}{9} x^3 + \dots \right) + c_0 \left(-2x - x^2 - \frac{14}{27} x^3 \dots \right)$$

Hint: $r_1 = r_2 = 0$

RR: $(r+n)^2 c_n = [(r+n-1)^2 + 1] c_{n-1}$

First solution $y(x, r)$ at $r = 0$

$$y_1 = c_0 x^r \left[1 + \frac{(r^2+1)}{(r+1)^2} x + \frac{[(r+1)^2+1][r^2+1]}{(r+2)^2(r+1)^2} x^2 + \dots \right]$$

Second solution $\frac{\partial y(x,r)}{\partial r}$ at $r = 0$

$$21. \quad xy'' + y' + xy = 0$$

$$\text{Ans. } y_1 = c_0 \left[1 - \frac{1}{2}x^2 + \frac{1}{2^2 4^2}x^4 - \frac{1}{2^2 4^2 6^2}x^6 + \dots \right]$$

$= J_0(x)$ = Bessel's function of first kind

$$y_2 = y_1 \ln x + c_0 \left[\frac{1}{2^2}x^2 - \frac{1}{2^2 4^2} \left(1 + \frac{1}{2} \right) x^4 + \frac{1}{2^2 4^2 6^2} \left(1 + \frac{1}{2} + \frac{1}{3} \right) x^6 + \dots \right]$$

$= y_0(x)$

= Bessel's function of second kind

Hint: $r_1 = r_2 = 0$, $a_1 = a_3 = a_5 = a_7 = \dots = 0$

First solution $y(x, r)$ at $r = 0$

$$y(x, r) = c_0 x^r \left[1 - \frac{x^2}{(r+2)^2} + \frac{x^4}{(r+2)^2(r+4)^2} - \frac{x^6}{(r+2)^2(r+4)^2(r+6)^2} + \dots \right]$$

Second solution is $\frac{\partial y(x,r)}{\partial r}$ at $r = 0$.

10.4 ORTHOGONALITY OF FUNCTIONS

Orthogonality is one of the most useful concept ever introduced in applied mathematics. Let $f(x)$ and $g(x)$ be any two functions which are piecewise continuous on the interval $a < x < b$. The *inner product* of f and g , denoted by $\langle f, g \rangle$ is defined as the number

$$\langle f, g \rangle = \int_a^b f(x)g(x)dx$$

The interval $a < x < b$ is known as the *fundamental interval*. The *norm* of $f(x)$, denoted by $\|f\|$, is defined by the non-negative number

$$\|f\| = \sqrt{\int_a^b [f(x)]^2 dx} = \langle f, f \rangle^{\frac{1}{2}}$$

Orthogonal: Two functions f and g are said to be orthogonal on the interval $a < x < b$ if their inner product is zero i.e.,

$$\int_a^b f(x)g(x)dx = 0.$$

An infinite sequence (system or set) of functions $\phi_1(x), \phi_2(x), \dots, \phi_n(x), \dots$ is said to be orthogonal on the interval $[a, b]$ if these functions are mutually

Orthogonal i.e.,

$$\int_a^b \phi_m(x)\phi_n(x)dx = 0 \quad \text{for } m \neq n$$

Any function $f(x)$, with non-zero norm, is said to be *normalized* by dividing it by its norm i.e., $\frac{f(x)}{\|f(x)\|}$

Suppose the norm of any of these functions is not zero, then the new sequence of functions

$$\frac{\phi_1(x)}{\|\phi_1(x)\|}, \frac{\phi_2(x)}{\|\phi_2(x)\|}, \dots, \frac{\phi_n(x)}{\|\phi_n(x)\|}, \dots$$

are said to be *orthonormal* because they are orthogonal and each have norm unity. Thus new set of functions

$$\psi_n(x) = \frac{\phi_n(x)}{\|\phi_n(x)\|} \quad \text{for } n = 1, 2, 3, \dots$$

are orthonormal if

$$\langle \psi_m, \psi_n \rangle = \int_a^b \psi_m(x)\psi_n(x)dx$$

$$\delta_{mn} = \begin{cases} 0 & \text{for } m \neq n \\ 1 & \text{for } m = n \end{cases}$$

Here δ_{mm} is the Kronecker* delta.

More generally these definitions are modified w.r.t. a *weight function* $P(x)$ as follows:

Inner product of f and g w.r.t. the weight function $P(x) > 0$ is

$$\langle f, g \rangle = \int_a^b P(x)f(x)g(x)dx$$

Two functions f and g are said to be orthogonal w.r.t. the weight function $P(x)$ on the interval $a < x < b$ if

$$\int_a^b P(x)f(x)g(x)dx = 0$$

Finally a set of functions $\phi_n(x)$ on (a, b) are said to be orthogonal w.r.t. the weight function $P(x) > 0$ if all pairs of distinct functions in the set are orthogonal i.e.,

$$\int_a^b P(x)\phi_m(x)\phi_n(x)dx = 0 \quad \text{for } m \neq n$$

Norm is similarly defined as

*Leopold Kronecker (1823-1891), German mathematician.

10.18 — HIGHER ENGINEERING MATHEMATICS—III

$$\|f\| = \langle f, f \rangle^{\frac{1}{2}} = \int_a^b P(x)[f(x)]^2 dx \geq 0$$

Note 1: Orthogonality w.r.t. $P(x) = 1$ is simply referred to as “orthogonal”.

Note 2: Weight functions other than unity will occur in Bessel functions, Hermite polynomials, Laguerre polynomials and several Sturm-Liouville problems.

Example 1: Hermite polynomials $H_n(x)$ are orthogonal w.r.t. the weight function e^{-x^2} on the interval $-\infty < x < \infty$. i.e.,

$$\int_{-\infty}^{\infty} e^{-x^2} H_m(x) H_n(x) dx = \begin{cases} 0 & \text{if } m \neq n \\ 2^n n! \sqrt{\pi} & \text{if } m = n \end{cases}$$

Generalized Fourier Series

A vector in three-dimensional space, in analytic geometry is represented in terms of an orthonormal set of vectors $\bar{i}, \bar{j}, \bar{k}$ as

$$\bar{A} = A_1 \bar{i} + A_2 \bar{j} + A_3 \bar{k}$$

Extending this concept, a vector in an n -dimensional Euclidean space E_n can be represented as

$$\bar{A} = A_1 \bar{e}_1 + A_2 \bar{e}_2 + \dots + A_n \bar{e}_n = \sum_{i=1}^n A_i \bar{e}_i$$

where the system of vectors $\{\bar{e}_1, \bar{e}_2, \dots, \bar{e}_n\}$ form an orthonormal set in E_n . In a similar way any given function $f(x)$ belonging to $C_p(a, b)$, the space of piecewise continuous functions on the interval $a < x < b$, can be represented in terms of an orthonormal set of functions $\phi_n(x)$, ($n = 1, 2, 3, \dots$) in the space $C_p(a, b)$ w.r.t. a weight function $P(x)$, as an infinite series of the form

$$f(x) = a_0 \phi_0(x) + a_1 \phi_1(x) + a_2 \phi_2(x) + \dots + a_n \phi_n(x) + \dots \quad (1)$$

The infinite series (1) is known as the *generalized Fourier series* of $f(x)$ w.r.t. the orthonormal set $\{\phi_n(x)\}$ on the interval $a < x < b$ with weight function $P(x)$. Series (1) is also known as *orthogonal expansion* or *eigenfunction expansion* (in case

$\phi(x)$ are eigenfunctions of a Sturm-Liouville problem). The coefficients c'_n s are known as *Fourier constants*, which can be determined using the orthogonality properties as follows. Multiplying (1) on both sides by $P(x)\phi_n(x)$ and integrating w.r.t. x from a to b , we get

$$\begin{aligned} \int_a^b P(x) f(x) \phi_n(x) dx &= \int_a^b P(x) \phi_n(x) \sum_{i=0}^{\infty} a_i \phi_i(x) dx \\ &= \int_a^b P(x) \sum_{i=0}^{\infty} a_i \phi_n(x) \phi_i(x) dx \\ &= \sum_{i=0}^{\infty} a_i \int_a^b P(x) \phi_n(x) \phi_i(x) dx \\ &= a_n \end{aligned}$$

since $\int_a^b P(x) \phi_n(x) \phi_m(x) dx = 0$ for $m \neq n$.

$$\text{Thus } \boxed{a_n = \int_a^b P(x) f(x) \phi_n(x) dx} \quad (2)$$

for $n = 0, 1, 2, 3, \dots$

Completeness

Given a set of orthonormal functions $\{\phi_n(x)\}$, in general, *no* nontrivial function $f(x)$ exists which is orthogonal to *all* $\phi_n(x)$. Thus an orthonormal set of functions $\{\phi_n(x)\}$ is said to be *complete* if any function $f(x)$ which is orthogonal to *all* $\phi_n(x)$ is a *null function* (which is identically zero with zero norm). In other words, the orthogonal set $\{\phi_n(x)\}$ is complete, if *each* function f can have formal representation (1).

Convergence

If the orthonormal set $\{\phi_n(x)\}$ is complete, then the formal representative of any function $f(x)$ by the infinite series (1) is valid and converges to $f(x)$ at all points of continuity and converges to the mean value $\frac{1}{2}[f(x+) + f(x-)]$ at points of discontinuity.

The classical example of orthogonal expansion (1) is the Fourier series, which is the daily bread of the physicist and engineer. Fourier series is discussed in detail in Chapter 17.

WORKED OUT EXAMPLES

Example 1: Show that $1, \cos 4nx, \sin 4nx, n = 1, 2, 3, \dots$ on $0 \leq x \leq \frac{\pi}{2}$ are orthogonal. Find the corresponding orthonormal set of functions.

Solution: Consider for any $n = 1, 2, 3, \dots$
 $\int_0^{\frac{\pi}{2}} 1 \cdot \cos 4nx = \frac{1}{4} \int_0^{2\pi} \cos nt \, dt$ where $4x = t$

$$= \frac{1}{4} \cdot \frac{\sin nt}{-n} \bigg|_0^{2\pi} = 0$$

So, the functions 1 and $\cos 4nx$ for $n = 1, 2, 3, \dots$ are orthogonal. Similarly $\int_0^{\frac{\pi}{2}} 1 \cdot \sin 4nx \, dx = \frac{1}{4} \int_0^{2\pi} \sin nt \, dt = \frac{1}{4} \cdot \frac{\cos nt}{n} \bigg|_0^{2\pi} = 0$

Also
 $\int_0^{\frac{\pi}{2}} \cos 4mx \cdot \sin 4nx \, dx = \frac{1}{4} \int_0^{2\pi} \cos mt \cdot \sin nt \, dt = 0$

Thus the set of functions $1, \cos 4nx, \sin 4nx$ for $n = 1, 2, 3, \dots$ are mutually orthogonal. Now since

$$\int_0^{\frac{\pi}{2}} 1 \cdot 1 \cdot dx = x \bigg|_0^{\frac{\pi}{2}} = \frac{\pi}{2},$$

therefore norm of the function 1 is $\sqrt{\frac{\pi}{2}}$. Similarly since $\int_0^{\frac{\pi}{2}} \cos 4nx \cdot \cos 4nx \, dx = \frac{1}{4} \int_0^{2\pi} \cos^2 nt \, dt = \frac{1}{4} \cdot \pi$

So the norm of the function $\cos 4nx$ is $\sqrt{\frac{\pi}{4}}$.

Finally norm of $\sin 4nx$ is $\sqrt{\frac{\pi}{4}}$. Then the orthonormal set of functions are obtained by dividing the functions by their norms. Thus the corresponding orthonormal set of functions are $\sqrt{\frac{2}{\pi}}, \frac{2}{\sqrt{\pi}} \cdot \cos 4nx, \frac{2}{\sqrt{\pi}} \sin 4nx$ for $n = 1, 2, \dots$

Example 2: Prove that the functions $f_1(x) = b$, and $f_2(x) = x^3$ are orthogonal on the interval $(-a, a)$ where a and b are real constants. Determine constants A and B such that the function $f_3(x) = 1 + Ax + Bx^2$ is orthogonal to both $f_1(x)$ and $f_2(x)$ on $(-a, a)$.

Solution: f_1, f_2 are orthogonal if $\int_{-a}^a f_1(x) f_2(x) \, dx = 0$. So consider $\int_{-a}^a b \cdot x^3 \, dx$

$= b \int_{-a}^a x^3 \, dx = b \cdot 0 = 0$. Thus f_1 and f_2 are orthogonal. Since f_3 is orthogonal to f_1 , we have

$$\int_{-a}^a (1 + Ax + Bx^2) \cdot 1 \, dx = 0$$

$$\text{or } \int_{-a}^a dx + A \int_{-a}^a x \, dx + B \int_{-a}^a x^2 \, dx = 0$$

$2a + A \cdot 0 + \frac{B}{3} 2a^3 = 0 \therefore B = \frac{-3}{a^2}$
 Also since f_3 is orthogonal to f_2 , we have

$$\int_{-a}^a (1 + Ax + Bx^2) x^3 \, dx = 0$$

or $\int_{-a}^a x^3 \, dx + A \int_{-a}^a x^4 \, dx + B \int_{-a}^a x^5 \, dx = 0$
 $0 + A \cdot \frac{2a^5}{5} + B \cdot 0 = 0 \therefore A = 0$

Example 3: Prove that the Laguerre* polynomials $f_1(x) = 1 - x$, $f_2(x) = 1 - 2x + \frac{1}{2}x^2$, $f_3(x) = 1 - 3x + \frac{3}{2}x^2 - \frac{1}{6}x^3$ are orthogonal w.r.t. the weight function e^{-x} on $0 \leq x \leq \infty$. Determine the corresponding orthonormal functions.

Solution: Consider

$$\begin{aligned} & \int_0^{\infty} P(x) f_1(x) f_2(x) \, dx = \\ & \int_0^{\infty} e^{-x} (1 - x) \left(1 - 2x + \frac{x^2}{2} \right) dx \\ & = \int_0^{\infty} e^{-x} \left(1 - 3x + \frac{5}{2}x^2 - \frac{1}{2}x^3 \right) dx \end{aligned}$$

We know that $\int_0^{\infty} x^n e^{-x} \, dx = n!$ for n positive integer. So

$$\begin{aligned} \int_0^{\infty} e^{-x} f_1 \cdot f_2 \, dx &= 1 \cdot 1 - 3 \cdot 1 + \frac{5}{2} \cdot 2! - \frac{1}{2} 3! \\ &= 1 - 3 + 5 - 3 = 0 \end{aligned}$$

Thus f_1 and f_2 are orthogonal w.r.t. e^{-x} on the interval $(0, \infty)$.

Now consider

$$\begin{aligned} & \int_0^{\infty} e^{-x} f_1(x) f_3(x) \, dx \\ &= \int_0^{\infty} e^{-x} (1 - x) \left(1 - 3x + \frac{3}{2}x^2 - \frac{1}{6}x^3 \right) dx \\ &= \int_0^{\infty} e^{-x} \left[1 - 4x + \frac{9}{2}x^2 - \frac{5}{3}x^3 + \frac{1}{6}x^4 \right] dx \end{aligned}$$

*Edmond Laguerre (1834-1886), French mathematician.

10.20 — HIGHER ENGINEERING MATHEMATICS—III

$$\begin{aligned}
 &= 1 \cdot 1 - 4 \cdot 1 + \frac{9}{2} \cdot 2! - \frac{5}{3} \cdot 3! + \frac{1}{6} \cdot 4! \\
 &= 1 - 4 + 9 - 10 + 4 = 0
 \end{aligned}$$

So f_1 and f_3 are orthogonal.

Finally consider

$$\begin{aligned}
 &\int_0^\infty e^{-x} f_2(x) f_3(x) dx \\
 &= \int_0^\infty e^{-x} \left(1 - 2x + \frac{x^2}{2}\right) \left(1 - 3x + \frac{3}{2}x^2 - \frac{1}{6}x^3\right) dx \\
 &= \int_0^\infty e^{-x} \left[1 - 5x + 8x^2 - \frac{28}{6}x^3 + \frac{13}{12}x^4 - \frac{1}{12}x^5\right] dx \\
 &= 1 \cdot 1 - 5 \cdot 1 + 8 \cdot 2! - \frac{28}{6} \cdot 3! + \frac{13}{12} \cdot 4! - \frac{1}{12} \cdot 6! \\
 &= 1 - 5 + 16 - 28 + 26 - 10 = 43 - 43 = 0
 \end{aligned}$$

Thus the functions f_1, f_2, f_3 are orthogonal w.r.t. e^{-x} on $(0, \infty)$.

Norm of the function $f_1(x)$ w.r.t. e^{-x} on $(0, \infty)$ is

$$\sqrt{\int_0^\infty e^{-x} \cdot f_1(x) \cdot f_1(x) dx}.$$

$$\begin{aligned}
 &\text{Since } \int_0^\infty e^{-x} (1-x)^2 dx \\
 &= \int_0^\infty e^{-x} (1+x^2-2x) dx \\
 &= 1 \cdot 1 + 1 \cdot 2 - 2 \cdot 1 = 1
 \end{aligned}$$

So the norm of f_1 is $\|f_1\| = 1$.

Similarly consider

$$\begin{aligned}
 &\int_0^\infty e^{-x} \left(1 - 2x + \frac{x^2}{2}\right)^2 dx \\
 &= \int_0^\infty e^{-x} \left[1 + 4x^2 + \frac{x^4}{4} - 4x - 2x^3 + x^2\right] dx \\
 &= 1 \cdot 1 - 4 \cdot 1 + 5 \cdot 2! - 2 \cdot 3! + \frac{1}{4} \cdot 4! = 1
 \end{aligned}$$

Then norm of f_2 is 1.

Also

$$\begin{aligned}
 &\int_0^\infty e^{-x} \left(1 - 3x + \frac{3}{2}x^2 - \frac{1}{6}x^3\right)^2 dx \\
 &= \int_0^\infty e^{-x} \left[1 + 9x^2 + \frac{9}{4}x^4 + \frac{1}{36}x^6 - 6x + 3x^2\right. \\
 &\quad \left. - \frac{1}{3}x^3 - 9x^3 + x^4 - \frac{1}{2}x^5\right] dx \\
 &= \int_0^\infty e^{-x} \left[1 - 6x + 12x^2 - \frac{28}{3}x^3 + \frac{13}{4}x^4\right. \\
 &\quad \left. - \frac{1}{2}x^5 + \frac{1}{36}x^6\right] dx
 \end{aligned}$$

$$\begin{aligned}
 &= 1 - 6 \cdot 1 + 12 \cdot 2! - \frac{28}{3} \cdot 3! + \frac{13}{4} \cdot 4! - \frac{1}{2} \cdot 5! + \\
 &\quad + \frac{1}{36} \cdot 6! = 1
 \end{aligned}$$

So norm of f_3 is one. Thus the orthonormal set is itself i.e., $f_1 = (1-x)$, $f_2 = \left(1 - 2x + \frac{x^2}{2}\right)$

$$\text{and } f_3(x) = 1 - 3x + \frac{3}{2}x^2 - \frac{1}{6}x^3$$

Orthogonality of Laguerre polynomials

Example 4: Prove that the Laguerre polynomials $L_n(x)$ are orthonormal w.r.t. the weight function e^{-x} on the interval $0 < x < \infty$.

Solution: The Laguerre polynomial $L_m(x)$ is defined by the generating function

$$\sum_{m=0}^{\infty} s^m L_m(x) = \frac{1}{(1-s)} e^{-\left(\frac{xs}{1-s}\right)} \quad (1)$$

Also

$$\sum_{n=0}^{\infty} t^n L_n(x) = \frac{1}{(1-t)} e^{-\left(\frac{xt}{1-t}\right)} \quad (2)$$

Multiplying (1) and (2), we get

$$\begin{aligned}
 &\left(\sum_{m=0}^{\infty} s^m \cdot L_m(x)\right) \left(\sum_{n=0}^{\infty} t^n \cdot L_n(x)\right) \\
 &= \frac{1}{(1-s)} \cdot \frac{1}{(1-t)} \cdot e^{-\left(\frac{xs}{1-s} + \frac{xt}{1-t}\right)} \\
 &\sum_{m,n=0}^{\infty} s^m \cdot t^n \cdot L_m(x) \cdot L_n(x) = \frac{1}{(1-s)(1-t)} e^{-\left(\frac{xs}{1-s} + \frac{xt}{1-t}\right)}
 \end{aligned}$$

Multiplying both sides by the weight function $P(x) = e^{-x}$ and integrating w.r.t. x from 0 to ∞ , we have

$$\begin{aligned}
 &\sum_{m,n=0}^{\infty} \left[\int_0^\infty e^{-x} L_m(x) \cdot L_n(x) dx \right] s^m \cdot t^n \\
 &= \frac{1}{(1-s)(1-t)} \int_0^\infty \exp \left\{ -x \left(1 + \frac{s}{1-s} + \frac{t}{1-t} \right) \right\} dx
 \end{aligned}$$

Integrating the RHS we get

$$\begin{aligned}
 &= \frac{1}{(1-s)(1-t)} \cdot \left(1 + \frac{s}{1-s} + \frac{t}{1-t} \right)^{-1} \\
 &= \frac{1}{(1-s)(1-t)} \frac{(1-s)(1-t)}{(1-s)(1-t) + s(1-t) + t(1-s)} = \frac{1}{1-st} \\
 &= \sum_{n=0}^{\infty} (st)^n
 \end{aligned}$$

Now compare the coefficients of like power of (st) on both sides. For $m \neq n$, the coefficients of terms containing $s^m t^n$ in the LHS should be zero (because no such terms exists in the RHS). Thus

$$\int_0^\infty e^{-x} L_m(x) L_n(x) dx = 0 \text{ for } m \neq n$$

For $m = n$, the coefficient of $(st)^n$ in the LHS is one. So

$$\int_0^\infty e^{-x} L_n^2(x) dx = 1 \quad \text{for } m = n$$

Thus the Laguerre polynomials $L_n(x)$ are orthonormal w.r.t. the weight function e^{-x} on the interval $(0, \infty)$.

EXERCISE

Orthogonality

Show that the set of functions $\{\phi_n(x)\}$ are orthogonal on the interval $a < x < b$. Normalize and obtain the orthonormal set $\{\psi_n(x)\}$, where

$$1. \phi_n(x) = \sin \frac{n\pi x}{c} \text{ in } 0 < x < c; n = 1, 2, 3, \dots$$

$$\text{Ans. } \psi_n(x) = \sqrt{\frac{2}{c}} \sin \left(\frac{n\pi x}{c} \right), n = 1, 2, 3, \dots$$

$$\text{Hint: } \int_0^c \sin \frac{n\pi x}{c} \cdot \sin \frac{m\pi x}{c} dx = \begin{cases} 0 & \text{for } m \neq n \\ \frac{c}{2} & \text{for } m = n \end{cases}$$

$$2. \phi_n(x) = \cos \frac{n\pi x}{c} \text{ in } 0 < x < c, n = 0, 1, 2, 3, \dots$$

$$\text{Ans. } \psi_0(x) = \frac{1}{\sqrt{c}}, \psi_n(x) = \sqrt{\frac{2}{c}} \cos \frac{n\pi x}{c}, n = 0, 1, 2, 3, \dots$$

$$\text{Hint: } \int_0^c \cos \frac{n\pi x}{c} \cdot \cos \frac{m\pi x}{c} dx = \begin{cases} 0 & \text{for } m \neq n \\ \frac{c}{2} & \text{for } m = n \end{cases}$$

$$3. 1, \cos nx, \sin nx, n = 1, 2, 3, \dots, [-\pi, \pi]$$

$$\text{Ans. } \frac{1}{\sqrt{2\pi}}, \frac{1}{\sqrt{\pi}} \cos n\pi, \frac{1}{\sqrt{\pi}} \sin n\pi$$

$$4. 1, \cos \frac{n\pi x}{L}, \sin \frac{n\pi x}{L}, n = 1, 2, 3, \dots, [-L, L]$$

$$\text{Ans. } \frac{1}{\sqrt{2L}}, \frac{1}{\sqrt{L}} \cos \left(\frac{n\pi x}{L} \right), \frac{1}{\sqrt{L}} \sin \frac{n\pi x}{L}$$

$$5. 1, \cos nx, n = 1, 2, 3, \dots, [0, \pi]$$

$$\text{Ans. } \frac{1}{\sqrt{\pi}}, \sqrt{\frac{2}{\pi}} \cos nx$$

$$6. \sin nx, n = 1, 2, 3, \dots [0, \pi].$$

$$\text{Ans. } \sqrt{\frac{2}{\pi}} \sin nx$$

$$7. \sin n\pi x, n = 1, 2, 3, \dots \left(-\frac{\pi}{\omega} \leq x \leq \frac{\pi}{\omega} \right)$$

$$\text{Ans. } \sqrt{\frac{\omega}{\pi}} \cdot \sin n\pi x$$

$$8. 1, \cos 2nx, n = 1, 2, 3, \dots, 0 \leq x \leq \pi$$

$$\text{Ans. } \frac{1}{\sqrt{\pi}}, \sqrt{\frac{2}{\pi}} \cos 2nx$$

$$9. 1, \cos \left(\frac{2n\pi x}{L} \right), \sin \left(\frac{2n\pi x}{L} \right), n = 1, 2, 3, \dots, -\frac{L}{2} \leq x \leq \frac{L}{2}$$

$$\text{Ans. } \frac{1}{\sqrt{L}}, \sqrt{\frac{2}{L}} \cos \left(\frac{2n\pi x}{L} \right), \sqrt{\frac{2}{L}} \sin \left(\frac{2n\pi x}{L} \right)$$

10. Find the function $f_3(x) = 1 + Ax + Bx^2$ such that $f_1 = 1, f_2(x) = x, f_3(x)$ and are orthogonal to each other on $(-1, 1)$.

$$\text{Ans. } A = 0, B = 3$$

10.5 STURM*-LIIOUVILLE** PROBLEMS

A Sturm-Liouville problem is a boundary value problem consisting of a linear homogeneous second order ordinary differential equation, together with a pair of homogeneous boundary conditions.

Consider any equation of the form

$$a_0(x) \frac{d^2 y}{dx^2} + a_1(x) \frac{dy}{dx} + [a_2(x) + \lambda a_3(x)] y = 0$$

defined on a finite interval $a < x < b$. This can be written, assuming $a_0(x) \neq 0$, $\frac{d^2 y}{dx^2} + \frac{a_1(x)}{a_0(x)} \frac{dy}{dx} + \left[\frac{a_2(x)}{a_0(x)} + \lambda \frac{a_3(x)}{a_0(x)} \right] y = 0$. Multiply the above equation

throughout by $r(x) = e^{\int \frac{a_1(x)}{a_0(x)} dx}$. Then the equation takes the form

$$r(x) \frac{d^2 y}{dx^2} + r(x) \frac{a_1(x)}{a_0(x)} \frac{dy}{dx} + [q(x) + \lambda P(x)] y = 0$$

$$\text{where } q(x) = \frac{a_2(x)}{a_0(x)} r(x), P(x) = \frac{a_3(x)}{a_0(x)} r(x).$$

Combining the first two terms, this equation can be rewritten as

$$\frac{d}{dx} \left[r(x) \frac{dy}{dx} \right] + [q(x) + \lambda P(x)] y = 0 \quad (1)$$

Here the functions $P(x), q(x), r(x), r'(x)$ are continuous real valued functions on $a \leq x \leq b$ and are free of the parameter λ . Also $P(x) > 0$ and $r(x) > 0$ when $a \leq x \leq b$, while $q(x)$ is non-positive. Equation (1) is known as *Sturm-Liouville* equation. Suppose $y(x)$ is required to satisfy the homogeneous *separated* boundary conditions

$$k_1 y(a) + k_2 y'(a) = 0 \quad (2)$$

*J.C.F. Sturm (1803-1855), Swiss mathematician.

** J. Liouville (1809-1882), French mathematician.

and

$$l_1 y(b) + l_2 y'(b) = 0 \quad (3)$$

where k_1, k_2, l_1, l_2 are real constants independent of λ . The conditions (2), (3) are called separated because (2) is satisfied at $x = a$ and (3) is satisfied at $x = b$. Further assume that *both* k_1 and k_2 are not zero in (2) and also *both* l_1 and l_2 are not zero in (3).

A *regular Sturm-Liouville problem* consists of the Sturm-Liouville equation (1) and the homogeneous boundary conditions (2) and (3).

The obvious solution $y(x) = 0$ is known as a trivial solution and is of no interest. Only non-trivial solutions $y \neq 0$ are of practical use. Although $p(x)$, $q(x)$, $r(x)$, a , b , k_1 , k_2 , m_1 , m_2 are all specified, λ is a free parameter. The value of λ for which a non-trivial solution $y(x)$ exists is known as *eigen value* or *characteristic value* or *eigenwerte* of the Sturm-Liouville problem and $y(x)$ is known as the *eigen function* or *characteristic function*. Thus the Sturm-Liouville problem in an eigenvalue problem. For any $c \neq 0$, $cy(x)$, is also an eigen function of the problem since equation (1) and the boundary conditions are linear. *Spectrum* of the problem is the set of eigenvalues.

In *singular* Sturm-Liouville problem, at least one of the regularity conditions is violated as follows:

$$(a) \quad r(a) = 0 \text{ and } r(b) \neq 0 \quad (4)$$

Then the first boundary condition (2) at ' a ' is dropped while (3) still holds, and y is bounded at ' a '. Omitting of (2) amounts to $k_1 = k_2 = 0$.

$$(b) \quad r(b) = 0 \text{ and } r(a) \neq 0. \quad (5)$$

Then the second boundary condition (3) at ' b ' is dropped while (2) still holds and y is bounded at b . Omitting of (3) amounts to $l_1 = l_2 = 0$.

$$(c) \quad r(a) = r(b) = 0 \quad (6)$$

Then both the boundary conditions (2) and (3) are dropped and y is bounded at a and b .

In *periodic* Sturm-Liouville problem $r(a) = r(b) \neq 0$ and the boundary conditions (2) and (3) are replaced by *non-separated periodic boundary conditions* given by

$$y(a) = y(b) \quad (7)$$

$$y'(a) = y'(b) \quad (8)$$

Orthogonality of Eigen Functions

Sturm-Liouville Theorem

The eigen functions $y_m(x)$ and $y_n(x)$ corresponding to *distinct* eigenvalues λ_m and λ_n of a regular (or singular or periodic) Sturm-Liouville problem are orthogonal on $[a, b]$ with respect to the weight function $P(x)$ i.e.,

$$\int_a^b P(x) y_m(x) y_n(x) dx = 0 \text{ when } m \neq n \quad (9)$$

Proof: I consider a regular Sturm-Liouville problem defined by (1), (2), (3). Since $y_m(x)$ and $y_n(x)$ are solutions of (1), we have

$$(r y_n')' + (q + \lambda_n p) y_n = 0 \quad (10)$$

and

$$(r y_m')' + (q + \lambda_m p) y_m = 0 \quad (11)$$

Multiplying (10) by y_m and (11) by y_n and subtracting, we get

$$\begin{aligned} (\lambda_m - \lambda_n) p y_m y_n &= y_m (r y_n')' - y_n (r y_m')' \\ &= [y_m r y_n' - y_n r y_m']' \\ &= [r (y_m y_n' - y_n y_m')] \end{aligned}$$

Integrating both sides w.r.t. x on $[a, b]$,

$$\begin{aligned} &(\lambda_m - \lambda_n) \int_a^b P y_m y_n dx \\ &= \int_a^b \frac{d}{dx} [r (y_m y_n' - y_n y_m')] dx \\ &= (r) [y_m y_n' - y_n y_m'] \Big|_{x=a}^b \\ &= r(b) [y_m(b) y_n'(b) - y_n(b) y_m'(b)] \\ &\quad - r(a) [y_m(a) y_n'(a) - y_n(a) y_m'(a)] \end{aligned}$$

Introducing the Wronskian of y_n, y_m we have

$$\Delta(x) = \begin{vmatrix} y_n(x) & y_n'(x) \\ y_m(x) & y_m'(x) \end{vmatrix}$$

Thus

$$\begin{aligned} &(\lambda_m - \lambda_n) \int_a^b P(x) y_m(x) y_n(x) dx \\ &= r(b) \Delta(b) - r(a) \Delta(a) \end{aligned} \quad (12)$$

Since $y_n(x)$ and $y_m(x)$ satisfy the boundary condition (2) we get

$$k_1 y_n(a) + k_2 y_n'(a) = 0$$

$$k_1 y_m(a) + k_2 y'_m(a) = 0$$

For a regular problem, both k_1 and k_2 are not zero. So necessary condition for the existence of a non-trivial solution (where *both* k_1 and k_2 are *not* zero) for the above homogeneous equations in k_1, k_2 is that the coefficient determinant should be zero i.e.

$$\begin{vmatrix} y_n(a) & y'_n(a) \\ y_m(a) & y'_m(a) \end{vmatrix} = \Delta(a) = 0 \quad (13)$$

Similarly from the regular boundary condition (3) for which *both* l_1 and l_2 are not zero, we get

$$\begin{vmatrix} y_n(b) & y'_n(b) \\ y_m(b) & y'_m(b) \end{vmatrix} = \Delta(b) = 0 \quad (14)$$

Note that $(\lambda_n - \lambda_m) \neq 0$ since λ_m, λ_n are distinct. Now using (13) and (14), $\Delta(a) = \Delta(b) = 0$, the RHS of (12) is zero, so we have

$$\int_a^b P(x) y_m(x) y_n(x) dx = 0 \quad (9)$$

which is the condition for orthogonality of y_m and y_n w.r.t. $P(x)$ over $[a, b]$.

II. Consider the three cases in the singular problem

- (a) $r(a) = 0$. Since (3) is valid we have $\Delta(b) = 0$ from (14). So RHS of (12) is zero and hence we get (9).
- (b) $r(b) = 0$. Since (2) is valid, from (13) we have $\Delta(a) = 0$. Again RHS of (12) is zero, hence we get (9).
- (c) When $r(a) = r(b) = 0$ from (12), condition (9) follows.

III Periodic Problem: Since $r(a) = r(b)$, the RHS of (12) reduces to $r(b)[\Delta(b) - \Delta(a)]$. Now

$$\begin{aligned} \Delta(b) - \Delta(a) &= [y_m(b) \cdot y'_n(b) - y_n(b) y'_m(b)] \\ &\quad - [y_m(a) y'_n(a) - y_n(a) \cdot y'_m(a)] \\ &= [y_m(b) y'_n(b) - y_m(a) \cdot y'_n(a)] + [y_n(a) y'_m(a) \\ &\quad - y_n(b) y'_m(b)] \end{aligned}$$

Since $y(a) = y(b)$ and $y'(a) = y'(b)$ we have $\Delta(b) - \Delta(a) = 0$. Thus RHS of (12) is zero and hence the result.

Corollary: Eigenvalues and eigen functions of the Sturm-Liouville Theorem are real.

Proof: Suppose the eigenvalue $\lambda = \alpha + i\beta$ is complex; with y as the corresponding eigen function. Then $\bar{\lambda}$ is the eigen value with $\bar{y}$ as the corresponding eigen function. Taking conjugate of (1), (2), (3), we get

$$\begin{aligned} \frac{d}{dx} \left[r(x) \frac{dy}{dx} \right] + [\overline{q(x) + \lambda P(x)}] \bar{y} &= 0 \\ \frac{d}{dx} \left[r(x) \frac{d\bar{y}}{dx} \right] + [q(x) + \bar{\lambda} P(x)] \bar{y} &= 0 \end{aligned}$$

since $r(x), q(x), P(x)$ are all real and

$$\begin{aligned} k_1 \bar{y}(a) + k_2 \bar{y}'(a) &= 0 \\ l_1 \bar{y}(b) + l_2 \bar{y}'(b) &= 0 \end{aligned}$$

Thus the nontrivial solution $\bar{y}$ is the eigen function corresponding to the eigenvalue $\bar{\lambda}$. If $\beta \neq 0$ then λ and $\bar{\lambda}$ are distinct. So by the Sturm-Liouville theorem, y and $\bar{y}$ should be orthogonal on $[a, b]$ w.r.t. the weight function $P(x)$. Thus

$$\begin{aligned} \int_a^b P(x) y(x) \bar{y}(x) dx &= 0 \\ \text{or } \int_a^b P(x) (u^2 + v^2) dx &= 0 \end{aligned}$$

But since $P(x) > 0$ and $y\bar{y} = u^2 + v^2 > 0$ so the above integral should have positive value. This contradiction is due to the wrong assumption that $\beta \neq 0$. So $\beta = 0$ or λ is real. Thus the eigen function $y(x)$ is also real except for the possible imaginary *constant* multiplicative factor.

WORKED OUT EXAMPLES

Laguerre Equation

Example 1: Express the Laguerre differential equation $xy'' + (1-x)y' + ny = 0$, $x \neq 0$ in the form of a Sturm-Liouville equation.

Solution: Here $a_0(x) = x$, $a_1(x) = 1 - x$, $a_2(x) = 0$, $a_3(x) = n$. Dividing by x the given equation takes the form

$$y'' + \left(\frac{1-x}{x} \right) y' + \frac{ny}{x} = 0$$

10.24 — HIGHER ENGINEERING MATHEMATICS—III

Then

$$r(x) = e^{\int \frac{1-x}{x} dx} = e^{\ln x - x} = x e^{-x}$$

Multiplying throughout by the integrating factor $r(x) = x e^{-x}$, we have

$$x e^{-x} y'' + \frac{(1-x)}{x} \cdot x e^{-x} \cdot y' + \frac{n y}{x} \cdot x e^{-x} = 0$$

$$\frac{d}{dx} [x e^{-x} y'] + (n e^{-x}) y = 0$$

which is the Sturm-Liouville equation with $r(x) = x e^{-x}$, $q(x) = 0$, $P(x) = e^{-x}$, $\lambda = n$.

Self-Adjoint

Example 2: Express the Sturm-Liouville equation using the linear differential operator L defined by $L = \frac{d}{dx} \left[r(x) \frac{d}{dx} \right] + q(x)$. Show that L is a self-adjoint operator.

Solution: The Sturm-Liouville equation

$$\frac{d}{dx} \left[r(x) \frac{dy}{dx} \right] + [q(x) + \lambda P(x)] y = 0$$

in terms of the operator L is

$$L[y(x)] + \lambda P(x) y(x) = 0$$

For a general second-order linear differential operator L defined by

$$L[y(x)] = A(x)y'' + B(x)y' + C(x)y$$

its adjoint operator L^* is defined as

$$\begin{aligned} L^*[y(x)] &= (Ay)'' - (By)' + Cy \\ &= (A'y + Ay')' - B'y - By' + Cy \\ &= A''y + 2A'y' + Ay'' - B'y - By' + Cy \\ &= Ay'' + (2A' - B)y' + [A'' - B' + C]y \end{aligned}$$

Now L is said to be self-adjoint operator if $L = L^*$. So the conditions for self-adjoint operator is $B = 2A' - B$ and $C = A'' - B' + C$ or $A' = B$. Now for the given operator L , we have

$$\begin{aligned} L(y) &= \frac{d}{dx} \left[r(x) \frac{dy}{dx} \right] + q(x) \\ &= r(x)y'' + r'(x)y' + q(x) \end{aligned}$$

We have $A(x) = r(x)$, $B(x) = r'(x)$, $C = q(x)$. Since $A'(x) = r'(x) = B(x)$, the operator L is a self adjoint operator.

Regular

Example 3: (a) Find the characteristic values and normalized characteristic functions of the Sturm-Liouville problem $(xy')' + \frac{\lambda}{x}y = 0$, with boundary $y(1) = 0$, $y(b) = 0$ on the interval $1 < x < b$ (b) Expand a piecewise differentiable function $f(x)$ defined in the interval $1 < x < b$ in terms of the characteristic functions obtained in (a). Determine the generalized Fourier series when (c) $f(x) = 1$ (d) $f(x) = x$.

Solution: The given equation $x^2 y'' + xy' + \lambda y = 0$ is an Euler-Cauchy equation which can be converted to DE with constant coefficients by the substitution $x = e^t$. The $x Dy = \mathcal{D}y$, $x^2 D^2 y = \mathcal{D}(\mathcal{D} - 1)y$ where $D = \frac{d}{dx}$ and $\mathcal{D} = \frac{d}{dt}$. Then the transformed equation with t as the independent variable is $\mathcal{D}(\mathcal{D} - 1)y + \mathcal{D}y + \lambda y = 0$ or $\mathcal{D}^2 y + \lambda y = 0$ i.e., $\frac{d^2 y}{dt^2} + \lambda y = 0$ in the interval $\ln 1 < \ln x < \ln b$, $0 < t < \ln b$ with the boundary conditions $y(t = 0) = 0$, $y(t = \ln b) = 0$. The general solution of DE is

$$y(t) = c_1 \cos \sqrt{\lambda} t + c_2 \sin \sqrt{\lambda} t$$

Since $0 = y(t = 0) = c_1 \cdot 1 + c_2 \cdot 0$, we get $c_1 = 0$. Since

$$0 = y(t = \ln b) = c_2 \cdot \sin \sqrt{\lambda} \ln b,$$

We get

$$\sin \sqrt{\lambda} \ln b = 0$$

because $c_2 \neq 0$ (otherwise we get $c_1 = 0$, $c_2 = 0$, leading to trivial solution).

$$\therefore \sqrt{\lambda} \ln b = \pi n$$

Thus the characteristic values are given by

$$\lambda_n = \left(\frac{\pi n}{\ln b} \right)^2 \text{ for } n = 1, 2, 3, \dots$$

The corresponding characteristic functions are

$$y_n(t) = c_2 \sin \sqrt{\lambda} t = \sin \left(\frac{\pi n}{\ln b} \right) t$$

or

$$y_n(x) = \sin\left(\frac{\pi n \ln x}{\ln b}\right)$$

where c_2 is taken as 1 for convenience. Here the weight function is $P(x) = \frac{1}{x}$.

The square of norm of $y_n(x)$ is

$$\begin{aligned} \|y_n(x)\|^2 &= \int_1^b \frac{1}{x} \cdot \sin^2\left(\frac{\pi n \ln x}{\ln b}\right) dx \\ &= \int_0^{\ln b} \sin^2\left(\frac{\pi n t}{\ln b}\right) dt \\ &= \ln b \int_0^1 \sin^2(\pi n y) dy = \frac{\ln b}{2} \end{aligned}$$

Recall that

$$\int_0^c \sin \frac{m\pi x}{c} \cdot \sin \frac{n\pi x}{c} dx = \begin{cases} 0 & \text{for } m \neq n \\ \frac{c}{2} & \text{for } m = n \end{cases}$$

Here $t = \ln x$, $y = \frac{t}{\ln b}$. Thus norm is $\sqrt{\frac{\ln b}{2}}$. So the normalized characteristic functions are

$$\phi_n(x) = \frac{y_n(x)}{\|y_n(x)\|} = \sqrt{\frac{2}{\ln b}} \sin\left(\frac{\pi n \ln x}{\ln b}\right)$$

for $n = 1, 2, 3, \dots$. Now the generalized Fourier series expansion of $f(x)$ in terms of the normalized characteristic functions $\phi_n(x)$ of the given Sturm-Liouville problem is

$$f(x) = \sum_{n=1}^{\infty} A_n \phi_n(x) = \sum_{n=1}^{\infty} A_n \sqrt{\frac{2}{\ln b}} \cdot \sin\left(\frac{\pi n \ln x}{\ln b}\right)$$

valid in the interval $1 < x < b$. To determine the unknown Fourier constants A_n 's multiple both sides by $\frac{1}{x} \sin\left(\frac{\pi m \ln x}{\ln b}\right)$ and integrate from w.r.t. x from 1 to b . Then

$$\begin{aligned} &\int_1^b \frac{1}{x} f_1(x) \cdot \sin\left(\frac{\pi m \ln x}{\ln b}\right) dx \\ &= \sum_{n=1}^{\infty} A_n \sqrt{\frac{2}{\ln b}} \int_1^b \frac{1}{x} \cdot \sin\left(\frac{\pi n \ln x}{\ln b}\right) \cdot \sin\left(\frac{\pi m \ln x}{\ln b}\right) dx \end{aligned}$$

where we have assumed termwise integration. Note that $\phi_n(x)$ are orthogonal functions in the interval

$1 < x < b$ w.r.t. the weight function $\frac{1}{x}$ i.e.,

$$\begin{aligned} &\int_1^b \frac{1}{x} \phi_n(x) \phi_m(x) dx \\ &= \int_1^b \frac{1}{x} \cdot \sin\left(\frac{\pi n \ln x}{\ln b}\right) \sin\left(\frac{\pi m \ln x}{\ln b}\right) dx \\ &= \begin{cases} 0 & \text{for } m \neq n \\ \frac{\ln b}{2} & \text{for } m = n \end{cases} \end{aligned}$$

Thus for $m = n$, in the RHS all the coefficients of A_n 's will vanish except when $m = n$. So the Fourier coefficients are

$$\sqrt{\frac{2}{\ln b}} \left(\frac{\ln b}{2}\right) A_n = \int_1^b \frac{1}{x} \cdot f(x) \cdot \sin\left(\frac{\pi n \ln x}{\ln b}\right) dx$$

$$\text{or } A_n = \sqrt{\frac{2}{\ln b}} \int_0^b \frac{1}{x} f(x) \cdot \sin\left(\frac{\pi n \ln x}{\ln b}\right) dx$$

for $m = 1, 2, 3, \dots$

(c) Expansion when $f(x) = 1$. In this case

$$A_n = \sqrt{\frac{2}{\ln b}} \times \int_0^b \frac{1}{x} \cdot 1 \sin\left(\frac{n\pi \ln x}{\ln b}\right) dx$$

$$A_n = \sqrt{\frac{2}{\ln b}} \times \int_0^{\ln b} \sin\left(\frac{n\pi t}{\ln b}\right) dt$$

where $t = \ln x$.

$$A_n = \sqrt{\frac{2}{\ln b}} \times \left[-\left(\frac{\ln b}{n\pi}\right) \cos\left(\frac{n\pi t}{\ln b}\right) \right]_{t=0}^{\ln b}$$

$$A_n = \sqrt{\frac{2}{\ln b}} \left(\frac{\ln b}{n\pi}\right) (1 - \cos n\pi)$$

$$= \frac{\sqrt{2 \ln b}}{n\pi} (1 - \cos n\pi)$$

$$f(x) = 1 = \sqrt{2 \ln b} \cdot \sum_{n=1}^{\infty} \frac{1}{n\pi} (1 - \cos n\pi) \sin\left(\frac{\pi n \ln x}{\ln b}\right)$$

(d) When $f(x) = x$. In this case

$$A_n = \sqrt{\frac{2}{\ln b}} \int_1^b \frac{1}{x} \cdot x \cdot \sin\left(\frac{n\pi \ln x}{\ln b}\right) dx$$

$$= \sqrt{\frac{2}{\ln b}} \cdot \int_0^{\ln b} e^t \cdot \sin\left(\frac{\pi n t}{\ln b}\right) dt \text{ where } t = \ln x$$

$$= \sqrt{\frac{2}{\ln b}} \cdot b \ln b \int_0^1 e^y \cdot \sin(\pi n y) dy \text{ where } y = \frac{t}{\ln b}$$

$$= b\sqrt{2\ln b} \left[\frac{e^y}{1 + \pi^2 n^2} (1 \cdot \sin \pi n y - \pi n \cos \pi n y) \right] \Big|_{y=0}^1 \quad \text{Thus}$$

$$= \frac{b\sqrt{2\ln b}}{1 + \pi^2 n^2} [e(-\pi n(-1)^n - \pi n(-1))]]$$

$$A_n = \frac{b\pi n\sqrt{2\ln b}}{1 + \pi^2 n^2} [e(-1)^n + 1]$$

$$\therefore f(x) = x = \sum_{n=1}^{\infty} \frac{2b}{1 + \pi^2 n^2} [1 + e(-1)^n] \sin \left(\frac{\pi n \ln x}{\ln b} \right)$$

Singular

Example 4: Expand $f(x) = 1 - x$ on $0 < x < 1$ in terms of the eigen functions of the Sturm-Liouville problem $(1 - x^2)y'' - 2xy' + \lambda y = 0$ with $y'(0) = 0$ and $y(1)$ is bounded. Write the first three terms of the expansion.

Solution: The given DE is Legendre's equation on $0 < x < 1$ which is singular at the end point $x = 1$. By the substitution $y(x) = \sum_{k=0}^{\infty} a_k x^k$, we get the general solution as

$$y(x) = a_0 \left[1 - \frac{\lambda}{2} x^2 - \frac{(6 - \lambda)\lambda}{24} x^4 - \frac{(20 - \lambda)(6 - \lambda)}{720} \lambda x^6 \dots \right] + a_1 \left[x + \frac{(2 - \lambda)}{6} x^3 + \frac{(12 - \lambda)(2 - \lambda)}{120} x^5 + \dots \right]$$

$$y(x) = a_0 y_1(x) + a_1 y_2(x)$$

Differentiating w.r.t. x , we have

$$y'(x) = a_0 y'_1(x) + a_1 y'_2(x)$$

Now

$$y'_1(x) = 0 - \lambda x - \frac{\lambda(6 - \lambda)}{6} x^3 - \frac{\lambda(20 - \lambda)(6 - \lambda)}{120} x^5 + \dots$$

$$\text{So } y'_1(0) = 0$$

$$\text{Also } y'_2(x) = 1 + \frac{2 - \lambda}{2} x^2 + \frac{(12 - \lambda)(2 - \lambda)}{24} x^4 + \dots$$

$$\text{So } y'_2(0) = 1$$

From the boundary condition

$$0 = y'(0) = a_0 y'_1(0) + a_1 y'_2(0) = a_0 \cdot 0 + a_1 \cdot 1$$

$$\therefore a_1 = 0$$

where $P_{2n}(x)$ is Legendre polynomial with even powers. So the eigen functions of the Sturm-Liouville problem are $P_{2n}(x)$ for $n = 0, 1, 2, \dots$ which are orthogonal w.r.t. the weight function 1. Norm of $P_{2n}(x)$ is $\sqrt{\int_0^1 P_{2n}(x) P_{2n}(x) dx} = \sqrt{\frac{1}{2(2n+1)}} \sqrt{\frac{1}{4n+1}}$. Normalized eigen functions are $\sqrt{4n+1} P_{2n}(x)$. The eigen-function expansion of the given function $f(x) = 1 - x$ on $0 < x < 1$ is given by

$$f(x) = 1 - x = \sum_{n=0}^{\infty} a_n P_{2n}(x)$$

where $a_n = (4n + 1) \int_0^1 (1 - x) P_{2n}(x) dx$
Now for $n = 0$, $P_0(x) = 1$, so

$$a_0 = 1 \cdot \int_0^1 (1 - x) \cdot 1 \cdot dx = \left(x - \frac{x^2}{2} \right) \Big|_{x=0}^1 = \frac{1}{2}$$

For $n = 1$, $P_2(x) = \frac{1}{2}(3x^2 - 1)$, so

$$a_1 = 5 \int_0^1 (1 - x) \frac{1}{2} (3x^2 - 1) dx$$

$$= \frac{5}{2} \left[\frac{3x^3}{3} - x - \frac{3x^4}{4} + \frac{x^2}{2} \right] \Big|_{x=0}^1 = -\frac{5}{8}$$

For $n = 2$, $P_4(x) = \frac{1}{8}(35x^4 - 30x^2 + 3)$ so

$$a_2 = 9 \int_0^1 (1 - x) \cdot \frac{1}{8} (35x^4 - 30x^2 + 3) dx$$

$$= \frac{9}{8} \left[35 \frac{x^5}{5} - 30 \frac{x^3}{3} + 3x - 35 \frac{x^6}{6} + 30 \frac{x^4}{4} - \frac{3x^2}{2} \right] \Big|_{x=0}^1$$

$$= \frac{9}{48}$$

Thus the expansion of $f(x) = 1 - x$ in terms of the eigen functions is

$$f(x) = 1 - x = \frac{1}{2} P_0(x) - \frac{5}{8} P_2(x) + \frac{9}{48} P_4(x) \dots$$

Periodic

Example 5: Find the eigenvalues and eigen functions of the periodic Sturm-Liouville problem $y'' + \lambda^2 y = 0$, $y(0) = y(2L)$ and $y'(0) = y'(2L)$. Verify orthogonality by direct calculations.

Solution: The general solution of $y'' + \lambda^2 y = 0$ is $y(x) = c_1 \cos \lambda x + c_2 \sin \lambda x$. Using the periodic boundary condition $y(0) = y(2L)$ we get $c_1 \cdot 1 + c_2 \cdot 0 = y(0) = y(2L) = c_1 \cos 2L\lambda + c_2 \sin 2L\lambda$. This is valid if $L\lambda = \pi n$ so $\lambda = \frac{\pi n}{L}$. Now $y'(x) = -c_1 \lambda \sin \lambda x + c_2 \lambda \cos \lambda x$. Using the second condition $y'(0) = y'(2L)$, we have $-c_1 \lambda \cdot 0 + c_2 \lambda \cdot 1 = y'(0) = y'(2L) = -c_1 \lambda \sin 2L\lambda + c_2 \lambda \cos 2L\lambda$ which is valid for $L\lambda = \pi n$ or $\lambda = \frac{\pi n}{L}$. Thus the eigenvalues are $\lambda = \frac{\pi n}{L}$ for $n = 0, 1, 2, \dots$ and the corresponding eigen functions are $\cos \frac{\pi n x}{L}$ and $\sin \frac{\pi n x}{L}$ for $n = 0, 1, 2, \dots$. These eigen functions are orthogonal w.r.t. the weight function $P(x) = 1$ since it is known

$$\int_0^{2\pi} \cos \frac{n\pi x}{L} \cdot \cos \frac{m\pi x}{L} dx = 0 \text{ for } m \neq n$$

and

$$\int_0^{2\pi} \sin \frac{n\pi x}{L} \cdot \sin \frac{m\pi x}{L} dx = 0 \text{ when } m \neq n$$

Example 6: Determine the eigen values and normalized eigen functions of the regular Sturm-Liouville problem

$$(x^2 y')' + \lambda y = 0, y(1) = 0, y(b) = 0, 1 < x < b$$

Solution: The given equation is

$$x^2 y'' + 2xy' + \lambda y = 0$$

Put $y = Y/\sqrt{x}$ then $y' = \frac{1}{\sqrt{x}} Y' - \frac{1}{2x^{3/2}} Y$ and $y'' = \frac{1}{\sqrt{x}} Y'' - \frac{1}{2x^{3/2}} Y' - \frac{1}{2x^{3/2}} Y' - \frac{1}{2} \left(-\frac{3}{2}\right) \frac{1}{x^{5/2}} Y$. Then the given equation transforms to $x^2 \left[\frac{1}{\sqrt{x}} Y'' - \frac{1}{x^{3/2}} Y' + \frac{3}{4} \frac{1}{x^{5/2}} Y \right] + 2x \left[\frac{1}{\sqrt{x}} Y' - \frac{1}{2x^{3/2}} Y \right] + \lambda \cdot \frac{Y}{\sqrt{x}} = 0$ or $x^{3/2} Y'' + x^{1/2} Y' + \left(\lambda - \frac{1}{4}\right) \frac{Y}{\sqrt{x}} = 0$ or $[xY']' + \mu \frac{Y}{x} = 0$ where $\mu = \lambda - \frac{1}{4}$.

From Example 3 above, the eigen values and normalized eigen functions of the present problem are

$$\lambda_n = \mu_n + \frac{1}{4} = \frac{1}{4} + \left(\frac{n\pi}{\log b} \right)^2 \text{ and}$$

$$\phi_n(x) = \sqrt{\frac{2}{x \log b}} \sin \left(\frac{n\pi \log x}{\log b} \right)$$

for $n = 1, 2, 3$

EXERCISE

Reduce each of the following differential equations (1 to 6) to the Sturm-Liouville equation form indicating the weight function $P(x)$.

1. $(1 - x^2)y'' - xy' + n^2 y = 0$ (Chebyshev equation)

Ans. $[(1 - x^2)^{1/2} y']' + \left[\frac{n^2}{(1 - x^2)^{1/2}} \right] y = 0, P(x) = (1 - x^2)^{-1/2}$

Hint: $r(x) = (1 - x^2)^{1/2}$, $q(x) = 0$, $P(x) = (1 - x^2)^{-1/2}$, $\lambda = n^2$

2. $y'' - 2xy' + 2ny = 0$ (Hermite equation)

Ans. $[e^{-x^2} y']' + [2ne^{-x^2}] y = 0, P(x) = e^{-x^2}$

Hint: $r(x) = e^{-x^2}$, $q(x) = 0$, $P(x) = e^{-x^2}$, $\lambda = 2n$

3. $xy'' + 2y' + (x + \lambda)y = 0$

Ans. $(x^2 y')' + (x^2 + \lambda x)y = 0, P(x) = x$

4. $y'' + y' \cot x + \lambda y = 0$

Ans. $(y' \sin x)' + \lambda y \sin x = 0, P(x) = \sin x$

5. $y'' + ay' + (b + \lambda)y = 0$

Ans. $(e^{ax} y')' + e^{ax}(b + \lambda)y = 0, P(x) = e^{ax}$

6. $xy'' + (c - x)y' - ay + \lambda y = 0$

Ans. $(x^c e^{-x} y')' + x^{c-1} e^{-x}(-a + \lambda)y = 0, P(x) = x^{c-1} e^{-x}$

Obtain the eigen values λ_n and eigen functions $y_n(x)$ of the given Sturm-Liouville problem. Find the norm and determine $\phi_n(x)$, normalized eigen functions. Verify that the eigen functions are orthogonal w.r.t. the weight

10.28 — HIGHER ENGINEERING MATHEMATICS—III

function $P(x)$. Finally expand $f(x)$ in generalized Fourier series in terms of these eigen functions in the interval $a < x < b$.

7. $y'' + \lambda y = 0$, $y(0) = y(L) = 0$, $f(x) = x$, $0 < x < L$

Ans. $\lambda_n = \frac{n^2\pi^2}{L^2}$, $y_n(x) = \sin\left(\frac{n\pi x}{L}\right)$, $P(x) = 1$
 norm = $\sqrt{\frac{L}{2}}$, $\phi_n(x) = \sqrt{\frac{2}{L}} \sin \frac{n\pi x}{L}$, $n = 1, 2, 3, \dots$, $f(x) = x = \frac{2L}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin \frac{n\pi x}{L}$

8. $y'' + \lambda y = 0$, $0 < x < L$, $y'(0) = 0$, $hy(L) + y'(L) = 0$, $h > 0$

Ans. $\lambda_n = \alpha_n^2$ when $\tan \alpha_n L = \frac{h}{\alpha_n}$, $\alpha_n > 0$, $y_n(x) = \cos \alpha_n x$, $n = 1, 2, 3, \dots$, norm = $\sqrt{\frac{2h}{hL + \sin^2 \alpha_n L}}$,
 $\phi_n(x) = \sqrt{\frac{2h}{hL + \sin^2 \alpha_n^2}} \cos \alpha_n x$

9. $(xy')' + \frac{\lambda}{x}y = 0$, $y'(1) = 0$, $hy(b) + y'(b) = 0$, $1 < x < b$; $b > 0$

Ans. $\lambda_n = \alpha_n^2$, $\tan(\alpha_n \log(b)) = \frac{hb}{\alpha_n}$, $\alpha_n > 0$,
 $y_n(x) = \cos(\alpha_n \log x)$, $n = 1, 2, \dots$, norm = $\sqrt{\frac{2hb}{hb \log b + \sin^2(\alpha_n \log b)}}$

10. $y'' + \lambda y = 0$, $y'(0) = 0$, $y(L) = 0$

Ans. $\lambda_n = \alpha_n^2$, $\phi_n(x) = \sqrt{\frac{2}{c}}$, $\cos \alpha_n x$, $n = 1, 2, \dots$,
 $\alpha_n = \frac{(2n-1)\pi}{2L}$

11. $y'' + \lambda y = 0$, $y(0) = 0$, $y'(L) = 0$

Ans. $\lambda_n = \left[(2n+1)\frac{\pi}{2L}\right]^2$, $n = 0, 1, 2, \dots$, $y_n(x) = \sin(2n+1)\frac{\pi x}{2L}$

12. $(xy')' + \frac{\lambda}{x}y = 0$, $y(1) = 0$, $y'(e) = 0$

Ans. $\lambda_n = \left[(2n+1)\frac{\pi}{2}\right]^2$, $n = 0, 1, 2, \dots$, $y_n(x) = \sin\left(n + \frac{1}{2}\right)\pi \ln|x|$

13. $y'' + \lambda y = 0$, $y(1) = 0$, $y(0) - 2y'(0) = 0$, $0 < x < 1$ (mixed boundary conditions).

Ans. λ_n are solutions of $\tan \sqrt{\lambda} = -2\sqrt{\lambda}$, $\sqrt{\lambda_n} \sim (2n-1)\frac{\pi}{2}$, $\lambda_1 = 3.3731$, $\lambda_2 = 23.19$, $\lambda_3 = 62.67$, $\phi_n(x) = 2\sqrt{\lambda_n} \cos \sqrt{\lambda_n}x + \sin \sqrt{\lambda_n}x$

14. $y'' - 2y' + \lambda y = 0$, $y(0) = 0$, $y(\pi) = 0$, $0 < x < \pi$

Ans. $\lambda_n = 1 + n^2$, for $n = 1, 2, 3, \dots$, $y_n(x) = e^x \sin nx$

15. Periodic: $y'' + \lambda y = 0$, $y(-L) = y(L)$, $y'(-L) = y'(L)$, $-L < x < L$

Ans. $\lambda_0 = 0$, $y_0(x) = 1$, $\lambda_n = \left(\frac{n\pi}{L}\right)^2$, $y_n(x) = \cos \frac{n\pi x}{L}$ and $\sin \frac{n\pi x}{L}$, $n = 1, 2, 3, \dots$

16. $y'' + \lambda^2 y = 0$, $y(0) = 0$, $hy(L) + y'(L) = 0$

Ans. $\lambda_n = \frac{zn}{L}$ where $\sin zn = -\alpha zn \cos zn$, $\alpha = \frac{1}{Lh}$, $y_n(x) = \sin \lambda_n x$.

10.6 GRAM*-SCHMIDT** ORTHOGONALIZATION PROCESS

Let $X = [x_1, x_2, \dots, x_n]^T$ and $Y = [y_1, y_2, \dots, y_n]^T$ be two vectors of $V_n(R)$, the n -dimensional Euclidean space of all real n -component vectors.

Inner product of the two vectors X and Y denoted by $X \cdot Y$, is a scalar defined as

$$X \cdot Y = \sum_{i=1}^{\infty} x_i y_i = x_1 y_1 + x_2 y_2 + \dots + x_n y_n$$

Orthogonal vectors

Two vectors X and Y are said to be orthogonal if $X \cdot Y = 0$ i.e., their inner product is zero.

Norm or length

Magnitude of a vector X , denoted by $\|X\|$, is defined by a non negative real number

$$\|X\| = \sqrt{X \cdot X} = \sqrt{\sum_{i=1}^n x_i^2} = \sqrt{x_1^2 + x_2^2 + \dots + x_n^2}$$

Normalized Vector

It is a unit vector whose norm or magnitude is unity. Thus given any non-zero vector X , we can define $Y = \frac{X}{\|X\|}$ which is a normalized vector with norm 1.

* Jorgen P. Gram (1850-1916).

** Erhardt Schmidt (1876-1959).

Orthonormal Set of Vectors

A set of n non-zero vectors $X_1, X_2, X_3, \dots, X_n$, are said to be (mutually) orthogonal if $X_i X_j = 0$ for $i \neq j$.

This orthogonal set $\{X_1, X_2, \dots, X_n\}$ can be normalized by dividing these vectors by their corresponding norms $\|X_i\|$. Now the set of vectors $\left\{ \frac{X_1}{\|X_1\|}, \frac{X_2}{\|X_2\|}, \dots, \frac{X_n}{\|X_n\|} \right\}$ is an orthogonal set of unit vectors. Introducing $Y_i = \frac{X_i}{\|X_i\|}$, the set of vectors $\{Y_1, Y_2, \dots, Y_n\}$, is said to be an orthonormal set of vectors. Thus for an orthonormal set

$$Y_i \cdot Y_j = \delta_{ij} = \begin{cases} 0 & \text{for } i \neq j \\ 1 & \text{for } i = j \end{cases}$$

Gram-Schmidt orthogonalization Process

Let $X_1, X_2, \dots, X_n$ be a given non-orthogonal basis of $V_n(R)$. Then an orthonormal basis of vectors $\{z_i = \frac{Y_i}{\|Y_i\|}\}$ can be constructed using the Gram-Schmidt orthogonalization process as follows. Choose $Y_1 = X_1$

Put $Y_2 = X_2 + a \cdot Y_1$

Since Y_1 and Y_2 are orthonormal, we have

$$Y_1 \cdot Y_2 = Y_1 \cdot (X_2 + aY_1) = Y_1 \cdot X_2 + aY_1 \cdot Y_1 =$$

0. So

$$a = -\frac{Y_1 \cdot X_2}{Y_1 \cdot Y_1}$$

Thus $Y_2 = X_2 - \frac{Y_1 \cdot X_2}{Y_1 \cdot Y_1} Y_1$.

Now put $Y_3 = X_3 + bY_2 + cY_1$

Since Y_1, Y_2, Y_3 are mutually orthogonal we have

$$Y_1 \cdot Y_3 = Y_1 \cdot (X_3 + bY_2 + cY_1) = 0 \text{ and}$$

or $Y_1 \cdot X_3 + bY_1 \cdot Y_2 + cY_1 \cdot Y_1 = 0$

or $c = \frac{-Y_1 \cdot X_3}{Y_1 \cdot Y_1}$

and $Y_2 \cdot Y_3 = Y_2 \cdot (X_3 + bY_2 + cY_1) = 0$

$$= Y_2 \cdot X_3 + bY_2 \cdot Y_2 + cY_2 \cdot Y_1 = 0$$

$$\text{or } b = \frac{-Y_2 \cdot X_3}{Y_2 \cdot Y_2}$$

Thus substituting values of b and c , we get

$$Y_3 = X_3 - \frac{Y_2 \cdot X_3}{Y_2 \cdot Y_2} Y_2 - \frac{Y_1 \cdot X_3}{Y_1 \cdot Y_1} Y_1$$

In a similar way, the remaining vectors can be obtained

$$Y_j = X_j - \sum_{i=1}^{j-1} \frac{(X_j \cdot Y_i)}{(Y_i \cdot Y_i)} Y_i \text{ for } j = 1, 2, 3, \dots, N.$$

Define $z_i = \frac{Y_i}{\|Y_i\|}$ then $\{z_i\}$ form an orthonormal basis.

Expansion in Terms of Orthogonal Basis

Theorem: If $\{e_1, e_2, \dots, e_k\}$ is an orthogonal basis, then any given vector $\bar{u}$ can be expanded in terms of the vectors $e_1, e_2, \dots, e_k$ as

$$\bar{u} = \frac{u \cdot e_1}{e_1 \cdot e_1} e_1 + \dots + \frac{u \cdot e_k}{e_k \cdot e_k} e_k = \sum_{j=1}^k \frac{(u \cdot e_j)}{(e_j \cdot e_j)} e_j$$

Further if $\{\hat{e}_1, \hat{e}_2, \dots, \hat{e}_k\}$ is an orthonormal basis then

$$\bar{u} = (u \cdot \hat{e}_1) \hat{e}_1 + \dots + (u \cdot \hat{e}_k) \hat{e}_k = \sum_{j=1}^k (u \cdot \hat{e}_j) \hat{e}_j$$

where $\hat{e}_1, \hat{e}_2, \dots, \hat{e}_k$ are unit vectors.

Proof: Suppose u is expanded in terms of $e_1, e_2, \dots, e_k$ as

$$u = \alpha_1 e_1 + \alpha_2 e_2 + \dots + \alpha_k e_k$$

where $\alpha_1, \alpha_2, \dots, \alpha_k$ are unknown coefficients. Taking inner product with e_1 we get

$$u \cdot e_1 = \alpha_1 e_1 \cdot e_1 + \alpha_2 e_2 \cdot e_1 + \dots + \alpha_k e_k \cdot e_1$$

Since $\{e_1, e_2, \dots, e_k\}$ is an orthogonal set, we have $e_2 \cdot e_1 = 0, e_3 \cdot e_1 = 0, \dots, e_k \cdot e_1 = 0$. So

$$\alpha_1 = \frac{u \cdot e_1}{e_1 \cdot e_1}$$

Thus taking inner product with e_j , we get

$$\alpha_j = \frac{u \cdot e_j}{e_j \cdot e_j}$$

Substituting these values we have

$$u = \sum_{j=1}^k \alpha_j u_j = \sum_{j=1}^k \frac{u \cdot e_j}{e_j \cdot e_j} u_j$$

If e'_j 's are unit vectors then $e_j \cdot e_j = 1$ and the second result in terms of unit vectors follows.

Gram-Schmidt orthogonalization process for functions

Suppose $f_1(x), f_2(x), \dots, f_n(x), \dots$ be a sequence of piecewise continuous non-orthogonal functions defined in the interval $a \leq x \leq b$. Assume that each of these functions have non-zero norm. Then using Gram-Schmidt orthogonalization process we can construct an orthonormal set of functions $\{\phi_n(x)\}$, $n = 1, 2, 3, \dots$ w.r.t. a weight function $P(x)$ over (a, b) .

$$\text{I. Choose } \phi_1(x) = \frac{f_1(x)}{\|f_1(x)\|} \quad (1)$$

$$\text{where } \|f_1(x)\|^2 = \int_a^b P(x) f_1^2(x) dx$$

$$\text{II Take } g_2(x) = f_2(x) + c\phi_1(x) \quad (2)$$

Determine c using orthogonality between $g_2(x)$ and $\phi_1(x)$. Then

$$\int_a^b P(x) g_2(x) \phi_1(x) dx = 0$$

$$\text{or } \int_a^b P(x) [f_2 + c_1 \phi_1] \phi_1 dx = 0$$

$$\text{so } c_1 = - \frac{\int_a^b P f_2 \phi_1 dx}{\int_a^b P \phi_1^2 dx} \quad (3)$$

Substituting c from (3) in (2) we get $g_2(x)$ and therefore

$$\phi_2(x) = \frac{g_2(x)}{\|g_2(x)\|} \quad (4)$$

and $\phi_1(x)$ form an orthonormal set of functions.

$$\text{III. Continuing this process we choose } g_3(x) = f_3(x) + c_1 \phi_1(x) + c_2 \phi_2(x) \quad (5)$$

Since ϕ_1 and g_3 are orthogonal, we have

$$\int_a^b P g_3 \phi_1 dx = \int_a^b P (f_3 + c_1 \phi_1 + c_2 \phi_2) \phi_1 dx = 0$$

$$\text{so } c_1 = - \frac{\int_a^b P f_3 \phi_1 dx}{\int_a^b P \phi_1^2 dx} \quad (6)$$

Since ϕ_1, ϕ_2 are orthogonal. Similarly since ϕ_2 and g_3 are orthogonal we have

$$\int_a^b P g_3 \phi_2 dx = \int_a^b P (f_3 + c_1 \phi_1 + c_2 \phi_2) \phi_2 dx = 0$$

$$\text{so } c_2 = - \frac{\int_a^b P f_3 \phi_2 dx}{\int_a^b P \phi_2^2 dx} \quad (7)$$

Substituting (6) and (7) in (5), $g_3(x)$ is completely determined. Then

$$\phi_3(x) = \frac{g_3(x)}{\|g_3(x)\|}$$

and ϕ_1, ϕ_2 form an orthonormal set. Continuing this process we get an orthonormal set of functions $\phi_1(x), \phi_2(x), \dots, \phi_n(x), \dots$ where $\phi_n(x) = \frac{g_n(x)}{\|g_n(x)\|}$ and

$$g_n(x) = f_n(x) - \phi(x) \int_a^b P(x) f_n(x) \phi_1(x) dx$$

$$- \phi_2(x) \int_a^b P(x) f_n(x) \phi_2(x) dx - \dots -$$

$$- \phi_{n-1}(x) \int_a^b P(x) f_n(x) \phi_{n-1}(x) dx$$

or

$$g_n(x) = f_n(x) - \sum_{i=1}^{n-1} \phi_i(x) \int_a^b P(x) f_n(x) \phi_i(x) dx$$

$$\text{Here } \|g_n(x)\|^2 = \int_a^b P(x) g_n^2(x) dx$$

WORKED OUT EXAMPLES

Example 1: If $X_1 = [1, 2, 1]^T$, $X_2 = [2, 1, 2]^T$, $X_3 = [2, 1, -4]^T$ find (a) the inner product of each pair (b) the length of each vector (c) a vector orthogonal to both X_1 and X_2 (d) a vector orthogonal to both X_1 and X_3 .

Solution: (a) Inner product of $X_1 X_2$ is $X_1^T X_2 =$

$$[1, 2, 1] \begin{bmatrix} 2 \\ 1 \\ 2 \end{bmatrix}$$

$$= 1 \cdot 2 + 2 \cdot 1 + 1 \cdot 2 = 2 + 2 + 2 = 6$$

$$X_1^T X_3 = [1 \ 2 \ 1] \begin{bmatrix} 2 \\ 1 \\ -4 \end{bmatrix} = 1 \cdot 2 + 2 \cdot 1 + 1 \cdot (-4) = 0$$

$$X_2^T X_3 = [2 \ 1 \ 2] \begin{bmatrix} 2 \\ 1 \\ -4 \end{bmatrix} = 2 \cdot 2 + 1 \cdot 1 + 2 \cdot (-4) = -3$$

(b) Length of the vector $X_1 = \|X_1\| = \sqrt{X \cdot X}$

$$X \cdot X = [1 \ 2 \ 1] \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}, \text{ so } \|X_1\| = \sqrt{6}$$

$$\text{Length of } X_2 = \|X_2\| = \sqrt{X_2 \cdot X_2}$$

$$= \sqrt{[2 \ 1 \ 2] \begin{bmatrix} 2 \\ 1 \\ 2 \end{bmatrix}} = \sqrt{4+1+4} = \sqrt{9} = 3$$

$$\text{Length of } X_3 = \|X_3\| = \sqrt{X_3 \cdot X_3}$$

$$= \sqrt{[2 \ 1 \ -4] \begin{bmatrix} 2 \\ 1 \\ -4 \end{bmatrix}} = \sqrt{4+1+16} = \sqrt{21}$$

(c) Let z_1 be the vector which is orthogonal to both X_1 and X_2 . Then

$$[X_1 \ X_2 \ 0] = \begin{bmatrix} 1 & 2 & 0 \\ 2 & 1 & 0 \\ 1 & 2 & 0 \end{bmatrix}$$

The cofactors of the elements of the column of zeros

$$\text{are } + \begin{vmatrix} 2 & 1 \\ 1 & 2 \end{vmatrix}, - \begin{vmatrix} 1 & 2 \\ 1 & 2 \end{vmatrix}, + \begin{vmatrix} 1 & 2 \\ 2 & 1 \end{vmatrix}$$

$$\text{So } z_1 = [3 \ 0 \ -3]^T = [1 \ 0 \ -1]^T$$

(d) If z_2 is the vector which is orthogonal to both X_1 and X_3 then the cofactors of the elements of the column of zeros in

$$[X_1 \ X_3 \ 0] = \begin{bmatrix} 1 & 2 & 0 \\ 2 & 1 & 0 \\ 1 & -4 & 0 \end{bmatrix} \text{ are}$$

$$+ \begin{vmatrix} 2 & 1 \\ 1 & -4 \end{vmatrix}, - \begin{vmatrix} 1 & 2 \\ 1 & -4 \end{vmatrix}, + \begin{vmatrix} 1 & 2 \\ 2 & 1 \end{vmatrix} \text{ i.e., } [-9 \ 6 \ -3]$$

$$= [3 \ -2 \ 1]$$

Example 2: Using Gram-Schmidt process construct an orthonormal set of basis vectors of $V_3(R)$ for the given vectors $X_1 = [1, -1, 0]^T$

$$X_2 = [2, -1, -2]^T, X_3 = [1, -1, -2]^T$$

Solution: Choose $Y_1 = X_1 = [1, -1, 0]^T$. Then

$$Y_2 = X_2 - \frac{Y_1 \cdot X_2}{Y_1 \cdot Y_1} Y_1$$

$$\text{Here } Y_1 \cdot Y_2 = X_1 \cdot X_2 = [1 \ -1 \ 0] \begin{bmatrix} 2 \\ -1 \\ -2 \end{bmatrix}$$

$$= 2 + 1 + 0 = 3$$

$$\text{and } Y_1 \cdot Y_1 = X_1 \cdot X_1 = [1 \ -1 \ 0] \begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix} =$$

$$1 + 1 + 0 = 2$$

$$\text{so } Y_2 = \begin{bmatrix} 2 \\ -1 \\ -2 \end{bmatrix} - \frac{3}{2} \begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix} = \begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \\ -2 \end{bmatrix}$$

$$\text{Now } Y_3 = X_3 - \frac{Y_2 \cdot X_3}{Y_2 \cdot Y_2} Y_2 - \frac{Y_1 \cdot X_3}{Y_1 \cdot Y_1} Y_1$$

$$\text{Here } Y_2 \cdot X_3 = \left[\frac{1}{2} \ \frac{1}{2} \ -2\right] \begin{bmatrix} 1 \\ -1 \\ -2 \end{bmatrix} = \frac{1}{2} - \frac{1}{2} + 4 = 4$$

$$Y_2 \cdot Y_2 = \left[\frac{1}{2} \ \frac{1}{2} \ -2\right] \begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \\ -2 \end{bmatrix} = \frac{1}{4} + \frac{1}{4} + 4 = \frac{9}{2}$$

$$Y_1 \cdot X_3 = [1 \ -1 \ 0] \begin{bmatrix} 1 \\ -1 \\ -2 \end{bmatrix} = 1 + 1 + 0 = 2$$

$$\text{So } Y_3 = \begin{bmatrix} 1 \\ -1 \\ -2 \end{bmatrix} - \frac{4}{\left(\frac{9}{2}\right)} \begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \\ -2 \end{bmatrix} - \frac{2}{2} \begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix} =$$

$$\begin{bmatrix} -\frac{4}{9} \\ -\frac{4}{9} \\ -\frac{2}{9} \end{bmatrix}$$

$$\text{Now } Y_3 \cdot Y_3 = \left[-\frac{4}{9} \ -\frac{4}{9} \ -\frac{2}{9}\right] \begin{bmatrix} -\frac{4}{9} \\ -\frac{4}{9} \\ -\frac{2}{9} \end{bmatrix} = \frac{16}{81} + \frac{16}{81} + \frac{4}{81}$$

$$= \frac{36}{81} = \frac{4}{9}$$

Normalizing the vectors we get the orthonormal set of vectors

$$z_1 = \frac{Y_1}{\|Y_1\|} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix}, z_2 = \frac{Y_2}{\|Y_2\|} = \frac{\sqrt{2}}{3} \begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \\ -2 \end{bmatrix}$$

$$\text{and } z_3 = \frac{Y_3}{\|Y_3\|} = \frac{3}{2} \begin{bmatrix} -\frac{4}{9} \\ -\frac{4}{9} \\ -\frac{2}{9} \end{bmatrix} = - \begin{bmatrix} 46pt \frac{2}{3} \\ \frac{2}{3} \\ \frac{1}{3} \end{bmatrix} = \frac{-1}{3} \begin{bmatrix} 2 \\ 2 \\ 1 \end{bmatrix}$$

10.32 — HIGHER ENGINEERING MATHEMATICS—III

Example 3: Given $X_1 = [1, 1, -1]^T$ and $X_2 = [2, 1, 0]^T$ obtain an orthonormal basis of $V_3(R)$.

Solution: Take $Y_1 = X_1 = [1, 1, -1]^T$. Let us construct Y_2 by Gram-Schmidt orthogonal process.

So $Y_2 = X_2 - \frac{Y_1 \cdot X_2}{Y_1 \cdot Y_1} Y_1$. Here $Y_1 \cdot Y_1 = X_1 \cdot X_1 =$

$$[1, 1, -1] \begin{bmatrix} 1 \\ 1 \\ -1 \end{bmatrix} = 1 + 1 + 1 = 3 \text{ and } Y_1 \cdot X_2 =$$

$$X_1 \cdot X_2 = [1 \ 1 \ -1] \begin{bmatrix} 2 \\ 1 \\ 0 \end{bmatrix} = 2 + 1 + 0 = 3. \text{ Thus}$$

$$Y_2 = \begin{bmatrix} 2 \\ 1 \\ 0 \end{bmatrix} - \frac{3}{3} \begin{bmatrix} 1 \\ 1 \\ -1 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}, Y_2 \cdot Y_2 = [1 \ 0 \ 1] \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} = 2$$

Normalizing the vectors

$$z_1 = \frac{Y_1}{\|Y_1\|} = \frac{1}{\sqrt{3}} \begin{bmatrix} 1 \\ 1 \\ -1 \end{bmatrix}, z_2 = \frac{Y_2}{\|Y_2\|} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

The third orthonormal vector z_3 is the vectors of the cofactors of the column of zeros in the matrix

$$[z_1 \ z_2 \ 0] = \begin{bmatrix} \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} & 0 \\ \frac{1}{\sqrt{3}} & 0 & 0 \\ -\frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} & 0 \end{bmatrix}$$

$$\text{i.e. } \begin{vmatrix} \frac{1}{\sqrt{3}} & 0 \\ -\frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} \end{vmatrix}, -\begin{vmatrix} \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} \end{vmatrix}, \begin{vmatrix} \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{3}} & 0 \end{vmatrix}$$

$$\text{or } z_3 = \left[\frac{1}{\sqrt{6}}, \frac{2}{\sqrt{6}}, -\frac{1}{\sqrt{6}} \right]^T$$

Example 4: (a) Expand the vector $u = (9, -2, 4)$ in terms of the orthogonal basis $\{e_1, e_2, e_3\}$ of R^3 where $e_1 = (2, 1, 3)$, $e_2 = (1, -2, 0)$, $e_3 = (6, 3, -5)$ (b) what is the expansion in terms orthonormal vectors $\hat{e}_1, \hat{e}_2, \hat{e}_3$.

Solution: (a) Here $\bar{u} \cdot e_1 = (9, -2, 4) \cdot (2, 1, 3) = 18 - 2 + 12 = 28$,

$$\bar{u} \cdot e_2 = (9, -2, 4) \cdot (1, -2, 0) = 9 + 4 = 13,$$

$$\bar{u} \cdot e_3 = (9, -2, 4) \cdot (6, 3, -5) = 54 - 6 - 20 = + 28. \text{ Also } e_1 \cdot e_1 = 4 + 1 + 9 = 14, e_2 \cdot e_2 = 1 + 4 + 0 = 5, e_3 \cdot e_3 = 36 + 9 + 25 = 70. \text{ Then}$$

$$(9, -2, 4) = \bar{u} = \frac{u \cdot e_1}{e_1 \cdot e_1} e_1 + \frac{u \cdot e_2}{e_2 \cdot e_2} e_2 + \frac{u \cdot e_3}{e_3 \cdot e_3} e_3$$

$$= \frac{28}{14} e_1 + \frac{13}{5} e_2 + \frac{28}{70} e_3$$

$$(9, -2, 4) = \bar{u} = 2e_1 + \frac{13}{5} e_2 + \frac{2}{5} e_3$$

(b) Normal of base vectors are $\|e_1\| = \sqrt{e_1 \cdot e_1} = \sqrt{14}$, $\|e_2\| = \sqrt{5}$, $\|e_3\| = \sqrt{70}$. Then $\hat{e}_1 = \frac{e_1}{\|e_1\|} = \frac{e_1}{\sqrt{14}}$, $\hat{e}_2 = \frac{e_2}{\sqrt{5}}$, $\hat{e}_3 = \frac{e_3}{\sqrt{70}}$

Then $\bar{u} = (u \cdot \hat{e}_1)\hat{e}_1 + (u \cdot \hat{e}_2)\hat{e}_2 + (u \cdot \hat{e}_3)\hat{e}_3$

$$= \frac{28}{\sqrt{14}} \hat{e}_1 + \frac{13}{\sqrt{5}} \hat{e}_2 + \frac{28}{\sqrt{70}} \hat{e}_3$$

$$= 2\sqrt{14} \hat{e}_1 + \frac{13}{\sqrt{5}} \hat{e}_2 + \frac{2}{5} \sqrt{70} \hat{e}_3$$

Example 5: Using Gram-Schmidt orthogonalization process, construct an orthonormal set for the given functions $f_1(x) = 1$, $f_2(x) = x$, $f_3(x) = x^2$ w.r.t. the weight function e^{-x} over the interval $0 < x < \infty$.

Solution: Take $\phi_1(x) = \frac{f_1(x)}{\|f_1(x)\|}$. Here $f_1(x) = 1$ norm of $f_1(x)$ w.r.t. e^{-x} over $(0, \infty)$ is $\|f_1(x)\| = \int_0^\infty e^{-x} \cdot 1 \cdot dx = \left. \frac{e^{-x}}{-1} \right|_0^\infty = 1$. Thus

$\phi_1(x) = \frac{1}{1} = 1$. Now take

$$g_2(x) = f_2(x) + c\phi_1(x)$$

and determine c using the fact that $g_2(x)$ and $\phi_1(x)$ are orthogonal. Then

$$\int_0^\infty e^{-x} \cdot g_2(x) \cdot \phi_1(x) dx = 0$$

$$\int_0^\infty e^{-x} (f_2(x) + c\phi_1(x)\phi_1(x)) dx = 0$$

$$\text{So } c = -\frac{\int_0^\infty e^{-x} \cdot x dx}{\int_0^\infty e^{-x} \cdot 1 \cdot 1 dx} = -\int_0^\infty x e^{-x} dx$$

$$= -\left[x \cdot \frac{e^{-x}}{-1} - 1 \cdot e^{-x} \right]_0^\infty = -1$$

Thus $g_2(x) = f_2(x) + c\phi_1(x) = x - 1 \cdot 1 = x - 1$. Norm of $g_2(x)$ is $\|g_2(x)\|$ where

$$\|g_2(x)\|^2 = \int_0^\infty e^{-x} (x - 1)^2 dx = \int_0^\infty e^{-x} (x^2 + 1 - 2x) dx$$

$$= 1 \cdot 2! + 1 \cdot 1 + 2 \cdot 1 = 1$$

Then $\phi_2(x) = \frac{g_2(x)}{\|g_2(x)\|} = \frac{x-1}{1} = x-1$.

Now take

$$g_3(x) = f_3(x) + c_1\phi_1(x) + c_2\phi_2(x)$$

We determine c_1 and c_2 using orthogonality property between g_3 , ϕ_1 and g_3 , ϕ_2 . Then since g_3 and ϕ_1 are orthogonal, we have

$$\int_0^\infty e^{-x} g_3(x) \phi_1(x) dx = 0$$

$$\text{or } \int_0^\infty e^{-x} (f_3 + c_1\phi_1 + c_2\phi_2) \phi_1 dx = 0$$

$$\text{so } c_1 = -\frac{\int_0^\infty e^{-x} f_3 \phi_1 dx}{\int_0^\infty e^{-x} \phi_1 \phi_1 dx} = -\int_0^\infty e^{-x} f_3 \phi_1 dx$$

$$c_1 = -\int_0^\infty e^{-x} x^2 \cdot 1 \cdot dx = -1 \cdot 2! = -2$$

Also since g_3 and ϕ_2 are orthogonal, we have

$$\int_0^\infty e^{-x} g_3(x) \phi_2(x) dx = 0$$

$$\text{or } \int_0^\infty e^{-x} (f_3 + c_1\phi_1 + c_2\phi_2) \phi_2 dx = 0$$

$$c_2 = -\frac{\int_0^\infty e^{-x} f_3 \phi_2 dx}{\int_0^\infty e^{-x} \phi_2 \phi_2 dx} = -\int_0^\infty e^{-x} f_3 \phi_2 dx$$

$$c_2 = -\int_0^\infty e^{-x} x^2 (x-1) dx = -[3! - 2!] = -4$$

Therefore

$$g_3(x) = f_3 + c_1\phi_1 + c_2\phi_2$$

$$= x^2 - 2 \cdot 1 - 4(x-1)$$

$$g_3(x) = x^2 - 4x + 2$$

Now

$$\|g_3(x)\|^2 = \int_0^\infty e^{-x} g_3^2(x) dx$$

$$= \int_0^\infty e^{-x} (x^2 - 4x + 2)^2 dx$$

$$= \int_0^\infty e^{-x} (x^4 - 16x^2 + 4 - 8x^3 - 16x + 4x^2) dx$$

$$= 4! - 8 \cdot 3! + 20 \cdot 2! - 16 \cdot 1 + 4 = 4$$

$$\therefore \phi_3(x) = \frac{g_3(x)}{\|g_3(x)\|} = \frac{x^2 - 4x + 2}{4}$$

Thus the three functions

$$\phi_1(x) = 1, \phi_2(x) = x-1, \phi_3(x) = \frac{x^2 - 4x + 2}{4}$$

which are constructed by Gram-Schmidt orthogonalization using the given function $f_1(x) =$

1 , $f_2(x) = x$, $f_3(x) = x^2$ form an orthonormal set of functions wrt e^{-x} over $(0, \infty)$.

EXERCISE

1. If $X_1 = [1, 2, 3]^T$ and $X_2 = [2, -3, 4]^T$ find (a) their inner product (b) length of each

Ans. (a) 8 (b) $\sqrt{14}$, $\sqrt{29}$

2. (a) Prove that $X_1 = [\frac{1}{3}, \frac{-2}{3}, \frac{-2}{3}]^T$ and $X_2 = [\frac{2}{3}, \frac{-1}{3}, \frac{-2}{3}]^T$ are orthogonal (b) Find a vector X_3 orthogonal to both X and Y .

Ans. (a) $X_1 \cdot X_2 = 0$

$$(b) X_3 = [\frac{-2}{3}, \frac{-2}{3}, \frac{1}{3}]^T$$

Hint: Elements of X_3 are the cofactors of the elements of the column of zeros in the matrix

$$\begin{bmatrix} \frac{1}{3} & \frac{2}{3} & 0 \\ -\frac{2}{3} & -\frac{1}{3} & 0 \\ -\frac{2}{3} & \frac{2}{3} & 0 \end{bmatrix}$$

3. Using Gram-Schmidt process, construct an ortho-normal basis of $V_3(R)$ given a basis of vectors X_1, X_2, X_3 where

$$(a) X_1 = [1, 1, 1]^T, X_2 = [1, -2, 1]^T, X_3 = [1, 2, 3]^T$$

$$(b) X_1 = [2, 1, 3]^T, X_2 = [1, 2, 3]^T, X_3 = [1, 1, 1]^T$$

$$(c) X_1 = [1, 0, 1]^T, X_2 = [1, 3, 1]^T, X_3 = [3, 2, 1]^T$$

$$(d) X_1 = [2, -1, 0], X_2 = [4, -1, 0], X_3 = [4, 0, -1]$$

$$(e) X_1 = [1, 1, 0], X_2 = [2, -1, 1], X_3 = [1, 0, 3]$$

Ans. (a) $\frac{1}{\sqrt{3}}[1, 1, 1], \frac{1}{\sqrt{6}}[1, -2, 1], \frac{1}{\sqrt{2}}[-1, 0, 1]$

$$(b) \frac{1}{\sqrt{14}}[2, 1, 3], \frac{1}{\sqrt{42}}[-4, 5, 1], \frac{1}{\sqrt{3}}[1, 1, -1]$$

$$(c) \frac{1}{\sqrt{2}}[1, 0, 1], \frac{1}{\sqrt{2}}[0, 1, 0], \frac{1}{\sqrt{2}}[1, 0, -1]$$

$$(d) \frac{1}{\sqrt{5}}[2, -1, 0], \frac{1}{\sqrt{5}}[1, 2, 0], \frac{1}{\sqrt{5}}[0, 0, -1]$$

$$(e) \frac{1}{\sqrt{2}}[1, 1, 0], \frac{1}{\sqrt{22}}[3, -3, 2], \frac{1}{\sqrt{11}}[-1, 1, 3]$$

4. Show that $X_1 = (1, 0, 0, 0)$, $X_2 = (0, \frac{1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}})$, $X_3 = (0, \frac{1}{\sqrt{2}}, 0 - \frac{1}{\sqrt{2}})$ form an orthonormal set.

10.34 — HIGHER ENGINEERING MATHEMATICS—III

5. Find scalars α, β, γ and the vectors u_1, u_2, u_3 such that $u_1 = u, u_2 = u + \alpha v, u_3 = u + \beta v + \gamma w$ is a non-zero orthogonal set. Normalize the set, given

$$u = (1, 3, 0), v = (2, 3, 0), w = (2, 1, -3)$$

Ans. $u_1 = u = (1, 3, 0), u_2 = u - \frac{10}{11}v = \left[-\frac{9}{11}, \frac{3}{11}, 0\right],$
 $u_3 = u - \frac{5}{4}v + \frac{3}{4}w = \left[0, 0, \frac{-9}{4}\right],$ normalized vector

$$X_1 = \frac{u_1}{\|u_1\|} = \left(\frac{1}{\sqrt{10}}, \frac{3}{\sqrt{10}}, 0\right),$$

$$X_2 = \frac{u_2}{\|u_2\|} = \left(-\frac{9}{\sqrt{90}}, \frac{3}{\sqrt{90}}, 0\right)$$

$$X_3 = \frac{u_3}{\|u_3\|} = [0, 0, -1]$$

6. Find all non-zero vectors (if any) orthogonal to the following vectors (a) $(3, 0, -1)$ (b) $(1, 3, 4, 0)$ and $(2, -1, 0, 5)$

Ans. (a) $u = \left[\frac{\alpha}{3}, \beta, \alpha\right]$ where α, β are arbitrary
 (b) $u = [-15\alpha - 4\beta, 5\alpha - 8\beta, 7\beta, 7\alpha]$ where α, β are arbitrary.

Hint. Assume $u = [\alpha, \beta, \gamma]$ solve for α, β, γ using orthogonality condition $u \cdot u_1 = 0$ etc.

7. Expand $u = (1, 0, 0, 0)$ in terms of orthogonal basis vectors $e_1 = (2, 0, -1, -5), e_2 = (2, 0, -1, 1), e_3 = (0, 1, 0, 0), e_4 = (1, 0, 2, 0)$

Ans. $\frac{1}{15}e_1 + \frac{1}{3} \cdot e_2 + 0 \cdot e_3 + \frac{1}{5}e_4$

8. (a) Expand $(4, 3, -3, 6)$ in terms of orthogonal basis vectors $e_1 = (1, 0, 2, 0), e_2 = (0, 1, 0, 0), e_3 = (-2, 0, 1, 5),$

$e_4 = (-2, 0, 1, -1)$ (b) What is the expansion in terms of unit vectors

Ans. (a) $-\frac{2}{5}e_1 + 3e_2 + \frac{19}{30}e_3 - \frac{17}{6}e_4$
 (b) $-\frac{2}{\sqrt{5}}\hat{e}_1 + 3\hat{e}_2 + \frac{19}{\sqrt{30}}\hat{e}_3 - \frac{17}{\sqrt{6}}\hat{e}_4.$

Using Gram-Schmidt orthogonalization process construct an orthonormal set of vectors from the given functions $f_1(x), f_2(x)$ and $f_3(x)$ over the interval (a, b) .

9. $f_1(x) = 1, f_2(x) = x, f_3(x) = x^2, 0 < x < 1.$

Ans. $\phi_1(x) = \frac{1}{\sqrt{2}}, \phi_2(x) = \sqrt{\frac{3}{2}}x, \phi_3(x) = \frac{1}{2}\sqrt{\frac{5}{2}}(2x^2 - 1)$

10. $f_1(x) = 1, f_2(x) = x, f_3(x) = x^2, -1 \leq x \leq 1$

Ans. $\phi_0 = \frac{1}{\sqrt{2}}, \phi_1 = \frac{x}{\sqrt{2/3}}, \phi_2 = \frac{x^2 - \frac{2}{3}}{\sqrt{2/5}}.$

Chapter 11

Special Functions—Gamma, Beta, Bessel and Legendre

INTRODUCTION

Algebraic function $f(x)$ is obtained by the algebraic operations of addition, subtraction, multiplication, division and square rooting of x polynomial and rational functions are such functions. Transcendental functions include trigonometric functions (sine, cosine, tan) exponential, logarithmic and hyperbolic functions.

Algebraic and transcendental functions together constitute the elementary functions. Special functions (or higher functions) are functions other than the elementary functions such as Gamma, Beta functions (expressed as integrals) Bessel's functions, Legendre polynomials (as solutions of ordinary differential equations). Special functions also include Laguerre, Hermite, Chebyshev polynomials, error function, sine integral, exponential integral, Fresnel integrals, etc.

Many integrals which can not be expressed in terms of elementary functions can be evaluated in terms of beta and gamma functions.

Heat equation, wave equation and Laplace's equation with cylindrical symmetry can be solved in terms of Bessel's functions, with spherical symmetry by Legendre polynomials. We consider Fourier-Legendre series and Fourier-Bessel series. Chebyshev-polynomials which are useful in approximation theory are also presented.

11.1 GAMMA FUNCTION

Gamma function denoted by $\Gamma(p)$ is defined by the improper integral which is dependent on the

parameter p ,

$$\Gamma(p) = \int_0^{\infty} e^{-t} t^{p-1} dt, \quad (p > 0) \quad (1)$$

Gamma function is also known as Euler's integral of the second kind.

Integrating by parts

$$\begin{aligned} \Gamma(p+1) &= \int_0^{\infty} e^{-t} t^p dt \\ &= -e^{-t} t^p \Big|_0^{\infty} + p \int_0^{\infty} e^{-t} t^{p-1} dt \\ &= 0 + p\Gamma(p) \end{aligned}$$

$$\text{Thus} \quad \Gamma(p+1) = p\Gamma(p) \quad (2)$$

(2) is known as the functional relation or reduction or recurrence formula for gamma function.

Result:

$$\Gamma(n+a) = (n+a-1)(n+a-2)(n+a-3) \cdots a \cdot \Gamma(a), \quad n \text{ is integer.}$$

By definition

$$\Gamma(1) = \int_0^{\infty} e^{-t} dt = \frac{e^{-t}}{-1} \Big|_0^{\infty} = 1 \quad (3)$$

By the reduction formula (2),

$$\Gamma(2) = 1 \cdot \Gamma(1) = 1$$

$$\text{and} \quad \Gamma(3) = 2 \cdot \Gamma(2) = 2 \cdot 1 = 2!$$

and in general when p is a positive integer n

$$\begin{aligned} \Gamma(n+1) &= n\Gamma(n) = n(n-1)\Gamma(n-1) \\ &= n(n-1)(n-2)\Gamma(n-2) \\ &= n \cdot (n-1)(n-2) \cdots 3 \cdot 2 \cdot 1 = n! \end{aligned}$$

11.2 — HIGHER ENGINEERING MATHEMATICS—III

Thus for $p = n$, positive integer

$$\Gamma(n+1) = n! \quad (4)$$

For this reason, Gamma function is regarded as the generalization of the elementary factorial function.

Gamma function for negative values of p i.e., $p < 0$: Rewrite (2) as left-marching recurrence formula,

$$\Gamma(p) = \frac{\Gamma(p+1)}{p} \quad (5)$$

$$\text{As } p \rightarrow 0, \quad \Gamma(0) = \lim_{p \rightarrow 0} \frac{\Gamma(1)}{p} = \lim_{p \rightarrow 0} \frac{1}{p} \rightarrow \infty$$

Thus $\Gamma(0)$ is undefined and it follows from (5) that $\Gamma(-1)$, $\Gamma(-2)$, $\Gamma(-3)$, etc. are all undefined.

Repeated application of (5) results in

$$\begin{aligned} \Gamma(p) &= \frac{\Gamma(p+1)}{p} = \frac{\Gamma(p+2)}{p(p+1)} = \dots \\ &= \frac{\Gamma(p+k+1)}{p(p+1) \dots (p+k)} \end{aligned} \quad (6)$$

Relation (6) is used to find gamma function for $p < 0$ (except at $p = 0, -1, -2, -3, \dots$).

Hence gamma function is continuous for any $p > 0$ and is discontinuous at $p = 0, -1, -2, -3, \dots$

Thus $\Gamma(p)$ is defined for all p , except for zero and negative integers.

Standard Results

$$1. \Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$$

By definition $\Gamma\left(\frac{1}{2}\right) = \int_0^\infty t^{-\frac{1}{2}} e^{-t} dt$, put $t = u^2$
then $\Gamma\left(\frac{1}{2}\right) = 2 \int_0^\infty e^{-u^2} du$

$$\begin{aligned} \Gamma\left(\frac{1}{2}\right) \cdot \Gamma\left(\frac{1}{2}\right) &= \left[2 \int_0^\infty e^{-u^2} du\right] \left[2 \int_0^\infty e^{-v^2} dv\right] \\ &= 4 \int_0^\infty \int_0^\infty e^{-(u^2+v^2)} du dv \end{aligned}$$

This double integral in the first quadrant is evaluated by changing to polar coordinates
 $u = r \cos \theta$, $v = r \sin \theta$, $J = r$

$$\begin{aligned} \left[\Gamma\left(\frac{1}{2}\right)\right]^2 &= 4 \int_{\theta=0}^{\frac{\pi}{2}} \int_{r=0}^\infty e^{-r^2} r dr d\theta \\ &= 4 \int_0^{\frac{\pi}{2}} -\frac{1}{2} e^{-r^2} \Big|_{r=0}^\infty d\theta \end{aligned}$$

$$= 2 \int_0^{\frac{\pi}{2}} d\theta = 2 \cdot \theta \Big|_0^{\frac{\pi}{2}} = 2 \cdot \frac{\pi}{2} = \pi.$$

$$\text{Hence } \Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$$

$$2. \Gamma\left(\frac{p+1}{q}\right) = qa^{(p+1)/q} \int_0^\infty x^p e^{-ax^q} dx; \quad p, q, a \text{ are positive constants}$$

Put $y = ax^q$ then $dy = aqx^{q-1} dx$

$$\begin{aligned} \int_0^\infty x^p e^{-ax^q} dx &= \int_0^\infty \left[\left(\frac{y}{a}\right)^{\frac{1}{q}}\right]^p e^{-y} \cdot \frac{1}{aqx^{q-1}} dy \\ &= \left[qa^{(p+1)/q}\right]^{-1} \int_0^\infty y^{(p+1-1)/q} e^{-y} dy \\ &= \frac{\Gamma\left(\frac{p+1}{q}\right)}{qa^{\frac{p+1}{q}}}. \end{aligned}$$

$$3. \Gamma(n+1) = (m+1)^{n+1} (-1)^n \int_0^1 x^m (\ln x)^n dx$$

where n is a positive integer and $m > -1$.

Put $x = e^{-y}$ then $dx = -e^{-y} dy = -x dy$

$$\begin{aligned} \int_0^1 x^m (\ln x)^n dx &= \int_0^\infty e^{-my} \cdot (-y)^n e^{-y} dy \\ &= (-1)^n \int_0^\infty y^n \cdot e^{-(m+1)y} dy, \end{aligned}$$

Put $(m+1)y = u$

$$\begin{aligned} &= (-1)^n \int_0^\infty \frac{u^n}{(m+1)^n} \cdot e^{-u} \cdot \frac{du}{m+1} \\ &= \frac{(-1)^n}{(m+1)^{n+1}} \int_0^\infty e^{-u} \cdot u^n du = \frac{(-1)^n}{(m+1)^{n+1}} \cdot \Gamma(n+1) \end{aligned}$$

11.2 BETA FUNCTION

Beta function $\beta(p, q)$ defined by

$$\beta(p, q) = \int_0^1 x^{p-1} (1-x)^{q-1} dx, \quad (p > 0, q > 0) \quad (1)$$

is convergent for $p > 0, q > 0$. This function is also known as Euler's integral of the first kind.

Standard Results

$$1. \text{ Symmetry: } \beta(p, q) = \beta(q, p) \quad (2)$$

$$\begin{aligned} \beta(p, q) &= \int_0^1 x^{p-1} (1-x)^{q-1} dx. \quad \text{Put } x = 1-y \\ &= \int_1^0 (1-y)^{p-1} \cdot y^{q-1} (-dy) \end{aligned}$$

$$= \int_1^0 y^{q-1} (1-y)^{p-1} dy = \beta(q, p).$$

2. Beta function in terms of trigonometric functions

$$\beta(p, q) = 2 \int_0^{\frac{\pi}{2}} \sin^{2p-1} x \cdot \cos^{2q-1} x \, dx \quad (3)$$

Putting $x = \sin^2 \theta$, $dx = 2 \sin \theta \cdot \cos \theta \, d\theta$ and $1-x = \cos^2 \theta$,

$$\begin{aligned} \beta(p, q) &= \int_0^1 x^{p-1} (1-x)^{q-1} dx \\ &= \int_0^{\frac{\pi}{2}} \sin^{2p-2} \theta \cdot \cos^{2q-2} \theta \cdot 2 \\ &\quad \times \sin \theta \cdot \cos \theta \, d\theta \end{aligned}$$

$$\begin{aligned} \beta(p, q) &= 2 \int_0^{\frac{\pi}{2}} \sin^{2p-1} \theta \cdot \cos^{2q-1} \theta \, d\theta \\ &= 2 \cdot I_{2p-1, 2q-1} \end{aligned}$$

$$\begin{aligned} \text{or } I_{p, q} &= \int_0^{\frac{\pi}{2}} \sin^p \theta \cos^q \theta \, d\theta \\ &= \frac{1}{2} \beta \left(\frac{p+1}{2}, \frac{q+1}{2} \right), \quad p > -1 \\ &\quad, q > -1 \quad (4) \end{aligned}$$

3. Beta function expressed as an improper integral

$$\begin{aligned} \beta(p, q) &= \int_0^\infty \frac{y^{p-1}}{(1+y)^{p+q}} dy \\ &= \int_0^\infty \frac{y^{q-1} dy}{(1+y)^{p+q}} \quad (5) \end{aligned}$$

Putting $x = \frac{y}{1+y}$ or $y = \frac{x}{1-x}$, limits for y are 0 to ∞ .

$$\begin{aligned} \beta(p, q) &= \int_0^1 x^{p-1} (1-x)^{q-1} dx \\ &= \int_0^\infty \frac{y^{p-1}}{(1+y)^{p+q}} \cdot \left(\frac{1}{1+y} \right)^{q-1} \cdot \frac{dy}{(1+y)^2} \\ &= \int_0^\infty \frac{y^{p-1}}{(1+y)^{p+q}} dy \\ &= \int_0^\infty \frac{y^{q-1}}{(1+y)^{q+p}} dy. \end{aligned}$$

The last integral follows from symmetry.

4. Relation between β and Γ functions

$$\beta(p, q) = \frac{\Gamma(p)\Gamma(q)}{\Gamma(p+q)} \quad (6)$$

By definition

$$\Gamma(p) = \int_0^\infty x^{p-1} e^{-x} \, dx,$$

Put $x = t^2$, $dx = 2t \, dt$

$$\begin{aligned} \Gamma(p) &= \int_0^\infty t^{2p-2} \cdot e^{-t^2} \cdot 2t \, dt \\ &= 2 \int_0^\infty t^{2p-1} \cdot e^{-t^2} \, dt \end{aligned}$$

$$\begin{aligned} \text{Then } \Gamma(p) \Gamma(q) &= \left[2 \int_0^\infty x^{2p-1} e^{-x^2} \, dx \right] \\ &\quad \times \left[2 \int_0^\infty y^{2q-1} e^{-y^2} \, dy \right] \end{aligned}$$

Here t, x, y are dummy variables.

$$= 4 \int_0^\infty \int_0^\infty x^{2p-1} \cdot y^{2q-1} \cdot e^{-(x^2+y^2)} \, dx \, dy.$$

Introduce polar coordinates

$$x = r \cos \theta, \quad y = r \sin \theta.$$

As x, y vary in the first quadrant (i.e., $0 < x < \infty, 0 < y < \infty$), r varies from 0 to ∞ and θ from 0 to $\frac{\pi}{2}$. Jacobian: r

$$\begin{aligned} \Gamma(p) \Gamma(q) &= 4 \int_0^{\frac{\pi}{2}} \int_0^\infty (r \cos \theta)^{2p-1} \cdot (r \sin \theta)^{2q-1} \\ &\quad \times e^{-r^2} \cdot r \, dr \, d\theta \\ &= 4 \left[\int_0^{\frac{\pi}{2}} \sin^{2q-1} \theta \cdot \cos^{2p-1} \theta \, d\theta \right] \\ &\quad \times \left[\int_0^\infty e^{-r^2} \cdot r^{2p+2q-1} \cdot dr \right] \end{aligned}$$

Using result 2 above in this page and putting $r^2 = t$

$$\Gamma(p) \Gamma(q) = 4 \cdot \left[\frac{1}{2} \beta(p, q) \right] \left[\frac{1}{2} \int_0^\infty e^{-t} \cdot t^{p+q-1} \, dt \right]$$

$\Gamma(p) \Gamma(q) = \beta(p, q) \cdot \Gamma(p+q)$, hence the result.

5. $\Gamma(p) \Gamma(1-p) = \frac{\pi}{\sin p\pi}, 0 < p < 1$

Put $q = 1-p$ in (6) and use (5)

$$\frac{\Gamma(p)\Gamma(1-p)}{\Gamma(p+1-p)} = \beta(p, 1-p)$$

$$= \int_0^\infty \frac{x^{p-1}}{1+x} dx = \frac{\pi}{\sin p\pi}$$

(which follows from residue theorem) and since $\Gamma(1) = 1$

6. $\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$

Put $p = q = \frac{1}{2}$ in (6) and use (3)

$$\begin{aligned} \frac{\Gamma\left(\frac{1}{2}\right) \Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{1}{2} + \frac{1}{2}\right)} &= \beta\left(\frac{1}{2}, \frac{1}{2}\right) = 2 \int_0^{\frac{\pi}{2}} \sin^\circ \theta \cos^\circ \theta d\theta \\ &= 2 \cdot \frac{\pi}{2} = \pi \end{aligned}$$

Since $\Gamma(1) = 1$, $\Gamma\left(\frac{1}{2}\right) \cdot \Gamma\left(\frac{1}{2}\right) = \pi$

7. $\int_0^{\frac{\pi}{2}} \sin^n x dx = \frac{1}{2} \beta\left(\frac{n+1}{2}, \frac{1}{2}\right) = \frac{\Gamma\left(\frac{n+1}{2}\right) \sqrt{\pi}}{\Gamma\left(\frac{n+2}{2}\right) 2}$

which follows from (4) with $p = n$ and $q = 0$

Similarly with $p = 0$, $q = n$ from (4), we get

8. $\int_0^{\frac{\pi}{2}} \cos^n x dx = \frac{1}{2} \beta\left(\frac{1}{2}, \frac{n+1}{2}\right) = \frac{\Gamma\left(\frac{n+1}{2}\right) \sqrt{\pi}}{\Gamma\left(\frac{n+2}{2}\right) 2}$

9. Legendre's duplication formula for Γ function:

$$\sqrt{\pi} \Gamma(2p) = 2^{2p-1} \cdot \Gamma(p) \Gamma\left(p + \frac{1}{2}\right)$$

Putting $p = q$ in (3), we get

$$\begin{aligned} \beta(p, p) &= 2 \int_0^{\frac{\pi}{2}} \sin^{2p-1} \theta \cdot \cos^{2p-1} \theta d\theta \\ &= 2 \int_0^{\frac{\pi}{2}} (\sin \theta \cdot \cos \theta)^{2p-1} d\theta \\ &= 2 \int_0^{\frac{\pi}{2}} \left(\frac{\sin 2\theta}{2}\right)^{2p-1} d\theta \\ &= \frac{2}{2^{2p-1}} \int_0^{\frac{\pi}{2}} (\sin 2\theta)^{2p-1} d\theta \end{aligned}$$

Put $2\theta = t$,

$$\begin{aligned} \beta(p, p) &= \frac{1}{2^{2p-1}} \cdot \int_0^\pi \sin^{2p-1} t dt \\ &= \frac{1}{2^{2p-1}} \left[2 \int_0^{\frac{\pi}{2}} \sin^{2p-1} t dt \right] \\ \beta(p, p) &= \frac{1}{2^{2p-1}} \cdot \beta\left(p, \frac{1}{2}\right) \end{aligned}$$

since from (3) with $q = \frac{1}{2}$,

$$\beta\left(p, \frac{1}{2}\right) = 2 \int_0^{\frac{\pi}{2}} \sin^{2p-1} x dx.$$

Using (6), express β in terms of Γ functions

$$2^{2p-1} \cdot \frac{\Gamma(p) \Gamma(p)}{\Gamma(p+p)} = \frac{\Gamma(p) \Gamma\left(\frac{1}{2}\right)}{\Gamma\left(p + \frac{1}{2}\right)}$$

$$\begin{aligned} \text{or } 2^{2p-1} \cdot \Gamma(p) \Gamma\left(p + \frac{1}{2}\right) &= \Gamma\left(\frac{1}{2}\right) \Gamma(2p) \\ &= \sqrt{\pi} \Gamma(2p) \end{aligned}$$

10. $I = \int_0^{\frac{\pi}{2}} \sin^p \theta d\theta = \int_0^{\frac{\pi}{2}} \cos^p \theta d\theta =$

a. $\frac{1 \cdot 3 \cdot 5 \cdots (p-1)}{2 \cdot 4 \cdot 6 \cdots p} \cdot \frac{\pi}{2}$ if p is an even positive integer and

b. $\frac{2 \cdot 4 \cdot 6 \cdots (p-1)}{1 \cdot 3 \cdot 5 \cdots p}$ if p is an odd positive integer.

a. $\int_0^{\frac{\pi}{2}} \sin^p \theta d\theta = \frac{\Gamma\left(\frac{1}{2}(p+1)\right) \Gamma\left(\frac{1}{2}\right)}{2\Gamma\left(\frac{1}{2}(p+2)\right)}$ from result 7.

If $p = 2r$,

$$\begin{aligned} I &= \frac{\Gamma\left(r + \frac{1}{2}\right) \sqrt{\pi}}{2\Gamma(r+1)} \\ &= \frac{\left(r - \frac{1}{2}\right) \left(r - \frac{3}{2}\right) \cdots \frac{3}{2} \cdot \frac{1}{2} \cdot \Gamma\left(\frac{1}{2}\right) \sqrt{\pi}}{2 \cdot r!} \\ I &= \frac{(2r-1)(2r-3) \cdots 3 \cdot 1}{2r \cdot (2r-2) \cdot (2r-4) \cdots 2} \cdot \frac{\pi}{2} \end{aligned}$$

b. If $p = 2r + 1$,

$$\begin{aligned} I &= \frac{\Gamma(r+1) \Gamma\left(\frac{1}{2}\right)}{2\Gamma\left(r + \frac{3}{2}\right)} \\ &= \frac{r! \sqrt{\pi}}{2 \left(r + \frac{1}{2}\right) \left(r - \frac{1}{2}\right) \left(r - \frac{3}{2}\right) \cdots \frac{3}{2} \cdot \frac{1}{2} \Gamma\left(\frac{1}{2}\right)} \\ &= \frac{2^r \cdot r!}{(2r+1)(2r-1) \cdots 5 \cdot 3 \cdot 1} \\ &= \frac{2 \cdot 4 \cdot 6 \cdots (2r-2) \cdot 2r}{1 \cdot 3 \cdot 5 \cdots (2r-1)(2r+1)} \end{aligned}$$

11. $\beta(p, q) = \beta(p+1, q) + \beta(p, q+1)$

By definition

$$\begin{aligned} & \beta(p+1, q) + \beta(p, q+1) \\ &= \int_0^1 x^p (1-x)^{q-1} dx + \int_0^1 x^{p-1} (1-x)^q dx \\ &= \int_0^1 x^{p-1} (1-x)^{q-1} [x + (1-x)] dx \\ &= \int_0^1 x^{p-1} (1-x)^{q-1} dx = \beta(p, q). \end{aligned}$$

12. $\beta(m, n) = \frac{(m-1)!(n-1)!}{(m+n-1)!}$ for m, n positive integers

From the above result 11

$$\beta(m, n) = \beta(m+1, n) + \beta(m, n+1)$$

Expressing in Γ functions using (6)

$$\beta(m, n) = \frac{\Gamma(m+1)\Gamma(n)}{\Gamma(m+n+1)} + \frac{\Gamma(m)\Gamma(n+1)}{\Gamma(m+n+1)}$$

Since m and n are positive integers

$$\begin{aligned} &= \frac{m!(n-1)! + (m-1)!n!}{(m+n)!} \\ &= \frac{(m-1)!(n-1)![m+n]}{(m+n)!} = \frac{(m-1)!(n-1)!}{(m+n-1)!} \end{aligned}$$

13. $\int_0^1 x^p (1-x^q)^r dx = \frac{1}{q} \beta\left(\frac{p+1}{q}, r+1\right)$

Put $x^q = y$, $qx^{q-1}dx = dy$ or $qy^{\left(\frac{q-1}{q}\right)}dx = dy$

$$\begin{aligned} \int_0^1 x^p (1-x^q)^r dx &= \int_0^1 y^{\left(\frac{p}{q}\right)} (1-y)^r \frac{1}{qy^{\left(\frac{q-1}{q}\right)}} dy \\ &= \frac{1}{q} \int_0^1 y^{(p-q+1)/q} (1-y)^r dy \\ &= \frac{1}{q} \beta\left(\frac{p-q+1}{q} + 1, r+1\right) \\ &= \frac{1}{q} \beta\left(\frac{p+1}{q}, r+1\right) \end{aligned}$$

Note: When $q = 1$, $\int_0^1 x^p (1-x)^r dx = \beta(p+1, r+1)$.

14. $\int_0^1 \frac{x^{m-1}(1-x)^{n-1}}{(b+cx)^{m+n}} dx = \frac{1}{b^n(b+c)^m} \cdot \beta(m, n)$

Put $y = \frac{x(1+a)}{b+cx}$ then $x = \frac{yb}{1+a-cy}$,

$$1-x = \frac{(1+a)-y(c+b)}{(1+a-cy)}, \quad b+cx = \frac{b(1+a)}{(1+a-cy)}$$

and $dx = \frac{(b+cx)dy}{(1+a-cy)} = \frac{b(1+a)dy}{(1+a-cy)^2}$.

Now y varies from 0 to $\frac{1+a}{b+c} = e$ say

$$\begin{aligned} & \int_0^1 \frac{x^{m-1}(1-x)^{n-1}}{(b+cx)^{m+n}} dx \\ &= \int_0^e \left(\frac{yb}{1+a-cy} \right)^{m-1} \left[\frac{(1+a)-y(c+b)}{1+a-cy} \right]^{n-1} \\ & \quad \times \frac{(1+a-cy)^{m+n}}{[b(1+a)]^{m+n}} \frac{b(1+a)dy}{(1+a-cy)^2} \\ &= \int_0^e \frac{1}{b^n(1+a)^{m+n-1}} y^{m-1} \\ & \quad \times \left[(1+a)-y(c+b) \right]^{n-1} dy \\ &= \frac{1}{b^n(1+a)^m} \int_0^e y^{m-1} \left(1 - \frac{y}{e} \right)^{n-1} dy \\ & \text{Put } \frac{1}{e} y = t \\ &= \frac{1}{b^n(1+a)^m} \int_0^1 (et)^{m-1} (1-t)^{n-1} \cdot e dt \\ &= \frac{1}{b^n(1+a)^m} \cdot \left(\frac{1+a}{b+c} \right)^m \cdot \int_0^1 t^{m-1} (1-t)^{n-1} dt \\ &= \frac{1}{b^n(b+c)^m} \cdot \beta(m, n). \end{aligned}$$

15. When $c = 1, b = a$, from above result 14,

$$\int_0^1 \frac{x^{m-1}(1-x)^{n-1}}{(a+x)^{m+n}} dx = \frac{1}{a^n(1+a)^m} \beta(m, n).$$

WORKED OUT EXAMPLES

Gamma and Beta functions

Example 1: Compute (a) $\Gamma(4.5)$ (b) $\Gamma(-3.5)$

(c) $\Gamma\left(\frac{1}{4}\right)\Gamma\left(\frac{3}{4}\right)$ (d) $\beta\left(\frac{5}{2}, \frac{3}{2}\right)$ (e) $\frac{\Gamma\left(n+\frac{1}{2}\right)}{\Gamma(n+1)}$.

11.6 — HIGHER ENGINEERING MATHEMATICS—III

Solution:

a. Using $\Gamma(p+1) = p\Gamma(p)$

$$\begin{aligned}\Gamma(4.5) &= \Gamma(3.5+1) = 3.5\Gamma(3.5) = (3.5)(2.5)\Gamma(2.5) \\ &= (3.5)(2.5)(1.5)(.5)\Gamma(.5) \\ &= 6.5625\sqrt{\pi} = 11.62875\end{aligned}$$

b. Using $\Gamma(p) = \frac{\Gamma(p+1)}{p}$

$$\begin{aligned}\Gamma(-3.5) &= \frac{\Gamma(-3.5+1)}{-3.5} = \frac{\Gamma(-2.5)}{-3.5} = \frac{\Gamma(-2.5+1)}{(-3.5)(-2.5)} \\ &= \frac{\Gamma(-1.5)}{(3.5)(2.5)} = \frac{\Gamma(-1.5+1)}{-(3.5)(2.5)(1.5)} \\ &= \frac{\Gamma(.5)}{(3.5)(2.5)(1.5)(.5)} = \frac{\sqrt{\pi}}{(3.5)(2.5)(1.5)(.5)} \\ &= .270019\end{aligned}$$

c. Using $\Gamma(n)\Gamma(1-n) = \frac{\pi}{\sin n\pi}$

$$\begin{aligned}\Gamma\left(\frac{1}{4}\right)\Gamma\left(1-\frac{1}{4}\right) &= \Gamma\left(\frac{1}{4}\right)\Gamma\left(\frac{3}{4}\right) \\ &= \frac{\pi}{\sin \frac{\pi}{4}} = \sqrt{2}\pi = 4.444\end{aligned}$$

$$\begin{aligned}\text{d. } \beta\left(\frac{5}{2}, \frac{3}{2}\right) &= \frac{\Gamma\left(\frac{5}{2}\right)\Gamma\left(\frac{3}{2}\right)}{\Gamma\left(\frac{5}{2}+\frac{3}{2}\right)} = \frac{\frac{3}{2}\Gamma\left(\frac{3}{2}\right) \cdot \Gamma\left(\frac{3}{2}\right)}{3!} \\ &= \frac{1}{4}\left[\frac{1}{2}\Gamma\left(\frac{1}{2}\right)\right]^2 = \frac{1}{4} \cdot \frac{1}{4} \cdot \pi = .1964\end{aligned}$$

$$\begin{aligned}\text{e. } \Gamma\left(n+\frac{1}{2}\right) &= \left(n+\frac{1}{2}-1\right)\left(n+\frac{1}{2}-2\right) \\ &\quad \times \left(n+\frac{1}{2}-3\right) \cdots \frac{1}{2}\Gamma\left(\frac{1}{2}\right) \\ &= \frac{(2n-1)}{2}\left(\frac{2n-3}{2}\right)\left(\frac{2n-5}{2}\right) \\ &\quad \times \cdots \frac{3}{2} \cdot \frac{1}{2} \cdot \sqrt{\pi} \\ &= \frac{[(2n-1)(2n-3)(2n-5) \cdots 1 \cdot \sqrt{\pi}]}{2^n}\end{aligned}$$

Since $\Gamma(n+1) = n!$ thus

$$\frac{\Gamma\left(n+\frac{1}{2}\right)}{\Gamma(n+1)} = \frac{1 \cdot 3 \cdot 5 \cdots (2n-3)(2n-1)}{2^n \cdot n!} \sqrt{\pi}.$$

Example 2: Evaluate $I = \int_0^\infty x^4 e^{-x^4} dx$.

Solution: Put $x^4 = t$, $4x^3 dx = dt$, $dx = \frac{1}{4}t^{-\frac{3}{4}} dt$

$$\begin{aligned}I &= \int_0^\infty t \cdot e^{-t} \cdot \frac{t^{-\frac{3}{4}}}{4} \cdot dt = \frac{1}{4} \int_0^\infty e^{-t} \cdot t^{\frac{1}{4}} dt \\ &= \frac{1}{4} \Gamma\left(1 + \frac{1}{4}\right) = \frac{1}{4} \Gamma\left(\frac{5}{4}\right).\end{aligned}$$

Example 3: Evaluate $I = \int_0^1 \sqrt[3]{x \ln\left(\frac{1}{x}\right)} dx$.

Solution: Put $\ln\left(\frac{1}{x}\right) = t$, $x = e^{-t}$, $dx = -e^{-t} dt$

$$\begin{aligned}I &= \int_\infty^0 (e^{-t} \cdot t)^{\frac{1}{3}} (-e^{-t}) dt \\ &= \int_0^\infty t^{\frac{1}{3}} e^{-\frac{4t}{3}} dt, \quad \text{Put } \frac{4t}{3} = y \\ &= \int_0^\infty \left(\frac{3}{4}\right)^{\frac{4}{3}} e^{-y} y^{\frac{1}{3}} dy = \left(\frac{3}{4}\right)^{\frac{4}{3}} \Gamma\left(\frac{1}{3} + 1\right) \\ &= \left(\frac{3}{4}\right)^{\frac{4}{3}} \Gamma\left(\frac{4}{3}\right).\end{aligned}$$

Example 4: Evaluate

a. $\int_0^{\frac{\pi}{2}} \sin^{10} \theta d\theta$

b. $\int_0^{\frac{\pi}{2}} \cos^9 \theta d\theta$

c. $\int_0^{\frac{\pi}{2}} \sin^6 \theta \cdot \cos^7 \theta d\theta$

d. $\int_0^{\frac{\pi}{2}} \left(\frac{\sqrt[3]{\sin 8x}}{\sqrt{\cos x}}\right) dx$

Solution:

a. $\int_0^{\frac{\pi}{2}} \sin^{10} \theta d\theta = \frac{1 \cdot 3 \cdot 5 \cdot 7 \cdot 9}{2 \cdot 4 \cdot 6 \cdot 8 \cdot 10} \frac{\pi}{2} = \frac{63}{256} \pi$, since $p = 8$ is even

b. $\int_0^{\frac{\pi}{2}} \cos^9 \theta d\theta = \frac{2 \cdot 4 \cdot 6 \cdot 8}{1 \cdot 3 \cdot 5 \cdot 7 \cdot 9}$, $p = 9$ is odd

c. $\int_0^{\frac{\pi}{2}} \sin^6 \theta \cdot \cos^7 \theta d\theta$

$$= \frac{1}{2} \beta\left(\frac{6+1}{2}, \frac{7+1}{2}\right) = \frac{1}{2} \frac{\Gamma\left(\frac{7}{2}\right)\Gamma(4)}{\Gamma\left(\frac{15}{2}\right)}$$

$$= \frac{1}{2} \frac{\left(\frac{7}{2}-1\right)\left(\frac{7}{2}-2\right)\left(\frac{7}{2}-3\right) \cdot 3!}{\left(\frac{15}{2}-1\right)\left(\frac{15}{2}-2\right)\left(\frac{15}{2}-3\right)\left(\frac{15}{2}-4\right)\left(\frac{15}{2}-5\right)\left(\frac{15}{2}-6\right)\left(\frac{15}{2}-7\right)}$$

$$= \frac{2^4}{3 \cdot 7 \cdot 11 \cdot 13}$$

$$\begin{aligned}
 \text{d. } \int_0^{\frac{\pi}{2}} \frac{\sqrt[3]{\sin 8x}}{\sqrt{\cos x}} dx &= \int_0^{\frac{\pi}{2}} \sin^{\frac{8}{3}} x \cdot \cos^{-\frac{1}{2}} x dx = \frac{1}{2} \beta \left(\frac{\frac{8}{3}+1}{2}, \frac{-\frac{1}{2}+1}{2} \right) \\
 &= \frac{1}{2} \beta \left(\frac{11}{6}, \frac{1}{4} \right) = \frac{1}{2} \frac{\Gamma\left(\frac{11}{6}\right) \Gamma\left(\frac{1}{4}\right)}{\Gamma\left(\frac{11}{6} + \frac{1}{4}\right)} \\
 &= \frac{1}{2} \cdot \frac{\left(\frac{5}{6}\right) \Gamma\left(\frac{5}{6}\right) \Gamma\left(\frac{1}{4}\right)}{\frac{13}{12} \cdot \frac{1}{12} \Gamma\left(\frac{1}{12}\right)} = \frac{60}{13} \frac{\Gamma\left(\frac{5}{6}\right) \Gamma\left(\frac{1}{4}\right)}{\Gamma\left(\frac{1}{12}\right)}.
 \end{aligned}$$

Example 5: Evaluate $I = \int_0^1 \left(\frac{x}{1-x^3}\right)^{\frac{1}{2}} dx$.

Solution: $I = \int_0^1 x^{\frac{1}{2}} (1-x^3)^{-\frac{1}{2}} dx$. put $x^3 = t$

$$\begin{aligned}
 I &= \int_0^1 t^{\frac{1}{2}} \cdot (1-t)^{-\frac{1}{2}} \cdot \frac{1}{3} t^{-\frac{2}{3}} dt \\
 &= \frac{1}{3} \int_0^1 t^{-\frac{1}{6}} \cdot (1-t)^{-\frac{1}{2}} dt = \frac{1}{2} \beta \left(1-\frac{1}{6}, 1-\frac{1}{2} \right) \\
 &= \frac{1}{3} \beta \left(\frac{5}{6}, \frac{1}{2} \right) = \frac{1}{3} \frac{\Gamma\left(\frac{5}{6}\right) \cdot \Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{5}{6} + \frac{1}{2}\right)} \\
 &= \frac{1}{3} \frac{\Gamma\left(\frac{5}{6}\right) \sqrt{\pi}}{\frac{1}{3} \Gamma\left(\frac{1}{3}\right)} = \frac{\sqrt{\pi}}{\Gamma\left(\frac{1}{3}\right)} \cdot \Gamma\left(\frac{1}{3} + \frac{1}{2}\right).
 \end{aligned}$$

using duplication form $\Gamma\left(\frac{1}{3} + \frac{1}{2}\right) \Gamma\left(\frac{1}{3}\right) = \frac{\sqrt{\pi} \Gamma\left(\frac{2}{3}\right)}{2^{\frac{2}{3}-1}}$

$$\text{Also } \Gamma\left(\frac{1}{3}\right) \Gamma\left(1 - \frac{1}{3}\right) = \Gamma\left(\frac{1}{3}\right) \Gamma\left(\frac{2}{3}\right) = \frac{\pi}{\sin \frac{\pi}{3}}.$$

Substituting

$$\begin{aligned}
 &= \frac{\sqrt{\pi}}{\Gamma\left(\frac{1}{3}\right)} \frac{\sqrt{\pi} \cdot \Gamma\left(\frac{2}{3}\right)}{\Gamma\left(\frac{1}{3}\right) \Gamma\left(\frac{1}{3}\right) \cdot 2^{\frac{1}{3}}} \\
 &= \frac{\pi}{\left[\Gamma\left(\frac{1}{3}\right)\right]^2 \cdot 2^{\frac{1}{3}}} \cdot \frac{\pi}{\Gamma\left(\frac{1}{3}\right) \cdot \sin\left(\frac{\pi}{3}\right)} \\
 I &= \frac{\pi^2 2^{-\frac{1}{3}}}{\left[\Gamma\left(\frac{1}{3}\right)\right]^3 \cdot \sin \frac{\pi}{3}}.
 \end{aligned}$$

Example 6: Evaluate $I = \int_0^\infty a^{-bx^2} dx$.

Solution: Put $a^{-bx^2} = e^{-t}$, $-bx^2 \ln a = -t$
 $2bx \ln a dx = dt$, also $x = \left(\frac{t}{b \ln a}\right)^{\frac{1}{2}}$

$$\text{So } dx = \frac{t^{-\frac{1}{2}} dt}{(2b \ln a)^{\frac{1}{2}}}$$

$$\begin{aligned}
 I &= \int_0^\infty \frac{e^{-t} \cdot t^{-\frac{1}{2}} dt}{(2b \ln a)^{\frac{1}{2}}} = \frac{1}{(2b \ln a)^{\frac{1}{2}}} \cdot \Gamma\left(1 - \frac{1}{2}\right) \\
 &= \frac{\sqrt{\pi}}{(2b \ln a)^{\frac{1}{2}}}.
 \end{aligned}$$

Example 7: Evaluate

$$I = \left[\int_0^\infty x e^{-x^8} dx \right] \times \left[\int_0^\infty x^2 e^{-x^4} dx \right].$$

Solution: $I = I_1 \times I_2$.

Put $x^8 = t$ in I_1 , $x = t^{\frac{1}{8}}$, $dx = \frac{1}{8} t^{-\frac{7}{8}} dt$

$$I_1 = \int_0^\infty x e^{-x^8} dx = \int_0^\infty t^{\frac{1}{8}} \cdot e^{-t} \cdot \frac{1}{8} t^{-\frac{7}{8}} dt$$

$$I_1 = \frac{1}{8} \int_0^\infty t^{-\frac{3}{4}} e^{-t} dt = \frac{1}{8} \Gamma\left(1 - \frac{3}{4}\right) = \frac{1}{8} \Gamma\left(\frac{1}{4}\right)$$

Put $x^4 = t$ in I_2 , so $x = t^{\frac{1}{4}}$, $dx = \frac{1}{4} t^{-\frac{3}{4}} dt$

$$\begin{aligned}
 I_2 &= \int_0^\infty x^2 e^{-x^4} dx = \int_0^\infty t^{\frac{1}{2}} \cdot e^{-t} \cdot \frac{1}{4} t^{-\frac{3}{4}} dt \\
 &= \frac{1}{4} \int_0^\infty t^{-\frac{1}{4}} e^{-t} dt = \frac{1}{4} \Gamma\left(1 - \frac{1}{4}\right) = \frac{1}{4} \Gamma\left(\frac{3}{4}\right)
 \end{aligned}$$

Thus

$$\begin{aligned}
 I &= I_1 \cdot I_2 = \frac{1}{8} \Gamma\left(\frac{1}{4}\right) \cdot \frac{1}{4} \Gamma\left(\frac{3}{4}\right) \\
 &= \frac{1}{32} \Gamma\left(\frac{1}{4}\right) \Gamma\left(1 - \frac{1}{4}\right) = \frac{1}{32} \cdot \frac{\pi}{\sin \frac{\pi}{4}} = \frac{\sqrt{2}\pi}{32}
 \end{aligned}$$

Since $\Gamma(n) \Gamma(1-n) = \frac{\pi}{\sin n\pi}$.

Example 8: Show that

$$\int_0^\infty \cos(bz^{\frac{1}{n}}) dz = \frac{\Gamma(n+1) \cdot \cos \frac{n\pi}{2}}{b^n}.$$

Solution: Put $z = x^n$, $x = z^{\frac{1}{n}}$, $dz = nx^{n-1} dx$

$$\int_0^\infty \cos(bz^{\frac{1}{n}}) dz = \int_0^\infty nx^{n-1} \cdot \cos(bx) dx$$

$$= \text{Real part of } \left\{ \int_0^\infty n x^{n-1} \cdot e^{-ibx} dx \right\}$$

$$\begin{aligned} \text{But } \int_0^\infty x^{n-1} e^{-ibx} dx \\ = \int_0^\infty \left(\frac{t}{ib} \right)^{n-1} \cdot e^{-t} \cdot \frac{dt}{ib} = \frac{1}{(ib)^n} \Gamma(n) \end{aligned}$$

where $t = ibx$.

$$\begin{aligned} \int_0^\infty \cos(bz^{\frac{1}{n}}) dz &= \operatorname{Re} \left\{ \frac{n \cdot \Gamma(n)}{b^n} (i)^{-n} \right\} \\ &= \operatorname{Re} \left\{ \frac{\Gamma(n+1)}{b^n} \left(\cos \frac{\pi}{2} + i \sin \frac{\pi}{2} \right)^{-n} \right\} \\ &= \operatorname{Re} \left\{ \frac{\Gamma(n+1)}{b^n} \left(\cos \frac{n\pi}{2} - i \sin \frac{n\pi}{2} \right) \right\} \\ &= \frac{\Gamma(n+1)}{b^n} \cdot \cos \frac{n\pi}{2}. \end{aligned}$$

Example 9: Prove that $\int_{-1}^1 (1-t^2)^n dt = \frac{2^{n+1} \cdot n!}{1 \cdot 3 \cdot 5 \cdots (2n+1)}$ for $n = 0, 1, 2, \dots$

Solution: Put $t = \sin \theta$, $1 - t^2 = 1 - \sin^2 \theta = \cos^2 \theta$, $dt = \cos \theta d\theta$

Limits for θ are $-\frac{\pi}{2}$ to $\frac{\pi}{2}$. Thus

$$\begin{aligned} \int_{-1}^1 (1-t^2)^n dt \\ = \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \cos^{2n} \theta \cdot \cos \theta d\theta = 2 \int_0^{\frac{\pi}{2}} \cos^{2n+1} \theta d\theta \\ = 2 \cdot \frac{2 \cdot 4 \cdot 6 \cdot 8 \cdots (2n)}{1 \cdot 3 \cdot 5 \cdots (2n+1)} = \frac{2 \cdot 2^n \cdot 1 \cdot 2 \cdot 3 \cdots n}{1 \cdot 3 \cdot 5 \cdots (2n+1)} \\ = \frac{2^{n+1} \cdot n!}{1 \cdot 3 \cdot 5 \cdots (2n+1)} \end{aligned}$$

Example 10: Show that $\int_0^\infty \frac{x^2 dx}{(1+x^4)^3} = \frac{5\pi\sqrt{2}}{128}$.

Solution: Put $x = \sqrt{\tan \theta}$, $dx = \frac{1}{2} \frac{1}{\sqrt{\tan \theta}} \cdot \sec^2 \theta d\theta$

$$\begin{aligned} \int_0^\infty \frac{x^2 dx}{(1+x^4)^3} \\ = \int_0^{\frac{\pi}{2}} \frac{\tan \theta \cdot \frac{1}{2} (\tan \theta)^{-\frac{1}{2}} \cdot \sec^2 \theta d\theta}{(1 + \tan^2 \theta)^3} \\ = \frac{1}{2} \int_0^{\frac{\pi}{2}} (\tan \theta)^{\frac{1}{2}} \cdot \sec^4 \theta d\theta \\ = \frac{1}{2} \int_0^{\frac{\pi}{2}} \sin^{\frac{1}{2}} \theta \cdot \cos^{\frac{7}{2}} \theta d\theta \\ = \frac{1}{2} \cdot \frac{1}{2} \cdot \beta \left(\frac{1+\frac{1}{2}}{2}, \frac{1+\frac{7}{2}}{2} \right) = \frac{1}{4} \beta \left(\frac{3}{4}, \frac{9}{4} \right) \end{aligned}$$

$$\begin{aligned} &= \frac{1}{4} \cdot \frac{\Gamma\left(\frac{3}{4}\right) \Gamma\left(\frac{9}{4}\right)}{\Gamma\left(\frac{3}{4} + \frac{9}{4}\right)} = \frac{1}{4} \frac{\Gamma\left(\frac{3}{4}\right) \cdot \frac{5}{4} \cdot \frac{1}{4} \Gamma\left(\frac{1}{4}\right)}{\Gamma(3)} \\ &= \frac{1}{4} \cdot \frac{5}{16} \cdot \frac{1}{2!} \Gamma\left(\frac{1}{4}\right) \Gamma\left(\frac{3}{4}\right) = \frac{5}{128} \cdot \pi \sqrt{2} \end{aligned}$$

since $\Gamma\left(\frac{1}{4}\right) \Gamma\left(\frac{3}{4}\right) = \sqrt{2}\pi$.

Example 11: Prove that

$$\int_0^{\frac{\pi}{2}} \frac{\cos^{2m-1} \theta \cdot \sin^{2n-1} \theta \cdot d\theta}{(a \cos^2 \theta + b \sin^2 \theta)^{m+n}} = \frac{\beta(m, n)}{2a^m b^n}$$

Solution: Put $\tan \theta = t$, $d\theta = \cos^2 \theta dt$,
 $\sin \theta = t \cos \theta$

$$\begin{aligned} \int_0^\infty \frac{\cos^{2m-1} \theta \cdot \sin^{2n-1} \theta d\theta}{(a \cos^2 \theta + b \sin^2 \theta)^{m+n}} \\ = \int_0^\infty \frac{\cos^{2m-1} \theta \cdot t^{2n-1} \cdot \cos^{2n-1} \theta \cdot \cos^2 \theta dt}{(a \cos^2 \theta + b t^2 \cos^2 \theta)^{m+n}} \\ = \int_0^\infty \frac{\cos^{2m+2n} \theta \cdot t^{2n-1} dt}{\cos^{2m+2n} \theta (a + b t^2)^{m+n}}, \quad \text{Put } \sqrt{bt} = \sqrt{ay} \\ = \int_0^\infty \frac{\left(\frac{ay}{b}\right)^{\left(\frac{2n-1}{2}\right)} \cdot \frac{a}{b} \frac{1}{2\sqrt{y}} dy}{(a + ay)^{m+n}} \\ = \frac{a^n}{2b^n a^{m+n}} \int_0^\infty \frac{y^{n-1} dy}{(1+y)^{m+n}} = \frac{1}{2a^m b^n} \cdot \beta(m, n). \end{aligned}$$

Example 12: Evaluate

$$I = \int_0^1 x^{\frac{3}{2}} (1-x^2)^{\frac{5}{2}} dx.$$

Solution: From result 13 Page 5 with $p = \frac{3}{2}$, $q = 2$,
 $r = \frac{5}{2}$

$$\begin{aligned} I &= \frac{1}{q} \beta \left(\frac{p+1}{q}, r+1 \right) = \frac{1}{2} \beta \left(\frac{\frac{3}{2}+1}{2}, \frac{5}{2}+1 \right) \\ &= \frac{1}{2} \beta \left(\frac{5}{4}, \frac{7}{2} \right) = \frac{1}{2} \frac{\Gamma\left(\frac{5}{4}\right) \Gamma\left(\frac{7}{2}\right)}{\Gamma\left(\frac{5}{4} + \frac{7}{2}\right)} \\ &= \frac{1}{2} \frac{1}{4} \Gamma\left(\frac{1}{4}\right) \cdot \frac{5}{2} \cdot \frac{3}{2} \cdot \frac{1}{2} \Gamma\left(\frac{1}{2}\right) \frac{1}{\Gamma\left(\frac{19}{4}\right)} \end{aligned}$$

Since $\Gamma\left(\frac{19}{4}\right) = \frac{15}{4} \cdot \frac{11}{4} \cdot \frac{7}{4} \cdot \frac{3}{4} \cdot \Gamma\left(\frac{3}{4}\right)$.

$$I = \frac{4\Gamma\left(\frac{1}{4}\right)\sqrt{\pi}}{\left[121\Gamma\left(\frac{3}{4}\right)\right]}.$$

EXERCISE**Gamma and Beta functions**

1. Compute (a) $\frac{\Gamma(6)}{2\Gamma(3)}$ (b) $\frac{\Gamma(\frac{5}{2})}{\Gamma(\frac{1}{2})}$ (c) $\frac{\Gamma(3)\Gamma(2.5)}{\Gamma(5.5)}$
 (d) $\Gamma(-\frac{5}{2})$.

Ans. (a) 30 (b) $\frac{3}{4}$ (c) $\frac{16}{315}$ (d) $-\frac{8\sqrt{\pi}}{15}$

2. Evaluate (a) $\int_0^\infty \sqrt{y}e^{-y^2}dy$ (b) $\int_0^\infty 3^{-4z^2}dz$
 (c) $\int_0^1 \frac{dx}{\sqrt{-\ln x}}$.

Ans. (a) $\frac{\sqrt{\pi}}{3}$ (b) $\frac{\sqrt{\pi}}{(4\sqrt{\ln 3})}$ (c) $\sqrt{\pi}$

3. Evaluate (a) $\int_0^1 x^4(1-x)^3dx$ (b) $\int_0^2 \frac{x^2dx}{\sqrt{2-x}}$
 (c) $\int_0^a y^4\sqrt{a^2-y^2}dy$.

Ans. (a) $\frac{1}{280}$ (b) $\frac{64\sqrt{2}}{15}$ (c) $\frac{\pi a^6}{32}$

4. Evaluate (a) $\int_0^{2\pi} \sin^8 \theta d\theta$ (b) $\int_0^{\frac{\pi}{2}} \cos^6 \theta d\theta$
 (c) $\int_0^{\frac{\pi}{2}} \sin^4 \theta \cdot \cos^5 \theta d\theta$.

Ans. (a) $I = 4 \int_0^{\frac{\pi}{2}} \sin^8 \theta d\theta = \frac{4 \cdot 1 \cdot 3 \cdot 5 \cdot 7}{(2 \cdot 4 \cdot 6 \cdot 8)} \frac{\pi}{2} = \frac{35\pi}{64}$
 (b) $\frac{5\pi}{32}$ (c) $\frac{8}{315}$

5. Show that $\int_0^2 x\sqrt{8-x^3}dx = \frac{16\pi}{(9\sqrt{3})}$

6. Find $\int_0^{\frac{\pi}{2}} \sqrt{\cot \theta} d\theta$.

Ans. $\frac{1}{2} \Gamma(\frac{1}{4}) \Gamma(\frac{3}{4}) = \frac{1}{2} \pi \sqrt{2}$

7. Show that $\int_0^{\frac{\pi}{2}} (\sqrt{\tan \theta} + \sqrt{\sec \theta}) d\theta =$
 $\frac{1}{2} \Gamma(\frac{1}{4}) \left\{ \Gamma(\frac{3}{4}) + \frac{\sqrt{(\pi)}}{\Gamma(\frac{3}{4})} \right\}$.

8. Prove that $\int_0^1 x^4 \left[\ln \left(\frac{1}{x} \right) \right]^3 dx = \frac{6}{625}$.

9. Show that $\left[\int_0^1 x^2(1-x^4)^{-\frac{1}{2}} dx \right] \times$
 $\left[\int_0^1 (1+x^4)^{-\frac{1}{2}} dx \right] = \frac{\pi}{4\sqrt{2}}$.

10. Prove that $\left[\int_0^{\frac{\pi}{2}} \sqrt{\sin \theta} d\theta \right] \left[\int_0^{\frac{\pi}{2}} (\sin \theta)^{-\frac{1}{2}} d\theta \right]$
 $= \pi$.

11. Show that $\int_0^{\frac{\pi}{2}} \sin^7 \theta \cdot \cos^7 \theta d\theta = \frac{1}{280}$.

12. Evaluate $\int_0^a x^3(a^3-x^3)^5 dx$.

Ans. $\frac{a^{19} \cdot 3^5}{19 \cdot 16 \cdot 13 \cdot 7}$

13. Prove that $\int_0^1 x^m (\ln x)^n dx = \frac{(-1)^n n!}{(m+1)^{n+1}}$ where n
 is a positive integer and $m > -1$.

14. Prove that $\int_0^\infty \frac{t^2 dt}{1+t^4} = \frac{\pi}{\sqrt{2}}$.

Hint: Put $t = \sqrt{\tan \theta}$.

15. Show that the area under the normal curve
 $y = \frac{1}{\sigma\sqrt{2\pi}} \cdot e^{-\frac{x^2}{2\sigma^2}}$ and x-axis is unity.

16. Show that $\frac{\beta(p,q)}{p+q} = \frac{\beta(p,q+1)}{q} = \frac{\beta(p+1,q)}{p}$.

17. Prove that $\beta(m,n) = \frac{1}{2} \int_0^\infty \frac{x^{m-1}+x^{n-1}}{(1+x)^{m+n}}$.

Hint: Use symmetry property of β function.

18. $\int_0^\infty x^{-\frac{3}{2}}(1-e^{-x})dx$.

Ans. $2\sqrt{\pi}$.

19. Show that $\int_b^a (x-b)^{m-1}(a-x)^{n-1}dx =$
 $(a-b)^{m+n-1} \cdot \beta(m,n)$

Hint: Put $x = \frac{(t-b)}{(a-b)}$.

20. Prove that $\int_0^\infty e^{-x^4}dx = \frac{1}{4}\Gamma(\frac{1}{4})$.

21. Evaluate $\int_0^\infty \frac{x^a}{a^x}dx$.

Ans. $\frac{\Gamma(a+1)}{(\ln a)^{a+1}}$

22. Show that $\int_0^1 \frac{x^{p-1}+x^{q-1}}{(1+x)^{p+q}}dx = \beta(p,q)$

Hint: From (5) $\beta(p,q) = \int_0^\infty \frac{y^{q-1}}{(1+y)^{p+q}}dy =$
 $\int_0^1 + \int_0^\infty$. Put $y = \frac{1}{z}$ in 2nd integral.

23. Show that $\int_{-1}^1 \sqrt{\frac{1+t}{1-t}} dt = \pi$.

24. Evaluate $\int_0^\infty \frac{x^8(1-x^6)}{(1+x)^{24}}dx$.

Ans. 0

25. Prove that $\int_0^\infty e^{-ax} \cdot x^{n-1}dx = \frac{\Gamma(n)}{a^n}$ where a
 and n are positive.

11.3 BESSEL'S FUNCTIONS

The boundary value problems (such as the one-dimensional heat equation) with cylindrical symmetry (independent of θ) reduces to two ordinary differential equations by the separation of variables technique. One of them is the most important differential equation known as **Bessel's* differential equation**

$$x^2 \frac{d^2 y}{dx^2} + x \frac{dy}{dx} + (x^2 - p^2)y = 0$$

$$x^2 y'' + xy' + (x^2 - p^2)y = 0 \quad (1)$$

Here p , which is a given constant (not necessarily an integer) is known as the order of the Bessel's equation.

* Friedrich Wilhelm Bessel (1784–1846) German mathematician.

Bessel's Functions (Cylindrical functions)

Bessel's functions (Cylindrical functions) are series solution of the Bessel's differential Equation (1) obtained by Frobenius method.

Assume that p is real and non-negative. Assume the series solution of (1) as

$$y(x) = \sum_{m=0}^{\infty} a_m x^{m+r} \quad (a_0 \neq 0) \quad (2)$$

To determine the unknown coefficients a_m and power (exponent) r , substitute (2) in (1), we get

$$\begin{aligned} \sum_{m=0}^{\infty} (m+r)(m+r-1)a_m x^{m+r} + \sum_{m=0}^{\infty} (m+r)a_m x^{m+r} \\ + \sum_{m=0}^{\infty} a_m x^{m+r+2} - p^2 \sum_{m=0}^{\infty} a_m x^{m+r} = 0 \end{aligned}$$

Now equate the sum of the coefficients of x^{s+r} to zero. For $s = 0$ and $s = 1$, the contribution comes from first, second and fourth series (not from third series because it starts with x^{r+2}). For $s \geq 2$, all the four terms contribute. Thus sum of the coefficients of powers of r , $r + 1$ and $s + r$ are respectively given by

$$r(r-1)a_0 + ra_0 - p^2 a_0 = 0 \quad (s = 0) \quad (4)$$

$$(r+1)ra_1 + (r+1)a_1 - p^2 a_1 = 0 \quad (s = 1) \quad (5)$$

$$\begin{aligned} (s+r)(s+r-1)a_s + (s+r)a_s + a_{s-2} \\ - p^2 a_s = 0 \quad (s = 2, 3, \dots) \quad (6) \end{aligned}$$

Solving (4), we get the indicial equation

$$(r+p)(r-p) = 0 \quad (7)$$

Solutions of (7) are $r_1 = p (\geq 0)$ and $r_2 = -p$.

Case 1: $r_1 = p$

With $r_1 = p$, Equation (5) becomes $(2p+1)a_1 = 0$ so $a_1 = 0$

Rewrite (6) as

$$(s+r+p)(s+r-p)a_s + a_{s-2} = 0$$

Substituting $r = p$, this becomes

$$s(s+2p)a_s + a_{s-2} = 0 \quad (8)$$

$$\text{or} \quad a_s = -\frac{a_{s-2}}{s(s+2p)}$$

$$\text{For} \quad s = 3, \quad a_3 = -\frac{a_1}{3(3+2p)}$$

Since $a_1 = 0$ and $p \geq 0$, then $a_3 = 0$. Thus from (8) it follows that

$$a_3 = 0, \quad a_5 = 0, \quad a_7 = 0 \text{ etc.}$$

i.e., all coefficients with odd subscripts are zero. Rewriting (8) with $s = 2m$, we have

$$2m(2m+2p)a_{2m} + a_{2m-2} = 0$$

Solving

$$a_{2m} = -\frac{1}{2^2 m(m+p)} \cdot a_{2m-2}, \quad m = 1, 2, \dots$$

$$\text{Thus} \quad a_2 = -\frac{a_0}{2^2(1+p)}$$

$$a_4 = -\frac{a_2}{2^2 \cdot 2(2+p)} = \frac{a_0}{2^4 2!(p+1)(p+2)}$$

In general

$$\begin{aligned} a_{2m} &= \frac{(-1)^m a_0}{2^{2m} \cdot m!(p+1)(p+2) \cdots (p+m)}, \\ m &= 1, 2, \dots \end{aligned} \quad (9)$$

a_0 which is arbitrary may be taken as

$$a_0 = \frac{1}{2^p \Gamma(p+1)}$$

$$\begin{aligned} \text{Then} \quad a_2 &= -\frac{a_0}{2^2(p+1)} = -\frac{1}{2^2 \cdot 2^p(p+1)\Gamma(p+1)} \\ &= \frac{-1}{2^{2+p}\Gamma(p+2)} \end{aligned}$$

since $\Gamma(\alpha+1) = \alpha\Gamma(\alpha)$.

Similarly,

$$\begin{aligned} a_4 &= \frac{-a_2}{2^2 \cdot 2 \cdot (p+2)} = \frac{1}{2^2 \cdot 2 \cdot 2^{2+p} \cdot (p+2)\Gamma(p+2)} \\ &= \frac{1}{2^{4+p} \cdot 2!\Gamma(p+3)} \end{aligned}$$

In general

$$a_{2m} = \frac{(-1)^m}{2^{2m+p} \cdot m!\Gamma(p+m+1)} \quad \text{for } m = 1, 2, \dots \quad (10)$$

By substituting these coefficients from (10) in (2) and observing that $a_1 = a_3 = a_5 = \dots = 0$, a particular solution of the Bessel's Equation (1) is obtained as

$$J_p(x) = x^p \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+p} \cdot m!\Gamma(p+m+1)} \quad (11)$$

(11) is known as the Bessel's function of the first kind of order p , which converges for all x (by ratio test).

Case 2: For $r_2 = -p$

By replacing p by $-p$ in (11), we get a second linearly independent solution of (1) as

$$J_{-p}(x) = x^{-p} \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m-p} m! \Gamma(m-p+1)} \quad (12)$$

Hence the general solution of Bessel's Equation (1) for all $x \neq 0$ is

$$y(x) = c_1 J_p(x) + c_2 J_{-p}(x) \quad (13)$$

provided p is not an integer.

Linear Dependence of Bessel's Functions: J_n and J_{-n}

Assume that $p = n$ where n is an integer.

Then from (11), we get

$$J_n(x) = x^n \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+n} \cdot m! \Gamma(n+m+1)}$$

Since $\Gamma(n+1) = n!$, we have $\Gamma(n+m+1) = (n+m)!$

$$J_n(x) = x^n \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+n} \cdot m! (m+n)!} \quad (14)$$

Book Work: Prove that $J_n(x)$ and $J_{-n}(x)$ are linearly dependent because

$$J_{-n}(x) = (-1)^n J_n(x) \quad \text{for } n = 1, 2, 3, \dots$$

Proof: Replacing p by $-n$ in (11), we get

$$J_{-n}(x) = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m-n}}{2^{2m-n} \cdot m! \Gamma(m-n+1)} \quad (15)$$

When $m-n+1 \leq 0$ or $m \leq (n-1)$, the gamma function of zero or negative integers is infinite. Therefore for $m = 0$ to $n-1$, the coefficients in (15) become zero. So m starts at n . Thus

$$J_{-n}(x) = \sum_{m=n}^{\infty} \frac{(-1)^m x^{2m-n}}{2^{2m-n} \cdot m! (m-n)!}$$

since $\Gamma(m-n+1) = (m-n)!$

Put $m-n = s$ then s varies from 0 to ∞ .

$$\begin{aligned} J_{-n}(x) &= \sum_{s=0}^{\infty} \frac{(-1)^{s+n} x^{2(s+n)-n}}{2^{2(s+n)-n} (s+n)! s!} \\ &= (-1)^n \sum_{s=0}^{\infty} \frac{(-1)^s x^{2s+n}}{2^{2s+n} \cdot s! (s+n)!} \end{aligned}$$

$$J_{-n}(x) = (-1)^n J_n(x). \quad (16)$$

Generating Function

Generating function of a sequence of functions $f_n(x)$ is

$$G(u, x) = \sum_{n=-\infty}^{\infty} f_n(x) \cdot u^n$$

which generates $f_n(x)$ i.e., $f_n(x)$ appear as coefficients of powers of u .

Theorem: Prove that the generating function for Bessel's functions of integral order is

$$e^{\frac{1}{2}x(t-\frac{1}{t})} \quad (17)$$

Proof: If $e^{\frac{1}{2}x(t-\frac{1}{t})}$ is the generating function of Bessel function then the coefficients of different powers of t in the expansion of (17) are the Bessel's functions of different integral orders.

Consider

$$e^{\frac{1}{2}x(t-\frac{1}{t})} = e^{\frac{xt}{2}} \cdot e^{-\frac{xt}{2}}$$

Expanding in series, we get

$$\begin{aligned} &= \left[1 + \frac{xt}{2} + \frac{1}{2!} \left(\frac{xt}{2} \right)^2 + \frac{1}{3!} \left(\frac{xt}{2} \right)^3 + \dots \right] \times \\ &\quad \times \left[1 - \frac{xt}{2} + \frac{1}{2!} \left(\frac{xt}{2} \right)^2 - \frac{1}{3!} \left(\frac{xt}{2} \right)^3 + \dots \right] \quad (18) \end{aligned}$$

Case 1: $n = 0$.

The coefficient of $t^0 = 1$ in the expansion (18) is

$$\begin{aligned} &1 - \left(\frac{x}{2} \right)^2 + \left(\frac{1}{2!} \right)^2 \left(\frac{x}{2} \right)^4 \\ &\quad - \left(\frac{1}{3!} \right)^2 \left(\frac{x}{2} \right)^6 + \left(\frac{1}{4!} \right)^2 \left(\frac{x}{2} \right)^8 - \dots \\ &= \sum_{m=0}^{\infty} \frac{(-1)^m}{(m!)^2} \left(\frac{x}{2} \right)^{2m} = J_0(x). \quad (19) \end{aligned}$$

11.12 — HIGHER ENGINEERING MATHEMATICS—III

Case 2: Positive powers of $t : t^n$

The coefficient of t^n in the above expansion (18) is

$$\begin{aligned} & \frac{1}{n!} \left(\frac{x}{2}\right)^n - \frac{1}{(n+1)!} \left(\frac{x}{2}\right)^{n+2} \\ & + \frac{1}{2!} \frac{1}{(n+2)!} \left(\frac{x}{2}\right)^{n+4} + \dots \\ & = \sum_{m=0}^{\infty} \frac{(-1)^m}{m!(n+m)!} \left(\frac{x}{2}\right)^{n+2m} \\ & = J_n(x). \end{aligned} \quad (20)$$

Case 3: Negative powers of $t : t^{-n}$

The coefficient of t^{-n} in the expansion (18) is

$$\begin{aligned} & \frac{(-1)^n}{n!} \left(\frac{x}{2}\right)^n + \left(\frac{x}{2}\right) \frac{(-1)^{n+1}}{(n+1)!} \left(\frac{x}{2}\right)^{n+1} \\ & + \frac{1}{2!} \left(\frac{x}{2}\right)^2 \frac{(-1)^{n+2}}{(n+2)!} \left(\frac{x}{2}\right)^{n+2} + \dots \\ & = (-1)^n \sum_{m=0}^{\infty} \frac{(-1)^m}{m!(n+m)!} \left(\frac{x}{2}\right)^{n+2m} \\ & = (-1)^n J_n(x) = J_{-n}(x) \end{aligned} \quad (21)$$

Thus from (19), (20) and (21), we have

$$e^{\frac{x}{2}\left(t-\frac{1}{t}\right)} = \sum_{n=-\infty}^{\infty} J_n(x)t^n.$$

Equation Reducible to Bessel's Equation

The differential equation

$$x^2 \frac{d^2 y}{dx^2} + x \frac{dy}{dx} + (\lambda^2 x^2 - p^2)y = 0 \quad (22)$$

where λ is a parameter, can be reduced Bessel's differential equation of order p in t ,

$$t^2 \frac{d^2 y}{dt^2} + t \frac{dy}{dt} + (t^2 - p^2)y = 0 \quad (23)$$

where $t = \lambda x$ (so $\frac{dy}{dx} = \lambda \frac{dy}{dt}$, $\frac{d^2 y}{dx^2} = \lambda^2 \frac{d^2 y}{dt^2}$).

For p non-integral, the general solution of Equation (23) is

$$y = c_1 J_n(t) + c_2 J_{-n}(t).$$

Thus the general solution of Equation (22) is

$$y(x) = c_1 J_n(\lambda x) + c_2 J_{-n}(\lambda x)$$

when p is non-integral.

Orthogonality of Bessel's Functions

Prove that

$$\int_0^a x J_n(\alpha x) J_n(\beta x) dx = \begin{cases} 0, & \text{if } \alpha \neq \beta \\ \frac{a^2}{2} J_{n+1}^2(a\alpha), & \text{if } \alpha = \beta \end{cases}$$

where α and β are roots of $J_n(ax) = 0$.

Proof: Let $u = J_n(\alpha x)$ and $v = J_n(\beta x)$ respectively be the solutions of the equations

$$x^2 u'' + xu' + (\alpha^2 x^2 - n^2)u = 0 \quad (1)$$

$$\text{and} \quad x^2 v'' + xv' + (\beta^2 x^2 - n^2)v = 0 \quad (2)$$

Multiplying (1) by $\frac{v}{x}$ and (2) by $\frac{u}{x}$ and subtracting

$$x(u''v - uv'') + (u'v - uv') + (\alpha^2 - \beta^2)xuv = 0$$

$$\text{or} \quad \frac{d}{dx} \{x(u'v - uv')\} = (\beta^2 - \alpha^2)xuv \quad (3)$$

Integrating both sides of (3) from $x = 0$ to a

$$\begin{aligned} (\beta^2 - \alpha^2) \int_0^a xuv dx &= \left[x(u'v - uv') \right]_0^a \\ &= a \left[u'(a)v(a) - u(a)v'(a) \right] \end{aligned} \quad (4)$$

where ' denotes differentiation w.r.t., x .

$$\text{Now} \quad u' = \frac{d}{dx} u = \frac{d}{dx} J_n(\alpha x) = \alpha J_n'(\alpha x) \quad (5)$$

$$\text{Similarly,} \quad v' = \frac{dv}{dx} = \frac{d}{dx} J_n(\beta x) = \beta J_n'(\beta x) \quad (6)$$

Substituting u' and v' from (5) and (6) in (4), we get

$$\begin{aligned} & \int_0^a x J_n(\alpha x) J_n(\beta x) dx \\ &= \frac{a}{\beta^2 - \alpha^2} \left[\alpha J_n'(\alpha a) J_n(\beta a) - \beta J_n(\alpha a) J_n'(\beta a) \right] \end{aligned} \quad (7)$$

Case 1: Suppose α and β are two distinct roots of $J_n(ax) = 0$ then $J_n(\alpha a) = J_n(\beta a) = 0$.

Thus for $\alpha \neq \beta$

$$\int_0^a x J_n(\alpha x) J_n(\beta x) dx = 0 \quad (8)$$

(8) is known as the orthogonality relation for Bessel's functions.

Case 2: Suppose $\beta = \alpha$; then R.H.S. of (4) is $\frac{0}{0}$ form. Assuming α as a root of $J_n(ax) = 0$, evaluate

R.H.S. of (4) as $\beta \rightarrow \alpha$

$$\begin{aligned} \lim_{\beta \rightarrow \alpha} \int_0^a x J_n(\alpha x) J_n(\beta x) dx \\ = \lim_{\beta \rightarrow \alpha} \left(\frac{a}{\beta^2 - \alpha^2} \right) \left[\alpha J'_n(a\alpha) J_n(a\beta) - 0 \right] \end{aligned}$$

Since $J_n(a\alpha) = 0$.

Now applying L'Hospital's rule (differentiating w.r.t., β), we get

$$\begin{aligned} &= \lim_{\beta \rightarrow \alpha} \frac{a}{2\beta} \left[\alpha J'_n(a\alpha) \cdot a J'_n(a\beta) \right] \\ &= \frac{a^2}{2} \left[J'_n(a\alpha) \right]^2 \end{aligned}$$

In the recurrence relation IV on Page 11.14

$$J_{n+1}(x) = \frac{n}{x} J_n(x) - J'_n(x)$$

Put $x = a\alpha$, then $J_{n+1}(a\alpha) = \frac{n}{a\alpha} J_n(a\alpha) - J'_n(a\alpha)$.
Since α is a root, $J_n(a\alpha) = 0$. Then

$$J'_n(a\alpha) = -J_{n+1}(a\alpha)$$

Thus for $\alpha \neq \beta$,

$$\begin{aligned} \int_0^a x J_n(\alpha x) J_n(\beta x) dx &= \frac{a^2}{2} \left[J'_n(a\alpha) \right]^2 \\ &= \frac{a^2}{2} \left[J_{n+1}(a\alpha) \right]^2 \end{aligned}$$

Note: Put $x = a\alpha$ in the recurrence relation VI on Page 11.14

$$J_{n-1}(a\alpha) + J_{n+1}(a\alpha) = \frac{2n}{a\alpha} J_n(a\alpha).$$

Since $J_n(a\alpha) = 0$, $J_{n-1}(a\alpha) = -J_{n+1}(a\alpha)$.

Thus

$$\int_0^a x J_n(\alpha x) J_n(\beta x) dx = \frac{a^2}{2} \left[J_{n-1}(a\alpha) \right]^2$$

Recurrence Relations (or identities) for Bessel's Functions

Valid for any p .

Prove that

$$\text{I. } \frac{d}{dx} \left\{ x^p J_p(x) \right\} = x^p J_{p-1}(x)$$

Proof: From (11)

$$J_p(x) = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+p}}{2^{2m+p} \cdot m! \Gamma(m+p+1)}$$

So

$$\begin{aligned} \frac{d}{dx} \left\{ x^p J_p(x) \right\} &= \frac{d}{dx} \left\{ \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+2p}}{2^{2m+p} \cdot m! \Gamma(m+p+1)} \right\} \\ &= \sum_{m=0}^{\infty} \frac{(-1)^m \cdot (2m+2p) x^{2m+2p-1}}{2^{2m+p} \cdot m! (m+p) \Gamma(m+p)} \\ &= x^p \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+(p-1)}}{2^{2m+(p-1)} \cdot m! \Gamma(m+(p-1)+1)} \\ &= x^p J_{p-1}(x) \end{aligned}$$

$$\text{II. } \frac{d}{dx} \left\{ x^{-p} J_p(x) \right\} = -x^{-p} J_{p+1}(x).$$

Proof: Multiplying (11) by x^{-p} and differentiating

$$\begin{aligned} \frac{d}{dx} \left\{ x^{-p} J_p(x) \right\} &= \frac{d}{dx} \left\{ \sum_{m=0}^{\infty} \frac{(-1)^m \cdot x^{2m}}{2^{2m+p} \cdot m! \Gamma(m+p+1)} \right\} \\ &= \sum_{m=1}^{\infty} \frac{(-1)^m \cdot 2m \cdot x^{2m-1}}{2^{2m+p} \cdot m! \Gamma(m+p+1)} \end{aligned}$$

since for $m = 0$, the first term in R.H.S. is zero.

$$= \sum_{m=1}^{\infty} \frac{(-1)^m \cdot x^{2m-1}}{2^{2m+p-1} \cdot (m-1)! \Gamma(m+p+1)}$$

Put $s = m - 1$ or $m = s + 1$ then

$$\begin{aligned} &= \sum_{s=0}^{\infty} \frac{(-1)^{s+1} \cdot x^{2(s+1)-1}}{2^{2(s+1)+p-1} \cdot s! \Gamma(s+1+p+1)} \\ &= -x^{-p} \sum_{s=0}^{\infty} \frac{(-1)^s x^{2s+(p+1)}}{2^{2s+(p+1)} s! \Gamma((s+1)+p+1)} \\ &= -x^{-p} \cdot J_{p+1}(x). \end{aligned}$$

$$\text{III. } \frac{d}{dx} \left\{ J_p(x) \right\} = J_{p-1}(x) - \frac{p}{x} J_p(x)$$

$$\text{or } x J'_p(x) = x J_{p-1}(x) - p J_p(x)$$

Proof: From recurrence relation (I)

$$\frac{d}{dx} \left\{ x^p J_p(x) \right\} = x^p J_{p-1}(x)$$

11.14 — HIGHER ENGINEERING MATHEMATICS—III

Performing the differentiation in the L.H.S.,

$$x^p \cdot \frac{d}{dx} \left\{ J_p(x) \right\} + px^{p-1} \cdot J_p(x) = x^p J_{p-1}(x)$$

$$\text{or} \quad J'_p(x) + \frac{p}{x} J_p(x) = J_{p-1}(x)$$

$$\text{or} \quad J'_p(x) = J_{p-1}(x) - \frac{p}{x} J_p(x)$$

$$\text{IV. } J'_p(x) = \frac{p}{x} J_p(x) - J_{p+1}(x)$$

Proof: From recurrence relation (II)

$$\frac{d}{dx} \left\{ x^{-p} J_p(x) \right\} = -x^{-p} J_{p+1}(x)$$

Performing the differentiation in the L.H.S.,

$$x^{-p} \cdot \frac{d}{dx} J_p(x) - px^{-p-1} J_p(x) = -x^{-p} J_{p+1}(x)$$

$$\text{or} \quad J'_p(x) - \frac{p}{x} J_p(x) = -J_{p+1}(x)$$

$$\text{or} \quad J'_p(x) = \frac{p}{x} J_p(x) - J_{p+1}(x)$$

V. $J'_p(x) = \frac{1}{2} \{ J_{p-1}(x) - J_{p+1}(x) \}$ is obtained by adding recurrence relations (III) and (IV)

VI. $J_{p-1}(x) + J_{p+1}(x) = \frac{2p}{x} J_p(x)$ is obtained by subtracting (IV) from (III).

Elementary Bessel's Functions

Bessel's functions J_p of orders $p = \pm \frac{1}{2}, \pm \frac{3}{2}, \pm \frac{5}{2}, \dots$ are elementary and can be expressed in terms of sine and cosines and powers of x .

$$\text{Result 1: } J_{\frac{1}{2}}(x) = \sqrt{\frac{2}{\pi x}} \cdot \sin x.$$

Proof: With $p = \frac{1}{2}$, (11) reduces to

$$J_{\frac{1}{2}}(x) = \sqrt{x} \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+\frac{1}{2}} \cdot m! \Gamma\left(m + \frac{3}{2}\right)}$$

Now

$$\begin{aligned} \Gamma\left(m + \frac{3}{2}\right) &= \left(m + \frac{1}{2}\right) \left(m - \frac{1}{2}\right) \left(m - \frac{3}{2}\right) \dots \\ &\quad \times \frac{3}{2} \cdot \frac{1}{2} \Gamma\left(\frac{1}{2}\right) \\ &= \frac{(2m+1)(2m-1)(2m-3) \dots 3 \cdot 1 \cdot \sqrt{\pi}}{2^{m+1}} \end{aligned}$$

Also

$$\begin{aligned} 2^{2m+1} \cdot m! &= 2^{m+1} \cdot 2^m \cdot m! \\ &= 2^{m+1} \cdot 2^m (m)(m-1) \dots 2 \cdot 1 \\ &= 2^{m+1} \cdot (2m)(2m-2) \dots 4 \cdot 2. \end{aligned}$$

Thus

$$\begin{aligned} &2^{2m+1} \cdot m! \cdot \Gamma\left(m + \frac{3}{2}\right) \\ &= \left[2^{m+1} \cdot 2m \cdot (2m-2) \dots 4 \cdot 2 \right] \\ &\quad \times \left[(2m+1)(2m-1) \dots 3 \cdot 1 \right] \cdot 2^{-(m+1)} \cdot \sqrt{\pi} \\ &= (2m+1)! \sqrt{\pi} \end{aligned}$$

Then

$$\begin{aligned} J_{\frac{1}{2}}(x) &= \sqrt{\frac{2}{x}} \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m-1}}{2^{2m+1} \cdot m! \Gamma\left(m + \frac{3}{2}\right)} \\ &= \sqrt{\frac{2}{x}} \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m-1}}{(2m+1)! \sqrt{\pi}} \\ &= \sqrt{\frac{2}{\pi x}} \cdot \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m-1}}{(2m+1)!} \\ &= \sqrt{\frac{2}{\pi x}} \cdot \sin x. \end{aligned}$$

Result 2: In the recurrence relation I, put $p = \frac{1}{2}$ then

$$\frac{d}{dx} \left\{ \sqrt{x} J_{\frac{1}{2}}(x) \right\} = \sqrt{x} J_{-\frac{1}{2}}(x)$$

$$\frac{d}{dx} \left\{ \sqrt{x} \sqrt{\frac{2}{\pi x}} \cdot \sin x \right\} = \sqrt{x} J_{-\frac{1}{2}}(x)$$

$$\sqrt{\frac{2}{\pi}} \cos x = \sqrt{x} J_{-\frac{1}{2}}(x)$$

$$\text{or} \quad J_{-\frac{1}{2}}(x) = \sqrt{\frac{2}{\pi x}} \cos x.$$

Similarly with $p = \frac{1}{2}$, we get from recurrence relation VI.

Result 3:

$$J_{-\frac{1}{2}}(x) + J_{\frac{3}{2}}(x) = \frac{1}{x} J_{\frac{1}{2}}(x)$$

$$\text{or} \quad J_{\frac{3}{2}}(x) = \frac{1}{x} J_{\frac{1}{2}}(x) - J_{-\frac{1}{2}}(x)$$

Using result (1) and (2) for $J_{\frac{1}{2}}$ and $J_{-\frac{1}{2}}$, we get

$$J_{\frac{3}{2}}(x) = \sqrt{\frac{2}{\pi x}} \left(\frac{\sin x}{x} - \cos x \right).$$

Similarly with $p = -\frac{1}{2}$ in recurrence relation VI

Result 4:
$$J_{-\frac{3}{2}}(x) = -\frac{1}{x} J_{-\frac{1}{2}}(x) - J_{\frac{1}{2}}(x)$$
$$= -\sqrt{\frac{2}{\pi x}} \left(\frac{\cos x}{x} + \sin x \right).$$

Integrals of Bessel's Functions

Integrating the recurrence relation

$$\frac{d}{dx} \left\{ x^p J_p(x) \right\} = x^p J_{p-1}(x), \quad \text{we get}$$
$$\int x^p J_{p-1}(x) dx = x^p J_p(x) + c \quad (1)$$

For $p = 1$,
$$\int x J_0(x) dx = x J_1(x) + c \quad (2)$$

Integrating the recurrence relation

$$\frac{d}{dx} \left\{ x^{-p} J_p(x) \right\} = -x^{-p} J_{p+1}(x), \quad \text{we get}$$
$$\int x^{-p} J_{p+1}(x) dx = -x^{-p} J_p(x) + c \quad (3)$$

For $p = 0$,
$$\int J_1(x) dx = -J_0(x) + c \quad (4)$$

In general $\int x^m J_n(x) dx$ for m and n integers with $m + n \geq 0$ can be integrated by parts completely if $m + n$ is odd. But when $m + n$ is even, the integral depends on the residual integral $\int J_0(x) dx$ which has been tabulated.

Integrating
$$J'_p(x) = \frac{1}{2} \left[J_{p-1}(x) - J_{p+1}(x) \right]$$
$$2J_p(x) = \int J_{p-1}(x) dx - \int J_{p+1}(x) dx$$

or
$$\int J_{p+1}(x) dx = \int J_{p-1}(x) dx - 2J_p(x).$$

Bessel's Function of Second Kind of Order n or Neumann Function

When n is integral, $J_n(x)$ and $J_{-n}(x)$ are linearly dependent and do not constitute the solution.

Let $y = u(x) J_n(x)$ be a solution of (1). Substituting in (1),

$$x^2(u'' J_n + 2u' J'_n + u J''_n) + x(u' J_n + u J'_n) + (x^2 - n^2)u J_n = 0$$

or
$$u \left\{ x^2 J''_n + x J'_n + (x^2 - n^2) J_n \right\} + x^2 u'' J_n + 2x^2 u' J'_n + x u' J_n = 0$$

Since J_n is a solution of (1), the first term is zero. Dividing throughout by $x^2 u' J_n$, we get

$$\frac{u''}{u} + 2 \frac{J'_n}{J_n} + \frac{1}{x} = 0$$

Integrating $\ln(u' J_n^2 \cdot x) = \ln B$ or $x u' J_n^2 = B$. Thus

$$u' = \frac{B}{x J_n^2}$$

Integrating

$$u = B \int \frac{dx}{x J_n^2} + c$$

Hence $y = A J_n(x) + B Y_n(x)$ is the complete solution of (1) where

$$Y_n(x) = J_n(x) \cdot \int \frac{dx}{x [J_n(x)]^2}$$

$Y_n(x)$ is known as Bessel's function of second kind of order n or Neumann function.

WORKED OUT EXAMPLES

Example 1: Find $J_0(x)$ and $J_1(x)$.

Solution: Put $n = 0$ in

$$J_n(x) = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+n}}{2^{2m+n} \cdot m! (m+n)!}$$

Then
$$J_0(x) = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m} (m!)^2} = 1 - \frac{1}{1!} \left(\frac{x}{2} \right)^2 + \frac{1}{(2!)^2} \left(\frac{x}{2} \right)^4 - \left(\frac{1}{3!} \right)^2 \left(\frac{x}{2} \right)^6 + \dots$$

11.16 — HIGHER ENGINEERING MATHEMATICS—III

For $n = 1$,

$$J_1(x) = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+1}}{2^{2m+1} m! (m+1)!}$$

or
$$J_1(x) = \frac{x}{2} \left[1 - \frac{1}{1!2!} \left(\frac{x}{2}\right)^2 + \frac{1}{2!3!} \left(\frac{x}{2}\right)^4 - \frac{1}{3!4!} \left(\frac{x}{2}\right)^6 + \dots \right].$$

Example 2: Show that $J_n(x)$ is an even function when n is even and odd function when n is odd.

Solution: Suppose n is even.

$$J_n(-x) = (-x)^n \sum_{m=0}^{\infty} \frac{(-1)^m (-x)^{2m}}{2^{2m+n} \cdot m! (m+n)!}$$

For n even $(-1)^n = 1$ and $(-1)^{2m} = 1$

$$J_n(-x) = x^n \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+n} \cdot m! (m+n)!} = J_n(x)$$

Thus $J_n(x)$ is an even function.

Suppose n is odd. Then $(-1)^n = -1$, so

$$J_n(-x) = -x^n \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+n} m! (m+n)!} = -J_n(x).$$

Thus $J_n(x)$ is an odd function.

Example 3: Express $J_6(x)$ in terms of $J_0(x)$ and $J_1(x)$.

Solution: Rewriting the recurrence relation (VI)

$$J_{n+1}(x) = \frac{2n}{x} J_n(x) - J_{n-1}(x) \quad (1)$$

Put $n = 1, 2, 3, 4, 5$ in (1), we get (suppressing the argument x)

$$J_2 = \frac{2}{x} J_1 - J_0 \quad (2)$$

$$J_3 = \frac{4}{x} J_2 - J_1 \quad (3)$$

$$J_4 = \frac{6}{x} J_3 - J_2 \quad (4)$$

$$J_5 = \frac{8}{x} J_4 - J_3 \quad (5)$$

$$J_6 = \frac{10}{x} J_5 - J_4 \quad (6)$$

Substituting (3) in (2),

$$J_3 = \left\{ \frac{8}{x^2} - 1 \right\} J_1 - \frac{4}{x} J_0 \quad (7)$$

Substituting (7) and (2) in (4),

$$J_4 = \left[\frac{48}{x^3} - \frac{8}{x} \right] J_1 + \left(1 - \frac{24}{x^2} \right) J_0 \quad (8)$$

Substituting (8), and (3) in (5)

$$J_5 = \left(\frac{384}{x^4} - \frac{72}{x^2} - 1 \right) J_1 + \left(\frac{12}{x} - \frac{192}{x^3} \right) J_0 \quad (9)$$

Substituting (9) and (8) in (6), we get

$$\begin{aligned} J_6 &= \frac{10}{x} \left\{ \left(\frac{384}{x^4} - \frac{72}{x^2} - 1 \right) J_1 + \left(\frac{12}{x} - \frac{192}{x^3} \right) J_0 \right\} \\ &\quad - \left(\frac{48}{x^3} - \frac{8}{x} \right) J_1 - \left(1 - \frac{24}{x^2} \right) J_0 \\ J_6(x) &= \left(\frac{3840}{x^4} - \frac{768}{x^3} - \frac{2}{x} \right) J_1(x) \\ &\quad + \left(\frac{144}{x^2} - 1 - \frac{1920}{x^4} \right) J_0(x). \end{aligned}$$

Example 4: Express $J_{\frac{7}{2}}(x)$ in terms of sine and cosine functions.

Solution: Put $n = \frac{5}{2}$ in the recurrence relation

$$J_{n+1}(x) = \frac{2n}{x} J_n(x) - J_{n-1}(x) \quad (1)$$

so
$$J_{\frac{7}{2}}(x) = \frac{5}{x} J_{\frac{5}{2}}(x) - J_{\frac{3}{2}}(x) \quad (2)$$

Put $n = \frac{3}{2}$ in (1) then

$$J_{\frac{5}{2}}(x) = \frac{3}{x} J_{\frac{3}{2}}(x) - J_{\frac{1}{2}}(x) \quad (3)$$

Put $n = \frac{1}{2}$ in (1) then

$$J_{\frac{3}{2}}(x) = \frac{1}{x} J_{\frac{1}{2}}(x) - J_{-\frac{1}{2}}(x)$$

Since
$$J_{\frac{1}{2}}(x) = \sqrt{\frac{2}{\pi x}} \sin x, \quad J_{-\frac{1}{2}}(x) = \sqrt{\frac{2}{\pi x}} \cos x$$

$$J_{\frac{3}{2}}(x) = \sqrt{\frac{2}{\pi x}} \left(\frac{\sin x}{x} - \cos x \right) \quad (4)$$

Substituting (4) and $J_{\frac{1}{2}}(x)$ in (3)

$$J_{\frac{5}{2}}(x) = \frac{3}{x} \left[\sqrt{\frac{2}{\pi x}} \left(\frac{\sin x}{x} - \cos x \right) \right] - \sqrt{\frac{2}{\pi x}} \sin x$$

$$J_{\frac{5}{2}}(x) = \sqrt{\frac{2}{\pi x}} \left[\left(\frac{3-x^2}{x^2} \right) \sin x - \frac{3}{x} \cos x \right] \quad (5)$$

Substituting (5) and (4) in (2), we get

$$\begin{aligned} J_{\frac{7}{2}}(x) &= \frac{5}{x} \cdot \sqrt{\frac{2}{\pi x}} \left[\left(\frac{3-x^2}{x^2} \right) \sin x - \frac{3}{x} \cos x \right] \\ &\quad - \sqrt{\frac{2}{\pi x}} \left(\frac{\sin x}{x} - \cos x \right) \\ &= \sqrt{\frac{2}{\pi x}} \left[\left(\frac{15-6x^2}{x^3} \right) \sin x + \left(\frac{15}{x^2} - 1 \right) \cos x \right]. \end{aligned}$$

Example 5: Show that $J_1''(x) = -J_1(x) + \frac{1}{x} J_2(x)$.

Solution: Put $n = 1$ in the recurrence relation III

$$J_n'(x) = J_{n-1}(x) - \frac{n}{x} J_n(x) \quad (1)$$

$$\text{Then} \quad J_1'(x) = J_0(x) - \frac{J_1(x)}{x} \quad (2)$$

Differentiating (2) w.r.t., 'x'

$$J_1''(x) = J_0'(x) + \frac{1}{x^2} J_1(x) - \frac{1}{x} J_1'(x) \quad (3)$$

Put $n = 0$, in (1) then

$$J_0'(x) = J_{-1}(x) - 0 \quad (4)$$

$$\text{But} \quad J_{-n}(x) = (-1)^n J_n(x)$$

$$\text{So with } n = +1, J_{-1}(x) = -J_1(x) \quad (5)$$

Substituting (5) in (4),

$$J_0'(x) = J_{-1}(x) = -J_1(x) \quad (6)$$

Put (6) and (2) in (3), we get

$$J_1'' = -J_1(x) + \frac{1}{x^2} J_1(x) - \frac{1}{x} \left\{ J_0(x) - \frac{J_1(x)}{x} \right\} \quad (7)$$

Put $n = 1$ in recurrence relation (VI)

$$J_{n+1}(x) = \frac{2n}{x} J_n(x) - J_{n-1}(x)$$

$$\text{Then} \quad J_2(x) = \frac{2}{x} J_1(x) - J_0(x) \quad (8)$$

$$\text{or} \quad J_0(x) = \frac{2}{x} J_1(x) - J_2(x) \quad (9)$$

Using (9) eliminate J_0 from (7) then

$$J_1'' = -J_1(x) + \frac{1}{x^2} J_1(x) - \frac{1}{x} \left\{ \frac{2}{x} J_1(x) - J_2(x) \right\} + \frac{J_1(x)}{x^2}$$

$$J_1''(x) = -J_1(x) + \frac{1}{x} J_2(x).$$

Example 6: Prove that

$$\frac{d}{dx} \left\{ J_n^2(x) \right\} = \frac{x}{2n} \left[J_{n-1}^2(x) - J_{n+1}^2(x) \right]$$

Solution: $\frac{d}{dx} \left\{ J_n^2(x) \right\} = 2 \cdot J_n(x) J_n'(x)$.

Using recurrence relation (V)

$$J_n'(x) = \frac{1}{2} \left\{ J_{n-1} - J_{n+1} \right\}$$

$$\frac{d}{dx} \{ J_n^2 \} = 2 \cdot J_n(x) \cdot \left[\frac{1}{2} (J_{n-1} - J_{n+1}) \right]$$

From recurrence relation VI

$$J_n(x) = \frac{x}{2n} \left[J_{n-1}(x) + J_{n+1}(x) \right]$$

$$\begin{aligned} \frac{d}{dx} \left\{ J_n^2(x) \right\} &= \frac{x}{2n} \left[J_{n-1}(x) + J_{n+1}(x) \right] \\ &\quad \times \left[J_{n-1}(x) - J_{n+1}(x) \right] \\ &= \frac{x}{2n} \left[J_{n-1}^2(x) - J_{n+1}^2(x) \right]. \end{aligned}$$

Example 7: Show that

$$J_2'(x) = \left(1 - \frac{4}{x^2} \right) J_1(x) + \frac{2}{x} J_0(x).$$

Solution: In recurrence relation

$$J_n'(x) = J_{n-1}(x) - \frac{n}{x} J_n(x)$$

$$\text{Put } n = 2, \quad J_2'(x) = J_1(x) - \frac{2}{x} J_2(x) \quad (1)$$

$$\text{Since} \quad J_{n+1}(x) + J_{n-1}(x) = \frac{2n}{x} J_n(x)$$

$$\text{for } n = 1, \quad J_2(x) + J_0(x) = \frac{2}{x} J_1(x) \quad (2)$$

Substituting J_2 from (2) in (1)

$$J_2'(x) = J_1(x) - \frac{2}{x} \left[\frac{2}{x} J_1(x) - J_0(x) \right]$$

$$J_2'(x) = \left(1 - \frac{4}{x^2} \right) J_1(x) + \frac{2}{x} J_0(x).$$

Example 8: Evaluate $\int J_5(x) dx$.

Solution: Putting $n = 4$ in

$$\int J_{p+1}(x) dx = \int J_{p-1}(x) dx - 2J_p(x),$$

11.18 — HIGHER ENGINEERING MATHEMATICS—III

we get

$$\int J_5(x)dx = \int J_3(x)dx - 2J_4(x) \quad (1)$$

Again with $p = 2$

$$\int J_3(x)dx = \int J_1(x)dx - 2J_2(x) \quad (2)$$

Also we know that

$$\int J_1(x)dx = -J_0(x) + c \quad (3)$$

Substituting (2) and (3) in (1)

$$\int J_5(x)dx = \left[-J_0(x) + c \right] - 2J_2(x) - 2J_4(x)$$

Example 9: Evaluate $\int x^2 J_1(x)dx$.

Solution: Put $p = 2$ in

$$\int x^p J_{p-1}(x)dx = x^p J_p(x) + c$$

Then $\int x^2 J_1(x)dx = x^2 J_2(x) + c$

But $J_2(x) = \left[\frac{2}{x} J_1(x) - J_0(x) \right]$

$$\int x^2 J_1(x)dx = x^2 \left[\frac{2}{x} J_1(x) - J_0(x) \right] + c$$

$$= 2x J_1(x) - x^2 J_0(x) + c.$$

Example 10: Evaluate $\int x^3 J_3(x)dx$.

Solution: Integrating by parts (suppressing argument x)

$$\begin{aligned} \int x^3 J_3 dx &= \int x^5 [x^{-2} J_3] dx = x^5 [x^{-2} J_2] \\ &\quad - \int -x^{-2} J_2 \cdot 5x^4 dx \\ &= -x^3 J_2 + 5 \int x^2 J_2 dx \end{aligned}$$

Now $\int x^2 J_2 dx = \int x^3 [x^{-1} J_2] dx = x^3 [-x^{-1} J_1]$

$$\begin{aligned} &\quad - \int -x^{-1} J_1 3x^2 dx \\ &= -x^2 J_1 + 3 \int x J_1 dx \end{aligned}$$

But $\int x J_1(x)dx = - \int x J'_0(x)dx$

$$= - \left[x J_0 - \int J_0(x)dx \right]$$

Substituting

$$\begin{aligned} \int x^3 J_3(x)dx &= -x^3 J_2(x) + 5 \left\{ -x^2 J_1(x) \right. \\ &\quad \left. + 3 \left[-x J_0(x) + \int J_0 dx \right] \right\} \\ &= -x^3 J_2(x) - 5x^2 J_1(x) - 15x J_0(x) \\ &\quad + 15 \int J_0(x)dx. \end{aligned}$$

Note: $\int J_0(x)dx$ can not be integrated but its values are tabulated.

EXERCISE

1. Show that **a.** $J'_0(x) = -J_1(x)$

b. $\frac{d}{dx}(x J_1) = x J_0$.

2. Express $J_{\frac{3}{2}}, J_{-\frac{3}{2}}$ in terms of sin and cos.

Ans. $J_{\frac{3}{2}} = \sqrt{\frac{2}{\pi x}} \left(\frac{\sin x}{x} - \cos x \right);$

$$J_{-\frac{3}{2}} = -\sqrt{\frac{2}{\pi x}} \left(\sin x + \frac{\cos x}{x} \right)$$

3. Express $J_{\frac{5}{2}}, J_{-\frac{5}{2}}$ in terms of sin and cos.

Ans. $J_{\frac{5}{2}} = \sqrt{\frac{2}{\pi x}} \left\{ \frac{3-x^2}{x^2} \sin x - \frac{3}{x} \cos x \right\}$

$$J_{-\frac{5}{2}} = \sqrt{\frac{2}{\pi x}} \left\{ \frac{3}{x} \sin x + \left(\frac{3}{x^2} - 1 \right) \cos x \right\}$$

4. Express $J_4(x)$ in terms of J_0 and J_1 .

Ans. $J_4 = \left(\frac{48}{x^3} - \frac{8}{x} \right) J_1(x) - \left(\frac{24}{x^2} - 1 \right) J_0(x)$

5. Express $J_5(x)$ in terms of J_0 and J_1 .

Ans. $J_5 = \left(\frac{384}{x^4} - \frac{72}{x^2} - 1 \right) J_1(x) +$

$$\left(\frac{12}{x} - \frac{192}{x^3} \right) J_0(x)$$

6. Prove that $J''_n = \frac{1}{4} [J_{n-2} - 2J_n + J_{n+2}]$.

7. Show that $\frac{d}{dx} \{x J_n \cdot J_{n+1}\} = x [J_n^2 - J_{n+1}^2]$.

8. Prove that $J_0'' = \frac{1}{2}[J_2 - J_0]$.

9. Show that $\frac{d}{dx}[J_n^2 + J_{n+1}^2] = 2\left[\frac{n}{x}J_n^2 - \frac{n+1}{x}J_{n+1}^2\right]$.

10. Prove that $J_n''' = \frac{1}{8}[J_{n-3} - 3J_{n-1} + 3J_{n+1} - J_{n+3}]$.

11. Show that $2J_0''(x) = J_2(x) - J_0(x)$.

12. Evaluate $\int J_3(x)dx$.

Ans. $-2J_1 - 2J_2 + c + \int J_0(x)dx$.

13. Evaluate: $\int x^3 J_0(x)dx$

Ans. $x^3 J_1(x) - 2x^2 J_2(x) + c$

14. Evaluate: $\int x^4 J_1(x)dx$

Ans. $(8x^2 - x^4)J_0(x) + (4x^3 - 16x)J_1(x)$

15. Establish the Jacobi series:

a. $\cos(x \cos \theta) = J_0 - 2J_2 \cos 2\theta + 2J_4 \cos 4\theta - \dots$

b. $\sin(x \cos \theta) = 2[J_1 \cos \theta - J_3 \cos 3\theta + J_5 \cos 5\theta - \dots]$.

Hint: $e^{\frac{x}{2}(t - \frac{1}{t})} = J_0 + (t - \frac{1}{t})J_1 + (t^2 - \frac{1}{t^2})J_2 + (t^3 - \frac{1}{t^3})J_3 + \dots$ obtained from generating function using $J_{-n}(x) = (-1)^n J_n(x)$. Put $t = \cos \theta + i \sin \theta$, $\frac{1}{t} = \cos \theta - i \sin \theta$, then $t^p + \frac{1}{t^p} = 2 \cos p\theta$, $t^p - \frac{1}{t^p} = 2i \sin p\theta$, $t - \frac{1}{t} = 2i \sin \theta$. Equate real and imaginary parts. Replace θ by $\frac{\pi}{2} - \theta$.

11.4 DIFFERENTIAL EQUATIONS REDUCIBLE TO BESSEL'S EQUATION

Various differential equations which are not Bessel's equations can be reduced to Bessel's equation by changing the dependent or independent variable.

The differential equation

$$x^2 y'' + x(a + 2bx^p)y' + [c + dx^{2q} + b(a + p - 1)x^p + b^2 x^{2p}]y = 0 \quad (1)$$

can be transformed to Bessel's equation in the new variables X and Y where

$$y = x^{(1-a)/2} e^{-(b/p)x^p} Y \text{ and } x = \left(\frac{qX}{\sqrt{|d|}}\right)^{1/q}.$$

Then the general solution of (1) is given by

$$y(x) = x^\alpha e^{-\beta x^p} [c_1 J_\nu(\lambda x^q) + c_2 Y_\nu(\lambda x^q)] \quad (2)$$

$$\text{Here } \alpha = \frac{1-a}{2}, \beta = \frac{b}{p}, \lambda = \frac{\sqrt{|d|}}{q}, \nu = \frac{\sqrt{(1-a)^2 - 4c}}{2q} \quad (3)$$

We assume that $d \neq 0$, $p \neq 0$, $q \neq 0$ and $(1-a)^2 \geq 4c$. Also if $d < 0$, replace J_ν and Y_ν by I_ν and K_ν respectively. When ν is not an integer, replace Y_ν and K_ν by $J_{-\nu}$ and $I_{-\nu}$ respectively.

Corollary: The general solution of

$$x^r y'' + r x^{r-1} y' + (a x^s + b x^{r-2})y = 0 \quad (4)$$

$$\text{is } y = x^\alpha [c_1 J_\nu(\lambda x^\gamma) + c_2 Y_\nu(\lambda x^\gamma)] \quad (5)$$

$$\text{where } \alpha = \frac{1-r}{2}, \gamma = \frac{2-r+s}{2}, \lambda = \frac{2\sqrt{|a|}}{2-r+s},$$

$$\nu = \frac{\sqrt{(1-r)^2 - 4b}}{2-r+s} \quad (6)$$

we assume that $2-r+s \neq 0$ and $(1-r)^2 \geq 4b$. If $a < 0$, replace J_ν and Y_ν by I_ν and K_ν respectively.

WORKED OUT EXAMPLES

Reduce the given differential equation to the Bessel's equation and solve.

Example 1: $y'' + \left(\varepsilon^2 - \frac{4n^2 - 1}{4x^2}\right)y = 0$

Solution: Rewriting the given D.E.

$$x^2 y'' + \left(\varepsilon^2 x^2 - \frac{4n^2 - 1}{4}\right)y = 0.$$

Comparing this with D.E. (1), we have

$a = 0$, $b = 0$, $c = -\frac{(4n^2 - 1)}{4}$, $d = \varepsilon^2$, $q = 1$. So from relations (3), $\alpha = \frac{1-0}{2} = \frac{1}{2}$, $\beta = 0$, $\lambda = \frac{\varepsilon}{1}$, $\nu = \frac{\sqrt{1+4n^2-1}}{1} = 2n$.

Then the general solution of the given D.E. is

$$y(x) = x^{1/2} [c_1 J_{2n}(\varepsilon x) + c_2 Y_{2n}(\varepsilon x)]$$

Example 2: $y'' + 2y' + \left(x^2 + 1 - \frac{2}{x^2}\right)y = 0.$

Solution: Rewriting

$$x^2 y'' + 2x^2 y' + (x^4 + x^2 - 2)y = 0$$

Comparing with D.E. (1), we have $a = 0$, $b = 1$, $p = 1$, $c = -2$, $d = 1$, $q = 2$. Then from (3) $\alpha = \frac{1}{2}$,

$\beta = \frac{1}{1} = 1$, $\lambda = \frac{1}{2}$, $v = \frac{\sqrt{(1-0)^2 - 4(-2)}}{4} = \frac{3}{4}$. Thus the general solution of given D.E. is

$$y = x^{1/2} e^{-x} \left[c_1 J_{3/4} \left(\frac{1}{2} x^2 \right) + c_2 Y_{3/4} \left(\frac{1}{2} x^2 \right) \right]$$

since $v = \frac{3}{4}$ is not an integer, we can replace $Y_{3/4}$ by $J_{-3/4}$, thus the general solution takes the form

$$y = \sqrt{x} e^{-x} \left[c_1 J_{3/4} \left(\frac{x^2}{2} \right) + c_2 J_{-3/4} \left(\frac{x^2}{2} \right) \right]$$

Example 3: $(x^5 y')' = y$

Solution: Rewriting $x^5 y'' + 5x^4 y' - y = 0$. Comparing this equation with (4), we have $r = 5$, $a = -1$, $s = 0$, $b = 0$ then from relations (5), $\alpha = \frac{1-5}{2} = -2$, $\gamma = \frac{2-5+0}{2} = -\frac{3}{2}$, $\lambda = \frac{2}{2-5+0} = \frac{-2}{3}$ and $v = \frac{\sqrt{(1-5)^2 - 0}}{2-5+0} = \frac{4}{-3}$. Thus the general solution from (6) is $y = x^{-2} \left[c_1 I_{4/3} \left(-\frac{2}{3} x^{-3/2} \right) + c_2 I_{-4/3} \left(-\frac{2}{3} x^{-3/2} \right) \right]$ since $a = -1 < 0$

Example 4: Show that the general solution of $y'' + \frac{1}{x} y' + \left(1 - \frac{1}{4x^2} \right) y = 0$ is $\sqrt{x} \cdot y = c_1 \sin x + c_2 \cos x$.

Solution: Comparing with D.E. (1), we have $a = 1$, $b = 0$, $c = -\frac{1}{4}$, $d = 1$, $q = 1$. So from (3) $\alpha = 0$, $\beta = 0$, $\lambda = 1$, $v = \frac{1}{2}$. Thus the general solution is $y(x) = c_1 J_{1/2}(x) + c_2 Y_{1/2}(x)$. Since $v = \frac{1}{2}$ is not an integer,

$$y(x) = c_1 J_{1/2}(x) + c_2 J_{-1/2}(x)$$

$$= c_1 \sqrt{\frac{2}{\pi x}} \sin x + c_2 \sqrt{\frac{2}{\pi x}} \cos x$$

$$\text{or } \sqrt{x} y(x) = c_1^* \sin x + c_2^* \cos x$$

EXERCISE

Reduce the given differential equations to the Bessel's equation and solve.

1. $y'' + \frac{1}{2x} y' + \frac{1}{16} (x^{-3/2} + \frac{15}{16} x^{-2}) y = 0$

Ans. $y = x^{1/4} [c_1 J_{1/4}(x^{1/4}) + c_2 J_{-1/4}(x^{1/4})]$

Hint: $a = \frac{1}{2}$, $b = 0$, $c = \frac{15}{256}$, $d = \frac{1}{16}$, $q = \frac{1}{4}$, $\alpha = \frac{1}{4}$, $\beta = 0$, $\lambda = 1$, $v = \frac{1}{4}$

2. $81x^2 y'' + 27xy' + (9x^{2/3} + 8)y = 0$

Ans. $y(x) = x^{1/3} [c_1 J_{1/3}(x^{1/3}) + c_2 J_{-1/3}(x^{1/3})]$

Hint: $a = \frac{1}{3}$, $b = 0$, $c = \frac{8}{81}$, $d = \frac{1}{9}$, $q = \frac{1}{3}$, $\alpha = \frac{1}{3}$, $\beta = 0$, $\lambda = 1$, $v = \frac{1}{3}$

3. $y'' + 3\sqrt{x}y = 0$

Ans. $y(x) = \sqrt{x} \left[c_1 J_{2/5} \left(\frac{4}{5} \sqrt{3} x^{5/4} \right) + c_2 Y_{2/5} \left(\frac{4}{5} \sqrt{3} x^{5/4} \right) \right]$

Hint: $a = 0$, $b = 0$, $c = 0$, $d = 3$, $q = \frac{5}{4}$, $\alpha = \frac{1}{2}$, $\beta = 0$, $\lambda = \frac{\sqrt{3}}{(5/4)}$, $v = \frac{2}{5}$

4. $xy'' + 3y' + y = 0$

Ans. $y(x) = x^{-1} [c_1 J_2(2\sqrt{x}) + c_2 Y_2(2\sqrt{x})]$

Hint: $a = 3$, $b = 0$, $c = 0$, $d = 1$, $q = \frac{1}{2}$, $\alpha = -1$, $\beta = 0$, $\lambda = 2$, $v = 2$

5. $(xy')' - 5x^3 y = 0$

Ans. $y(x) = c_1 I_0 \left(\frac{\sqrt{5}}{2} x^2 \right) + c_2 k_0 \left(\frac{\sqrt{5}}{2} x^2 \right)$

Hint: $a = 1$, $b = 0$, $c = 0$, $d = -5$, $q = 2$, $\alpha = 0$, $\beta = 0$, $\lambda = \frac{\sqrt{5}}{2}$, $v = 0$

6. $y'' + \frac{y'}{x} + \left(1 - \frac{1}{9x^2} \right) y = 0$

Ans. $y(x) = c_1 J_{1/3}(x) + c_2 J_{-1/3}(x)$

Hint: $a = 1$, $b = 0$, $c = -\frac{1}{9}$, $d = 1$, $q = 1$, $\alpha = 0$, $\beta = 0$, $\lambda = 1$, $v = \frac{1}{3}$

7. $x^2 y'' + xy' + \left(x^2 - \frac{1}{6.25} \right) y = 0$

Ans. $y(x) = c_1 J_{2/5}(x) + c_2 J_{-2/5}(x)$

Hint: $a = 1$, $b = 0$, $c = -\frac{1}{6.25}$, $d = 1$, $q = 1$, $\alpha = 0$, $\beta = 0$, $v = \frac{2}{5}$

8. $x^2 y'' + x(4x^4 - 3)y' + (4x^8 - 5x^2 + 3)y = 0$

$$\text{Ans. } y(x) = x^2 e^{-x^{4/2}} [c_1 I_1(\sqrt{5}x) + c_2 k_1 \sqrt{5}x]$$

$$\text{Hint: } a = -3, b = 2, p = 4, c = 3, d = -5, \\ q = 1, \alpha = 2, \beta = \frac{1}{2}, \lambda = \sqrt{5}, v = 1$$

$$9. \left(\frac{1}{x}y'\right)' + \left(\frac{1}{x^2} + \frac{1}{x^3}\right)y = 0$$

$$\text{Ans. } y = x[c_1 J_0(2\sqrt{x}) + c_2 Y_0(2\sqrt{x})]$$

$$\text{Hint: } r = -1, s = -2, a = b = 1, \alpha = 1, \\ v = \frac{1}{2}, \lambda = 2, v = 0$$

$$10. x^2 y'' - 2xy' + (2 - x^3)y = 0$$

$$\text{Ans. } y = x^{3/2} \left[c_1 I_{1/3} \left(\frac{2}{3} x^{3/2} \right) + c_2 I_{-1/3} \left(\frac{2}{3} x^{3/2} \right) \right]$$

$$\text{Hint: } a = -2, b = 0, c = 2, d = -1, q = \frac{3}{2}, \\ \alpha = \frac{3}{2}, \beta = 0, \lambda = 2/3, v = 1/3$$

$$11. x^2 y'' + xy' + 8x^2 = y$$

$$\text{Ans. } y = c_1 J_1(2\sqrt{2}x) + c_2 Y_1(2\sqrt{2}x)$$

$$\text{Hint: } a = 1, b = 0, c = -1, d = 8, q = 1, \\ \alpha = 0, \beta = 0, \lambda = 2\sqrt{2}, v = 1$$

$$12. 4y'' + 9xy = 0$$

$$\text{Ans. } y = \sqrt{x} [c_1 J_{1/3}(x^{3/2}) + c_2 J_{-1/3}(x^{3/2})]$$

$$\text{Hint: } a = 0, b = 0, c = 0, d = \frac{9}{4}, q = \frac{3}{2}, \alpha = \\ \frac{1}{2}, \beta = 0, \lambda = 1, v = \frac{1}{3}$$

$$13. 9x^2 y'' + 9xy' + (36x^4 - 16)y = 0$$

$$\text{Ans. } y(x) = c_1 J_{2/3}(x^2) + c_2 J_{-2/3}(x^2)$$

$$\text{Hint: } a = 1, b = 0, c = -\frac{16}{9}, d = 4, q = 2, \\ \alpha = 0, \beta = 0, \lambda = 1, v = \frac{2}{3}$$

$$14. y'' + k^2 x^4 y = 0$$

$$\text{Ans. } y = \sqrt{x} [c_1 J_{1/4} \left(\frac{1}{2} k x^2 \right) + c_2 Y_{1/4} \left(\frac{1}{2} k x^2 \right)]$$

$$\text{Hint: } a = 0, b = 0, c = 0, d = k^2, q = 2, \\ \alpha = \frac{1}{2}, \beta = 0, \lambda = \frac{k}{2}, v = \frac{1}{4}$$

$$15. 2xy'' + 4y' + xy = 0$$

$$\text{Ans. } y = [c_1 J_{1/2}(x/\sqrt{2}) + c_2 J_{-1/2}(x/\sqrt{2})]x^{-1/2}$$

$$\text{Hint: } a = 2, b = 0, c = 0, d = \frac{1}{2}, q = +1, \\ \alpha = -\frac{1}{2}, \beta = 0, \lambda = \frac{1}{\sqrt{2}}, v = \frac{1}{2}$$

11.5 LEGENDRE* FUNCTIONS

The boundary value problems with spherical symmetry (independent of θ) by the application of separation of variables reduces two ordinary differential equations. One of them is the very important

differential equation

$$(1 - x^2) \frac{d^2 y}{dx^2} - 2x \frac{dy}{dx} + n(n + 1)y = 0 \quad (1)$$

known as the Legendre's differential equation.

The parameter n is given integer, (although it could be a real number).

The solution of Legendre's Equation (1) is known as Legendre's function of order n .

Assume a power series solution of (1) as

$$y(x) = \sum_{m=0}^{\infty} a_m x^m \quad (2)$$

Substitute (2) and its derivatives in (1), then

$$(1 - x^2) \sum_{m=2}^{\infty} m(m-1)a_m x^{m-2} - 2x \sum_{m=1}^{\infty} m a_m x^{m-1} \\ + k \sum_{m=0}^{\infty} a_m x^m = 0$$

where $k = n(n + 1)$. Rewriting

$$\sum_{m=2}^{\infty} m(m-1)a_m x^{m-2} - \sum_{m=2}^{\infty} m(m-1)a_m x^m \\ - 2 \sum_{m=1}^{\infty} m a_m x^m + k \sum_{m=0}^{\infty} a_m x^m = 0 \quad (3)$$

(3) is an identity since (2) is a solution of (1). So equate the sum of the coefficients of each power of x to zero.

Coefficient of x^0 arise from 1st and fourth series in (3). Thus

$$2a_2 + n(n + 1)a_0 = 0 \quad (4)$$

coefficient of x^1 arise from 1st, 3rd and 4th series in (3). So

$$6a_3 + [-2 + n(n + 1)]a_1 = 0 \quad (5)$$

All the four series in (3) contribute coefficients of x^s for $s \geq 2$. Thus

$$(s + 2)(s + 1)a_{s+2} + [-s(s - 1) - 2s \\ + n(n + 1)]a_s = 0 \quad (6)$$

Solving (6)

$$a_{s+2} = - \frac{(n - s)(n + s + 1)}{(s + 2)(s + 1)} a_s$$

$$\text{for } s = 0, 1, 2, \dots \quad (7)$$

* Adrien Marie Legendre (1752–1833), French mathematician.

since $-s(s-1) - 2s + n(n+1)$

$$\begin{aligned} &= -s^2 + s - 2s + n^2 + n \\ &= (n^2 - s^2 + n - s) \\ &= (n-s)(n+s+1). \end{aligned}$$

(7) is known as a recurrence relation or recursion formula, which determines all coefficients in terms of a_1 or a_0 . Here a_0 and a_1 are arbitrary constants, to be chosen appropriately. Thus

$$\begin{aligned} a_2 &= \frac{-(n)(n+1)}{2!}a_0, \quad a_3 = \frac{-(n-1)(n+2)}{3!}a_1 \\ a_4 &= \frac{-(n-2)(n+3)}{4 \cdot 3}a_2, \quad a_5 = \frac{-(n-3)(n+4)}{5 \cdot 4}a_3 \\ a_4 &= \frac{(n-2)n(n+1)(n+3)}{4!}a_0, \\ a_5 &= \frac{-(n-3)(n-1)(n+2)(n+4)}{5!}a_1 \end{aligned}$$

In general, the coefficients with even subscripts are

$$a_{2m} = \frac{-(n-2m+2)(n+2m-1)}{(2m)(2m-1)}a_{2m-2}$$

and the coefficients with odd subscripts are

$$a_{2m+1} = \frac{-(n-2m+1)(n+2m)}{(2m)(2m+1)}a_{2m-1}$$

Substituting these coefficients in (2), we get

$$y(x) = a_0 y_1(x) + a_1 y_2(x) \quad (8)$$

$$\begin{aligned} \text{where } y_1(x) &= 1 - \frac{n(n+1)}{2!}x^2 \\ &\quad + \frac{(n-2)n(n+1)(n+3)}{4!}x^4 - \dots \end{aligned} \quad (9)$$

$$\begin{aligned} \text{and } y_2(x) &= x - \frac{(n-1)(n+2)}{3!}x^3 \\ &\quad + \frac{(n-3)(n-1)(n+2)(n+4)}{5!}x^5 - \dots \end{aligned} \quad (10)$$

Both the series (9) and (10) converge for $|x| < 1$. y_1 and y_2 are linearly independent (i.e., y_1/y_2 is not a constant) because y_1 contains only even powers of x while y_2 contains only odd powers of x . Thus $y(x)$ given by (8) is the general solution of Legendre's Equation (1) and is valid for $-1 < x < 1$.

Legendre Polynomials

Assume that the parameter n is non-negative integer i.e., $n \geq 0$, n integer. Since $(n-s)$ appears in the recurrence relation (7), with $s = n$, the coefficients $a_{n+2}, a_{n+4}, a_{n+6}$, etc., are all zero i.e., $a_{m+2} = 0$ when $m \geq n$. If n is even, then $y_1(x)$ reduces to a polynomial of degree n (while $y_2(x)$ remains an infinite series).

Similarly if n is odd, then $y_2(x)$ becomes a polynomial of degree n (while $y_1(x)$ remains an infinite series).

In either of these cases, the series which reduces to a finite sum (a polynomial), multiplied by some constant, is known as the Legendre polynomial or zonal harmonic of order n denoted by $P_n(x)$. The series which remain infinite is known as the Legendre's function of the second kind denoted by $Q_n(x)$. Thus for a non-negative integer n , the general solution (2) of Legendre's Equation (1) is the sum a polynomial solution and an infinite series solution i.e.,

$$y(x) = AP_n(x) + BQ_n(x) \quad (11)$$

Note: $Q_n(x)$ is unbounded at $x = \pm 1$.

Derivation of Legendre Polynomial $P_n(x)$

Rewriting (7),

$$a_m = \frac{-(m+2)(m+1)}{(n-m)(n+m+1)}a_{m+2} \quad \text{for } m \leq n-2 \quad (12)$$

(12) expresses all non-vanishing coefficients in terms of a_n , which is coefficient of the highest power of x i.e., x^n in the polynomial. The arbitrary coefficient a_n may be chosen as

$$a_n = 1 \quad \text{for } n = 0$$

$$\text{and } a_n = \frac{(2n)!}{2^n(n!)^2} \quad \text{for } n = 1, 2, \dots \quad (13)$$

For this choice of a_n , $P_n(x = 1) = 1$.

The non-vanishing coefficients are obtained from (12) and (13)

$$\begin{aligned} a_{n-2} &= \frac{-n(n-1)}{2(2n-1)}a_n \quad (\text{for } m = n-2) \\ &= \frac{-n(n-1)}{2(2n-1)} \cdot \frac{(2n)!}{2^n(n!)^2} \end{aligned}$$

$$= \frac{-n(n-1) \cdot 2n(2n-1)(2n-2)!}{2(2n-1)2^n \cdot n(n-1)!n(n-1)(n-2)!}$$

$$a_{n-2} = \frac{-(2n-2)!}{2^n(n-1)!(n-2)!}$$

Similarly, for $m = n - 4$, we get

$$a_{n-4} = \frac{-(n-2)(n-3)}{4(2n-3)} a_{n-2} = \frac{(2n-4)!}{2^n 2!(n-2)!(n-4)!}$$

In general for $n - 2m \geq 0$

$$a_{n-2m} = \frac{(-1)^m (2n-2m)!}{2^n m!(n-m)!(n-2m)!} \quad (14)$$

By inserting these coefficients (14) in (9) or (10), we get a polynomial $P_n(x)$ known as the Legendre's polynomial of degree n and is given by (Fig. 11.1)

$$P_n(x) = \sum_{m=0}^M \frac{(-1)^m (2n-2m)!}{2^n m!(n-m)!(n-2m)!} \cdot x^{n-2m} \quad (15)$$

where $M = \frac{n}{2}$ or $\frac{n-1}{2}$ according as n is even or n is odd (whichever is an integer).

Fig. 11.1

In particular,

$$P_0(x) = 1 \quad (\text{for } n = 0, M = 0)$$

$$P_1(x) = x \quad (\text{for } n = 1, M = 0)$$

$$P_2(x) = \frac{1}{2}(3x^2 - 1) \quad (\text{for } n = 2, M = 1, m = 0 \text{ to } 1)$$

$$P_3(x) = \frac{1}{2}(5x^3 - 3x) \quad (\text{for } n = 3, M = 1, m = 0 \text{ to } 1)$$

$$P_4(x) = \frac{1}{8}(35x^4 - 30x^2 + 3)$$

(for $n = 4, M = 2, m = 0$ to 2)

$$P_5(x) = \frac{1}{8}(63x^5 - 70x^3 + 15x) \quad (\text{for } n = 5, M = 2, m = 0 \text{ to } 2)$$

$$P_6(x) = \frac{1}{16}(231x^6 - 315x^4 + 105x^2 - 5) \quad (\text{for } n = 6, M = 3, m = 0 \text{ to } 3).$$

Note 1: At $x = 1$, $P_n(x = 1) = P_n(1) = 1$.

Note 2: Any polynomial $f(x)$ of degree n can be expressed in terms of $P_n(x)$ as

$$f(x) = \sum_{m=0}^n c_m P_m(x).$$

Rodrigue's* Formula

Show that

$$P_n(x) = \frac{1}{n!2^n} \frac{d^n}{dx^n} (x^2 - 1)^n \quad (16)$$

Proof: Let

$$v = (x^2 - 1)^n$$

$$\text{Then } \frac{dv}{dx} = n(x^2 - 1)^{n-1} \cdot 2x$$

$$\text{or } -(1 - x^2) \frac{dv}{dx} = 2nx \cdot (x^2 - 1)^n = 2nxv$$

$$\text{i.e., } (1 - x^2) \frac{dv}{dx} + 2nxv = 0 \quad (17)$$

Differentiating (17), $(n + 1)$ times by Leibnitz's rule

$$\left[(1 - x^2) \frac{d^{n+2}v}{dx^{n+2}} + (n+1)(-2x) \frac{d^{n+1}v}{dx^{n+1}} - (n+1)n \frac{d^n v}{dx^n} \right]$$

$$+ 2n \left[x \frac{d^{n+1}v}{dx^{n+1}} + (n+1) \cdot 1 \cdot \frac{d^n v}{dx^n} \right] = 0$$

$$\text{or } (1 - x^2) \frac{d^{n+2}v}{dx^{n+2}} - 2x \frac{d^{n+1}v}{dx^{n+1}} + n(n+1) \frac{d^n v}{dx^n} = 0$$

Put $U = \frac{d^n v}{dx^n}$ then

$$(1 - x^2) \frac{d^2 U}{dx^2} - 2x \frac{dU}{dx} + n(n+1)U = 0$$

which is a Legendre's equation of order n and has a finite series solution $P_n(x)$. Thus

$$U = C P_n(x) \quad (18)$$

* Olinde Rodrigues (1794–1851), French mathematician.

11.24 — HIGHER ENGINEERING MATHEMATICS—III

Here C is an arbitrary constant which is determined by equating the coefficient of x^n on both sides of (18) i.e.,

$$\frac{d^n}{dx^n}(x^2 - 1)^n = \frac{d^n}{dx^n}v = U = C \cdot P_n(x) \quad (18)$$

The coefficient of x^n in $P_n(x)$ is $\frac{(2n)!}{2^n(n!)^2}$ (obtained by putting $m = 0$ in (15)).

The coefficient of x^n in L.H.S. of (18) arises solely from the n -fold differentiation of the term of highest degree i.e., x^{2n}

$$\begin{aligned} & 2n(2n-1)(2n-2)\cdots(2n-(n-1)) \\ &= (2n)(2n-1)(2n-2)\cdots(n+1) \cdot \frac{n!}{n!} \\ &= \frac{(2n)!}{n!} \end{aligned}$$

Thus $\frac{(2n)!}{n!} = C \cdot \frac{(2n)!}{2^n(n!)^2}$
or $C = 2^n \cdot n! \quad (19)$

Putting C from (19) in (18), we get the Rodrigue's formula

$$P_n(x) = \frac{1}{C}U = \frac{1}{2^n n!} \cdot \frac{d^n}{dx^n} \left\{ (x^2 - 1)^n \right\}$$

Generating Function for Legendre Polynomials

Prove that

$$(1 - 2xt + t^2)^{-\frac{1}{2}} = \sum_{n=0}^{\infty} t^n \cdot P_n(x) \quad (20)$$

Proof:

$$\begin{aligned} (1-y)^{-n} &= 1 + ny + \frac{n(n+1)}{1 \cdot 2} y^2 \\ &\quad + \frac{n(n+1)(n+2)}{1 \cdot 2 \cdot 3} y^3 + \dots \end{aligned}$$

$$\begin{aligned} (1-y)^{-\frac{1}{2}} &= 1 + \frac{1}{2}y + \frac{\frac{1}{2} \cdot \frac{3}{2}}{2!} y^2 \\ &\quad + \frac{\frac{1}{2} \cdot \frac{3}{2} \cdot \frac{5}{2}}{3!} y^3 + \dots \end{aligned}$$

$$\begin{aligned} (1-y)^{-\frac{1}{2}} &= 1 + \frac{1}{2}y + \frac{1 \cdot 3}{2 \cdot 4} y^2 + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6} y^3 + \dots \\ &\quad + \frac{1 \cdot 3 \cdots (2n-1)}{2 \cdot 4 \cdots 2n} \cdot y^n + \dots \end{aligned}$$

Rewriting

$$\begin{aligned} & \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots 2n} \\ &= \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots 2n} \cdot \frac{2 \cdot 4 \cdots 2n}{2 \cdot 4 \cdots 2n} \\ &= \frac{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdots (2n-1) \cdot 2n}{2^n \cdot n! \cdot 2^n \cdot n!} = \frac{(2n)!}{2^{2n}(n!)^2} \end{aligned}$$

Now using this result, expand

$$\begin{aligned} & (1 - 2xt + t^2)^{-\frac{1}{2}} \\ &= \left[1 - (2xt - t^2) \right]^{-\frac{1}{2}} = \left[1 - \left\{ t(2x - t) \right\} \right]^{-\frac{1}{2}} \\ &= 1 + \frac{2!}{2^2(1!)^2} t \cdot (2x - t) + \frac{4!}{2^4(2!)^2} t^2 (2x - t)^2 + \dots \\ &\quad + \frac{(2(n-k))!}{2^{2(n-k)} \{(n-k)!\}^2} t^{n-k} (2x - t)^{n-k} + \dots \\ &\quad + \frac{(2n)!}{2^{2n} \cdot (n!)^2} t^n (2x - t)^n + \dots \quad (21) \end{aligned}$$

Coefficients of t^n appear only in the first $(n+1)$ terms. Consider the $(n-k)$ th term: t^n arises as product of t^{n-k} and t^k arising out of $(2x - t)^{n-k}$. Thus the coefficient of t^n in $t^{n-k} \cdot (2x - t)^{n-k}$ is the coefficient of t^k in $(2x - t)^{n-k}$

i.e., $(n-k)C_k(2x)^{(n-k)-k} \cdot (-1)^k$
 $= \frac{(n-k)!(-1)^k}{k!(n-2k)!} \cdot (2x)^{n-2k} \quad (22)$

Therefore the coefficient of t^n is (see 21)

$$\begin{aligned} & \left[\frac{(2n-2k)!}{2^{2n-2k} \{(n-k)!\}^2} \right] \cdot \left[\frac{(n-k)!}{k!(n-2k)!} (-1)^k (2x)^{n-2k} \right] \\ &= \frac{(-1)^k (2n-2k)!}{2^{2n} k! (n-k)! (n-2k)!} \cdot x^{n-2k} \end{aligned}$$

collecting and summing up for k all the coefficients of t^n from the first $(n+1)$ terms, we get

$$\sum_{k=0}^M \frac{(-1)^k (2n-2k)!}{2^{2n} (n-k)! k! (n-2k)!} \cdot x^{n-2k} = P_n(x)$$

where $M = \frac{n}{2}$ or $\frac{n-1}{2}$ according as n is even or odd.

Thus the Legendre polynomials $P_0(x)$, $P_1(x)$, $P_2(x) \cdots P_n(x) \cdots$ appear as coefficients of t^0 , t^1 , $t^2, \dots, t^n \dots$ etc. in the expansion of $(1 - 2xt + t^2)^{-\frac{1}{2}}$. Hence $(1 - 2xt + t^2)^{-\frac{1}{2}}$ is the generating function of the Legendre polynomials i.e.,

$$(1 - 2xt + t^2)^{-\frac{1}{2}} = \sum_{n=0}^{\infty} P_n(x) \cdot t^n \quad (20)$$

Result 1: $P_n(1) = 1$ for any n .

Put $x = 1$ in (20). Then

$$\begin{aligned} \sum_{n=0}^{\infty} P_n(1)t^n &= (1 - 2t + t^2)^{-\frac{1}{2}} \\ &= \left((1 - t)^2\right)^{-\frac{1}{2}} = (1 - t)^{-1} \\ &= 1 + t + t^2 + \cdots + t^n + \cdots \end{aligned}$$

Equating the coefficients of t^n on both sides

$$P_n(1) = 1 \quad \text{for any } n.$$

Result 2: $P_n(-1) = (-1)^n$ for any n .

Put $x = -1$ in (20). Then

$$\begin{aligned} \sum_{n=0}^{\infty} P_n(-1)t^n &= (1 + 2t + t^2)^{-\frac{1}{2}} \\ &= \left[(1 + t)^2\right]^{-\frac{1}{2}} = (1 + t)^{-1} \\ &= 1 - t + t^2 - \cdots + (-1)^n t^n + \cdots \end{aligned}$$

Equating the coefficients of t^n , $P_n(-1) = (-1)^n$.

Result 3:

$$P_n(0) = \begin{cases} 0, & \text{when } n \text{ is odd} \\ (-1)^{\frac{n}{2}} \cdot \frac{1 \cdot 3 \cdot 5 \cdots (n-1)}{2 \cdot 4 \cdot 6 \cdots n}, & \text{if } n \text{ is even} \end{cases}$$

Put $x = 0$ in (20). Then

$$\begin{aligned} \sum_{n=0}^{\infty} P_n(0)t^n &= (1 + t^2)^{-\frac{1}{2}} \\ &= 1 - \frac{1}{2}t^2 + \frac{\left(-\frac{1}{2}\right)\left(-\frac{1}{2} + 1\right)}{1 \cdot 2}t^4 + \cdots \\ &\quad + \frac{\left(-\frac{1}{2}\right)\left(-\frac{1}{2} + 1\right) \cdots \left(-\frac{1}{2} - (n-1)\right)}{1 \cdot 2 \cdot 3 \cdots n}t^{2n} + \cdots \\ &= 1 - \frac{1}{2}t^2 + \frac{1 \cdot 3}{2 \cdot 4}t^4 + \cdots \\ &\quad + \frac{(-1)^n 1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots 2n} \cdot t^{2n} + \cdots \end{aligned}$$

Equating the coefficients of t^{2m}

$$P_{2m}(0) = (-1)^m \frac{1 \cdot 3 \cdot 5 \cdots (2m-1)}{2 \cdot 4 \cdot 6 \cdots 2m}$$

Since the R.H.S. contains only even powers of t , coefficients of odd powers of t are all zero i.e., $P_{2m+1}(0) = 0$.

Recurrence Relations for $P_n(x)$

I. $P'_n(x) = x P'_{n-1}(x) + n P_{n-1}(x)$

Proof: From Rodrigue's formula

$$P_n(x) = \frac{1}{2^n n!} \frac{d^n}{dx^n} (x^2 - 1)^n$$

Differentiating w.r.t., x

$$\frac{d}{dx} \{P_n(x)\} = P'_n(x) = \frac{1}{2^n \cdot n!} \cdot \frac{d^n}{dx^n} \left\{ n(x^2 - 1)^{n-1} \cdot 2x \right\}$$

$$P'_n(x) = \frac{1}{2^{n-1} \cdot (n-1)!} \frac{d^n}{dx^n} \left\{ x(x^2 - 1)^{n-1} \right\}$$

Differentiating by Leibnitz's rule

$$\begin{aligned} &= \frac{1}{2^{n-1}(n-1)!} \left[x \cdot \frac{d^n}{dx^n} (x^2 - 1)^{n-1} + \right. \\ &\quad \left. + n \cdot 1 \cdot \frac{d^{n-1}(x^2 - 1)^{n-1}}{dx^{n-1}} \right] \\ &= x \cdot \frac{d}{dx} \left\{ \frac{1}{2^{n-1}(n-1)!} \frac{d^{n-1}}{dx^{n-1}} (x^2 - 1)^{n-1} \right\} \\ &\quad + n \frac{1}{2^{n-1}(n-1)!} \frac{d^{n-1}}{dx^{n-1}} (x^2 - 1)^{n-1} \end{aligned}$$

$$P'_m x = x \cdot \frac{d}{dx} P_{n-1} + n P_{n-1} = x P'_{n-1}(x) + n P_{n-1}(x).$$

II. $P'_{n+1}(x) - P'_{n-1}(x) = (2n+1)P_n(x)$.

Proof:

$$\begin{aligned} P'_{n+1}(x) &= \frac{d}{dx} P_{n+1}(x) \\ &= \frac{d}{dx} \left\{ \frac{1}{2^{n+1}(n+1)!} \frac{d^{n+1}}{dx^{n+1}} (x^2 - 1)^{n+1} \right\} \\ &= \frac{1}{2^{n+1}(n+1)!} \cdot \frac{d^{n+1}}{dx^{n+1}} \left\{ (n+1)x(x^2 - 1)^n \cdot 2x \right\} \end{aligned}$$

$$\begin{aligned}
 &= \frac{1}{2^n} \cdot \frac{1}{n!} \frac{d^{n+1}}{dx^{n+1}} \left\{ x(x^2 - 1)^n \right\} \\
 &= \frac{1}{2^n} \cdot \frac{1}{n!} \frac{d^n}{dx^n} \left\{ x \cdot n(x^2 - 1)^{n-1} \cdot 2x + (x^2 - 1)^n \right\} \\
 &= \frac{1}{2^{n-1} \cdot (n-1)!} \frac{d^n}{dx^n} \left\{ x^2(x^2 - 1)^{n-1} \right\} + P_n(x) \\
 &= \frac{1}{2^{n-1} \cdot (n-1)!} \cdot \frac{d^n}{dx^n} \left\{ (x^2 - 1 + 1) \right. \\
 &\quad \left. \times (x^2 - 1)^{n-1} \right\} + P_n(x) \\
 &= \frac{1}{2^{n-1}(n-1)!} \cdot \frac{d^n}{dx^n} \cdot (x^2 - 1)^n \\
 &\quad + \frac{1}{2^{n-1}(n-1)!} \frac{d^n}{dx^n} (x^2 - 1)^{n-1} + P_n \\
 &= 2n \cdot P_n(x) + \frac{d}{dx} P_{n-1}(x) + P_n(x)
 \end{aligned}$$

$$P'_n(x) - P'_{n-1}(x) = (2n+1)P_n(x).$$

$$\text{III. } x P'_n(x) = n P_n(x) + P'_{n-1}(x).$$

Proof: In the recurrence relation I

$$P'_n = x P'_{n-1} + n P_{n-1}$$

replace n by $n+1$ and rewrite

$$x P'_n = P'_{n+1} - (n+1)P_n$$

From recurrence relation II,

$$P'_{n+1} = P'_{n-1} + (2n+1)P_n$$

Substituting P'_{n+1} , we get

$$x P'_n = P'_{n-1} + (2n+1)P_n - (n+1)P_n$$

$$x P'_n = P'_{n-1} + n P_n$$

$$\text{IV. } (1 - x^2)P'_{n-1} = n(x P_{n-1} - P_n)$$

$$\text{From R.R. I : } P'_n = x P'_{n-1} + n P_{n-1} \quad (1)$$

$$\text{From R.R. III : } x P'_n = P'_{n-1} + n P_n \quad (2)$$

Multiply (1) by x and subtract (2) from (1)

$$0 = x[x P'_{n-1} + n P_{n-1}] - [P'_{n-1} + n P_n]$$

$$0 = (x^2 - 1)(P'_{n-1}) + n(x P_{n-1} - P_n)$$

$$\text{or } (1 - x^2)P'_{n-1} = n(x P_{n-1} - P_n).$$

$$\text{V. } (x^2 - 1)P'_n = n(x P_n - P_{n-1})$$

$$\text{From R.R. I : } P'_n = x P'_{n-1} + n P_{n-1} \quad (1)$$

$$\text{From R.R. III : } x P'_n = P'_{n-1} + n P_n \quad (2)$$

Multiply (2) by x and subtract (1) from (2)

$$(x^2 - 1)P'_n = n x P_n - n P_{n-1} = n(x P_n - P_{n-1}).$$

$$\text{VI. } (n+1)P_{n+1} = (2n+1)x P_n - n P_{n-1}$$

$$\text{From R.R. IV : } (1 - x^2)P'_{n-1} = n[x P_{n-1} - P_n]$$

Replace n by $n+1$ and rewrite

$$(n+1)P_{n+1} = (n+1)x P_n - (1 - x^2)P'_n$$

$$\text{From R.R. V : } (x^2 - 1)P'_n = n(x P_n - P_{n-1})$$

Eliminating P'_n using R.R. V.

$$(n+1)P_{n+1} = (n+1)x P_n + n(x P_n - P_{n-1})$$

$$(n+1)P_{n+1} = (2n+1)x P_n - n P_{n-1}.$$

Orthogonality of Legendre Polynomials

Prove that

$$\text{a. } \int_{-1}^1 P_m(x) P_n(x) dx = 0 \quad \text{if } m \neq n$$

This is known as the orthogonality property of Legendre polynomial

$$\text{b. } \int_{-1}^1 P_n^2(x) dx = \frac{2}{2n+1} \quad \text{for } n = 0, 1, 2, \dots$$

Proof: (a) Let $P_m(x)$ and $P_n(x)$ be Legendre polynomials of order m and n satisfying respectively the Legendre equations

$$(1 - x^2)P''_m - 2xP'_m + m(m+1)P_m = 0$$

or rewritten as

$$\left[(1 - x^2)P'_m \right]' = -m(m+1)P_m \quad (1)$$

$$\text{and } \left[(1 - x^2)P'_n \right]' = -n(n+1)P_n \quad (2)$$

Multiply (1) by P_n and (2) by P_m and add

$$\begin{aligned} & [n(n+1) - m(m+1)] P_n(x) \cdot P_m(x) \\ &= \left[(1-x^2) P'_m \right]' P_n - \left[(1-x^2) P'_n \right]' P_m \quad (3) \end{aligned}$$

Put $c = n(n+1) - m(m+1) = n^2 - m^2 + (n-m) = (n-m)(n-m+1) \neq 0$ when $m \neq n$.

Integrate both sides of (3) w.r.t., x from -1 to 1

$$\begin{aligned} I &= c \int_{-1}^1 P_n(x) P_m(x) dx \\ &= \int_{-1}^1 \left[(1-x^2) P'_m \right]' P_n dx - \int_{-1}^1 \left[(1-x^2) P'_n \right]' P_m dx \\ &= I_1 - I_2 \end{aligned}$$

Consider

$$\begin{aligned} I_1 &= \int_{-1}^1 \left[(1-x^2) P'_m \right]' P_n dx \\ &= \int_{-1}^1 \frac{d}{dx} \left[(1-x^2) \frac{dP_m}{dx} \right] P_n dx. \text{ Integrating by parts} \\ &= P_n \cdot (1-x^2) \frac{dP_m}{dx} \Big|_{-1}^1 - \int_{-1}^1 (1-x^2) P'_m P'_n dx \\ &= 0 - \int_{-1}^1 (1-x^2) P'_m P'_n dx \end{aligned}$$

Similarly,

$$\begin{aligned} I_2 &= \int_{-1}^1 \left[(1-x^2) P'_n \right]' P_m dx \\ &= - \int_{-1}^1 (1-x^2) P'_n P'_m dx \end{aligned}$$

Thus

$$c \int_{-1}^1 P_n(x) P_m(x) dx = 0 \quad \text{since } I_1 = I_2$$

For $m \neq n$, $c \neq 0$, therefore $\int_{-1}^1 P_n P_m dx = 0$

(b) From Rodrigue's formula

$$2^n \cdot n! P_n(x) = \frac{d^n}{dx^n} (x^2 - 1)^n \quad (1)$$

Multiplying (1) with itself and integrating w.r.t., x from -1 to 1 , and denoting $\frac{d}{dx}$ by D , we have

$$\begin{aligned} & (2^n \cdot n!)^2 \int_{-1}^1 P_n^2(x) dx \\ &= \int_{-1}^1 D^n (x^2 - 1)^n \left[D^n (x^2 - 1)^n \right] dx \end{aligned}$$

Integrating by parts

$$\begin{aligned} &= D^n (x^2 - 1)^n \cdot D^{n-1} (x^2 - 1)^n \Big|_{-1}^1 \\ &\quad - \int_{-1}^1 \left[D^{n+1} (x^2 - 1)^n \right] \left[D^{n-1} (x^2 - 1)^n \right] dx \end{aligned}$$

The first term on the R.H.S. becomes zero at $x = \pm 1$ because after $(n-1)$ differentiations of $(x^2 - 1)^n$, the factor $(x^2 - 1)$ will still be present.

So

$$\begin{aligned} (2^n n!)^2 \int_{-1}^1 P_n^2 dx &= - \int_{-1}^1 \left[D^{n+1} (x^2 - 1)^n \right] \\ &\quad \times \left[D^{n-1} (x^2 - 1)^n \right] dx \end{aligned}$$

Integrating by parts $(n-1)$ times, we get

$$\begin{aligned} (2^n n!)^2 \int_{-1}^1 P_n^2 dx &= (-1)^n \int_{-1}^1 (x^2 - 1)^n \\ &\quad \times D^{n+1+n-1} (x^2 - 1)^n dx \end{aligned}$$

But $D^{2n} (x^2 - 1)^n = (2n)!$

$$\begin{aligned} &= (-1)^n \int_{-1}^1 (x^2 - 1)^n \cdot (2n)! dx \\ &= 2(-1)^n (2n)! \int_0^1 (x^2 - 1)^n dx \\ &= 2(2n)! \int_0^1 (1 - x^2)^n dx \end{aligned}$$

Put $x = \sin \theta$, limits for θ are 0 to $\frac{\pi}{2}$

$$\begin{aligned} &= 2(2n)! \int_0^{\frac{\pi}{2}} \cos^{2n} \theta \cos \theta d\theta \\ &= 2(2n)! \int_0^{\frac{\pi}{2}} \cos^{2n+1} \theta d\theta \\ &= 2(2n)! \left[\frac{2n \cdot (2n-2) \cdots 4 \cdot 2}{(2n+1)(2n-1) \cdots 2 \cdot 1} \right] \end{aligned}$$

$$(2^n n!)^2 \int_{-1}^1 P_n^2 dx = 2(2n)! \cdot \left[\frac{2^{2n} (n!)^2}{(2n+1)!} \right]$$

$$\therefore \int_{-1}^1 P_n^2(x) dx = \frac{2(2n)!}{(2n+1)} = \frac{2}{(2n+1)}.$$

WORKED OUT EXAMPLES

Example 1: Find $P_6(x)$.

Solution:

$$P_n(x) = \sum_{m=0}^M \frac{(-1)^m (2n-2m)!}{2^n m! (n-m)! (n-2m)!} x^{n-2m}$$

Here $n = 6 = \text{even}$, $M = \frac{n}{2} = \frac{6}{2} = 3$,
 m : varies from 0 to 3

$$\begin{aligned} P_6(x) &= \sum_{m=0}^3 \frac{(-1)^m (12-2m)!}{2^6 m! (6-m)! (6-2m)!} x^{6-2m} \\ &= \frac{12!x^6}{2^6 \cdot 6!6!} - \frac{10!x^4}{2^6 \cdot 1!5!4!} + \frac{8!x^2}{2^6 2!4!2!} - \frac{6!x^0}{2^6 3!3!} \\ P_6(x) &= \frac{1}{16} [231x^6 - 315x^4 + 105x^2 - 5]. \end{aligned}$$

Example 2: Express x^5 in terms of Legendre polynomials.

Solution: We know that $P_5(x) = \frac{1}{8}(63x^5 - 70x^3 + 15x)$

Solving $x^5 = \frac{8}{63}P_5 + \frac{70}{63}x^3 - \frac{15}{63}x$

Since $P_3 = \frac{(5x^3-3x)}{2}$, we have

$$x^3 = \frac{2}{5}P_3 + \frac{3}{5}x = \frac{2}{5}P_3 + \frac{3}{5}P_1$$

Substituting x^3

$$x^5 = \frac{8}{63}P_5 + \frac{70}{63} \left[\frac{2}{5}P_3 + \frac{3}{5}P_1 \right] - \frac{15}{63}P_1 \quad \text{since } P_1 = x$$

$$x^5 = \frac{8}{63}P_5 + \frac{28}{63}P_3 + \frac{27}{63}P_1.$$

Example 3: Express the polynomial $f(x) = 4x^3 - 2x^2 - 3x + 8$ in terms of Legendre polynomials.

Solution: Since the polynomial $f(x)$ is of degree 3, write

$$\begin{aligned} f(x) &= C_0P_0 + C_1P_1 + C_2P_2 + C_3P_3 \\ 4x^3 - 2x^2 - 3x + 8 &= C_0 \cdot 1 + C_1x \\ &\quad + C_2 \left(\frac{3x^2-1}{2} \right) + C_3 \left(\frac{5x^3-3x}{2} \right) \end{aligned}$$

Equating the coefficients of like powers of x on both sides, we get

$$x^3: \quad 4 = \frac{5}{2}C_3 \quad \therefore C_3 = \frac{8}{5}$$

$$x^2: \quad -2 = \frac{3}{2}C_2 \quad \therefore C_2 = \frac{-4}{3}$$

$$x: \quad -3 = C_1 - \frac{3C_3}{2} \quad \therefore C_1 = \frac{-3}{5}$$

$$x^0: \quad 8 = C_0 - \frac{C_2}{2} \quad \therefore C_0 = \frac{22}{3}$$

Thus

$$4x^3 - 2x^2 - 3x + 8 = \frac{22}{3}P_0 - \frac{3}{5}P_1 - \frac{4}{3}P_2 + \frac{8}{5}P_3.$$

Example 4: Show that (a) $P_n(-x) = (-1)^n P_n(x)$ and (b) $P'_n(-x) = (-1)^{n+1} P'_n(x)$.

Solution:

$$P_n(x) = \sum_{m=0}^M \frac{(-1)^m (2n-2m)!}{2^n \cdot m! (n-m)! (n-2m)!} x^{n-2m}$$

$$P_n(-x) = \sum_{m=0}^M \frac{(-1)^m (2n-2m)!}{2^n m! (n-m)! (n-2m)!} (-x)^{n-2m}$$

$$P_n(-x) = (-1)^n (-1)^{-2m} \cdot P_n(x) = (-1)^n P_n(x)$$

Differentiating w.r.t., x

$$(-1)P_n(-x) = (-1)^n \cdot P'_n(x)$$

$$\therefore P'_n(-x) = (-1)^{n+1} P'_n(x).$$

Example 5: Prove that

$$(2n+1)(1-x^2)P'_n(x) = n(n+1) \left[P_{n-1}(x) - P_{n+1}(x) \right]$$

Solution: Consider R.R. V

$$(x^2-1)P'_n = n(xP_n - P_{n-1}) \quad (1)$$

Multiplying (1) by $-(2n+1)$, we get

$$(2n+1)(1-x^2)P'_n = n(2n+1)(P_{n-1} - xP_n) \quad (2)$$

Solving R.R. 6 for P_n

$$(n+1)P_{n+1} = (2n+1)xP_n - nP_{n-1},$$

We get

$$(2n+1)xP_n = (n+1)P_{n+1} + nP_{n-1} \quad (3)$$

Using (3) eliminate P_n from (2) then

$$\begin{aligned}(2n+1)(1-x^2)P'_n &= n(2n+1)P_{n-1} - \\ &\quad -n \left[(n+1)P_{n+1} + nP_{n-1} \right] \\ &= (2n^2 + n - n^2)P_{n-1} \\ &\quad -n(n+1)P_{n+1} \\ (2n+1)(1-x^2)P'_n &= n(n+1)[P_{n-1} - P_{n+1}].\end{aligned}$$

Example 6: Show that

a. $\int_{-1}^1 f(x)P_n(x)dx = \frac{(-1)^n}{2^n n!} \int_{-1}^1 f^{(n)}(x)(x^2-1)^n dx$

Hence deduce that

b. $\int_{-1}^1 x^m P_n(x)dx \begin{cases} 0, & \text{if } m < n \\ \frac{2^{n+1} \cdot (n!)^2}{(2n+1)!}, & \text{if } m = n \end{cases}$

Solution: Using Rodrigue's formula

$$\int_{-1}^1 f(x)P_n(x)dx = \int_{-1}^1 f(x) \cdot \frac{1}{2^n \cdot n!} \frac{d^n}{dx^n} (x^2-1)^n dx$$

Integrating by parts

$$\begin{aligned}&= \frac{1}{2^n \cdot n!} \left[\left\{ f(x) \cdot \frac{d^{n-1}}{dx^{n-1}} (x^2-1)^n \right\} \Big|_{-1}^1 \right. \\ &\quad \left. - \int_{-1}^1 f'(x) \cdot \frac{d^{n-1}}{dx^{n-1}} (x^2-1)^n dx \right]\end{aligned}$$

The first term in the R.H.S. becomes zero at both the limits $x = \pm 1$ because $\frac{d^{n-1}}{dx^{n-1}} (x^2-1)^n$ contains

a. Factor of $x^2 - 1$. Integrating by parts $(n-1)$ times

$$= \frac{1}{2^n \cdot n!} (-1)^n \int_{-1}^1 (x^2-1)^n \cdot \frac{d^n f(x)}{dx^n} dx.$$

b. Take $f(x) = x^m$, then

$$\frac{d^n f}{dx^n} = \frac{d^n x^m}{dx^n} = 0$$

whenever $m < n$. Thus

$$\int_{-1}^1 x^m P_n(x)dx = 0$$

c. Take $f(x) = x^n$. Then

$$\frac{d^n f}{dx^n} = \frac{d^n x^n}{dx^n} = n!$$

Thus

$$\begin{aligned}\int_{-1}^1 x^n P_n(x)dx &= \frac{1}{2^n \cdot n!} (-1)^n \int_{-1}^1 (x^2-1)^n \cdot n! dx \\ &= \frac{2}{2^n} \int_0^1 (1-x^2)^n dx. \quad \text{put } x = \sin \theta \\ &= \frac{2}{2^n} \int_0^{\frac{\pi}{2}} \cos^{2n} \theta d\theta \\ &= \frac{2}{2^n} \left[\frac{2n \cdot (2n-2) \cdots 4 \cdot 2}{(2n+1)(2n-1) \cdots 2 \cdot 1} \right], \\ &\quad \text{using result 10 on page 11.4} \\ &= \frac{2}{2^n} \left[\frac{2^{2n} \cdot (n!)^2}{(2n+1)!} \right] = \frac{2^{n+1} \cdot (n!)^2}{(2n+1)!}.\end{aligned}$$

EXERCISE

1. Find $P_5(x)$

Ans. $P_5(x) = \frac{1}{8}(63x^5 - 70x^3 + 15x)$

2. Express x^0, x, x^2, x^3 and x^4 in terms of Legendre polynomials

Ans. $1 = P_0(x), x = P_1(x), x^2 = \frac{2}{3}P_2(x) + \frac{1}{3}P_0(x), x^3 = \frac{2}{5}P_3(x) + \frac{3}{5}P_1(x),$
 $x^4 = \frac{8}{35}P_4(x) + \frac{4}{7}P_2(x) + \frac{7}{35}P_0(x)$

Express the polynomial $f(x)$ in terms of Legendre polynomials where

3. $f(x) = x^4 + 3x^3 - x^2 + 5x - 2$

Ans. $f(x) = \frac{8}{35}P_4 + \frac{6}{5}P_3 - \frac{2}{21}P_2 + \frac{34}{5}P_1 - \frac{224}{105}P_0$

4. $f(x) = 1 - 3x + 3x^2$

Ans. $2P_0 - 3P_1 + 2P_2$

5. $f(x) = 2x + 10x^3$

Ans. $8P_1 + 4P_3$

6. $f(x) = x^3 + 2x^2 - x - 3$

Ans. $\frac{2}{5}P_3 + \frac{4}{3}P_2 - \frac{2}{5}P_1 - \frac{7}{3}P_0$

11.30 — HIGHER ENGINEERING MATHEMATICS—III

7. Show that

$$\int_{-1}^1 x^2 P_{n-1} \cdot P_{n+1} dx = \frac{2n(n+1)}{(2n-1)(2n+1)(2n+3)}$$

Hint: Use R.R. VI, $x P_{n-1} = \frac{(nP_n + (n-1)P_{n-2})}{(2n-1)}$

Replace n by $n+2$,

$$x P_{n+1} = \frac{((n+2)P_{n+2} + (n+1)P_n)}{(2n+3)}$$

Multiply, integrate -1 to 1 , use orthogonality.

8. Prove that

a. $P_{2n+1}(0) = 0$,

b. $P_{2n}(0) = \frac{(-1)^n (2n)!}{2^{2n} \cdot (n!)^2}$

Hint: Use generating function $\sum P_n(x)t^n = (1 - 2xt + t^2)^{-\frac{1}{2}}$. Put $x = 0$, equate coefficients of even powers and odd powers on t on both sides.

9. Show that

a. $P'_n(1) = \frac{n(n+1)}{2}$

b. $P'_n(-1) = (-1)^n \frac{n(n+1)}{2}$.

10. Prove that

$$\int_{-1}^1 (1-x^2) P'_m P'_n dx = \begin{cases} 0, & \text{if } m \neq n \\ \frac{2n(n+1)}{2n+1}, & \text{if } m = n \end{cases}$$

Hint: Multiply Legendre's equation for P_m by P_n , integrate -1 to 1 , use orthogonality.

11. Show that $\int_{-1}^1 P_n(x) dx = 0$, for $n \neq 0$

Hint: Use Rodrigue's formula, differentiate $(n-1)$ times.

12. Prove that

$$\int_{-1}^1 P_n(x) \cdot (1 - 2xt + t^2)^{-\frac{1}{2}} dx = \frac{2t^n}{2n+1}$$

when n is a positive integer.

Hint: Express $(1 - 2xt + t^2)^{-\frac{1}{2}}$ as $\sum t^n P_n(x) dx$, use orthogonality.

11.6 FOURIER-LEGENDRE AND FOURIER-BESSEL SERIES

Another two important generalized Fourier series are Fouries-Legendre series and Fouries-Bessel series.

Fourier-Legendre Series

The Fourier-Legendre series is an eigen function expansion of a given function $f(x)$ on the interval $-1 \leq x \leq 1$ w.r.t. the weight function $P(x) = 1$ and is given by

$$f(x) = \sum_{n=0}^{\infty} a_n P_n(x)$$

where $P_n(x)$ are Legendre polynomials. Here

$$a_n = \frac{\int_{-1}^1 f(x) P_n(x) dx}{\int_{-1}^1 P_n^2(x) dx} = \frac{(2n+1)}{2} \int_{-1}^1 f(x) P_n(x) dx$$

$$\text{since } \int_{-1}^1 P_n^2(x) dx = \frac{2}{2n+1}$$

Fourier-Bessel Series

The Fourier-Bessel series is an orthogonal expansion of a given function $f(x)$ defined on the interval $0 \leq x \leq R$ w.r.t. the weight function $P(x) = x$ and in terms of orthogonal Bessel functions $J_n(K_{1n}x)$, $J_n(K_{2n}x)$, $\dots$, where n is fixed and $R \cdot K_{mn}$ are the zeros of the Bessel functions. (i.e., $J_n(RK_{mn}) = 0$). It is given by

$$f(x) = \sum_{m=1}^{\infty} a_m J_n(K_{mn}x)$$

or

$$f(x) = a_1 J_n(K_{1n}x) + a_2 J_n(K_{2n}x) + a_3 J_n(K_{3n}x) + \dots$$

Here

$$a_m = \frac{2}{R^2 J_{n+1}^2(K_{mn}R)} \int_0^R x \cdot f(x) \cdot J_n(K_{mn}x) dx$$

for $m = 1, 2, 3, \dots$

WORKED OUT EXAMPLES

Example 1: Compute the first three non-vanishing terms in the Fourier-Legendre series over the interval $(-1, 1)$ of the function

$$f(x) = \begin{cases} \frac{1}{2\epsilon}, & |x| < \epsilon \\ 0, & \epsilon < |x| < 1 \end{cases}$$

Solution: Let the Fourier-Legendre series be

$$f(x) = \sum_{n=0}^{\infty} a_n P_n(x)$$

where $a_n = \frac{2n+1}{2} \int_{-1}^1 f(x) P_n(x) dx$

For $n = 0$

$$a_0 = \frac{1}{2} \int_{-1}^1 f(x) P_0(x) dx = \frac{1}{2} \int_{-1}^1 f(x) \cdot 1 \cdot dx$$

$$a_0 = \frac{1}{2} \int_{-\epsilon}^{\epsilon} \frac{1}{2\epsilon} dx = \frac{1}{4\epsilon} x \Big|_{-\epsilon}^{\epsilon} = \frac{2\epsilon}{4\epsilon} = \frac{1}{2}$$

For $n = 1$,

$$a_1 = \frac{3}{2} \int_{-1}^1 f(x) P_1(x) dx = \frac{3}{2} \int_{-\epsilon}^{\epsilon} \frac{1}{2\epsilon} x dx = 0$$

When n is odd, $P_n(x)$ is an odd (polynomial) function. So $f(x)P_n(x)$ is odd since $f(x)$ is constant. Therefore $a_n = 0$ for all n odd.

Now for $n = 2$,

$$a_2 = \frac{5}{2} \int_{-\epsilon}^{\epsilon} \frac{1}{2\epsilon} P_2(x) dx$$

$$\begin{aligned} a_2 &= \frac{5}{4\epsilon} \int_{-\epsilon}^{\epsilon} \frac{1}{2} (3x^2 - 1) dx = \frac{5}{8\epsilon} \left[x^3 - \frac{x^2}{2} \right]_{-\epsilon}^{\epsilon} \\ &= \frac{5}{4} (\epsilon^2 - 1) \end{aligned}$$

Now

$$\begin{aligned} a_4 &= \frac{9}{2} \int_{-\epsilon}^{\epsilon} \frac{1}{2\epsilon} P_4(x) dx \\ &= \frac{9}{4\epsilon} \int_{-\epsilon}^{\epsilon} \frac{1}{8} (35x^4 - 30x^2 + 3) dx \\ &= \frac{9}{32\epsilon} [7x^5 - 10x^3 + 3x] \Big|_{-\epsilon}^{\epsilon} \\ a_4 &= \frac{9}{16} [7\epsilon^4 - 10\epsilon^2 + 3] \end{aligned}$$

Thus the Fourier-Legendre series

$$\begin{aligned} f(x) &= \frac{1}{2} P_0(x) - 0 + \frac{5}{4} (\epsilon^2 - 1) P_2(x) + 0 \\ &+ \frac{9}{16} [7\epsilon^4 - 10\epsilon^2 + 3] P_4(x) + 0 \dots \end{aligned}$$

Example 2: Expand $f(x) = \cos \frac{\pi}{2} x$ in Fourier-Legendre series.

Solution: Here $a_n = \frac{2n+1}{2} \int_{-1}^1 f(x) P_n(x) dx$

or $a_n = \frac{2n+1}{2} \int_{-1}^1 \cos \frac{\pi}{2} x \cdot P_n(x) dx.$

For $n = 0$,

$$a_0 = \frac{1}{2} \int_{-1}^1 \cos \frac{\pi}{2} x \cdot 1 dx = \frac{1}{2} \cdot \frac{2}{\pi} \cdot \sin \frac{\pi}{2} x \Big|_{-1}^1$$

$$a_0 = \frac{2}{\pi} = 0.6366.$$

When n is odd, $P_n(x)$ is odd. So the product $\cos \frac{\pi}{2} x \cdot P_n(x)$ is odd and therefore $a_n = 0$ for n odd. Thus, for $n = 1$,

$$\begin{aligned} a_1 &= \frac{3}{2} \int_{-1}^1 \left(\cos \frac{\pi}{2} x \right) P_1(x) dx = \\ &= \frac{3}{2} \int_{-1}^1 x \cdot \cos \frac{\pi}{2} x dx \end{aligned}$$

11.32 — HIGHER ENGINEERING MATHEMATICS—III

$$a_1 = \frac{3}{2} \left[x \cdot \frac{2}{\pi} \sin \frac{\pi}{2} x + 1 \cdot \frac{4}{\pi^2} \cos \frac{\pi}{2} x \right]_{-1}^1 = 0$$

$$\text{For } n = 2, a_2 = \frac{5}{2} \int_{-1}^1 \cos \frac{\pi}{2} x \cdot P_2(x) dx$$

$$a_2 = \frac{5}{2} \int_{-1}^1 \cos \frac{\pi}{2} x \cdot \left[\frac{1}{2}(3x^2 - 1) \right] dx =$$

$$= \frac{15}{4} \int_{-1}^1 x^2 \cos \frac{\pi}{2} x - \frac{5}{4} \int_{-1}^1 \cos \frac{\pi}{2} x dx$$

$$a_2 = \frac{15}{4} \left[x^2 \frac{2}{\pi} \cdot \sin \frac{\pi}{2} x + 2x \cdot \frac{4}{\pi^2} \cos \frac{\pi}{2} x \right. \\ \left. + 2 \cdot \frac{8}{\pi^3} \sin \frac{\pi}{2} x \right]_{-1}^1 -$$

$$- \frac{5}{4} \left[\frac{2}{\pi} \cdot \sin \frac{\pi}{2} x \right]_{-1}^1$$

$$a_2 = \frac{15}{4} \left[\frac{4}{\pi} + 0 + \frac{32}{\pi^3} \right] - \frac{5}{4} \left[\frac{4}{\pi} \right]$$

Now

$$a_4 = \frac{9}{2} \int_{-1}^1 \frac{1}{8} (35x^4 - 30x^2 + 3) \cos \frac{\pi}{2} x dx$$

Recall that

$$\int_{-1}^1 x^n \cos \frac{\pi}{2} x dx = \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \left(\frac{2}{\pi} \right)^{n+1} \cdot t^n \cos t dt$$

where $\frac{\pi}{2} x = t$. For n odd, this integral is zero since the integrand is odd.

For n even,

$$I_n = \int_{-1}^1 x^n \cos \frac{\pi}{2} x dx = 2 \left(\frac{2}{\pi} \right)^{n+1} \int_0^{\frac{\pi}{2}} t^n \cos t dt$$

Now by reduction formula

$$I_n = 2 \left(\frac{2}{\pi} \right)^{n+1} \left[n \cdot \left(\frac{\pi}{2} \right)^{n-1} - n(n-1) I_{n-2} \right]$$

for $n > 1$.

So

$$I_2 = 2 \left(\frac{2}{\pi} \right)^3 \left[2 \cdot \left(\frac{\pi}{2} \right) - 2I_0 \right];$$

Here

$$I_0 = \frac{4}{\pi}$$

then,

$$I_2 = 4 \left(\frac{2}{\pi} \right)^3 \left[\frac{\pi}{2} - \frac{4}{\pi} \right],$$

$$I_4 = 2 \left(\frac{2}{\pi} \right)^5 \left[4 \left(\frac{\pi}{2} \right)^3 - 12I_2 \right] =$$

$$= 8 \left(\frac{2}{\pi} \right)^5 \left[\left(\frac{\pi}{2} \right)^3 - 3 \cdot 4 \left(\frac{2}{\pi} \right)^3 \left(\frac{\pi}{2} - \frac{4}{\pi} \right) \right]$$

$$a_4 = \frac{9}{16} \int_{-1}^1 (35x^4 - 30x^2 + 3) \cos \frac{\pi}{2} x dx$$

$$a_4 = \frac{9}{16} [35I_4 - 30I_2 + 3I_0]$$

Similarly for $n = 6$,

$$a_6 = \frac{13}{2} \int_{-1}^1 P_6(x) \cos \frac{\pi}{2} x dx$$

$$a_6 = \frac{13}{2} \int_{-1}^1 \frac{1}{16} (231x^6 - 315x^4 + 105x^2 - 5) \cos \frac{\pi}{2} x dx$$

$$a_6 = \frac{13}{32} [231I_6 - 315I_4 + 105I_2 - I_0]$$

Here

$$I_6 = 2 \left(\frac{2}{\pi} \right)^7 \left[6 \left(\frac{\pi}{2} \right)^5 - 30I_4 \right]$$

Thus, the Legendre series is

$$\cos \frac{\pi}{2} x = 0.6366 P_0 - 0.6871 P_2 + 0.0518 P_4 \\ - 0.0013 P_6 + \dots$$

Fourier-Bessel Series

Example 1: Expand $f(x) = x^4$, in Fourier-Bessel series in terms of Bessel functions of order zero ($n = 0$) and w.r.t. the weight function $P(x) = x$ over the interval $0 < x < R$.

Solution: With $n = 0$, weight function x and interval $0 < x < R$, the required Fourier Bessel series is given by

$$f(x) = a_1 J_0(K_{10}x) + a_2 J_0(K_{20}x) + a_3 J_0(K_{30}x) + \dots$$

where

$$a_m = \frac{2}{R^2 J_1^2(K_{m1}R)} \int_0^R x \cdot f(x) J_0(K_{m0}x) dx$$

Here $f(x) = x^4$, so

$$a_m = \frac{2}{R^2 J_1^2(K_{m1}R)} \int_0^R x^5 J_0(K_{m0}x) dx$$

Put $K_{m0}x = t$ then $K_{m0}dx = dt$, then

$$\begin{aligned} \int_0^R x^5 J_0(K_{m0}x) dx &= \int_0^{RK_{m0}} \frac{1}{K_{m0}^5} t^5 \cdot J_0(t) \frac{dt}{K_{m0}} \\ &= \frac{1}{(K_{m0})^6} \int_0^{RK_{m0}} t^5 J_0(t) dt \end{aligned}$$

we know that

$$\int x^n J_{n-1}(x) dx = x^n J_n(x) + c$$

Integrating by parts

$$\begin{aligned} \int_0^{RK_{m0}} t^5 J_0(t) dt &= \int_0^{RK_{m0}} t^4 (t J_0) dt \\ &= t^4 (t J_1) \Big|_0^{RK_{m0}} - \int_0^{RK_{m0}} (t J_1) 4t^3 dt \end{aligned}$$

Similarly

$$\begin{aligned} \int_0^{RK_{m0}} t^4 J_1 dt &= \int_0^{RK_{m0}} t^2 (t^2 J_1) dt = \\ &= (t^2 J_2) t^2 \Big|_0^{RK_{m0}} - \int_0^{RK_{m0}} (t^2 J_2) 2t dt \end{aligned}$$

Finally

$$\int_0^{RK_{m0}} t^3 J_2 dt = t^3 J_3 \Big|_0^{RK_{m0}}$$

Thus substituting these values, we get

$$\begin{aligned} \int_0^{RK_{m0}} t^5 J_0 dt &= t^5 J_1 - 4[t^4 J_2 - 2t^3 J_3] \Big|_{t=0}^{RK_{m0}} \\ &= (RK_{m0})^5 J_1 - 4(RK_{m0})^4 J_2 + 8(RK_{m0})^3 J_3 \end{aligned}$$

Then the Fourier coefficients

$$\begin{aligned} a_m &= \frac{1}{(K_{m0})^6} \frac{2}{R^2 J_1^2(RK_{m1})} [(RK_{m0})]^3 \times \\ &\quad \times [(RK_{m0})^2 J_1 - 4RK_{m0} J_2 + 8J_3] \end{aligned}$$

or

$$\begin{aligned} a_m &= 2R [R^2 K_{m0}^2 J_1(K_{m0}R) - 4RK_{m0} J_2(K_{m0}R) + \\ &\quad 8J_3(K_{m0}R)] / [K_{m0}^3 J_1^2(K_{m0}R)] \end{aligned}$$

Example 2: Find Fourier-Bessel series of $f(x) = x - x^3$ in terms of Bessel functions of order one ($n = 1$) over the interval $0 < x < 1$.

Solution: The required Fourier-Bessel series with $n = 1$ over the interval $0 < x < 1$ is $f(x) = a_1 J_1(K_{11}x) + a_2 J_1(K_{21}x) + a_3 J_1(K_{31}x) + \dots$ where

$$a_m = \frac{2}{J_2^2(K_{m1}R)} \int_0^1 x \cdot f(x) J_1(K_{m1}x) dx$$

Here $f(x) = x - x^3$ so

$$\begin{aligned} \int_0^1 x f(x) J_1(K_{m1}x) dx &= \int_0^1 x(x - x^3) J_1(K_{m1}x) dx \\ &= \int_0^1 x^2 J_1(K_{m1}x) dx - \int_0^1 x^4 J_1(K_{m1}x) dx = I_1 - I_2 \end{aligned}$$

Put $K_{m1}x = t$ then

$$I_1 = \int_0^1 x^2 J_1(K_{m1}x) dx = \int_0^{K_{m1}} \left(\frac{t}{K_{m1}} \right)^2 J_1(t) \cdot \frac{dt}{K_{m1}}$$

$$= \frac{1}{(K_{m1})^3} \int_0^{K_{m1}} t^2 J_1(t) dt = \frac{1}{(K_{m1})^3} \cdot t^2 J_2(t) \Big|_{t=0}^{K_{m1}}$$

$$I_1 = \frac{1}{K_{m1}^3} \cdot K_{m1}^2 J_2(K_{m1}) = \frac{J_2(K_{m1})}{K_{m1}}$$

Now

$$I_2 = \int_0^1 x^4 J_1(K_{m1}x) dx = \int_0^{K_{m1}} \left(\frac{t}{K_{m1}} \right)^4 J_1(t) \cdot \frac{dt}{K_{m1}}$$

$$= \frac{1}{K_{m1}^5} \int_0^{K_{m1}} t^2 (t^2 J_1) dt = \frac{1}{K_{m1}^5} [(t^2 J_2)t^2 - \int (t^2 J_2) 2t dt]$$

But $\int t^3 J_2 dt = t^3 J_3$. Thus

$$I_2 = \frac{1}{K_{m1}^5} [K_{m1}^4 J_2(K_{m1}) - 2K_{m1}^3 J_3(K_{m1})].$$

$$I_2 = \frac{1}{K_{m1}^2} [K_{m1} J_2(K_{m1}) - 2J_3(K_{m1})]$$

Therefore

$$a_m = \frac{2}{J_2^2(K_{m1}R)} \left[\frac{J_2(K_{m1})}{K_{m1}} - \frac{1}{K_{m1}^2} (K_{m1} J_2(K_{m1}) - 2J_3(K_{m1})) \right]$$

or

$$a_m = \frac{4J_3(K_{m1})}{K_{m1}^2 J_2^2(K_{m1}R)}$$

EXERCISE

Generalised Fourier Series

Legende Series

1. Expand $f(x)$ in Fourier-Legendre series where

$$f(x) = \begin{cases} 0, & -1 < x < 0 \\ x, & 0 < x < 1 \end{cases}$$

Ans. $f(x) = \frac{1}{4}P_0(x) + \frac{1}{2}P_1(x) + \frac{5}{16}P_2(x)$

$$- \frac{3}{32}P_4(x) + \frac{13}{256}P_6(x) + \dots$$

2. Develop the Legendre series for $f(x) = \sin \pi x$

Ans. $f(x) = 0.95493P_1(x) - 1.15824P_3(x) + 0.21429P_5(x) - 0.01664P_7(x) + 0.00069P_9(x) - 0.00002P_{11}(x) + \dots$

3. Find the Fourier-Legendre series expansion for $f(x) = x^3 + x$ on $-1 \leq x \leq 1$.

Ans. $[8P_1(x) + 2P_3(x)]/5$

4. Obtain Legendre series for $f(x) = 1$, $0 < x < 1$.

Ans. $1 = \sum_{n=0}^{\infty} (-1)^n \binom{4n+3}{2n+2} \frac{(2n)!}{(2^{2n}/n!)^2} P_{2n+1}(x)$

5. Expand $f(x) = \begin{cases} 0, & -1 < x < 0 \\ 1, & 0 < x < 1 \end{cases}$ is a series of Legendre polynomials.

Ans. $f(x) = \frac{1}{2}P_0(x) + \sum_{n=1}^{\infty} \frac{1}{2} \{P_{n-1}(0) - P_{n+1}(0)\} P_n(x)$

Hint: $A_0 = \frac{1}{2}, A_1 = \frac{3}{4}, A_2 = 0, A_3 = -\frac{7}{16}, A_4 = 0, A_5 = \frac{11}{32}$.

Bessel Series

6. Find the Fourier-Bessel series expansion of $f(x) = 4x - x^3$ in terms of Bessel functions

of order one ($n = 1$) in the interval $[0, 2]$ satisfying the boundary condition $y(2) = 0$ and bounded at the origin

$$\text{Ans. } 4x - x^3 = -16 \sum_{n=1}^{\infty} \frac{J_1(K_{n1}x)}{K_{n1}^3 J_0(2K_{n1})}$$

Hint: K_{m1} are zeros of $J_1(2K) = 0$ and

$$a_n = \int_0^2 x(4x - x^3) J_1(K_{n1}x) dx / (2J_2^2(2K_{n1})),$$

$$\int_0^2 x^4 J_1(K_{n1}x) dx = \left(\frac{-16}{K_{n1}} + \frac{32}{K_{n1}^3} \right) J_0(2K_{n1}).$$

$$7. \text{ Show that } \frac{x}{2} = \sum_{j=1}^{\infty} \frac{J_1(K_{j1}x)}{K_{j1} J_2(K_{j1})} = 0 < x < 1$$

Hint: Expand $\frac{x}{2}$ in Bessel functions of order one in $0 < x < 1$.

8. Obtain the Fourier-Bessel series expansion of $f(x) = R^2 - x^2$, $0 < x < R$ in terms of $J_0(K_{n0}x)$.

$$\text{Ans. } \sum_{j=1}^{\infty} a_j J_0(K_{j0}x); a_j = \frac{4J_2(K_{j0}R)}{K_{j0}^2 J_1^2(K_{j0}R)}$$

$$9. \text{ Prove that } \frac{c}{2} = \sum_{j=1}^{\infty} \frac{J_0(K_{j0}x)}{K_{j0} J_1(K_{j0}c)}, 0 < x < c$$

10. Develop $f(x) = x^2$ in terms of Bessel functions of order $2(n = 2)$ in the interval $0 < x < 2$.

$$\text{Ans. } x^2 = 4 \sum_{n=1}^{\infty} \frac{J_2(K_{n2}x)}{K_{n2} J_3(2K_{n2})}$$

$$11. \text{ Show that } x^3 = \sum_{n=1}^{\infty} \frac{6J_1(K_{n1}x)}{K_{n1}^2 J_2^2(3K_{n1})} \times$$

$$\times [3K_{n1} J_2(3K_{n1}) - 2J_3(3K_{n1})]$$

Hint: Expand x^3 in $0 < x < 3$ in J_1 's. Also

$$\int_0^3 x^4 J_1(K_{n1}x) dx = \frac{81K_{n1} J_2(3K_{n1}) - 54J_3(3K_{n1})}{K_{n1}^2}$$

11.7 CHEBYSHEV* POLYNOMIAL

Chebyshev polynomials (of the first kind) are very useful in approximation work.

The second order homogeneous differential equation with variable coefficients

$$(1 - x^2) \frac{d^2 y}{dx^2} - x \frac{dy}{dx} + \lambda y = 0 \quad (1)$$

is known as *Chebyshev equation*. Here, $-1 < x < 1$ and $y(-1)$, $y^1(-1)$, $y(1)$ and $y^1(1)$ are to be bounded.

Changing the variable by

$$x = \cos \theta \quad (2)$$

The Chebyshev D.E. (1) reduces to

$$\frac{d^2 Y}{d\theta^2} + \lambda Y = 0, \quad 0 < \theta < \pi \quad (3)$$

where $Y(\theta) = y(x(\theta)) = y(\cos \theta)$ since $1 - x^2 = \sin^2 \theta$, $\frac{dy}{dx} = \frac{dy}{d\theta} \frac{d\theta}{dx} = -\frac{1}{\sin \theta} \frac{dy}{d\theta}$ and

$$\frac{d^2 y}{dx^2} = \frac{d}{d\theta} \left(-\frac{1}{\sin \theta} \frac{dy}{d\theta} \right) \frac{d\theta}{dx} = \frac{1}{\sin^2 \theta} \frac{d^2 y}{d\theta^2} - \frac{\cos \theta}{\sin^3 \theta} \frac{dy}{d\theta}$$

The general solution of (3) in terms of θ is

$$\left. \begin{aligned} Y(\theta) &= A \cos \sqrt{\lambda} \theta + B \sin \sqrt{\lambda} \theta & \text{when } \lambda \neq 0 \\ Y(\theta) &= C + D\theta & \text{when } \lambda = 0 \end{aligned} \right\} \quad (4)$$

At $\theta = 0 (x = 1)$ and $\theta = \pi (x = -1)$, the solutions $\cos \sqrt{\lambda} \theta$, $\sin \sqrt{\lambda} \theta$, 1 and θ are bounded.

However

$$y'(x) = -A \sin(\sqrt{\lambda} \cos^{-1} x) \sqrt{\lambda} \left(\frac{-1}{\sqrt{1-x^2}} \right) +$$

$$+ B \cos(\sqrt{\lambda} \cos^{-1} x) \sqrt{\lambda} \left(-\frac{1}{\sqrt{1-x^2}} \right) \text{ for } \lambda \neq 0$$

and

$$y'(x) = 0 + D \left(\frac{-1}{\sqrt{1-x^2}} \right) \text{ for } \lambda = 0$$

and bounded at $x = \pm 1$ only if $B = D = 0$ and $\sqrt{\lambda} = n = 1, 2, 3, \dots$. Thus the eigen functions of (1) in terms of θ are. $\cos n\theta$, $n = 1, 2, \dots$ and 1 or

* Pafnuti Chebyshev (1821–1894), Russian mathematician, often transliterated as Tchebichef or Tschebysheff.

11.36 — HIGHER ENGINEERING MATHEMATICS—III

equivalently, $\cos n\theta$, for $n = 0, 1, 2, \dots$. Thus the eigenvalues are

$$\lambda_n = n^2 \quad (5)$$

and eigen functions of Chebyshev D.E. (1), are

$$T_n(x) = \cos \sqrt{\lambda} \theta = \cos n\theta \quad (6)$$

$$T_n(x) = \cos(n \cos^{-1} x), \quad n = 0, 1, 2, \dots$$

Here T is used in honour of Chebyshev.

Note: Since $T_n(1) = 1$ and $T_n(-1) = (-1)^n$ (See W.E.: 6) so for $-1 \leq x \leq 1$, $|T_n(x)| \leq 1$.

Chebyshev Polynomial

Consider

$$\begin{aligned} T_n(x) &= \cos(n\theta) \\ &= \frac{1}{2}[e^{in\theta} + e^{-in\theta}] \\ &= \frac{1}{2}[(\cos \theta + i \sin \theta)^n + (\cos \theta - i \sin \theta)^n] \\ &= \frac{1}{2}[x + i\sqrt{1-x^2}]^n + \frac{1}{2}[x - i\sqrt{1-x^2}]^n \end{aligned}$$

Expanding by binomial series

$$\begin{aligned} T_n(x) &= \frac{1}{2} \sum_{m=0}^n {}^nC_m x^{n-m} (i\sqrt{1-x^2})^m + \\ &\quad + \frac{1}{2} \sum_{m=0}^n {}^nC_m x^{n-m} (-i\sqrt{1-x^2})^m \\ &= \frac{1}{2} \sum_{m=0}^n {}^nC_m x^{n-m} \{1^n + (-1)^m\} i^m (1-x^2)^{m/2} \end{aligned}$$

when m is odd, $1^m + (-1)^m = 0$. When m is even, $1^m + (-1)^m = 2$.

Take $m = 2r$ and $m \leq n$ i.e., $r \leq \frac{n}{2}$. Put $N = \left[\frac{n}{2}\right]$,

$$\begin{aligned} T_n(x) &= \sum_{r=0}^N {}^nC_{2r} x^{n-2r} i^{2r} (1-x^2)^r \\ &= \sum_{r=0}^N {}^nC_{2r} (-1)^r (1-x^2)^r x^{n-2r} \end{aligned}$$

since $i^{2r} = (i^2)^r = (-1)^r$. Thus

$$T_n(x) = \sum_{m=0}^N (-1)^m \frac{n!}{(2m)!(n-2m)!} x^{n-2m} \quad (7)$$

where $N = \left[\frac{n}{2}\right]$ is $\frac{n}{2}$ when n is even and $N = \frac{n+1}{2}$ when n is odd.

$T_n(x)$ given by (7) is an n th degree polynomial in x .

$T_n(x)$ which is a solution of D.E. (1) is known as Chebyshev polynomial (of the first kind).

In the expanded form, the Chebyshev polynomial is given by

$$\begin{aligned} T_n(x) &= 2^{n-1} \left[x^n - \frac{n}{1!2^2} x^{n-2} + \frac{n(n-3)}{2!2^4} x^{n-4} \right. \\ &\quad \left. - \frac{n(n-4)(n-5)}{3!2^6} x^{n-6} + \dots \right] \end{aligned}$$

Derivation of Chebyshev Polynomials

Since $T_n(x) = \cos n\theta$, for $n = 0$

$$T_0(x) = \cos 0 = 1$$

$$\text{For } n = 1, T_1(x) = \cos \theta = x$$

$$\text{For } n = 2, T_2(x) = \cos 2\theta = 2\cos^2 \theta - 1 = 2x^2 - 1$$

$$\text{For } n = 3, T_3(x) = \cos 3\theta = 4\cos^3 \theta - 3\cos \theta = 4x^3 - 3x$$

$$\text{For } n = 4, T_4(x) = \cos 4\theta =$$

$$8\cos^4 \theta - 8\cos^2 \theta + 1 = 8x^4 - 8x^2 + 1$$

$$\begin{aligned} \text{For } n = 5, T_5(x) &= \cos 5\theta = 16\cos^5 \theta - 20\cos^3 \theta + 5\cos \theta \\ &= 16x^5 - 20x^3 + 5x \end{aligned}$$

Fig. 11.2

Graphs of $T_0(x)$, $T_1(x)$, $T_2(x)$, $T_3(x)$, $T_4(x)$,

$$T_6(x) = 32x^6 - 48x^4 + 18x^2 - 1.$$

Thus $T_n(x)$ is even polynomial when n is even and odd polynomial when n is odd.

Powers of x in terms of $T_n(x)$

We can express x^n in terms of the Chebyshev polynomials $T_n(x)$ by solving the above results. Thus

$$1 = T_0$$

$$x = T_1$$

$$x^2 = \frac{1}{2}(T_2 + 1) = \frac{1}{2}(T_0 + T_2)$$

$$x^3 = \frac{1}{4}(T_3 + 3x) = \frac{1}{4}(3T_1 + T_3)$$

$$x^4(T_4 + 8x^2 - 1)/8$$

or

$$x^4 = \frac{1}{8} \left[T_4 + 8 \left\{ \frac{1}{2}(T_0 + T_2) \right\} - T_0 \right]$$

$$= \frac{1}{8} [3T_0 + 4T_2 + T_4]$$

$$x^5 = (T_5 + 20x^3 - 5x)/16$$

$$x^5 = \frac{1}{16} \left[T_5 + 20 \left\{ \frac{1}{4}(3T_1 + T_3) \right\} - 5T_1 \right]$$

$$= \frac{1}{16} [10T_1 + 5T_3 + T_5]$$

Now

$$x^6 = (T_6 + 48x^4 - 18x^2 + 1)/32$$

or

$$x^6 = \left[T_6 + \frac{48}{8}(3T_0 + 4T_2 + T_4) - \frac{18}{2}(T_0 + T_2) + T_0 \right] / 32$$

Thus

$$x^6 = \frac{1}{32} [10T_0 + 15T_2 + 6T_4 + T_6]$$

Note that the coefficient of x^n in $T_n(x)$ is always 2^{n-1} (see exercise example 7 on page 11.44).

Zeros of $T_n(x)$

Equating to zero, we get

$$T_n(x) = \cos(n \cos^{-1} x) = 0$$

Then

$$n \cos^{-1} x = (2k + 1) \frac{\pi}{2} \text{ for } k = 0, 1, 2, \dots, (n - 1)$$

or $x = \cos \frac{(2k+1)\pi}{2n}$ are the n simple zeros of $T_n(x)$.

Extrema of $T_n(x)$

The stationary points of $T_n(x)$ are given by

$$T'_n(x) = \frac{n \cdot \sin(n \cos^{-1} x)}{\sqrt{1 - x^2}} = 0.$$

or $n \cos^{-1} x = K\pi$. Thus $x_k = \cos \left(\frac{K\pi}{n} \right)$ for $K = 1, 2, \dots, n - 1$ are the $(n - 1)$ stationary points. The extrema at these $(n - 1)$ points are

$$T_n(x_k) = \cos(n \cos^{-1} x_k) = \cos(K\pi) = (-1)^k$$

Also we know that (worked example 6) at the end points of the interval $(-1, 1)$, $T_n(-1) = (-1)^n$ and $T_n(1) = 1$. Thus $T_n(x)$ attains extrema at $(n + 1)$ points given by

$$x_K = \cos \left(\frac{K\pi}{n} \right)$$

where $K = 0, 1, 2, \dots, n$.

Integrals of $T_n(x)$

With $x = \cos \theta$, $dx = -\sin \theta d\theta$,

$$\int T_n(x) dx = \int \cos(n\theta) \cdot (-\sin \theta) d\theta$$

$$= \frac{1}{2} \int (\sin(n - 1)\theta - \sin(n + 1)\theta) d\theta$$

$$= \frac{1}{2} \left[\frac{\cos(n + 1)\theta}{n + 1} - \frac{\cos(n - 1)\theta}{n - 1} \right]$$

$$= \frac{1}{2} \left[\frac{1}{n + 1} T_{n+1}(x) - \frac{1}{n - 1} \cdot T_{n-1}(x) \right] \text{ for } n \geq 2$$

For $n = 0$, $\int T_0(x) dx = x = T_1$ and for $n = 1$, $\int T_1(x) dx = \frac{x^2}{2} = \frac{1}{4} [T_0 + T_2]$.

Generating Function

Prove that

$$\frac{1 - xt}{1 - 2xt + t^2} = \sum_{n=0}^{\infty} T_n(x) \cdot t^n, \quad -1 < t < 1 \quad (8)$$

11.38 — HIGHER ENGINEERING MATHEMATICS—III

Note: LHS of (8) is known as the generating function of the Chebyshev polynomials.

Proof: Put $x = \cos \theta$ then

$$\text{L.H.S.} = \frac{1 - xt}{1 - 2xt + t^2} = \frac{1 - t \cdot \cos \theta}{1 - 2t \cos \theta + t^2}$$

Replacing $\cos \theta$ by $(e^{i\theta} + e^{-i\theta})/2$, we have

$$\begin{aligned} \text{L.H.S.} &= \frac{1}{2} \left[\frac{2 - t(e^{i\theta} + e^{-i\theta})}{1 - t(e^{i\theta} + e^{-i\theta}) + t^2} \right] \\ &= \frac{1}{2} \left[\frac{2 - t(e^{i\theta} + e^{-i\theta})}{(1 - te^{i\theta})(1 - te^{-i\theta})} \right] \\ &= \frac{1}{2} \left[\frac{1}{1 - te^{i\theta}} + \frac{1}{1 - te^{-i\theta}} \right] \end{aligned}$$

Expanding by binomial series

$$\begin{aligned} &= \frac{1}{2} \left[\sum_{n=0}^{\infty} (te^{i\theta})^n + \sum_{n=0}^{\infty} (te^{-i\theta})^n \right] \\ &= \frac{1}{2} \sum_{n=0}^{\infty} t^n (e^{in\theta} + e^{-in\theta}). \end{aligned}$$

Thus

$$\frac{1 - xt}{1 - 2xt + t^2} = \sum_{n=0}^{\infty} t^n \cdot \cos n\theta = \sum_{n=0}^{\infty} T_n(x)t^n$$

Orthogonality

Prove that

$$\int_{-1}^1 \frac{1}{\sqrt{1-x^2}} \cdot T_m(x) \cdot T_n(x) dx = \begin{cases} 0 & \text{if } m \neq n \\ \frac{\pi}{2} & \text{if } m = n \neq 0 \\ \pi & \text{if } m = n = 0 \end{cases} \quad (9)$$

ie, the Chebyshev polynomials are orthogonal on $(-1, 1)$ w.r.t. the weight function

$$\frac{1}{\sqrt{1-x^2}}$$

Proof: We know that $x = \cos \theta$, $dx = -\sin \theta d\theta$, $\sqrt{1-x^2} = \sin \theta$, $T_m(x) = \cos m\theta$, $T_n(x) = \cos n\theta$, and limits: $\theta = 0$ when $x = 1$ and $\theta = \pi$ when $x = -1$.

Now

$$\begin{aligned} I &= \int_{-1}^1 \frac{1}{\sqrt{1-x^2}} \cdot T_m(x) T_n(x) dx \\ &= \int_{\pi}^0 \frac{1}{\sin \theta} \cdot \cos m\theta \cdot \cos n\theta \cdot (-\sin \theta) d\theta \\ &= \int_0^{\pi} \cos m\theta \cdot \cos n\theta d\theta \end{aligned}$$

Case (i) when $m \neq n$

$$\begin{aligned} I &= \frac{1}{2} \int_0^{\pi} [\cos(m+n)\theta + \cos(m-n)\theta] d\theta \\ &= \frac{1}{2} \left[\frac{\sin(m+n)\theta}{m+n} + \frac{\sin(m-n)\theta}{m-n} \right]_0^{\pi} = 0 \end{aligned}$$

Case (ii) when $m = n \neq 0$

$$\begin{aligned} I &= \int_0^{\pi} \cos^2 n\theta d\theta = \frac{1}{2} \int_0^{\pi} (1 + \cos 2n\theta) d\theta \\ &= \frac{1}{2} \left[\theta + \frac{\sin 2n\theta}{2n} \right]_0^{\pi} = \frac{\pi}{2} \end{aligned}$$

Case (iii) when $m = n = 0$

$$I = \int_0^{\pi} 1 \cdot 1 \cdot d\theta = \pi$$

Recall that

$$\int_0^{\pi} \cos m\theta \cdot \cos n\theta \cdot d\theta = \begin{cases} 0, & m \neq n \\ \frac{\pi}{2}, & m = n \neq 0 \\ \pi, & m = n = 0 \end{cases}$$

Recurrence Relations

I. Prove that $T_{n+1}(x) + T_{n-1}(x) = 2xT_n(x)$.

Proof:

$$\begin{aligned} T_{n+1}(x) + T_{n-1}(x) &= \cos(n+1)\theta + \cos(n-1)\theta \\ &= 2 \cos n\theta \cdot \cos \theta = 2T_n(x) \cdot x = 2xT_n(x) \end{aligned}$$

II. Prove that

$$(1-x^2)T_n'(x) = n\{T_{n-1}(x) - xT_n(x)\}$$

Proof: Differentiating w.r.t. x

$$\begin{aligned}\frac{d}{dx}T_n(x) &= \frac{d}{dx}\{\cos(n\theta)\} = \frac{d}{dx}\{\cos(n \cos^{-1} x)\} \\ &= -\sin(n \cos^{-1} x) \cdot n \cdot \left(-\frac{1}{\sqrt{1-x^2}}\right) \\ \sqrt{1-x^2}T'_n(x) &= n \cdot \sin(n\theta)\end{aligned}$$

Multiplying by

$$\sqrt{1-x^2} = \sin \theta$$

we get

$$\begin{aligned}(1-x^2)T'_n(x) &= n \cdot \sin \theta \cdot \sin(n\theta) \\ &= \frac{1}{2}n \cdot [\cos(n-1)\theta - \cos(n+1)\theta] \\ &= \frac{n}{2}[T_{n-1}(x) - T_{n+1}(x)]\end{aligned}$$

Eliminate $T_{n+1}(x)$ using RRI i.e., $T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$ then

$$\begin{aligned}(1-x^2)T'_n(x) &= \frac{n}{2}[T_{n-1}(x) - 2xT_n(x) + T_{n-1}(x)] \\ &= n[T_{n-1}(x) - xT_n(x)]\end{aligned}$$

Chebyshev Series

The Chebyshev D.E. (1) can be written as

$$y'' - \frac{x}{(1-x^2)}y' + \frac{\lambda}{(1-x^2)}y = 0$$

with an integrating factor $e^{\int \frac{-x}{(1-x^2)}dx} = e^{+\frac{1}{2}\ln(1-x^2)} = \sqrt{1-x^2}$. Multiplying through-out by this integrating factor, the D.E. takes the form

$$\sqrt{1-x^2}y'' - \frac{x}{\sqrt{1-x^2}}y' + \frac{\lambda}{\sqrt{1-x^2}}y = 0$$

or in the Sturm-Liouville equation form

$$\left[\sqrt{1-x^2}y'\right]' + \frac{1}{\sqrt{1-x^2}}\lambda y = 0 \quad (10)$$

with the weight function $P(x) = \frac{1}{\sqrt{1-x^2}}$. The eigen-values of (10) are

$$\lambda_n = n^2, \quad n = 0, 1, 2, \dots \quad (5)$$

and eigen functions are

$$T_n(x) = \cos(n \cos^{-1} x) \quad (6)$$

Any given piecewise continuous function $f(x)$ on $-1 < x < 1$, can be expanded in terms of the eigen functions (6) as

$$f(x) = a_0T_0(x) + a_1T_1(x) + a_2T_2(x) + \dots$$

or

$$f(x) = \sum_{n=0}^{\infty} a_n T_n(x) \quad (11)$$

The infinite series (11) is known as Chebyshev series which expresses $f(x)$ in terms of Chebyshev polynomials $T_n(x)$. The unknown coefficients a_n 's are determined using the orthogonality property (9). Multiplying (11) on both sides $T_n(x) \cdot \frac{1}{\sqrt{1-x^2}}$ and integrating w.r.t. x from -1 to 1 , we get

$$\begin{aligned}\int_{-1}^1 \frac{1}{\sqrt{1-x^2}} f(x) T_n(x) dx &= \\ \int_{-1}^1 \frac{1}{\sqrt{1-x^2}} T_n \left(\sum_{m=0}^{\infty} a_m T_m(x) \right) dx \\ &= \sum_{m=0}^{\infty} a_m \int_{-1}^1 \frac{1}{\sqrt{1-x^2}} T_n(x) \cdot T_m(x) dx\end{aligned}$$

From (9) for $m = n = 0$, the RHS reduces to $a_0\pi$ while all other coefficients are zero (because of orthogonality). Thus

$$a_0 = \frac{1}{\pi} \int_{-1}^1 \frac{1}{\sqrt{1-x^2}} f(x) dx \quad (12)$$

since $T_0(x) = 1$.

From (9) for $m = n \neq 0$, the RHS reduces to $\frac{\pi a_n}{2}$. Thus

$$a_n = \frac{2}{\pi} \int_{-1}^1 \frac{1}{\sqrt{1-x^2}} f(x) T_n(x) dx \quad (13)$$

for $n = 1, 2, 3, \dots$

WORKED OUT EXAMPLES

Example 1: Prove that $T_n(x) - 2xT_{n-1}(x) + T_{n-2}(x) = 0$

11.40 — HIGHER ENGINEERING MATHEMATICS—III

Solution: Consider $T_n(x) + T_{n-2}(x)$

$$\begin{aligned} &= \cos n\theta + \cos(n-2)\theta \\ &= \cos n\theta + \cos n\theta \cdot \cos 2\theta + \sin n\theta \cdot \sin 2\theta \\ &= \cos n\theta(1 + \cos 2\theta) + \sin n\theta \cdot 2 \sin \theta \cdot \cos \theta \\ &= \cos n\theta \cdot 2 \cdot \cos^2 \theta + 2 \sin \theta - \cos \theta \cdot \sin n\theta \\ &= 2 \cos \theta [\cos n\theta \cdot \cos \theta + \sin \theta \cdot \sin n\theta] \\ &= 2 \cos \theta [\cos(n-1)\theta] \\ &= 2x \cdot T_{n-1}(x) \end{aligned}$$

Example 2: Prove that

$$T_{m+n}(x) + T_{m-n}(x) = 2T_m(x) \cdot T_n(x)$$

Solution:

$$\begin{aligned} &T_{m+n}(x) + T_{m-n}(x) \\ &= \cos(m+n)\theta + \cos(m-n)\theta \\ &= [\cos m\theta \cdot \cos n\theta - \sin m\theta \cdot \sin n\theta] + \\ &\quad [\cos m\theta \cdot \cos n\theta + \sin m\theta \cdot \sin n\theta] \\ &= 2 \cos m\theta \cdot \cos n\theta = 2T_m(x)T_n(x). \end{aligned}$$

Example 3: Show that

$$2[T_n(x)]^2 = 1 + T_{2n}(x)$$

Solution: Consider

$$\begin{aligned} &2[T_n(x)]^2 - T_{2n}(x) = \\ &= 2 \cos^2 n\theta - \cos 2n\theta = 2 \cos^2 n\theta - (\cos^2 n\theta - \sin^2 n\theta) \\ &= \cos^2 n\theta + \sin^2 n\theta = 1 \end{aligned}$$

Example 4: Prove that

$$\int_{-1}^1 x^6 (1-x^2)^{-\frac{1}{2}} T_8(x) dx = 0$$

Solution: Put $x = \cos \theta$, $1 - x^2 = \sin^2 \theta$, when $x = 1$, $\theta = 0$ and $x = -1$, $\theta = \pi$. Substituting in the integral

$$\begin{aligned} I &= \int_{-1}^1 x^6 (1-x^2)^{-\frac{1}{2}} T_8(x) dx \\ &= \int_{\pi}^0 \cos^6 \theta \cdot \frac{1}{\sin \theta} \cdot T_8(\cos \theta) \cdot (-) \sin \theta d\theta \end{aligned}$$

$$= \int_0^{\pi} \cos^6 \theta \cdot \cos 8\theta d\theta$$

Now $\cos^6 \theta = \cos^3 \theta \cdot \cos^3 \theta$

$$\begin{aligned} &= \frac{1}{4} [\cos 3\theta + 3 \cos \theta] \frac{1}{4} [\cos 3\theta + 3 \cos \theta] \\ &= \frac{1}{16} [\cos^2 3\theta + 9 \cos^2 \theta + 6 \cos \theta \cos 3\theta] \\ &= \frac{1}{16} \left[\left(\frac{1 + \cos 6\theta}{2} \right) + 9 \left(\frac{1 + \cos 2\theta}{2} \right) \right. \\ &\quad \left. + 3(\cos 4\theta + \cos 2\theta) \right] \end{aligned}$$

$$I = \int_0^{\pi} \frac{1}{32} [\cos 6\theta + 6 \cos 4\theta + 15 \cos 2\theta + 10]$$

$$\cos 8\theta d\theta = 0$$

since

$$\int_0^{\pi} \cos m\theta \cdot \cos n\theta d\theta = 0$$

for $m \neq n$

Example 5: Derive $T_6(x)$ and $T_7(x)$.

Solution: Put $n = 5$ in the recurrence relation $T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$, then

$$T_6(x) = 2xT_5(x) - T_4(x)$$

Substituting $T_4(x) = 8x^4 - 8x^2 + 1$ and

$$T_5(x) = 16x^5 - 20x^3 + 5x$$

We have

$$T_6(x) = 2x[16x^5 - 20x^3 + 5x] - [8x^4 - 8x^2 + 1]$$

$$T_6(x) = 32x^6 - 48x^4 + 18x^2 - 1$$

Put $n = 6$ in the recurrence relation. Then

$$T_7(x) = 2xT_6(x) - T_5(x)$$

$$= 2x[32x^6 - 48x^4 + 18x^2 - 1] - [16x^5 - 20x^3 + 5x]$$

$$T_7(x) = 64x^7 - 112x^5 + 56x^3 - 7x.$$

Example 6: Prove that

$$(a) \quad T_n(1) = 1$$

- (b) $T_n(-1) = (-1)^n$
 (c) $T_{2n}(0) = (-1)^n$
 (d) $T_{2n+1}(0) = 0$

Solution: By definition

$$T_n(x) = \cos(n \cos^{-1} x) \quad (1)$$

- (a) Put $x = 1$ in (1). Then

$$T_n(1) = \cos(n \cos^{-1} 1) = \cos(n \cdot 0) = 1$$

- (b) Put $x = -1$ in (1). Then

$$T_n(-1) = \cos(n \cos^{-1}(-1)) = \cos(n\pi) = (-1)^n$$

[(c, d)] Put $x = 0$ in (1). Then

$$T_n(0) = \cos(n \cdot \cos^{-1} 0) = \cos\left(\frac{n\pi}{2}\right)$$

For $n = 2m$ = even,

$$T_n(0) = T_{2m}(0) = \cos\left(\frac{2m\pi}{2}\right) = (-1)^m$$

For $n = 2m + 1$ = odd

$$\begin{aligned} T_n(0) &= T_{2m+1}(0) = \cos\left\{(2m+1)\frac{\pi}{2}\right\} \\ &= \cos\left(m\pi + \frac{\pi}{2}\right) = (-1)^m \cdot \cos\frac{\pi}{2} = 0 \end{aligned}$$

Example 7: Express the polynomial $16x^4 + 12x^3 + 6x^2 + 4x - 1$ in terms of $T_n(x)$.

Solution: Substitute the values of x^4, x^3, x^2, x in the given polynomial; then

$$\begin{aligned} 16x^4 + 12x^3 + 6x^2 + 4x - 1 &= 16\frac{1}{8}[3T_0 + 4T_2 + T_4] + \\ &+ 12 \cdot \frac{1}{4}[3T_1 + T_3] + 6 \cdot \frac{1}{2}(T_0 + T_2) - T_0 \\ &= 2T_4 + 3T_3 + 11T_2 + 9T_1 + 8T_0 \end{aligned}$$

Example 8: Expand $f(x) = x^4 + 3x^3 + 2x^2 + 5x + 1$ as a Chebyshev series in terms of $T_n(x)$. Verify the result by direct substitution of x^n in $f(x)$.

Solution: The Chebyshev series in terms of Chebyshev polynomials is

$$f(x) = a_0T_0(x) + a_1T_1(x) + a_2T_2(x) + \dots$$

Here

$$a_0 = \frac{1}{\pi} \int_{-1}^1 \frac{f(x)}{\sqrt{1-x^2}} dx = \frac{1}{\pi} \int_{-1}^1 \frac{x^4 + 3x^3 + 2x^2 + 5x + 1}{\sqrt{1-x^2}} dx$$

Note that $\sqrt{1-x^2}$ is an even function and $\int_{-a}^a f(x)dx = 0$ when $f(x)$ is an odd function.

Thus $a_0 = \frac{2}{\pi} \int_0^1 \frac{x^4 + 2x^2 + 1}{\sqrt{1-x^2}} dx$. Put $x = \cos \theta$, so $dx = -\sin \theta d\theta$, $\sqrt{1-x^2} = \sqrt{1-\cos^2 \theta} = \sin \theta$, limits for θ : $x = 0, \theta = \frac{\pi}{2}$ and $x = 1, \theta = 0$. Then

$$a_0 = \frac{2}{\pi} \int_{\frac{\pi}{2}}^0 \frac{\cos^4 \theta + 2\cos^2 \theta + 1}{\sin \theta} (-\sin \theta) d\theta$$

$$a_0 = \frac{2}{\pi} \int_0^{\frac{\pi}{2}} (\cos^4 \theta + 2\cos^2 \theta + 1) d\theta$$

Recall that $\int_0^{\frac{\pi}{2}} \cos^n \theta d\theta = \frac{(n-1)(n-3)(n-5)\dots}{n(n-2)(n-4)\dots} \times \left(\frac{\pi}{2}\right)$ only when n is even).

$$\begin{aligned} a_0 &= \frac{2}{\pi} \left[\frac{3 \cdot 1}{4 \cdot 2} \cdot \frac{\pi}{2} + 2 \cdot \frac{1}{2} \cdot \frac{\pi}{2} + \frac{\pi}{2} \right] \\ &= \frac{3}{8} + 1 + 1 = \frac{19}{8} \end{aligned}$$

Now

$$a_n = \frac{2}{\pi} \int_{-1}^1 \frac{f(x)T_n(x)}{\sqrt{1-x^2}} dx \quad \text{for } n = 1, 2, 3, \dots$$

So

$$a_1 = \frac{2}{\pi} \int_{-1}^1 \frac{(x^4 + 3x^3 + 2x^2 + 5x + 1)x}{\sqrt{1-x^2}} dx$$

$$a_1 = \frac{4}{\pi} \int_0^1 \frac{3x^4 + 5x^2}{\sqrt{1-x^2}} dx$$

$$= \frac{4}{\pi} \int_0^{\frac{\pi}{2}} (3\cos^4 \theta + 5\cos^2 \theta) d\theta$$

11.42 — HIGHER ENGINEERING MATHEMATICS—III

$$a_1 = \frac{4}{\pi} \left[3 \cdot \frac{3 \cdot 1}{4 \cdot 2} + 5 \cdot \frac{1}{2} \right] \frac{\pi}{2} = \frac{29}{4}$$

Now

$$\begin{aligned} a_2 &= \frac{2}{\pi} \int_{-1}^1 \frac{(x^4 + 3x^3 + 2x^2 + 5x + 1)(2x^2 - 1)}{\sqrt{1-x^2}} dx \\ &= \frac{4}{\pi} \int_0^1 \frac{(2x^6 + 3x^4 - 1)}{\sqrt{1-x^2}} dx \\ &= \frac{4}{\pi} \int_0^{\pi/2} (2 \cos^6 \theta + 3 \cos^4 \theta - 1) d\theta \\ a_2 &= \frac{4}{\pi} \left[2 \cdot \frac{5 \cdot 3 \cdot 1}{6 \cdot 4 \cdot 2} + 3 \cdot \frac{3 \cdot 1}{4 \cdot 2} - 1 \right] \frac{\pi}{2} = \frac{3}{2} \end{aligned}$$

Now

$$\begin{aligned} a_3 &= \frac{2}{\pi} \int_{-1}^1 \frac{(x^4 + 3x^3 + 2x^2 + 5x + 1)(4x^3 - 3x)}{\sqrt{1-x^2}} dx \\ &= \frac{4}{\pi} \int_0^1 \frac{(12x^6 + 11x^4 - 15x^2)}{\sqrt{1-x^2}} dx \\ &= \frac{4}{\pi} \left[\int_0^{\pi/2} (12 \cos^6 \theta + 11 \cos^4 \theta - 15 \cos^2 \theta) d\theta \right] \\ &= \frac{4}{\pi} \left[12 \cdot \frac{5 \cdot 3 \cdot 1}{6 \cdot 4 \cdot 2} + 11 \cdot \frac{3 \cdot 1}{4 \cdot 2} - 15 \cdot \frac{1}{2} \right] \frac{\pi}{2} = \frac{3}{4} \end{aligned}$$

Finally

$$\begin{aligned} a_4 &= \frac{2}{\pi} \int_{-1}^1 \frac{(x^4 + 3x^3 + 2x^2 + 5x + 1)(8x^4 - 8x^2 + 1)}{\sqrt{1-x^2}} dx \\ &= \frac{4}{\pi} \int_0^1 \frac{(8x^8 + 8x^6 - 7x^4 - 6x^2 + 1)}{\sqrt{1-x^2}} dx \\ &= \frac{4}{\pi} \int_0^{\pi/2} (8 \cos^8 \theta + 8 \cos^6 \theta - 7 \cos^4 \theta - 6 \cos^2 \theta + 1) d\theta \\ &= \frac{4}{\pi} \left[8 \cdot \frac{7 \cdot 5 \cdot 3 \cdot 1}{8 \cdot 6 \cdot 4 \cdot 2} + 8 \cdot \frac{5 \cdot 3 \cdot 1}{6 \cdot 4 \cdot 2} - 7 \cdot \frac{3 \cdot 1}{4 \cdot 2} - 6 \cdot \frac{1}{2} + 1 \right] \frac{\pi}{2} \\ a_4 &= \frac{1}{8} \end{aligned}$$

All the remaining coefficients are zero i.e., $a_n = 0$ for $n \geq 5$ because of the result

$$\int_{-1}^1 \frac{x^m T_n(x)}{\sqrt{1-x^2}} dx = 0 \quad \text{when } m < n$$

(see W.E. 9 on page 11.43).

Here the given function $f(x) = x^4 + 3x^2 + 2x^2 + 5x + 1$ is a polynomial of degree $m = 4$ and $n \geq 5$.

Thus the required Chebyshev series is

$$\begin{aligned} f(x) &= x^4 + 3x^3 + 2x^2 + 5x + 1 \\ &= \frac{19}{8}T_0 + \frac{29}{8}T_1 + \frac{3}{2}T_2 + \frac{3}{4}T_3 + \frac{1}{8}T_4 \end{aligned}$$

Direct Verification

Substitution $x^4, x^3, x^2, x, 1$ in terms of $T_n(x)$, we have

$$\begin{aligned} x^4 + 3x^3 + 2x^2 + 5x + 1 &= \frac{1}{8}[3T_0 + 4T_2 + T_4] \\ &+ 3 \cdot \frac{1}{4}[3T_1 + T_3] + 2 \cdot \frac{1}{2}(T_0 + T_2) + 5 \cdot T_1 + T_0 \\ &= \frac{19}{8}T_0 + \frac{29}{8}T_1 + \frac{3}{2}T_2 + \frac{3}{4}T_3 + \frac{1}{8}T_4 \end{aligned}$$

Example 9: Show that $\int_{-1}^1 \frac{x^m T_n(x)}{\sqrt{1-x^2}} dx = 0$ when $m < n$.

Solution: By Chebyshev series

$$x^m = \sum_{i=0}^m a_i T_i(x)$$

For m even, all the odd coefficients $a_1, a_3, \dots$ will be zero, while for m odd, the even coefficients $a_0, a_2, a_4, \dots$ will be zero.

Now

$$\begin{aligned} \int_{-1}^1 \frac{x^m T_n(x)}{\sqrt{1-x^2}} dx &= \int_{-1}^1 \frac{\left[\sum_{i=0}^m a_i T_i(x) \right] T_n(x)}{\sqrt{1-x^2}} dx \sqrt{1-x^2} \\ &= \sum_{i=0}^m a_i \int_{-1}^1 \frac{T_i(x) \cdot T_n(x)}{\sqrt{1-x^2}} dx \end{aligned}$$

For $m < n$ since the index i takes the values $0, 1, 2, 3, \dots, m$, all, these indices are less than n and therefore not equal to n . Using orthogonality of Chebyshev polynomials the integral on the RHS vanishes for $i = 0, 1, 2, \dots, m$ each of which is not equal to n .

EXERCISE

1. Prove that $[T_n(x)]^2 - T_{n+1}(x) \cdot T_{n-1}(x) = 1 - x^2$

Hint: LHS = $\cos^2 n\theta - \cos(n+1)\theta \cdot \cos(n-1)\theta$
 $= \cos^2 \theta - (\cos^2 n\theta - \sin^2 \theta) = \sin^2 \theta = 1 - x^2$

2. Prove that

$$\frac{1-t^2}{1-2tx+t^2} = T_0(x) + 2 \sum_{n=1}^{\infty} T_n(x) \cdot t^n$$

Hint: Put $x = \cos \theta = \frac{1}{2}(e^{i\theta} + e^{-i\theta})$ in LHS

$$\sum_{r,s=0}^{\infty} t^{r+s} e^{i(r-s)\theta} - \sum_{r,s=0}^{\infty} t^{r+s+2} \cdot e^{i(r-s)\theta}$$

coefficient of t^0 , ($r = 0, s = 0$) : $T_0(x)$.

coefficient of t^1 : ($r = 0, s = 1$) : $2x = 2T_1(x)$

coefficient of t^n : ($s = n - r$) : $2 \cos n\theta = 2T_n(x)$.

3. Prove that $T_n(x)$ is a polynomial of n th degree in x .

4. Express the following polynomials in $T_n(x)$

- (a) $x^3 + 3x^2 - 5x + 2$
 (b) $5x^4 - x^3 + 3$
 (c) $12x^3 + 6x^2 + 4x + 1$
 (d) $16x^4 + 4x^3 + 2x^2 + 4x + 5$

- Ans. (a) $\frac{1}{4}T_3 + \frac{3}{2}T_2 - \frac{17}{4}T_1 + \frac{7}{2}T_0$
 (b) $\frac{5}{8}T_4 - \frac{1}{4}T_3 + \frac{5}{2}T_2 + \frac{9}{4}T_1 + \frac{15}{8}T_0$
 (c) $3T_3 + 3T_2 + 13T_1 + 4T_0$
 (d) $2T_4 + T_3 + 9T_2 + 7T_1 + 12T_0$

5. Express x^7 in terms of $T_n(x)$

Ans. $x^7 = (T_7 + 7T_5 + 21T_3 + 35T_1)/64$

Hint: $x^7 = (T_7 + 112x^5 - 56x^3 + 7x)/64$

6. Obtain the Chebyshev series of $f(x) = x^3 + x$.

Ans. $f(x) = x^3 + x = \frac{1}{4}(T_3 + 7T_1)$.

Hint: $a_0 = 0, a_1 = \frac{7}{4}, a_2 = 0, a_3 = \frac{1}{4}, a_n = 0$ for $n \geq 4$.

Note that $f(x) = x^3 + x$ is an odd function.

7. Show that the leading coefficient of x^n in $T_n(x)$ is 2^{n-1} .

Hint: $T_n(x) = \cos n\theta = \operatorname{Re}(e^{in\theta}) = \operatorname{Re}(\cos \theta)^n$
 $= \operatorname{Re}[\cos^n \theta - n c_2 \cos^{n-1} \theta \cdot \sin^2 \theta + n_{n_4} \cos^{n-4} \theta \cdot \sin^4 \theta + \dots] = x^n$
 $- n c_2 x^{n-2} \cdot (1 - x^2) + n_{c_4} x^{n-4} (1 - x^2) + \dots]$,
 coefficient of x^n is $1 + n_{c_2} + n_{c_4} + \dots = 2^{n-1}$.

8. Show that Chebyshev polynomials are solutions of Chebyshev differential equation.

Hint: $y = T_n(x) = \cos(n \cos^{-1} x)$,
 $y' = \frac{n \sin}{\sqrt{1-x^2}} (n \cos^{-1} x)$, $y'' = \frac{nx}{(1-x^2)^{3/2}} \times$
 $\cdot \sin(n \cos^{-1} x)$ or $(1 - x^2)y'' = xy' - n^2 y$

9. Determine $T_7(x)T_8(x), T_9(x), T_{10}(x)$ in powers of x

Ans. $T_7(x) = 64x^7 - 112x^5 + 56x^3 - 7x$
 $T_8(x) = 128x^8 - 256x^6 + 160x^4 - 32x^2 + 1$
 $T_9(x) = 256x^9 - 576x^7 + 432x^5 - 120x^3 + 9x$
 $T_{10}(x) = 512x^{10} - 1280x^8 + 1120x^6 - 400x^4 + 50x^2 - 1$

Chapter 12

Laplace Transform

INTRODUCTION

Laplace transform is useful since (i) particular solution is obtained without first determining the general solution, (ii) non homogeneous equations are solved without obtaining the complementary integral (iii) solutions of mechanical or electrical problems involving discontinuous force function (RHS function $F(x)$) or periodic functions other than cos and sine are obtained easily (iv) system of DE, PDE and integral equations.

Before the advent of calculators and computers, logarithms were extensively used to replace multiplication (or division) of two large numbers by addition (or subtraction) of two numbers. The crucial idea which made the Laplace* transform (L.T.) a very powerful technique is that it replaces operations of calculus by operations of algebra. For example, with the application of Laplace transform to an initial value problem, consisting of an ordinary (or partial) differential equation (O.D.E.) together with initial conditions (I.C.) is reduced to a problem of solving an algebraic equation (with any given initial conditions automatically taken care) as shown in Fig. 12.1.

12.1 LAPLACE TRANSFORM

Definition: Let $f(t)$ be a given function defined for all $t \geq 0$. Laplace transform of $f(t)$ denoted by

* Pierre Simon Marquis De Laplace (1749–1827), French mathematician, known as the Newton of France and teacher to Napoleon Bonaparte.

Fig. 12.1

$L\{f(t)\}$ or simply $L\{f\}$ is defined as

$$L\{f(t)\} = \int_0^{\infty} e^{-st} f(t) dt = F(s) \quad (1)$$

L is known as Laplace transform operator. The original given function $f(t)$ known as determining function depends on t , while the new function to be determined $F(s)$, called as generating function, depends only on s (because the improper integral on the R.H.S. of (1) is integrated with respect to t).

$F(s)$ in (1) is known as the Laplace transform of $f(t)$.

Equation (1) is known as direct transform or simply transform, in which $f(t)$ is given and $F(s)$ is to be determined.

Thus Laplace transform transforms one class of complicated functions $f(t)$ to produce another class of simpler functions $F(s)$.

Notation: Original given functions are denoted by lower case letters say $f(t)$ and their Laplace transforms by the *same* letters in capitals say $F(s)$. (Sometimes Laplace transform of $f(t)$ is denoted by $\bar{f}(s)$).

12.2 — HIGHER ENGINEERING MATHEMATICS—III

Laplace Transform of Some Elementary Functions

Example: Find Laplace transform of

$$f(t) = k$$

where k is a constant and $t \geq 0$.

Solution:

$$L\{f(t)\} = L\{k\} = \int_0^{\infty} e^{-st} k dt = -\frac{k}{s} e^{-st} \Big|_0^{\infty}$$

$$L\{k\} = \frac{k}{s} \quad \text{when } s > 0$$

Note: L.T. does not exist for $s \leq 0$

It follows for $k = 0$

$$L\{0\} = 0$$

for $k = 1$

$$L\{1\} = \frac{1}{s}$$

Example:

$$\begin{aligned} L\{e^{at}\} &= \int_0^{\infty} e^{-st} \cdot e^{at} dt = \int_0^{\infty} e^{-(s-a)t} dt \\ &= \frac{e^{-(s-a)t}}{-(s-a)} \Big|_{t=0}^{\infty} = \frac{1}{s-a} \end{aligned}$$

Thus $L\{e^{at}\} = \frac{1}{s-a}$ when $s > a$

Note: L.T. does not exist when $s \leq a$.

Example: Let $f(t) = t^b$, where b is non-negative real number i.e., $b > 0$, then

$$\begin{aligned} L\{t^b\} &= \int_0^{\infty} e^{-st} t^b dt, \quad \text{put } st = x \\ &= \int_0^{\infty} e^{-x} \left(\frac{x}{s}\right)^b \frac{dx}{s} = \frac{1}{s^{b+1}} \int_0^{\infty} e^{-x} x^b dx. \end{aligned}$$

$L\{t^b\} = \frac{1}{s^{b+1}} \Gamma(b+1)$ when $s > 0$ and $b+1 > 0$
Here the Gamma function is defined as

$$\Gamma(\alpha) = \int_0^{\infty} e^{-t} t^{\alpha-1} dt, \quad \text{with } \alpha > 0.$$

Example: When $b = n = \text{non-negative integer}$, then

$$L\{t^n\} = \frac{1}{s^{n+1}} \Gamma(n+1) = \frac{n!}{s^{n+1}}$$

Since $\Gamma(n+1) = n!$

Thus

$$L\{t^n\} = \frac{n!}{s^{n+1}} \quad \text{for } n = 0, 1, 2, 3, \dots$$

Example: When $b = \frac{1}{2}$

$$L\{t^{\frac{1}{2}}\} = \frac{\Gamma\left(\frac{1}{2} + 1\right)}{s^{\frac{1}{2}+1}} = \frac{\frac{1}{2} \Gamma\left(\frac{1}{2}\right)}{s^{\frac{3}{2}}} = \frac{\sqrt{\pi}}{2s^{\frac{3}{2}}}$$

since $\Gamma(\alpha+1) = \alpha\Gamma(\alpha)$ and $\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$.

Example: When $b = -\frac{1}{2}$

$$L\{t^{-\frac{1}{2}}\} = \frac{\Gamma\left(-\frac{1}{2} + 1\right)}{s^{-\frac{1}{2}+1}} = \frac{\Gamma\left(\frac{1}{2}\right)}{s^{\frac{1}{2}}} = \sqrt{\frac{\pi}{s}}.$$

WORKED OUT EXAMPLES

Laplace transform of piecewise continuous functions

Example 1: (refer Fig. 12.2)

$$\begin{aligned} f(t) &= 0, & 0 < t < 1 \\ &= t, & 1 < t < 4 \\ &= 0, & t > 4 \end{aligned}$$

Fig. 12.2

Solution:

$$\begin{aligned} L\{f\} &= \int_0^{\infty} e^{-st} f(t) dt \\ &= \int_0^1 0 \cdot e^{-st} dt + \int_1^4 t \cdot e^{-st} dt + \int_4^{\infty} 0 \cdot e^{-st} dt \end{aligned}$$

Integrating by parts

$$\begin{aligned} &= -\frac{t}{s} e^{-st} - \frac{e^{-st}}{s^2} \Big|_1^4 \\ &= e^{-s} \left(\frac{1}{s} + \frac{1}{s^2} \right) - e^{-4s} \left(\frac{4}{s} - \frac{1}{s^2} \right). \end{aligned}$$

EXERCISE**Piecewise continuous functions**

Find the Laplace Transform (L.T.) of the following piecewise continuous functions:

$$1. f(t) = \begin{cases} 4, & 0 < t < 1 \\ 3, & t > 1 \end{cases}$$

Ans. $\frac{1}{s}(4 - e^{-s})$

$$2. f(t) = \begin{cases} \sin 2t, & 0 < t \leq \pi \\ 0, & t > \pi \end{cases}$$

Ans. $\frac{2(1 - e^{-\pi s})}{s^2 + 4}$

$$3. f(t) = \begin{cases} e^t, & 0 < t < 1 \\ 0, & t > 1 \end{cases}$$

Ans. $\frac{e^{1-s} - 1}{1-s}$

$$4. f(t) = \begin{cases} t, & 0 \leq t < 1 \\ 2-t, & 1 \leq t < 2 \\ 0, & t \geq 2 \end{cases}$$

Ans. $\frac{1}{s^2}(1 - 2e^{-s} + e^{-2s})$.

12.2 APPLICATIONS, ADVANTAGES AND SUFFICIENT CONDITIONS FOR EXISTENCE OF LAPLACE TRANSFORM

Applications

Laplace transform is very useful in obtaining solution of linear differential equations, both ordinary and partial, solution of system of simultaneous differential equations, solution of integral equations, solution of linear difference equations and in the evaluation of definite integrals.

Advantages

1. With the application of Laplace transform, particular solution of differential equation (D.E.) is obtained directly without the necessity of first determining general solution and then obtaining the particular solution (by substitution of initial conditions).
2. L.T. solves non-homogeneous D.E. without the necessity of first solving the corresponding homogeneous D.E.

3. L.T. is applicable not only to continuous functions but also to piecewise continuous functions, complicated periodic functions, step functions and impulse functions.
4. Laplace transforms of various functions are readily available (in tabulated form). In Section 12.12 Laplace transforms of some most often used functions are tabulated.

Sufficient Conditions for the Existence of Laplace Transform of $f(t)$

The L.T. of $f(t)$ exists i.e., the improper integral in the R.H.S. of (1) converges (has a finite value) when the following sufficient conditions are satisfied:

- a. $f(t)$ is piecewise (or sectionally) continuous i.e., $f(t)$ is continuous in every subinterval and has finite limits at end points of each of these sub-intervals and
- b. $f(t)$ is of exponential order of γ i.e., there exists M, γ such that $|f(t)| < Me^{\gamma t}$. In other words functions of exponential order do *not* grow faster than $e^{\gamma t}$.

Example: Since $\lim_{t \rightarrow \infty} \frac{t^2}{e^{3t}} = \text{finite}$, $f(t) = t^2$ is of exponential order say 3.

Example: Since $\lim_{t \rightarrow \infty} \frac{e^{t^2}}{e^{\gamma t}} = \text{not finite}$, $f(t) = e^{t^2}$ is *not* of exponential order.

Note: Above conditions (a) and (b) are not necessary conditions.

12.3 GENERAL PROPERTIES OF LAPLACE TRANSFORM

Although theoretically $F(s)$, the Laplace transform of $f(t)$ is obtained from the definition (1) (in Section 12.2), in practice most of the time Laplace transforms are obtained by the judicious application of some of the following important properties. In a nutshell, they are:

1. Linearity property states that L.T. of a linear combination (sum) is the linear combination (sum) of Laplace transforms.
2. In change of scale, where the argument t of f is multiplied by a constant a , s is replaced by $\frac{s}{a}$ in $F(s)$ and then multiplied by $\frac{1}{a}$.

12.4 — HIGHER ENGINEERING MATHEMATICS—III

3. First shift theorem proves that multiplication of $f(t)$ by e^{at} amounts to replacement of s by $s - a$ in $F(s)$.
4. L.T. of a derivative f' amounts to multiplication of $F(s)$ by s (approximately but for the constant $-f(0)$).
5. L.T. of an integral of f amounts to division of $F(s)$ by s .
6. Multiplication of $f(t)$ by t^n amounts to differentiation of $F(s)$ n times w.r.t. s (with $(-1)^n$ as sign).
7. Division of $f(t)$ by t amounts to integration of $F(s)$ between the limits s to ∞ .
8. Second shift theorem proves that the L.T. of shifted function $f(t - a)u(t - a)$ is obtained by multiplying $F(s)$ by e^{-as} . The above important properties are tabulated in Section 12.12.

Linearity Property (Principle)

Book Work: If $L\{f(t)\} = F(s)$ and $L\{g(t)\} = G(s)$

$$\begin{aligned}\text{Then } L\{c_1 f(t) + c_2 g(t)\} &= c_1 L\{f(t)\} + c_2 L\{g(t)\} \\ &= c_1 F(s) + c_2 G(s)\end{aligned}$$

where c_1 and c_2 are any two constants.

Proof:

$$\begin{aligned}L\{c_1 f(t) + c_2 g(t)\} &= \int_0^\infty e^{-st} \{c_1 f(t) + c_2 g(t)\} dt \\ &= c_1 \int_0^\infty e^{-st} f(t) dt + c_2 \int_0^\infty e^{-st} g(t) dt \\ &= c_1 L\{f(t)\} + c_2 L\{g(t)\} \\ &= c_1 F(s) + c_2 G(s).\end{aligned}$$

Thus Laplace transform is a linear operator, additive and homogeneous (like the differential operator $D = \frac{d}{dx}$).

This result can easily be generalized to more than two functions.

Example: Find $L\{\cosh at\}$

$$\text{Solution: } L\{\cosh at\} = L\left\{\frac{e^{at} + e^{-at}}{2}\right\}$$

By Linearity property

$$L\{\cosh at\} = \frac{1}{2} L\{e^{at}\} + \frac{1}{2} L\{e^{-at}\}$$

$$L\{\cosh at\} = \frac{1}{2} \frac{1}{s - a} + \frac{1}{2} \frac{1}{s + a} = \frac{s}{s^2 - a^2}, s > a \geq 0.$$

Similarly,

$$\text{Example: } L\{\sinh at\} = \frac{a}{s^2 - a^2}$$

Example:

$$L\{e^{iwt}\} = \frac{1}{s - iw} = \frac{s + iw}{(s - iw)(s + iw)} = \frac{s + iw}{s^2 + w^2}$$

since $e^{i\theta} = \cos \theta + i \sin \theta$, by linearity property

$$\begin{aligned}L\{e^{iwt}\} &= L\{\cos wt + i \sin wt\} \\ &= L\{\cos wt\} + i L\{\sin wt\} \\ &= \frac{s + iw}{s^2 + w^2}\end{aligned}$$

Comparing the real and imaginary parts on both sides, we have

$$L\{\cos wt\} = \frac{s}{s^2 + w^2}$$

and

$$L\{\sin wt\} = \frac{w}{s^2 + w^2}.$$

WORKED OUT EXAMPLES

Linearity property

Find the Laplace transform of the following:

Example 1: $e^{at} - e^{bt}$

Solution:

$$\begin{aligned}L\{e^{at} - e^{bt}\} &= L\{e^{at}\} - L\{e^{bt}\} \\ &= \frac{1}{s - a} - \frac{1}{s - b} = \frac{a - b}{(s - a)(s - b)}\end{aligned}$$

Example 2: $\cos^2 kt$

Solution:

$$\begin{aligned}L\{\cos^2 kt\} &= L\left\{\frac{1 + \cos 2kt}{2}\right\} \\ &= \frac{1}{2} L\{1\} + \frac{1}{2} L\{\cos 2kt\} = \frac{1}{2} \frac{1}{s} + \frac{1}{2} \frac{s}{s^2 + 4k^2}.\end{aligned}$$

Example 3: $(5e^{2t} - 3)^2$ *Solution:*

$$\begin{aligned}
 L\{(5e^{2t} - 3)^2\} &= L\{25e^{4t} - 30e^{2t} + 9\} \\
 &= 25L\{e^{4t}\} - 30L\{e^{2t}\} + 9L\{1\} \\
 &= 25 \cdot \frac{1}{s-4} - 30 \frac{1}{s-2} + 9 \cdot \frac{1}{s}.
 \end{aligned}$$

Example 4: $3t^4 - 2t^3 + 4e^{-3t} - 2 \sin 5t + 3 \cos 2t$ *Solution:*

$$\begin{aligned}
 L\{3t^4 - 2t^3 + 4e^{-3t} - 2 \sin 5t + 3 \cos 2t\} \\
 &= 3L\{t^4\} - 2L\{t^3\} + 4L\{e^{-3t}\} - 2L\{\sin 5t\} \\
 &\quad + 3L\{\cos 2t\} \\
 &= 3 \frac{4!}{t^5} - 2 \frac{3!}{t^4} + 4 \frac{1}{s+3} - 2 \cdot \frac{5}{s^2+5^2} + 3 \cdot \frac{s}{s^2+2^2}.
 \end{aligned}$$

Example 5: $\cos \sqrt{t}$ *Solution:* Expanding in series

$$\cos \sqrt{t} = \sum_{n=0}^{\infty} \frac{(-1)^n (t^{\frac{1}{2}})^{2n}}{(2n)!} = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} t^n$$

$$L\{\cos \sqrt{t}\} = L\left\{\sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} t^n\right\}$$

By linearity principle

$$\begin{aligned}
 &= \sum_{n=0}^{\infty} L\left\{\frac{(-1)^n}{(2n)!} t^n\right\} \\
 &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} L\{t^n\} \\
 &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} \frac{n!}{s^{n+1}}.
 \end{aligned}$$

EXERCISE**Linearity property**

Find the Laplace transform of the following:

$$1. \left(\sqrt{t} \pm \frac{1}{\sqrt{t}}\right)^3$$

$$\text{Ans. } \frac{\sqrt{\pi}}{4} \left(\frac{3}{s^{\frac{5}{2}}} \pm \frac{6}{s^{\frac{3}{2}}} + \frac{12}{s^{\frac{1}{2}}} \pm \frac{8}{s^{-\frac{1}{2}}} \right)$$

$$2. \sin^2 kt$$

$$\text{Ans. } \frac{2k^2}{s(s^2+4k^2)}$$

$$3. 4e^{5t} + 6t^3 - 3 \sin 4t + 2 \cos 2t$$

$$\text{Ans. } \frac{4}{s-5} + \frac{36}{s^4} - \frac{12}{s^2+16} + \frac{2s}{s^2+4}$$

$$4. \cos^3 at$$

$$\text{Ans. } \frac{s(s^2+7a^2)}{(s^2+a^2)(s^2+9a^2)}$$

$$5. \cos 3t \cdot \cos 2t \cos t$$

$$\text{Ans. } \frac{1}{4} \left(\frac{s}{s^2+36} + \frac{s}{s^2+16} + \frac{s}{s^2+4} + \frac{1}{s} \right)$$

$$6. \sin \sqrt{t}$$

Hint: Use $\Gamma\left(n + \frac{1}{2}\right) = \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2^n} \sqrt{\pi}$ for n positive integer.

$$\text{Ans. } \frac{\sqrt{\pi}}{2s\sqrt{s}} \sum_{n=1}^{\infty} \frac{1}{(n-1)!} \left(-\frac{1}{4s}\right)^{n-1} = \frac{\sqrt{\pi}}{2s\sqrt{s}} e^{-\left(\frac{1}{4s}\right)}.$$

Change of Scale Property**Book Work:** If $L\{f(t)\} = F(s)$ then

$$L\{f(at)\} = \frac{1}{a} F\left(\frac{s}{a}\right).$$

Proof:

$$L\{f(at)\} = \int_0^{\infty} e^{-st} f(at) dt$$

Put $at = u$, $a dt = du$

$$\begin{aligned}
 L\{f(at)\} &= \int_0^{\infty} e^{-s\left(\frac{u}{a}\right)} f(u) \frac{du}{a} \\
 &= \frac{1}{a} \int_0^{\infty} e^{-\frac{s}{a}u} f(u) du
 \end{aligned}$$

$$L\{f(at)\} = \frac{1}{a} F\left(\frac{s}{a}\right)$$

Thus when the argument t of f is multiplied by a then s is replaced by $\frac{s}{a}$ in transform $F(s)$ and is multiplied by $\frac{1}{a}$.

WORKED OUT EXAMPLES**Change of scale**

Example 1: If $L\{f(t)\} = \frac{e^{-\frac{1}{s}}}{s}$ find $L\{e^{-t} f(3t)\}$.

12.6 — HIGHER ENGINEERING MATHEMATICS—III

Solution: From change of scale property with $a = 3$, replace s by $\frac{s}{3}$

$$L\{f(3t)\} = \frac{1}{3} \frac{e^{-\frac{3}{s}}}{\frac{s}{3}} = \frac{e^{-\frac{3}{s}}}{s}$$

Applying first shift theorem

$$L\{e^{-t} f(3t)\} = \frac{e^{-\frac{3}{s+1}}}{s+1}$$

Obtained by replacing s by $s - a = s - (-1) = s + 1$.

EXERCISE

Change of scale

1. If $L\left\{\frac{\sin t}{t}\right\} = \tan^{-1}\left(\frac{1}{s}\right)$ find $L\left\{\frac{\sin at}{t}\right\}$

Ans. $\tan^{-1}(a/s)$

2. If $L\{f(t)\} = \frac{20-4s}{s^2-4s+20}$ find $L\{f(3t)\}$

Ans. $4(15-s)/(s^2-12s+180)$

3. If $L\{\sin t\} = \frac{1}{s^2+1}$, find $L\{\sin 3t\}$

Ans. $\frac{3}{s^2+9}$.

First Shifting or First Translation or s-Shift Theorem: Replacement of s by $s-a$ in transform

Book Work: If $L\{f(t)\} = F(s)$ then

$$L\{e^{at} f(t)\} = F(s-a)$$

Proof: Consider $F(s-a) = \int_0^\infty e^{-(s-a)t} f(t) dt$

$$\begin{aligned} F(s-a) &= \int_0^\infty e^{-sa} \cdot \{e^{at} f(t)\} dt \\ &= L\{e^{at} f(t)\} \end{aligned}$$

Thus the Laplace transform of $f(t)$ multiplied by e^{at} is obtained by replacing s by $s-a$ in $F(s)$ which is the Laplace transform of $f(t)$.

Example: Find $L\{e^{at} \sin at\}$

Solution: We know that $L\{\sin at\} = \frac{a}{s^2+a^2}$.

By first shifting theorem, replace s by $s-a$ in $F(s)$, the Laplace transform of $\sin at$ i.e.,

$$L\{e^{at} \sin at\} = \frac{a}{s^2+a^2} \Big|_{s=s-a} = \frac{a}{(s-a)^2+a^2}$$

Similarly,

Example: $L\{e^{at} \cos at\} = \frac{s}{s^2+a^2} \Big|_{s=s-a} = \frac{s-a}{(s-a)^2+a^2}$

Example: $L\{e^{at} \sin wt\} = \frac{w}{(s-a)^2+w^2}$

Example: $L\{e^{at} \cos wt\} = \frac{s-a}{(s-a)^2+w^2}$

Example: $L\{e^{at} \cdot t^n\} = \frac{n!}{s^{n+1}} \Big|_{s=s-a} = \frac{n!}{(s-a)^{n+1}}$.

WORKED OUT EXAMPLES

Find the Laplace transform of $f(t)$:

Example 1: $f(t) = t^{\frac{7}{2}} e^{3t}$

Solution:

$$L\{t^{\frac{7}{2}}\} = \frac{\Gamma\left(\frac{7}{2}+1\right)}{s^{\frac{7}{2}+1}} = \frac{\frac{7}{2} \cdot \frac{5}{2} \cdot \frac{3}{2} \cdot \frac{1}{2} \Gamma\left(\frac{1}{2}\right)}{s^{\frac{9}{2}}} = \frac{105\sqrt{\pi}}{16s^{\frac{9}{2}}}$$

By first shift theorem,

$$L\{e^{3t} \cdot t^{\frac{7}{2}}\} = \frac{105\sqrt{\pi}}{16s^{\frac{9}{2}}} \Big|_{\text{at } s=s-3} = \frac{105\sqrt{\pi}}{16(s-3)^{\frac{9}{2}}}$$

Example 2: $\{3t^5 - 2t^4 + 4e^{-5t} - 3 \sin 6t + 4 \cos 4t\} e^{2t}$

Solution:

$$\begin{aligned} L\{3t^5 - 2t^4 + 4e^{-5t} - 3 \sin 6t + 4 \cos 4t\} \\ &= 3L\{t^5\} - 2L\{t^4\} + 4L\{e^{-5t}\} \\ &\quad - 3L\{\sin 6t\} + 4L\{\cos 4t\} \\ &= 3 \frac{5!}{s^6} - 2 \frac{4!}{s^5} + 4 \frac{1}{s+5} - 3 \frac{6}{s^2+36} + 4 \frac{s}{s^2+16} \end{aligned}$$

Applying first shift theorem,

$$\begin{aligned} L\{(3t^5 - 2t^4 + 4e^{-5t} - 3 \sin 6t + 4 \cos 4t) e^{2t}\} \\ &= \frac{360}{s^6} - \frac{48}{s^5} + \frac{4}{s+5} - \frac{18}{s^2+36} + \frac{4s}{s^2+16} \Big| \end{aligned}$$

with s replaced by $s - 2$

$$= \frac{360}{(s-2)^6} - \frac{48}{(s-2)^5} + \frac{4}{s+3} - \frac{18}{(s-2)^2+36} + \frac{4(s-2)}{(s-2)^2+16}.$$

Example 3: $f(t) = \cosh at \cdot \cos bt$

Solution:

$$\begin{aligned} L\{\cosh at \cdot \cos bt\} &= L\left\{\frac{1}{2}(e^{at} + e^{-at}) \cdot \cos bt\right\} \\ &= \frac{1}{2}L\{e^{at} \cos bt\} + \frac{1}{2}L\{e^{-at} \cos bt\} \end{aligned}$$

By first shift theorem,

$$\begin{aligned} &= \frac{1}{2} \frac{s}{s^2 + b^2} \Big|_{s=s-a} + \frac{1}{2} \frac{s}{s^2 + b^2} \Big|_{s=s+a} \\ &= \frac{1}{2} \frac{s-a}{(s-a)^2 + b^2} + \frac{1}{2} \frac{s+a}{(s+a)^2 + b^2}. \end{aligned}$$

EXERCISE

Find the Laplace transform of $f(t)$ given by:

1. $(t+2)^2 e^t$

Ans. $(4s^2 - 4s + 2)/(s-1)^3$

2. $e^{-4t} \cosh 2t$

Ans. $(s+4)/(s^2+8s+12)$

3. $\sinh at \sin at$

Ans. $2a^2 s/(s^4+4a^4)$

4. $e^{2t}(3 \sin 4t - 4 \cos 4t)$

Ans. $(20-4s)/(s^2-4s+20)$

5. $e^{-t} \sin^2 t$

Ans. $2/[(s+1)(s^2+2s+5)]$

6. $t \sin at$

Ans. $2as/(s^2+a^2)^2$

7. $t \cos at$

Hint: For problems 6 and 7

$$\begin{aligned} L\{t e^{iat}\} &= \frac{1}{s^2} \Big|_{s=s-ia} = \frac{1}{(s-ia)^2} \frac{(s+ia)^2}{(s+ia)^2} \\ &= \frac{s^2 - a^2 + 2ias}{(s^2 + a^2)^2} \end{aligned}$$

Comparing the real and imaginary parts on both sides, the results 6, 7 are obtained.

Ans. $(s^2 - a^2)/(s^2 + a^2)^2$

8. $\frac{t^{n-1}}{1-e^{-t}}$

Hint:

$$\begin{aligned} \frac{t^{n-1}}{1-e^{-t}} &= t^{n-1}(1-e^{-t})^{-1} \\ &= t^{n-1}(1+e^{-t}+e^{-2t}+e^{-3t}+\dots) \\ &= \sum_{m=0}^{\infty} t^{n-1} e^{-mt}. \end{aligned}$$

Ans. $\sum_{m=0}^{\infty} \frac{\Gamma(n)}{(s+m)^n}$

9. If $L\{f(t)\} = F(s)$ then prove that

a. $L\{\cosh at \cdot f(t)\} = \frac{1}{2}[F(s-a) + F(s+a)]$

b. $L\{\sinh at \cdot f(t)\} = \frac{1}{2}[F(s-a) - F(s+a)]$

Hint: Express $\cosh$, $\sinh$ in e^{at} and use first shifting theorem.

10. $e^{-2t} \sin^3 t$

Ans. $\frac{3}{4} \frac{1}{s^2+4s+5} - \frac{3}{4} \frac{1}{s^2+4s+13}$

11. $\sin^4 t \cdot e^{2t}$

Ans. $\frac{1}{8} \left[\frac{3}{s-2} - \frac{4(s-2)}{(s-2)^2+4} + \frac{s-2}{(s-2)^2+16} \right]$

12. $e^{4t} \sin 2t \cdot \cos t$

Ans. $\frac{1}{2} \left[\frac{3}{(s-4)^2+9} + \frac{1}{(s-4)^2+1} \right].$

Laplace Transform of Derivatives (Multiplication by s)

Differentiation of $f(t)$ is replaced by multiplication of the transform $F(s) = L(f)$ by s , roughly.

Theorem: Laplace transform of the derivative of $f(t)$ (Multiplication by s)

$$L\{f'\} = sL\{f\} - f(0) \quad (s > 0)$$

Proof:

$$\begin{aligned} L\{f'\} &= \int_0^{\infty} e^{-st} f' dt : \quad \text{Integrating by parts} \\ &= e^{-st} \cdot f \Big|_0^{\infty} + s \int_0^{\infty} e^{-st} f dt \end{aligned}$$

12.8 — HIGHER ENGINEERING MATHEMATICS—III

since f is of exponential order the first term is R.H.S. becomes zero at the upper limit ∞ . Thus

$$L\{f'\} = -f(0) + sL\{f\}.$$

Result 1: By applying the above theorem to f'' , we have

$$\begin{aligned} L\{f''\} &= sL\{f'\} - f'(0) \\ &= s\{sL\{f\} - f(0)\} - f'(0) \end{aligned}$$

$$\therefore L\{f''\} = s^2L\{f\} - sf(0) - f'(0)$$

Result 2: Similarly, for L.T. of derivatives of order n :

$$L\{f^{(n)}\} = s^n L\{f\} - s^{n-1}f(0) - s^{n-2}f'(0) - \dots - f^{(n-1)}(0).$$

Note: L.T. of functions (listed in the L.T. table) can also be (re)derived by the application of transform of derivative theorem.

WORKED OUT EXAMPLES

Find Laplace transform of the following functions using the theorem of transform of derivative:

Example 1: $f(t) = t^2$

Solution: $f(0) = 0, f'(0) = 0, f''(t) = 2$

By theorem

$$L\{f''\} = s^2L\{f\} - sf(0) - f'(0)$$

$$L\{2\} = s^2L\{t^2\} - s \cdot 0 - 0$$

$$\therefore L\{t^2\} = \frac{1}{s^2}L\{2\} = \frac{2}{s^2}L\{1\} = \frac{2}{s^2} \cdot \frac{1}{s} = \frac{2}{s^3}.$$

Example 2: $f(t) = t \cdot \cos at$

Solution:

$$f' = -at \cdot \sin at + \cos at$$

$$f'' = -a(at \cos at + \sin at) - a \sin at$$

$$f'' = -a^2t \cos at - 2a \sin at$$

$$f(0) = 0, f'(0) = 1$$

Using theorem for 2nd derivative

$$L\{-a^2t \cos at - 2a \sin at\} = s^2L\{t \cos at\} - s \cdot 0 - 1.$$

Rearranging

$$(s^2 + a^2)L\{t \cos at\} = 1 - 2aL\{\sin at\}$$

$$= 1 - 2a \cdot \frac{a}{s^2 + a^2}$$

$$= \frac{s^2 - a^2}{s^2 + a^2}$$

$$\therefore L\{t \cos at\} = \frac{s^2 - a^2}{(s^2 + a^2)^2}.$$

Example 3: Given $L\{\sin \sqrt{t}\} = \frac{\sqrt{\pi}}{2s^{\frac{3}{2}}} e^{-\frac{1}{4s}}$. Prove

that $L\left\{\frac{\cos \sqrt{t}}{\sqrt{t}}\right\} = \left(\frac{\pi}{s}\right)^{\frac{1}{2}} e^{-\frac{1}{4s}}$.

Solution: Take $f(t) = \frac{\cos \sqrt{t}}{\sqrt{t}}$

Since $\frac{\cos \sqrt{t}}{2\sqrt{t}}$ is the derivative of $\sin \sqrt{t}$, choose

$$g(t) = \sin \sqrt{t}, \quad \text{then} \quad g'(t) = \frac{\cos \sqrt{t}}{2\sqrt{t}}$$

$$g(0) = 0$$

Using theorem $L\{g'\} = sL\{g\} - g(0)$ we have

$$L\left\{\frac{\cos \sqrt{t}}{2\sqrt{t}}\right\} = s \cdot L\{\sin \sqrt{t}\} - 0$$

$$\frac{1}{2}L\left\{\frac{\cos \sqrt{t}}{\sqrt{t}}\right\} = s \cdot \sqrt{\pi} \cdot \frac{e^{-\frac{1}{4s}}}{2s^{\frac{3}{2}}}$$

$$L\left\{\frac{\cos \sqrt{t}}{\sqrt{t}}\right\} = \sqrt{\frac{\pi}{s}} \cdot e^{-\frac{1}{4s}}.$$

EXERCISE

Find the Laplace transform of the following functions using the theorem on transform of derivatives:

1. t^n Ans. $\frac{n!}{s^{n+1}}$

2. $\sin^2 t$ Ans. $\frac{2}{s(s^2+4)}$

3. $\cos at$ Ans. $\frac{s}{s^2+a^2}$

4. $t^2 \sin at$ Ans. $\frac{2a}{(s^2+a^2)^2} + \frac{4a(s^2-a^2)}{(s^2+a^2)^3}$

5. $t \cosh at$ Ans. $\frac{s^2+a^2}{(s^2-a^2)^2}$

Laplace Transform of the Integral of a Function

Just as division is the inverse operation of multiplication, differentiation and integration are inverse operations. Thus, while differentiation of a function corresponds to multiplication of the transform by s , integration of a function corresponds to division of the transform by s .

Theorem: Integration of $f(t)$ (Division by s).
If $L\{f(t)\} = F(s)$, then

$$L\left\{\int_0^t f(u)du\right\} = \frac{F(s)}{s}, \quad s > 0$$

Proof: Let $g(t) = \int_0^t f(u)du$. Then $g'(t) = f(t)$ and $g(0) = 0$

By derivative theorem

$$F(s) = L\{f(t)\} = L\{g'(t)\} = sL\{g(t)\} - g(0) \\ = s \cdot L\{g(t)\}$$

$$\therefore L\{g(t)\} = \frac{F(s)}{s}$$

$$\text{or } L\left\{\int_0^t f(u)du\right\} = \frac{F(s)}{s}.$$

Result: Similarly if $L\{f(t)\} = F(s)$, then

$$L\left\{\int_0^t dt_1 \int_0^{t_1} f(u)du\right\} = \frac{F(s)}{s^2}$$

The double integral can also be written briefly as

$$\int_0^t \int_0^t f(t)dt^2$$

Generalization for n th integral

$$L\left\{\int_0^t \int_0^t \dots \int_0^t f(t)dt\right\} = \frac{F(s)}{s^n}.$$

WORKED OUT EXAMPLES

Example 1: $L\left\{\int_0^t \frac{1-e^{-u}}{u} du\right\}$.

Solution: Here the integrand is $f(t) = (1 - e^{-t})/t$, we know that

$$L\{f(t)\} = L\left\{\frac{1 - e^{-t}}{t}\right\} = F(s) = \ln\left(1 + \frac{1}{s}\right)$$

Using the theorem of L.T. of integrals

$$L\left\{\int_0^t \frac{1 - e^{-u}}{u} du\right\} = \frac{1}{s} \cdot \ln\left(1 + \frac{1}{s}\right).$$

Example 2: $L\left\{\int_0^t \int_0^t \int_0^t \cos au du du du\right\}$

Solution: Here integrand is $f(t) = \cos at$

$$L\{f(t)\} = L\{\cos at\} = \frac{s}{s^2 + a^2}$$

Using the theorem on L.T. of integrals

$$L\left\{\int_0^t \cos au du\right\} = \frac{1}{s} \cdot \frac{s}{s^2 + a^2} = \frac{1}{s^2 + a^2}$$

Applying repeatedly.

$$L\left\{\int_0^t \int_0^t \cos au du du\right\} = \frac{1}{s} \cdot \frac{1}{s^2 + a^2} \\ \therefore L\left\{\int_0^t \int_0^t \int_0^t \cos au du du du\right\} = \frac{1}{s^2} \cdot \frac{1}{s^2 + a^2}.$$

Example 3: $L\left\{\int_0^t \frac{\sin u}{u} du\right\}$.

Solution: The integrand is $f(t) = \frac{\sin t}{t}$, we know that

$$L\{\sin t\} = \frac{1}{s^2 + 1}$$

Using division by t

$$L\left\{\frac{\sin t}{t}\right\} = \int_s^\infty \frac{du}{u^2 + 1} = \tan^{-1} \frac{1}{u} \Big|_s^\infty = \tan^{-1} \frac{1}{s}$$

$\therefore$ Using theorem on L.T. of integral

$$L\left\{\int_0^t \frac{\sin u}{u} du\right\} = \frac{1}{s} \tan^{-1} \frac{1}{s}.$$

Example 4: Show that $\int_{t=0}^\infty \int_{u=0}^t \frac{e^{-t} \sin u}{u} du dt = \frac{\pi}{4}$

Solution: The given double integral on the L.H.S. is the Laplace transform of $\int_0^t \frac{\sin u}{u} du$ with $s = 1$. We know that

$$L\left\{\int_0^t \frac{\sin u}{u} du\right\} = \int_{t=0}^\infty \int_{u=0}^t \frac{e^{-st} \sin u}{u} du dt \\ = \frac{1}{s} \tan^{-1} \frac{1}{s} \Big|_{s=1} = \tan^{-1} 1 = \frac{\pi}{4}.$$

12.10 — HIGHER ENGINEERING MATHEMATICS—III

Example 5: $L \left\{ \int_0^t u e^{-u} \cdot \sin 4u \, du \right\}$

Solution:

$$\begin{aligned} L\{\sin 4t\} &= \frac{4}{s^2 + 4^2} = \frac{4}{s^2 + 16} \\ L\{e^{-t} \sin 4t\} &= \frac{4}{(s+1)^2 + 16} = \frac{4}{s^2 + 2s + 17} \\ L\{t e^{-t} \sin 4t\} &= -\frac{d}{ds} \left[\frac{4}{s^2 + 2s + 17} \right] \\ &= \frac{4(2s+2)}{(s^2 + 2s + 17)^2} \\ \therefore L \left\{ \int_0^t u e^{-u} \sin 4u \, du \right\} &= \frac{8}{s} \frac{(s+1)}{(s^2 + 2s + 17)^2}. \end{aligned}$$

Example 6: $L \left\{ \sinh ct \int_0^t e^{au} \sinh bu \, du \right\}$

Solution:

$$\begin{aligned} L\{\sinh bt\} &= \frac{b}{s^2 - b^2} \\ L\{e^{at} \sinh bt\} &= \frac{b}{(s-a)^2 - b^2} \\ L \left\{ \int_0^t e^{au} \sinh bu \, du \right\} &= \frac{1}{s} \cdot \frac{b}{(s-a)^2 - b^2} \quad (*) \end{aligned}$$

Now consider

$$\begin{aligned} L\{\sinh ct \int_0^t e^{au} \sinh bu \, du\} &= L \left\{ \left(\frac{e^{ct} - e^{-ct}}{2} \right) \int_0^t e^{au} \sinh bu \, du \right\} \\ &= \frac{1}{2} L \left\{ e^{ct} \int_0^t e^{au} \sinh bu \, du \right\} \\ &\quad + \frac{1}{2} L \left\{ e^{-ct} \int_0^t e^{au} \sinh bu \, du \right\} \end{aligned}$$

Using (*)

$$\begin{aligned} &= \frac{1}{2} \frac{b}{s[(s-a)^2 - b^2]} \Big|_{s=s-c} + \frac{1}{2} \frac{b}{s[(s-a)^2 - b^2]} \Big|_{s=s+c} \\ &= \frac{1}{2} \frac{b}{(s-c)[(s-c-a)^2 - b^2]} \\ &\quad + \frac{1}{2} \frac{b}{(s+c)[(s+c-a)^2 - b^2]}. \end{aligned}$$

EXERCISE

Find the Laplace Transform of:

- $\int_0^t e^{-u} \cos u \, du$ *Ans.* $\frac{1}{s} \frac{(s+1)}{(s^2 + 2s + 2)}$
- $\int_0^t e^u \cdot \frac{\sin u}{u} \, du$ *Ans.* $\frac{1}{s} \cot^{-1}(s-1)$
- $\int_0^t \frac{e^{-4u} \sin 3u}{u} \, du$ *Ans.* $\frac{1}{s} \cot^{-1} \left(\frac{s+4}{3} \right)$
- $\cosh t \int_0^t e^u \cosh u \, du$ *Ans.* $\frac{1}{2} \left[\frac{s-2}{(s-1)^2(s-3)} + \frac{s}{(s+1)^2(s-1)} \right]$
- $e^{-4t} \int_0^t \frac{\sin 3u}{u} \, du$ *Ans.* $\frac{1}{s+4} \cot^{-1} \left(\frac{s+4}{3} \right)$

Differentiation of Transforms: Multiplication by t

Differentiation of the transform of a function corresponds to the multiplication of the function by $-t$.

Theorem: If $L\{f(t)\} = F(s)$ then

$$\begin{aligned} L\{-t f(t)\} &= \frac{d}{ds} F(s) \\ \text{or} \quad L\{t \cdot f(t)\} &= -\frac{d}{ds} F(s) \end{aligned}$$

In general,

$$L\{t^n f(t)\} = (-1)^n \frac{d^n}{ds^n} F(s), \quad \text{for } n = 1, 2, 3, \dots$$

Proof: We know that $F(s) = \int_0^\infty e^{-st} f(t) dt$.

By Leibnitz's rule for differentiating under the integral sign

$$\begin{aligned} \frac{dF(s)}{ds} &= \frac{d}{ds} \int_0^\infty e^{-st} f(t) dt = \int_0^\infty f(t) \left(\frac{\partial}{\partial s} e^{-st} \right) dt \\ &= \int_0^\infty f(t) \cdot (-t e^{-st}) dt \\ &= - \int_0^\infty e^{-st} \{t f(t)\} dt = -L\{t f(t)\} \\ \therefore L\{t f(t)\} &= -\frac{dF(s)}{ds} \end{aligned}$$

By mathematical induction the result for n th derivative follows.

WORKED OUT EXAMPLES

Example 1: Show that $L\{t \sin at\} = \frac{1}{(s-a)^2}$.

Solution:

$$L\{\sin at\} = \frac{a}{s^2 + a^2}$$

$$\therefore L\{t \cdot \sin at\} = -\frac{d}{ds} \left\{ \frac{a}{s^2 + a^2} \right\} = \frac{2as}{(s^2 + a^2)^2}.$$

Example 2: $L\{t \cdot e^{-2t} \sin t\}$.

Solution:

$$L\{\sin\} = \frac{1}{s^2 + 1}$$

$$L\{e^{-2t} \cdot \sin t\} = \frac{1}{(s+2)^2 + 1} = \frac{1}{s^2 + 4s + 5}$$

by first shift theorem.

Using theorem on multiplication by t

$$\begin{aligned} L\{t \cdot (e^{-2t} \cdot \sin t)\} &= -\frac{d}{ds} \left\{ \frac{1}{s^2 + 4s + 5} \right\} \\ &= \frac{2s + 4}{(s^2 + 4s + 5)^2}. \end{aligned}$$

Example 3: $L\{(t^2 - 3t + 2) \sin 3t\}$.

Solution:

$$L\{\sin 3t\} = \frac{3}{s^2 + 3^2} = \frac{3}{s^2 + 9}$$

$$\begin{aligned} L\{(t^2 - 3t + 2) \sin 3t\} &= L\{t^2 \cdot \sin 3t\} - 3L\{t \cdot \sin 3t\} \\ &\quad + 2L\{\sin 3t\}. \end{aligned}$$

Using multiplication by t

$$\begin{aligned} &= (-1)^2 \frac{d^2}{ds^2} \left\{ \frac{3}{s^2 + 9} \right\} - 3 \cdot (-1) \frac{d}{ds} \left\{ \frac{3}{s^2 + 9} \right\} \\ &\quad + 2 \cdot \frac{3}{s^2 + 9} \\ &= \frac{(-6 + 24s^2)}{(s^2 + 9)^3} + 3 \cdot \frac{(-6s)}{(s^2 + 9)^2} + \frac{6}{s^2 + 9} \\ &= \frac{6s^4 - 18s^3 + 126s^2 - 162s + 432}{(s^2 + 9)^3} \end{aligned}$$

Example 4: Show that $\int_0^\infty t^2 e^{-4t} \cdot \sin 2t \, dt = \frac{11}{500}$.

Solution: L.H.S. is rewritten as

$$\int_0^\infty e^{-4t} \cdot (t^2 \sin 2t) \, dt$$

i.e., it is L.T. of $t^2 \sin 2t$ with $s = 4$. We know that

$$L\{\sin 2t\} = \frac{2}{s^2 + 2^2} = \frac{2}{s^2 + 4}.$$

Using multiplication by t

$$\begin{aligned} L\{t^2 \sin 2t\} &= (-1)^2 \frac{d^2}{ds^2} \left\{ \frac{2}{s^2 + 4} \right\} = \frac{d}{ds} \left\{ \frac{-4s}{(s^2 + 4)^2} \right\} \\ &= -4 \cdot \frac{(4 - 3s^2)}{(s^2 + 4)^3} \Bigg|_{s=4} = \frac{11}{500}. \end{aligned}$$

EXERCISE

Find Laplace theorem using the theorem of differentiation of L.T.:

- | | |
|-----------------------------------|---|
| 1. $t \cos at$ | Ans. $\frac{s^2 - a^2}{(s^2 + a^2)^2}$ |
| 2. $t^2 \sin t$ | Ans. $\frac{6s^2 - 2}{(s^2 + 1)^3}$ |
| 3. $t \cdot \sinh 2t$ | Ans. $\frac{4s}{(s^2 - 4)^2}$ |
| 4. $t(3 \sin 2t - 2 \cos 2t)$ | Ans. $\frac{8 + 12s - 2s^2}{(s^2 + 4)^2}$ |
| 5. $t^3 \cdot \cos t$ | Ans. $\frac{6s^4 - 36s^2 + 6}{(s^2 + 1)^4}$ |
| 6. $t \cdot e^{at} \cdot \sin at$ | Ans. $\frac{2a}{(s-a)(s^2 - 2as + 2a^2)^2}$ |

Prove the following:

$$7. \int_0^\infty t \cdot e^{-3t} \cdot \sin t \, dt = \frac{3}{50}$$

Hint: L.T. of $t \sin t$ with $s = 3$

$$8. \int_0^\infty t^3 e^{-t} \cdot \sin t \, dt = 0$$

Hint: L.T. of $t^3 \sin t$ with $t = 1$

$$9. \int_0^\infty e^{-3t} t \cos t \, dt = \frac{2}{25}$$

Hint: L.T. of $t \cos t$ with $s = 3$

$$10. \int_0^\infty e^{-2t} \sin^3 t \, dt = \frac{6}{65}$$

Ans. L.T. of $\sin^3 t$ with $s = 2$.

Integration of Transform: Division by t

Integration of the transform of a function $f(t)$ corresponds to the division of $f(t)$ by t .

Theorem: If $L\{f(t)\} = F(s)$ then

$$L\left\{\frac{f(t)}{t}\right\} = \int_s^\infty F(u) \, du$$

12.12 — HIGHER ENGINEERING MATHEMATICS—III

Proof: $F(s) = L\{f(t)\} = \int_0^\infty e^{-st} f(t) dt$

Integrating on both sides w.r.t. s from s to ∞ , we have

$$\int_s^\infty F(u) du = \int_s^\infty \int_0^\infty e^{-st} f(t) dt.$$

Since s and t are independent variables, interchanging the order of integration, we get

$$\begin{aligned} \int_s^\infty F(u) du &= \int_0^\infty f(t) \left\{ \int_s^\infty e^{-st} ds \right\} dt \\ &= \int_0^\infty f(t) \left(\frac{e^{-st}}{-t} \right) \Big|_{s=s}^\infty dt \\ &= \int_0^\infty f(t) \cdot \left(\frac{-e^{-st}}{-t} \right) dt \\ &= \int_0^\infty e^{-st} \left(\frac{f(t)}{t} \right) dt = L \left\{ \frac{f(t)}{t} \right\}. \end{aligned}$$

WORKED OUT EXAMPLES

Find Laplace theorem of the following functions $f(t)$:

Example 1: $\frac{e^{-at} - e^{-bt}}{t}$

Solution:

$$\begin{aligned} L\{e^{-at} - e^{-bt}\} &= L\{e^{-at}\} - L\{e^{-bt}\} \\ &= \frac{1}{s+a} - \frac{1}{s+b}. \end{aligned}$$

Division by t amounts to integration

$$\begin{aligned} L \left\{ \frac{1}{t} (e^{-at} - e^{-bt}) \right\} &= \int_s^\infty \left(\frac{1}{u+a} - \frac{1}{u+b} \right) du = \ln \left(\frac{u+a}{u+b} \right) \Big|_s^\infty \\ &= 0 - \ln \left(\frac{s+a}{s+b} \right) = \ln \left(\frac{s+b}{s+a} \right). \end{aligned}$$

Example 2: $\frac{\sin^2 t}{t}$.

Solution:

$$\begin{aligned} L(\sin^2 t) &= L \left(\frac{1 - \cos 2t}{2} \right) = L \left(\frac{1}{2} \right) - \frac{1}{2} L(\cos 2t) \\ &= \frac{1}{2} \frac{1}{s} - \frac{1}{2} \frac{s}{s^2 + 2^2}. \end{aligned}$$

Using division by t

$$\begin{aligned} L \left\{ \frac{1}{t} \cdot \sin^2 t \right\} &= \frac{1}{2} \int_s^\infty \left(\frac{du}{u} - \frac{u du}{u^2 + 4} \right) \\ &= \frac{1}{2} \ln s - \frac{1}{4} \ln(s^2 + 4) \Big|_s^\infty \\ &= \ln \left(\frac{\sqrt{s}}{(s^2 + 4)^{\frac{1}{4}}} \right) \Big|_s^\infty = \frac{1}{4} \ln \left(\frac{s^2 + 4}{s^2} \right). \end{aligned}$$

Example 3: $\frac{\cos at - \cos bt}{t}$.

Solution:

$$\begin{aligned} L(\cos at - \cos bt) &= L(\cos at) - L(\cos bt) \\ &= \frac{s}{s^2 + a^2} - \frac{s}{s^2 + b^2} \end{aligned}$$

Using theorem on integration

$$\begin{aligned} L \left\{ \frac{1}{t} (\cos at - \cos bt) \right\} &= \int_s^\infty \left(\frac{s}{s^2 + a^2} - \frac{s}{s^2 + b^2} \right) ds \\ &= \frac{1}{2} \ln \left(\frac{s^2 + a^2}{s^2 + b^2} \right) \Big|_s^\infty = \frac{1}{2} \left[0 - \ln \left(\frac{s^2 + a^2}{s^2 + b^2} \right) \right] \\ &= \frac{1}{2} \ln \left(\frac{s^2 + b^2}{s^2 + a^2} \right). \end{aligned}$$

Example 4: $\int_0^\infty \frac{\cos 6t - \cos 4t}{t} dt$.

Solution: This integral can be looked upon as

$$\int_0^\infty e^{-0 \cdot t} \cdot \left(\frac{\cos 6t - \cos 4t}{t} \right) dt$$

so that the given integral is L.T. of $\frac{\cos 6t - \cos 4t}{t}$ with $s = 0$. From above Worked Out Example 3.

$$\begin{aligned} L \left(\frac{\cos 6t - \cos 4t}{t} \right)_{\text{with } s=0} &= \frac{1}{2} \ln \left(\frac{s^2 + b^2}{s^2 + a^2} \right) \Big|_{\substack{s=0 \\ a=6 \\ b=4}} = \ln \frac{2}{3}. \end{aligned}$$

Example 5: Evaluate $\int_0^\infty e^{-t} \frac{\sin^2 t}{t} dt$.

Solution: The given integral is the Laplace transform of $\frac{\sin^2 t}{t}$ with $s = 1$, i.e.,

$$\begin{aligned} L \left\{ \frac{\sin^2 t}{t} \right\} \Big|_{s=1} &= \int_0^\infty e^{-st} \cdot \frac{\sin^2 t}{t} dt \Big|_{s=1} \\ &= \int_0^\infty e^{-t} \frac{\sin^2 t}{t} dt. \end{aligned}$$

From Example 2 above, we know that

$$L \left\{ \frac{\sin^2 t}{t} \right\} = \frac{1}{4} \ln \left(\frac{s^2 + 4}{s^2} \right)$$

Thus

$$\begin{aligned} \int_0^\infty e^{-t} \frac{\sin^2 t}{t} dt &= L \left\{ \frac{\sin^2 t}{t} \right\} \Big|_{s=1} \\ &= \frac{1}{4} \ln \left(\frac{s^2 + 4}{s^2} \right) \Big|_{s=1} = \frac{1}{4} \ln 5. \end{aligned}$$

EXERCISE

1. $\frac{1-e^{2t}}{t}$ *Ans.* $\ln \frac{s-2}{s}$
2. $\frac{\sinh t}{t}$ *Ans.* $\frac{1}{2} \ln \left(\frac{s+1}{s-1} \right)$
3. $\frac{1-\cos at}{t}$ *Ans.* $\frac{1}{2} \ln \frac{s^2+a^2}{s}$
4. $\frac{\sin 3t \cdot \cos t}{t}$

Ans. $\frac{1}{2} \left[\pi - \tan^{-1} \left(\frac{s}{4} \right) - \tan^{-1} \left(\frac{s}{2} \right) \right]$

5. Show that $\int_0^\infty \frac{e^{-3t} - e^{-6t}}{t} dt = \ln 2$

Hint: Use Example 1 with $a = 3$, $b = 6$ and $s = 0$

6. Show that $\int_0^\infty \frac{\sin^2 t}{t^2} dt = \frac{\pi}{2}$

7. Find the L.T. of $\left\{ \int_0^t e^t \cdot \frac{\sin t}{t} dt \right\}$

Ans. $\frac{1}{s} \cot^{-1}(s-1)$

8. Show that $\int_0^\infty e^{-t} \cdot \frac{\sin^2 t}{t} dt = \frac{1}{2} \ln 5$

9. $\int_0^\infty e^{-2t} \frac{(2 \sin t - 3 \sinh t)}{t} dt = 2 \cot^{-1} 2 + \frac{3}{2} \log \left(\frac{1}{3} \right)$

Hint: L.T. of $\frac{2 \sin t - 3 \sinh t}{t}$ with $s = 2$.

Unit step function ("Heavisides"* unit function)

It is defined as (Fig. 12.3)

$$\begin{aligned} u(t-a) &= 0 & \text{if } t < a \\ &= 1 & \text{if } t > a \end{aligned}$$

Fig. 12.3

Note: $u(t-a)$ is also denoted as $u_a(t)$. In particular when $a = 0$,

$$\begin{aligned} u(t) &= 0 & \text{if } t < 0 \\ &= 1 & \text{if } t > 0 \end{aligned}$$

Multiplying a given function $f(t)$ with the "engineering function" the unit step function $u(t-a)$, several effects can be produced as shown in Fig. 12.4.

$f(t-3) u(t-3)$
Shifted to the
right by 3 units

Fig. 12.4

* Oliver Heaviside (1850–1925), English electrical engineer.

12.14 — HIGHER ENGINEERING MATHEMATICS—III

Second Translation (Or Second Shifting Theorem)

t-Shifting (replacing *t* by (*t* - *a*) in *f*(*t*))

Theorem: If $L\{f(t)\} = F(s)$ and the shifted function

$$g(t) = f(t - a)u(t - a) = \begin{cases} 0 & \text{if } t < a \\ f(t - a) & \text{if } t > a \end{cases}$$

Then

$$L\{g(t)\} = L\{f(t - a)u(t - a)\} = e^{-as}F(s).$$

Proof:

$$\begin{aligned} L\{g(t)\} &= \int_0^{\infty} e^{-st} g(t) dt \\ &= \int_0^a e^{-st} g(t) dt + \int_a^{\infty} e^{-st} g(t) dt \\ &= 0 + \int_a^{\infty} e^{-st} f(t - a) dt \end{aligned}$$

Put $t - a = u$, $dt = du$ then

$$\begin{aligned} L\{g(t)\} &= \int_0^{\infty} e^{-s(u+a)} f(u) du \\ &= e^{-sa} \int_0^{\infty} e^{-su} f(u) du \\ L\{g(t)\} &= e^{-sa} L\{f(t)\} = e^{-sa} F(s) \end{aligned}$$

Corollary: L.T. of unit step function (put $f(t) = 1$)

$$L\{u(t - a)\} = \frac{e^{-as}}{s}$$

Various discontinuous functions can often be expressed in terms of Heaviside unit step functions as follows:

Book Work: Show that

$$\begin{aligned} f(t) &= f_1(t), 0 < t < a \\ &= f_2(t), t > a \end{aligned}$$

can be written as

$$f(t) = f_1(t) + \{f_2(t) - f_1(t)\}u(t - a)$$

Proof: When $t < a$, $u(t - a) = 0$ so that

$$f(t) = f_1(t) \quad \text{for } t < a$$

when $t > a$, $u(t - a) = 1$ so that

$$\begin{aligned} f(t) &= f_1(t) + \{f_2(t) - f_1(t)\} \\ &= f_2(t) \quad \text{for } t > a. \end{aligned}$$

In general,
if

$$\begin{aligned} f(t) &= f_1(t) & \text{for } 0 < t < a_1 \\ &= f_2(t) & \text{for } a_1 < t < a_2 \\ &\equiv \\ &= f_{n-1}(t) & \text{for } a_{n-2} < t < a_{n-1} \\ &= f_n(t) & \text{for } t > a_{n-1} \end{aligned}$$

then

$$\begin{aligned} f(t) &= f_1(t) + \{f_2(t) - f_1(t)\}u(t - a_1) + \cdots \\ &\quad + \{f_n(t) - f_{n-1}(t)\}u(t - a_{n-1}). \end{aligned}$$

WORKED OUT EXAMPLES

Find the Laplace transform of the following functions using second translation theorem:

Example 1: Express in terms of Heaviside's unit step function

$$\begin{aligned} f(t) &= \sin t, & 0 < t < \pi \\ &= \sin 2t, & \pi < t < 2\pi \\ &= \sin 3t, & t > 2\pi. \end{aligned}$$

Solution: Let

$$f_1(t) = \sin t, f_2(t) = \sin 2t, f_3(t) = \sin 3t$$

so that

$$\begin{aligned} f(t) &= f_1(t) + (f_2 - f_1)u(t - \pi) + (f_3 - f_2)u(t - 2\pi) \\ &= \sin t + (\sin 2t - \sin t)u(t - \pi) \\ &\quad + (\sin 3t - \sin 2t)u(t - 2\pi). \end{aligned}$$

Example 2: Given

$$\begin{aligned} f(t) &= e^{-t}, & 0 < t < 3 \\ &= 0, & t > 3 \end{aligned}$$

write $f(t)$ in terms of Heaviside's unit step function and hence find the Laplace transform of $f(t)$.

Solution: Let $f_1(t) = e^{-t}$ and $f_2(t) = 0$ then $f(t)$ can be written as

$$\begin{aligned} f(t) &= f_1(t) + \{f_2(t) - f_1(t)\}u(t-3) \\ &= e^{-t} + (0 - e^{-t})u(t-3) \\ &= e^{-t}(1 - u(t-3)) \\ L\{f(t)\} &= L\{e^{-t} - e^{-t}u(t-3)\} \\ &= L\{e^{-t}\} - L\{e^{-t}u(t-3)\} \\ &= \frac{1}{s+1} - \frac{e^{-3(s+1)}}{s+1} \end{aligned}$$

Since $L\{u(t-3)\} = e^{-3s}/s$ and $L\{e^{-t} \cdot u(t-3)\} = e^{-3(s+1)}/(s+1)$.

Example 3: $g(t) = 0, \quad 0 < t < 5$
 $= t - 3, \quad t > 5$

Solution: To apply the t -shift theorem, express the functional values $t - 3$ for $t > 5$ in terms of $t - 5$ i.e., express $t - 3$ as $(t - 5) + 2$ and rewrite

$$\begin{aligned} g(t) &= 0, \quad 0 < t < 5 \\ &= (t - 5) + 2, \quad t > 5 \end{aligned}$$

Thus $g(t) = u(t-5)f(t-5)$ where $f(t) = t + 2, t > 0$.

Applying t -shift theorem

$$L\{u(t-5)f(t-5)\} = e^{-5s}F(s)$$

where

$$\begin{aligned} F(s) &= L\{f(t)\} = L\{t+2\} = L\{t\} + L\{2\} \\ &= \frac{1}{s^2} + \frac{2}{s} \end{aligned}$$

$$\begin{aligned} \therefore L\{g(t)\} &= L\{u(t-5)f(t-5)\} = e^{-5s} \cdot F(s) \\ &= e^{-5s} \left[\frac{1}{s^2} + \frac{2}{s} \right]. \end{aligned}$$

Example 4: $g(t) = 0, \quad 0 < t < \frac{\pi}{2}$
 $= \sin t, \quad t > \frac{\pi}{2}$

Solution: Express $\sin t$ in terms of $t - \frac{\pi}{2}$ by observing that $\sin t = \cos(t - \frac{\pi}{2})$ hence

$$g(t) = u\left(t - \frac{\pi}{2}\right) \cdot f\left(t - \frac{\pi}{2}\right) = \begin{cases} 0, & 0 < t < \frac{\pi}{2} \\ \cos(t - \frac{\pi}{2}), & t > \frac{\pi}{2} \end{cases}$$

where $f(t) = \cos t, \quad t > 0$

$$L\{g(t)\} = L\left\{u\left(t - \frac{\pi}{2}\right) \cdot f\left(t - \frac{\pi}{2}\right)\right\} = e^{-\frac{\pi}{2}s} \cdot F(s)$$

where $F(s) = L\{f(t)\} = L\{\cos t\} = \frac{s}{s^2+1}$

$$\therefore L\{g(t)\} = \frac{se^{-\frac{\pi}{2}s}}{s^2+1}.$$

Example 5: $4 \sin(t-3)u(t-3)$

Solution: We know that

$$L\{4 \sin t\} = F(s) = \frac{4}{s^2+1}$$

Applying t -shift

$$L\{4 \sin(t-3)u(t-3)\} = e^{-3s}F(s) = e^{-3s} \frac{4}{(s^2+1)}.$$

EXERCISE

Find the Laplace transform of the following:

$$1. f(t) = \begin{cases} 1, & 0 < t < 2 \\ 2, & 2 < t < 4 \\ 3, & 4 < t < 6 \\ 0, & t > 6 \end{cases}$$

$$\text{Ans. } \frac{1+e^{-2s}+e^{-4s}-3e^{-6s}}{s}$$

$$2. f(t) = \begin{cases} t, & 0 < t < 3 \\ 3, & t > 3 \end{cases}$$

$$\text{Ans. } \frac{1}{s^2}(1 - e^{-3s})$$

3. Express $f(t)$ in terms of heavisides unit step function

$$f(t) = \begin{cases} t^2, & 0 < t < 2 \\ 4t, & t > 2 \end{cases}$$

$$\text{Ans. } t^2 + (4t - t^2)u(t-2)$$

$$4. f(t) = \begin{cases} \sin t, & t > \pi \\ \cos t, & t < \pi \end{cases}$$

$$\text{Ans. } \cos t + (\sin t - \cos t)u(t - \pi).$$

12.16 — HIGHER ENGINEERING MATHEMATICS—III

Find L.T. by expressing $f(t)$ in unit step functions:

$$5. f(t) = \begin{cases} t^2, & 0 < t \leq 2 \\ 0, & t > 2. \end{cases}$$

$$\text{Ans. } t^2 [u(t) - u(t - 2)] = \frac{2(1 - e^{-2s})}{s^3} - \frac{4e^{-2s}(1 + s)}{s^2}.$$

$$6. f(t) = \begin{cases} 2, & 0 < t < \pi \\ 0, & \pi < t < 2\pi \\ \sin t, & t > 2\pi \end{cases}$$

$$\text{Ans. } f(t) = 2 - 2u(t - \pi) + u(t - 2\pi) \sin t.$$

$$F(s) = \frac{2}{s} - \frac{2e^{-\pi s}}{s} + \frac{e^{-2\pi s}}{s^2 + 1}$$

$$7. 4u(t - \pi) \cos t$$

$$\text{Ans. } -4e^{-\pi s} \cdot s/(s^2 + 1)$$

$$8. f(t) = t - 1, \quad 1 < t < 2$$

$$= 3 - t, \quad 2 < t < 3$$

$$\text{Ans. } (e^{-s} - 2e^{-2s} + e^{-3s})/s^2$$

9. Staircase function

$$f(t) = 1, \quad 0 < t < 1$$

$$= 2, \quad 1 < t < 2$$

$$= 3, \quad 2 < t < 3$$

$$\dots$$

$$\dots$$

$$\text{Ans. } \frac{1}{s(1 - e^{-s})}$$

10. Saw tooth function (Fig. 12.5)

Fig. 12.5

$$\text{Ans. } \frac{k}{as^2} - \frac{ke^{-as}}{s} \left(\frac{1}{1 - e^{-as}} \right).$$

Dirac's* Delta Function (or Unit Impulse Function)

Forces (like earthquake) that produce large effects on a system when applied for a very short time interval

can be represented by an impulse function which is a discontinuous function and is highly irregular from the mathematical point of view.

Impulse of a forces $f(t)$ in the interval $(a, a + \epsilon)$

$$= \int_a^{a+\epsilon} f(t) dt$$

Now define the function

$$f_\epsilon(t - a) = \begin{cases} 0 & \text{for } t < a \\ \frac{1}{\epsilon} & \text{for } a \leq t \leq a + \epsilon \\ 0 & \text{for } t > a + \epsilon \end{cases}$$

Fig. 12.6

This can also be represented in terms of two unit step functions as follows

$$f_\epsilon(t - a) = \frac{1}{\epsilon} [u(t - a) - u(t - (a + \epsilon))]$$

Note that

$$\int_0^\infty f_\epsilon(t - a) dt = \int_0^a 0 + \int_a^{a+\epsilon} \frac{1}{\epsilon} dt + \int_{a+\epsilon}^\infty 0 = 1$$

Thus the impulse I_ϵ is 1.

Taking Laplace transform

$$L\{f_\epsilon(t - a)\} = \frac{1}{\epsilon} L\{u(t - a) - u(t - (a + \epsilon))\}$$

$$= \frac{1}{\epsilon s} [e^{-as} - e^{-(a+\epsilon)s}]$$

$$= e^{-as} \cdot \frac{(1 - e^{-\epsilon s})}{\epsilon s}$$

Dirac delta function (or unit impulse function) denoted by $\delta(t - a)$ is defined as the limit of $f_\epsilon(t - a)$ as $\epsilon \rightarrow 0$ i.e.,

$$\delta(t - a) = \lim_{\epsilon \rightarrow 0} f_\epsilon(t - a).$$

* Paul Dirac (1902–1984), English physicist, Nobel prize winner.

Then the Laplace transform of Dirac delta function is obtained as

$$\begin{aligned} L\{\delta(t-a)\} &= \lim_{\epsilon \rightarrow 0} L\{f_\epsilon(t-a)\} \\ &= \lim_{\epsilon \rightarrow 0} e^{-as} \cdot \frac{(1-e^{-\epsilon s})}{\epsilon s} \\ L\{\delta(t-a)\} &= e^{-as}. \end{aligned}$$

Thus the Dirac delta function is a “generalized function” defined as

$$\delta(t-a) = \begin{cases} \infty & \text{when } t = a \\ 0 & \text{otherwise} \end{cases}$$

subject to $\int_0^\infty \delta(t-a) dt = 1$.

WORKED OUT EXAMPLES

Example: A beam has its ends clamped at $x = 0$ and $x = L$. A concentrated load W acts vertically downwards at the point $x = \frac{L}{3}$. Find the resulting deflection.

Solution: The differential equation for deflection is

$$\frac{d^4 y}{dx^4} = \frac{W}{EI} \delta\left(x - \frac{L}{3}\right) \quad (1)$$

Taking the Laplace transform on both sides of (1)

$$s^4 Y - s^3 y(0) - s^2 y'(0) - s y''(0) - y'''(0) = \frac{W}{EI} e^{-\frac{Ls}{3}} \quad (2)$$

where $Y = L\{y(x)\}$.

Since the end $x = 0$ is clamped, we have $y(0) = 0$, $y'(0) = 0$. Put $y''(0) = c_1$ and $y'''(0) = c_2$ where c_1 and c_2 are constants. Then (2) reduces to

$$s^4 Y - s c_1 - c_2 = \frac{W}{EI} e^{-\frac{Ls}{3}}$$

Solving,

$$Y = \frac{c_1}{s^3} + \frac{c_2}{s^4} + \frac{W}{EI} \frac{e^{-\frac{Ls}{3}}}{s^4} \quad (3)$$

Taking the inverse Laplace transform of (3),

$$y(x) = c_1 \frac{x^2}{2!} + c_2 \frac{x^3}{3!} + \frac{W}{EI} \frac{\left(x - \frac{L}{3}\right)^3}{3!} \left[u\left(x - \frac{L}{3}\right) \right] \quad (4)$$

or

$$y(x) = c_1 \frac{x^2}{2} + c_2 \frac{x^3}{6} \quad \text{when } 0 < x < \frac{L}{3} \quad (5)$$

$$y(x) = c_1 \frac{x^2}{2} + c_2 \frac{x^3}{6} + \frac{W}{6EI} \left(x - \frac{L}{3}\right)^3 \quad \text{when } \frac{L}{3} < x < L \quad (6)$$

To determine c_1 and c_2 use the condition that the other end $x = L$ is clamped i.e., $y(L) = y'(L) = 0$. From (6)

$$0 = y(L) = c_1 \frac{L^2}{2} + c_2 \frac{L^3}{6} + \frac{W}{EI} \frac{4}{81} L^3 \quad (7)$$

Differentiating (6) and putting $x = L$,

$$0 = y'(L) = c_1 L + c_2 \frac{L^2}{2} + \frac{W}{EI} \frac{2}{9} L^2 \quad (8)$$

Solving (7) and (8), we get

$$c_1 = \frac{12}{81} L \frac{W}{EI} \quad (9)$$

and

$$c_2 = -\frac{60}{81} \frac{W}{EI} \quad (10)$$

Thus the deflection of the beam is given by (5) and (6) where c_1 and c_2 are given by (9) and (10).

EXERCISE

1. An impulsive voltage $E\delta(t)$ is applied to a circuit consisting of L , R , C in series with zero initial conditions. Find the limit of I as $t \rightarrow 0$ where I is the current at any subsequent time t .

Hint: Equation of circuit is

$$L \frac{dI}{dt} + RI + \frac{1}{c} \int_0^t I dt = E \cdot \delta(t)$$

where $I(0) = 0$.

Ans. $I = E/L$

2. A beam is simply supported at its end $x = 0$ and is clamped at the other end $x = L$. It carries a load W at $x = \frac{L}{4}$. Find the resulting deflection at any point.

12.18 — HIGHER ENGINEERING MATHEMATICS—III

Hint: D.E. for deflection is $\frac{d^4 y}{dx^4} = \frac{W}{EI} \delta\left(x - \frac{L}{4}\right)$ with boundary conditions $y(0) = y''(0) = 0$ and

$$y(L) = y'(L) = 0.$$

Ans. $y = c_1 x + \frac{1}{6} c_2 x^3, \quad 0 < x < \frac{L}{4}$

$$y = c_1 x + \frac{1}{6} c_2 x^3 + \frac{W}{6EI} \left(x - \frac{L}{4}\right)^3, \quad \frac{L}{4} < x < L$$

where $c_1 = \frac{9WL^2}{256EI}, \quad c_2 = -\frac{81W}{128EI}$

3. Obtain the deflection of a weightless beam of length L and freely supported at ends, when a concentrated load W acts at $x = a$.

Ans. $y(x) = \frac{W}{6EI} \left[\frac{ab(L+b)}{L} x - \frac{b}{L} x^3 \right], \quad 0 < x < a$

$$y(x) = \frac{W}{6EI} \left[\frac{ab(L+b)}{L} x - \frac{b}{L} x^3 + (x-a)^3 \right],$$

$$a < x < L$$

4. Determine the response of the damped mass-spring system governed by $y'' + 3y' + 2y = r(t)$, $y(0) = 0$, $y'(0) = 0$ where $r(t)$ is (a) square wave

$$r(t) = u(t-1) - u(t-2)$$

and (b) the unit impulse at time $t = 1$

$$r(t) = \delta(t-1)$$

Hint: Subsidiary equation is

$$s^2 Y + 3sY + 2Y = e^{-s}$$

Ans. a.

$$y(t) = \begin{cases} 0, & 0 < t < 1 \\ \frac{1}{2} - e^{-(t-1)} + \frac{1}{2} e^{-2(t-1)}, & 1 < t < 2 \\ -e^{-(t-1)} + e^{-(t-2)} + \frac{1}{2} e^{-2(t-1)} - \frac{1}{2} e^{-2(t-2)}, & \text{for } t < 2 \end{cases}$$

b. $y(t) = \begin{cases} 0, & 0 \leq t < 1 \\ e^{-(t-1)} - e^{-2(t-1)}, & t > 1 \end{cases}$

12.4 LAPLACE TRANSFORM OF PERIODIC FUNCTION

A function $f(t)$ is said to be a periodic function of period $T > 0$ if

$$f(t) = f(T+t) = f(2T+t) = \dots = f(nT+t).$$

Example: $\sin t, \cos t$ are periodic functions of period 2π .

Theorem: The Laplace transform of a piecewise periodic function $f(t)$ with period p is

$$L\{f(t)\} = \frac{1}{1 - e^{-ps}} \int_0^p e^{-st} \cdot f(t) dt; s > 0$$

Proof:

$$\begin{aligned} L\{f(t)\} &= \int_0^\infty e^{-st} f(t) dt \quad \text{by definition} \\ &= \int_0^p e^{-st} f(t) dt + \int_p^{2p} e^{-st} f(t) dt \\ &\quad + \int_{2p}^{3p} e^{-st} f(t) dt + \dots \end{aligned}$$

Put $t = u + p$ in the 2nd integral,

$$t = u + 2p \text{ in the 3rd integral}$$

$\vdots$

$$t = u + (n-1)p \text{ in the } n\text{th integral}$$

Then the new limits for each integral are 0 to p and by periodicity

$$f(t+p) = f(t), f(t+2p) = f(t)$$

and so on.

Therefore

$$\begin{aligned} L\{f(t)\} &= \int_0^p e^{-su} f(u) du + \int_0^p e^{-s(u+p)} f(u) du \\ &\quad + \int_0^p e^{-s(u+2p)} \cdot f(u) du + \dots \\ &= [1 + e^{-sp} + e^{-2sp} + \dots] \int_0^p e^{-su} f(u) du \end{aligned}$$

$$L\{f\} = \frac{1}{1 - e^{-ps}} \int_0^p e^{-st} f(t) dt, s > 0$$

since the bracketed quantity in R.H.S. is geometric series

$$\text{i.e., } \frac{1}{1-r} = 1 + r + r^2 + r^3 + \dots, |r| < 1 \text{ with } r = e^{-ps}$$

Result: Thus the Laplace transform of a periodic function $f(t)$ of period p is obtained by integrating $e^{-st} f(t)$ in the interval $(0, p)$ with respect to t and multiplying the resultant by the factor $(1 - e^{-ps})^{-1}$.

WORKED OUT EXAMPLES

Find the Laplace transform of the following periodic functions:

Example 1: Half wave rectifier (Fig. 12.7)

Fig. 12.7

$$f(t) = \sin wt, \quad 0 < t < \frac{\pi}{w}$$

$$= 0, \quad \frac{\pi}{w} < t < \frac{2\pi}{w}$$

and periodic of period $\frac{2\pi}{w}$.

Solution:

$$L(f(t)) = \frac{1}{1 - e^{-ps}} \int_0^p e^{-st} f(t) dt$$

$$= \frac{1}{1 - e^{-2\pi s/w}} \int_0^{2\pi/w} e^{-st} \cdot f(t) dt$$

$$= \frac{1}{1 - e^{-2\pi s/w}} \left[\int_0^{\pi/w} e^{-st} \cdot \sin wt dt + \int_{\pi/w}^{2\pi/w} 0 \right]$$

Consider $\int_0^{\pi/w} e^{-st} \cdot \sin wt dt$

$$= \text{Im. p. of } \left\{ \int_0^{\pi/w} e^{(-s+iw)t} dt \right\}$$

$$= \text{Im. p. of } \left\{ \frac{1}{-s+iw} e^{(-s+iw)t} \right\} \Bigg|_0^{\pi/w}$$

$$= \text{Im. p. of } \left\{ \frac{(s+iw)}{(s^2+w^2)} (1 + e^{-s\pi/w}) \right\}$$

$$= \frac{w}{s^2+w^2} (e^{-s\pi/w} + 1)$$

$$\therefore L\{f(t)\} = \frac{1}{1 - e^{-2\pi s/w}} \cdot \frac{w}{s^2+w^2} (1 + e^{-s\pi/w})$$

$$= \frac{w}{(s^2+w^2)} \cdot \frac{1}{(1 - e^{-\pi s/w})}$$

Example 2: Saw-tooth wave (Fig. 12.8)

Fig. 12.8

$$f(t) = \frac{k}{p}t, \quad 0 < t < p$$

and

$$f(t+p) = f(t)$$

Solution:

$$L(f(t)) = \frac{1}{1 - e^{-sp}} \int_0^p e^{-st} \cdot \left(\frac{k}{p}t\right) dt,$$

Integrating by parts

$$\int_0^p t \cdot e^{-st} dt = -\frac{t}{s} e^{-st} \Bigg|_0^p + \frac{1}{s} \int_0^p e^{-st} dt$$

$$= -\frac{t}{s} e^{-st} \Bigg|_0^p - \frac{1}{s^2} e^{-st} \Bigg|_0^p$$

$$= -\frac{p}{s} e^{-sp} - \frac{1}{s^2} (e^{-sp} - 1)$$

$$\therefore L(f(t)) = \frac{1}{(1 - e^{-sp})} \frac{k}{p}$$

$$\times \left[-\frac{p}{s} e^{-sp} - \frac{1}{s^2} (e^{-sp} - 1) \right]$$

$$= \frac{k}{ps^2} - \frac{ke^{-sp}}{s(1 - e^{-ps})}, s > 0$$

Example 3: (refer Fig. 12.9)

$$f(t) = 1, \quad 0 \leq t < 2$$

$$= -1, \quad 2 \leq t < 4$$

$$f(t+4) = f(t)$$

Fig. 12.9

12.20 — HIGHER ENGINEERING MATHEMATICS—III

Solution: Here $p = 4$. Applying theorem

$$\begin{aligned} L\{f(t)\} &= \frac{\int_0^4 e^{-st} f(t) dt}{1 - e^{-4s}} \\ &= \frac{1}{1 - e^{-4s}} \left[\int_0^2 e^{-st} \cdot 1 dt + \int_2^4 e^{-st} (-1) dt \right] \\ &= \frac{1}{1 - e^{-4s}} \cdot \left[\frac{e^{-st}}{s} \Big|_0^2 + \frac{e^{-st}}{s} \Big|_2^4 \right] \\ &= \frac{1}{1 - e^{-4s}} \left(\frac{1}{s} \right) \left[-e^{-2s} + 1 + e^{-4s} - e^{-2s} \right] \\ &= \frac{1 - e^{-2s}}{s(1 + e^{-2s})}. \end{aligned}$$

EXERCISE

Find the Laplace transform of the following periodic functions:

$$\begin{aligned} 1. \quad f(t) &= t, & 0 < t < a \\ &= -t + 2a, & a < t < 2a \end{aligned}$$

Ans. $\frac{1}{s^2} \tanh \frac{as}{2}$

$$2. \quad f(t) = t^2, \quad 0 < t < \alpha \text{ and } f(t + \alpha) = f(t)$$

Ans. $\frac{1}{(1 - e^{-\alpha s})s^3} [2 - e^{-\alpha s}(\alpha^2 s^2 + 2\alpha s + 2)]$

$$\begin{aligned} 3. \quad f(t) &= 1, & 0 < t < 1 \\ &= 0, & 1 < t < 2 \\ &= -1, & 2 < t < 3 \end{aligned} \quad \text{Period 3}$$

Ans. $\frac{1}{s} \left[\frac{3}{(1 - e^{-3s})} - \frac{1}{(1 - e^{-s})} - 1 \right]$

$$\begin{aligned} 4. \quad f(t) &= t, & 0 < t < \pi \\ &= 0, & \pi < t < 2\pi \end{aligned} \quad \text{Period } 2\pi$$

Ans. $\frac{1}{s^2} [(1 - e^{-\pi s}) - \frac{\pi}{s} e^{-\pi s}] / (1 - e^{-2\pi s})$

$$5. \quad f(t) = \begin{cases} a, & \text{for } 0 \leq t \leq a \\ -a, & \text{for } a < t \leq 2a \end{cases}$$

Ans. $\frac{a}{s} \tanh \left(\frac{as}{2} \right)$

$$6. \quad f(t) = \begin{cases} \cos t, & 0 \leq t \leq \pi \\ -1, & \pi \leq t < 2\pi \end{cases}$$

Ans. $\frac{s}{(1+s^2)(1-e^{-\pi s})} - \frac{e^{-s\pi}}{s(1+e^{-\pi s})}$

$$7. \quad f(t) = \sin t, \quad 0 \leq t \leq \pi$$

Ans. $\frac{\coth(\pi s/3)}{1+s^2}$

$$8. \quad f(t) = \begin{cases} 1+t, & 0 \leq t < 1 \\ 3-t, & 1 \leq t < 2, \end{cases} \quad f(t+2) = f(t)$$

Ans. $\frac{1}{s} + \frac{1-e^{-s}}{1+e^{-s}} \frac{1}{s^2}.$

12.5 INVERSE LAPLACE TRANSFORM

If $L\{f(t)\} = F(s)$ then $f(t)$ is known as the inverse Laplace transform (I.L.T.) or inverse transform or simply inverse of $F(s)$ and is denoted by $L^{-1}\{F(s)\}$. Thus

$$f(t) = L^{-1}\{F(s)\} \quad (1)$$

L^{-1} is known as the inverse Laplace transform operator and is such that

$$LL^{-1} = L^{-1}L = 1$$

In the inverse problem (1), $F(s)$ is given (known) and $f(t)$ is to be determined.

Note: I.L.T. of $F(s)$ need not exist for all $F(s)$.

Inverse Laplace Transform of Some Elementary Functions

Example: Find $f(t)$ the inverse Laplace transform of $F(s) = \frac{k}{s}$ where k is a constant.

Solution: We know that $L\{k\} = \frac{k}{s}$. Taking inverse Laplace transform on both sides, we have

$$k = L^{-1} \left\{ \frac{k}{s} \right\}$$

That $f(t) = k = L^{-1} \left\{ \frac{k}{s} \right\} = L^{-1}\{F(s)\}$

Similarly, since $L\{e^{at}\} = \frac{1}{s-a}$ it follows that

$$L^{-1} \left\{ \frac{1}{s-a} \right\} = e^{at}$$

In a similar way, since $L\{\cos at\} = \frac{s}{s^2+a^2}$, we readily get

$$L^{-1} \left\{ \frac{s}{s^2+a^2} \right\} = \cos at$$

and so on. Thus for each direct Laplace transform result (listed in table of L.T. in Section 12.12) a corresponding inverse Laplace transform result can be read accordingly.

The proficiency in solving O.D.E./P.D.E. using L.T. is practically synonymous with the proficiency in determining inverse Laplace transform (I.L.T.).

Evaluation of I.L.T., $L^{-1}\{F(s)\}$ essentially reduces to expressing $F(s)$ as some combination of functions, each of whose I.L.T. can be read from the L.T. tables or otherwise. Some methods for finding I.L.T. are:

- Use of L.T. tables(12.12 on page 12.41)
- Use of some important properties of I.L.T.(12.11 on page 12.41)
- Convolution(12.8 on page 12.33)
- Use of partial fractions.(12.7 on page 12.30)

12.6 GENERAL PROPERTIES OF INVERSE LAPLACE TRANSFORM

For each property (Theorem) on Laplace transform, there is a corresponding property (Theorem) on inverse Laplace transform which readily follow from the definitions.

Linearity Property

Book Work: Let $L\{f(t)\} = F(s)$ and $L\{g(t)\} = G(s)$ then

$$\begin{aligned} L^{-1}\{c_1 F(s) + c_2 G(s)\} &= c_1 L^{-1}\{F(s)\} + c_2 L^{-1}\{G(s)\} \\ &= c_1 f(t) + c_2 g(t) \end{aligned}$$

where c_1 and c_2 are any two constants.

Proof: From the Linearity property for L.T., we know that

$$\begin{aligned} L\{c_1 f(t) + c_2 g(t)\} &= c_1 L\{f(t)\} + c_2 L\{g(t)\} \\ &= c_1 F(s) + c_2 G(s). \end{aligned}$$

Taking inverse L.T. on either side, we get

$$c_1 f(t) + c_2 g(t) = L^{-1}\{c_1 F(s) + c_2 G(s)\}$$

Since $f(t) = L^{-1}\{F(s)\}$ and $g(t) = L^{-1}\{G(s)\}$, we have

$$c_1 L^{-1}\{F(s)\} + c_2 L^{-1}\{G(s)\} = L^{-1}\{c_1 F(s) + c_2 G(s)\}.$$

Result: Thus L^{-1} the Inverse Laplace Transform operator is a linear operator.

Note: This result can readily be extended to more than two functions.

First Shift or Translation Theorem

Book Work: If $L^{-1}\{F(s)\} = f(t)$ then

$$L^{-1}\{F(s-a)\} = e^{at} f(t) = e^{at} L^{-1}\{F(s)\}$$

Proof: From the first translation property on L.T., we have

$$L\{e^{at} f(t)\} = F(s-a)$$

then

$$e^{at} f(t) = L^{-1}\{F(s-a)\}.$$

Result: Thus if s is replaced by $s-a$ in $F(s)$ then $f(t)$ is multiplied by e^{at} .

Change of Scale Property

Book Work: $L^{-1}\{F(ks)\} = \frac{1}{k} f\left(\frac{t}{k}\right)$

Proof: From change of scale property for L.T.

$$L\{f(at)\} = \frac{1}{a} F\left(\frac{s}{a}\right)$$

Take $a = \frac{1}{k}$ then

$$L\left\{f\left(\frac{t}{k}\right)\right\} = k F(ks)$$

$$\text{or } f\left(\frac{t}{k}\right) = L^{-1}\{k F(ks)\}$$

Thus

$$L^{-1}\{F(ks)\} = \frac{1}{k} f\left(\frac{t}{k}\right).$$

WORKED OUT EXAMPLES

Linearity property

Find the inverse Laplace transform of the following:

Example 1: $\frac{2s+1}{s^2-4}$

12.22 — HIGHER ENGINEERING MATHEMATICS—III

Solution:

$$\begin{aligned} L^{-1} \left\{ \frac{2s+1}{s^2-4} \right\} &= L^{-1} \left\{ \frac{2s}{s^2-4} \right\} + L^{-1} \left\{ \frac{1}{s^2-4} \right\} \\ &= 2 \cdot \cosh 2t + \frac{1}{2} \sinh 2t. \end{aligned}$$

Example 2: $\frac{3(s^2-2)^2}{2s^5}$

Solution:

$$\begin{aligned} L^{-1} \left\{ \frac{3(s^4 - 4s^2 + 4)}{2s^5} \right\} \\ &= L^{-1} \left\{ \frac{3}{2} \frac{1}{s} - 6 \frac{1}{s^3} + 6 \frac{1}{s^5} \right\} \\ &= \frac{3}{2} L^{-1} \left\{ \frac{1}{s} \right\} - 6 L^{-1} \left\{ \frac{1}{s^3} \right\} + 6 L^{-1} \left\{ \frac{1}{s^5} \right\} \\ &= \frac{3}{2} - 6 \cdot \frac{t^2}{2!} + 6 \cdot \frac{t^4}{4!} = \frac{3}{2} - 3t^2 + \frac{1}{4}t^4. \end{aligned}$$

Example 3: $\frac{1}{s} e^{-\frac{1}{\sqrt{s}}}$

Solution: We know that

$$e^{-\frac{1}{\sqrt{s}}} = \sum_{n=0}^{\infty} \left(-\frac{1}{\sqrt{s}} \right)^n \frac{1}{n!} = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \frac{1}{s^{\frac{n}{2}}}$$

$$\frac{1}{s} e^{-\frac{1}{\sqrt{s}}} = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \frac{1}{s^{\frac{n}{2}+1}}$$

$$\begin{aligned} L^{-1} \left\{ \frac{1}{s} e^{-\frac{1}{\sqrt{s}}} \right\} &= L^{-1} \left\{ \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \frac{1}{s^{\frac{n}{2}+1}} \right\} \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} L^{-1} \left\{ \frac{1}{s^{\frac{n}{2}+1}} \right\} \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \frac{t^{\frac{n}{2}}}{\Gamma\left(\frac{n}{2}+1\right)}. \end{aligned}$$

EXERCISE

Find the inverse Laplace transform $f(t)$ of each of the following functions $F(s)$:

1. $\frac{3}{s+4}$ *Ans.* $3e^{-4t}$

2. $\frac{8s}{s^2+16}$ *Ans.* $8 \cdot \cos 4t$

3. $\frac{1}{2s-5}$ *Ans.* $\frac{1}{2} e^{\frac{5t}{2}}$

4. $\frac{6}{s^2+4}$ *Ans.* $3 \sin 2t$

5. $\frac{3s-12}{s^2+8}$

Ans. $3 \cos 2\sqrt{2}t - 3\sqrt{2} \sin 2\sqrt{2}t$

6. $(2s-5)/(s^2-9)$ *Ans.* $2 \cosh 3t - \frac{5}{3} \sinh 3t$

7. $s^{-\frac{7}{2}}$ *Ans.* $8t^{\frac{5}{2}}/(15\sqrt{\pi})$

8. $\frac{s+1}{s^{\frac{4}{3}}}$ *Ans.* $(t^{-\frac{2}{3}} + 3t^{\frac{1}{3}})/\Gamma\left(\frac{1}{3}\right)$

9. $\left(\frac{\sqrt{s}-1}{s}\right)^2$ *Ans.* $1+t - \frac{4t^{\frac{1}{2}}}{\sqrt{\pi}}$

10. $\frac{3s-8}{4s^2+25}$ *Ans.* $\frac{3}{4} \cos \frac{5t}{2} - \frac{4}{5} \sin \frac{5t}{2}$

11. $\frac{5s+10}{9s^2-16}$ *Ans.* $\frac{5}{9} \cosh \frac{4t}{3} + \frac{5}{6} \sinh \frac{4t}{3}$

12. $\frac{3(s^2-1)^2}{2s^5} + \frac{4s-18}{9-s^2} + \frac{(s+1)(2-s^{\frac{1}{2}})}{s^{\frac{5}{2}}}$

Ans. $\frac{1}{2} - t - \frac{3}{2}t^2 + \frac{1}{16}t^4 + 4\frac{t^{\frac{1}{2}}}{\sqrt{\pi}} + \frac{8t^{\frac{3}{2}}}{3\sqrt{\pi}} - 4 \cosh 3t + 6 \sinh 3t$

13. $\frac{1}{s} \sin\left(\frac{1}{s}\right)$ *Ans.* $\sum_{n=0}^{\infty} \frac{(-1)^{n-1}}{[(2n-1)!]^2} t^{2n-1}$

14. $\frac{1}{s} e^{-\frac{1}{s}}$ *Ans.* $\sum_{n=0}^{\infty} \frac{(-1)^n t^n}{(n!)^2}$

Hint: For Examples 13, 14, expand sin and exponential in series of s .

WORKED OUT EXAMPLES

Change of scale property

Example: Find

$$L^{-1} \left\{ \frac{64}{81s^4 - 256} \right\}$$

Solution: We know that

$$\begin{aligned} L^{-1} \left\{ \frac{a^3}{s^4 - a^4} \right\} &= \frac{1}{2} L^{-1} \left\{ \frac{a}{s^2 - a^2} - \frac{a}{s^2 + a^2} \right\} \\ &= \frac{1}{2} (\sinh at - \sin at) \end{aligned}$$

Rewriting

$$\begin{aligned} L^{-1} \left\{ \frac{64}{81s^4 - 256} \right\} &= L^{-1} \left\{ \frac{4^3}{(3s)^4 - 4^4} \right\} \\ &= L^{-1} \{F(3s)\} \text{ with } a = 4 \end{aligned}$$

where $F(s) = \frac{a^3}{s^4 - a^4}$ and

$$f(t) = \frac{1}{2}(\sinh at - \sin at).$$

Thus applying change of scale property (with $a = 3$)

$$L^{-1} \{F(3s)\} = \frac{1}{3} f\left(\frac{t}{3}\right) = \frac{1}{3} \left[\frac{1}{2} \sinh 4\frac{t}{3} - \sin \frac{4t}{3} \right].$$

EXERCISE

Change of scale property

1. If $L^{-1} \left\{ e^{-\frac{1}{s}} / \sqrt{s} \right\} = \frac{\cos 2\sqrt{t}}{\sqrt{\pi t}}$ show that

$$L^{-1} \left\{ \frac{e^{-\frac{a}{s}}}{\sqrt{s}} \right\} = \frac{\cos 2\sqrt{at}}{\sqrt{\pi t}}, \quad \text{when } a > 0.$$

2. If $L^{-1} \{F(s)\} = f(t)$ prove that

$$L^{-1} \{F(as + b)\} = \frac{1}{a} e^{-(b/a)t} f\left(\frac{t}{a}\right) \text{ where } a > 0.$$

Hint: Take s as $as + b$ in the definition of L.T.

3. If $L^{-1} \left\{ \frac{s}{(s^2+1)^2} \right\} = \frac{t \sin t}{2}$ show that

$$L^{-1} \left\{ \frac{8s}{(4s^2+1)^2} \right\} = \frac{t}{2} \sin \frac{t}{2}.$$

4. If $L^{-1} \left\{ \frac{s^2-1}{(s^2+1)^2} \right\} = t \cos t$ show that

$$L^{-1} \left\{ \frac{9s^2-1}{(9s^2+1)^2} \right\} = \frac{t}{9} \cos \frac{t}{3}.$$

WORKED OUT EXAMPLES

First shift theorem

Find the inverse transform:

Example 1: $\frac{1}{(s+a)^{n+1}}$, n : non-negative integer

Solution:

$$L^{-1} \left\{ \frac{1}{(s+a)^{n+1}} \right\} = e^{-at} L^{-1} \left\{ \frac{1}{s^{n+1}} \right\}$$

by shift theorem.

$$= e^{-at} \frac{t^n}{n!}.$$

Example 2: $\frac{s}{(s+a)^2+b^2}$.

Solution:

$$L^{-1} \left[\frac{s}{(s+a)^2+b^2} \right] = e^{-at} L^{-1} \left[\frac{s-a}{s^2+b^2} \right]$$

by shift theorem

$$\begin{aligned} &= e^{-at} \left\{ L^{-1} \left[\frac{s}{s^2+b^2} \right] - \frac{a}{b} L^{-1} \left[\frac{b}{s^2+b^2} \right] \right\} \\ &= e^{-at} \left\{ \cos bt - \frac{a}{b} \cdot \sin bt \right\}. \end{aligned}$$

Example 3: $\frac{3s}{s^2-25}$.

Solution: $L^{-1} \left\{ \frac{3s}{s^2-25} \right\} = 3L^{-1} \left\{ \frac{s}{s^2-5^2} \right\} = 3 \cosh 5t.$

Example 4: $\frac{1}{s^{\frac{3}{2}}}$.

Solution:

$$L^{-1} \left\{ \frac{1}{s^{\frac{3}{2}}} \right\} = \frac{t^{\frac{1}{2}}}{\Gamma\left(\frac{3}{2}\right)} = \frac{t^{\frac{1}{2}}}{\frac{1}{2}\Gamma\left(\frac{1}{2}\right)} = 2\sqrt{\frac{t}{\pi}}$$

Example 5: $\frac{3s+1}{(s+1)^4}$.

Solution:

$$\begin{aligned} L^{-1} \left(\frac{3s+1}{(s+1)^4} \right) &= e^{-t} L^{-1} \left(\frac{3(s-1)+1}{s^4} \right) \\ &= e^{-t} \left\{ 3L^{-1} \left(\frac{1}{s^3} \right) - 2L^{-1} \left(\frac{1}{s^4} \right) \right\} \\ &= e^{-t} \left\{ 3 \cdot \frac{t^2}{2!} - 2 \cdot \frac{t^3}{3!} \right\} \\ &= e^{-t} \left\{ \frac{3}{2}t^2 - \frac{1}{3}t^3 \right\}. \end{aligned}$$

Example 6: $\frac{s+1}{s^2-6s+25}$.

12.24 — HIGHER ENGINEERING MATHEMATICS—III

Solution: $L^{-1} \left(\frac{s+1}{s^2+6s+25} \right) = L^{-1} \left(\frac{s+1}{(s+3)^2+16} \right).$

Applying shift theorem.

$$= e^{-3t} L^{-1} \left(\frac{(s-3)+1}{s^2+16} \right) = e^{-3t} \left\{ L^{-1} \left\{ \frac{s-2}{s^2+16} \right\} \right\}$$

$$= e^{-3t} \cdot \left\{ \cos 4t - \frac{1}{2} \sin 4t \right\}.$$

Example 7: $F(as+b).$

Solution: $F(as+b) = \int_0^\infty e^{-(as+b)t} f(t) dt$

$$= \int_0^\infty e^{-ast} \cdot e^{-bt} \cdot f(t) dt$$

Put $at = u, dt = \frac{du}{a}$

$$F(as+b) = \int_0^\infty e^{-su} \cdot e^{-\frac{b}{a}u} \cdot f\left(\frac{u}{a}\right) \cdot \frac{1}{a} \cdot du$$

$$= \frac{1}{a} \int_0^\infty e^{-su} \left\{ e^{-\frac{b}{a}u} \cdot f\left(\frac{u}{a}\right) \right\} du$$

$$= \frac{1}{a} L \left\{ e^{-\frac{bu}{a}} \cdot f\left(\frac{u}{a}\right) \right\}.$$

Result: $L^{-1} \{F(as+b)\} = \frac{1}{a} e^{-\frac{bt}{a}} \cdot f\left(\frac{t}{a}\right).$

Example 8: $\frac{1}{\sqrt{2s+3}}$

Solution:

$$L^{-1} \left\{ \frac{1}{\sqrt{2s+3}} \right\} = \frac{1}{\sqrt{2}} L^{-1} \left\{ \frac{1}{\left(s + \frac{3}{2}\right)^{\frac{1}{2}}} \right\}.$$

By shift theorem

$$= \frac{1}{\sqrt{2}} e^{-\frac{3t}{2}} \cdot L^{-1} \left\{ \frac{1}{s^{\frac{1}{2}}} \right\}$$

$$= \frac{1}{\sqrt{2}} e^{-\frac{3t}{2}} \cdot \frac{t^{-\frac{1}{2}}}{\Gamma\left(\frac{1}{2}\right)} = \frac{1}{\sqrt{2\pi}} t^{-1/2} \cdot e^{-\frac{3t}{2}}.$$

EXERCISE

First shift theorem

Find the inverse Laplace transform of the following:

1. $\frac{5}{(s+2)^5}$

Ans. $\frac{5}{24} t^4 e^{-2t}$

2. $\frac{4s+12}{s^2+8s+16}$

Ans. $4e^{-4t}(1-t)$

3. $\frac{s}{(s+1)^5}$

Ans. $\frac{e^{-t}}{24} (4t^3 - t^4)$

4. $\frac{s}{(s+1)^{\frac{5}{2}}}$

Ans. $\frac{2t^{\frac{1}{2}}(3-2t)}{3\sqrt{\pi}}$

5. $\frac{1}{\sqrt[3]{8s-27}}$

Ans. $\frac{t^{-\frac{2}{3}} e^{\frac{27t}{8}}}{2\Gamma\left(\frac{1}{3}\right)}$

6. $\frac{3s-14}{s^2-4s+8}$

Ans. $e^{2t}(3 \cos 2t - 4 \sin 2t)$

7. $\frac{5s-2}{s^2+4s+8}$

Ans. $\frac{e^{-\frac{2t}{5}}}{15} \{25 \cos 2\sqrt{5}t/3 - 24\sqrt{5} \sin 2\sqrt{5}t/3\}$

8. $\frac{3s+2}{4s^2+12s+9}$

Ans. $\frac{3}{4} e^{-\frac{3t}{2}} - \frac{5}{8} t e^{-\frac{3t}{2}}$

9. $\frac{8s+20}{s^2-12s+32}$

Ans. $2e^{6t}(4 \cosh 2t + 17 \sinh 2t)$

10. $\frac{1}{(s^2+2s+5)^2}$

Ans. $\frac{e^{-t}}{16} (\sin 2t - 2t \cos 2t)$

Inverse L.T. of Derivatives

$$L^{-1}\{F^{(n)}(s)\} = (-1)^n \cdot t^n f(t), n = 1, 2, 3, \dots$$

WORKED OUT EXAMPLES

Example 1: $\frac{s+1}{(s^2+2s+2)^2}.$

Solution:

$$L^{-1} \left\{ \frac{s+1}{(s^2+2s+2)^2} \right\} = L^{-1} \left\{ \frac{s+1}{((s+1)^2+1)^2} \right\}$$

$$= e^{-t} \cdot L^{-1} \left\{ \frac{s}{(s^2+1)^2} \right\}$$

We know that $\frac{d}{ds} \left\{ \frac{1}{s^2+1} \right\} = \frac{-2s}{(s^2+1)^2}$

so that $\frac{s}{(s^2+1)^2} = -\frac{1}{2} \frac{d}{ds} \left\{ \frac{1}{s^2+1} \right\}$

But $L^{-1} \left\{ \frac{1}{s^2+1} \right\} = \sin t$

Using I.L.T. of derivatives [(with $n = 1$ (one differentiation)]

$$\begin{aligned} L^{-1} \left\{ \frac{s+1}{(s^2+2s+2)^2} \right\} &= e^{-t} L^{-1} \left\{ \frac{s}{(s^2+1)^2} \right\} \\ &= e^{-t} \cdot \frac{-1}{2} L^{-1} \left\{ \frac{d}{ds} \left(\frac{1}{(s^2+1)} \right) \right\} \\ &= -\frac{1}{2} e^{-t} \cdot (-1)^1 \cdot t^1 \cdot L^{-1} \left\{ \frac{1}{s^2+1} \right\} \\ &= \frac{1}{2} e^{-t} \cdot t \cdot \sin t. \end{aligned}$$

Example 2: $\frac{1}{(s-a)^3}$.

Solution: We know that $L^{-1} \left(\frac{1}{s-a} \right) = e^{at}$

Let $F(s) = \frac{1}{(s-a)}$ so that

$$f(t) = L^{-1}\{F(s)\} = e^{at}$$

Then

$$F'(s) = \frac{-1}{(s-a)^2}, F''(s) = \frac{(-1)(-2)}{(s-a)^3} = \frac{2}{(s-a)^3}$$

By I.L.T. of derivatives with $n = 2$

$$\begin{aligned} L^{-1} \left\{ \frac{1}{(s-a)^3} \right\} &= \frac{1}{2} L^{-1}\{F''(s)\} = \frac{(-1)^2}{2} t^2 f(t) \\ &= 1 \cdot \frac{t^2 \cdot e^{at}}{2} = \frac{t^2 e^{at}}{2}. \end{aligned}$$

Example 3: $\frac{1}{2} \ln \frac{s^2+b^2}{s^2+a^2}$.

Solution: Here $F(s) = \frac{1}{2} \ln \frac{s^2+b^2}{s^2+a^2}$

$$\begin{aligned} F(s) &= \frac{1}{2} [\ln(s^2+b^2) - \ln(s^2+a^2)] \\ F'(s) &= \frac{1}{2} \frac{2s}{s^2+b^2} - \frac{1}{2} \frac{2s}{s^2+a^2} \\ &= \frac{s}{s^2+b^2} - \frac{s}{s^2+a^2} \\ L^{-1}\{F'(s)\} &= L^{-1} \left\{ \frac{s}{s^2+b^2} - \frac{s}{s^2+a^2} \right\} \\ &= L^{-1} \left\{ \frac{s}{s^2+b^2} \right\} - L^{-1} \left\{ \frac{s}{s^2+a^2} \right\} \\ &= \cos bt - \cos at \end{aligned}$$

Using I.L.T. of derivatives

$$-tf(t) = L^{-1}\{F'(s)\} = \cos bt - \cos at$$

Thus

$$f(t) = -\frac{(\cos bt - \cos at)}{t}.$$

Example 4: $\cot^{-1} \left(\frac{s+a}{b} \right)$.

Solution: $F(s) = \cot^{-1} \left(\frac{s+a}{b} \right)$, $F'(s) = -\frac{1}{1+(\frac{s+a}{b})^2} \cdot \frac{1}{b}$

$F'(s) = \frac{1}{b} \frac{-b^2}{(s+a)^2+b^2}$, so

$$L^{-1}\{F'(s)\} = -L^{-1} \left\{ \frac{b}{(s+a)^2+b^2} \right\} = -e^{-at} \cdot \sin bt$$

Since $-tf(t) = L^{-1}\{F'(s)\} = -e^{-at} \sin bt$

Thus $f(t) = \frac{e^{-at}}{t} \sin bt$.

EXERCISE

Find the inverse Laplace transform of the following:

- $\frac{1}{(s-a)^n}$, $n = 1, 2, 3$ Ans. $\frac{t^{n-1} \cdot e^{at}}{(n-1)!}$
- $\frac{s}{(s^2+a^2)^2}$ Ans. $\frac{t \sin at}{2a}$
- $\frac{1}{s^2+4s+5}$ Ans. $\frac{te^{-2t} \sin t}{2}$
- $\log \left(\frac{s+a}{s+b} \right)$ Ans. $\frac{e^{-at} - e^{-bt}}{-t}$
- $\tan^{-1} \frac{2}{s^2}$ Ans. $\frac{2}{t} \cdot \sinh t \cdot \sin t$
- $\log \frac{s(s+1)}{(s^2+4)}$ Ans. $\frac{2 \cos 2t - e^{-t} - 1}{t}$
- $\log \left(1 - \frac{a^2}{s^2} \right)$ Ans. $\frac{2}{t} (1 - \cosh at)$
- $\log \frac{s+1}{s-1}$ Ans. $\frac{2 \sinh t}{t}$
- $\cot^{-1} \left(\frac{s+3}{2} \right)$ Ans. $\frac{2}{t} e^{-3t} \sin 2t$.

Inverse Laplace Transform of Integrals

If $L^{-1}\{F(s)\} = f(t)$ then $L^{-1}\left\{\int_s^\infty F(u)du\right\} = \frac{f(t)}{t}$

WORKED OUT EXAMPLES

Evaluate the following:

Example 1: $L^{-1} \left\{ \frac{1}{2} \ln \left(\frac{s+1}{s-1} \right) \right\}$

Solution:

$$\begin{aligned}\frac{1}{2} \ln \left(\frac{s+1}{s-1} \right) &= \frac{1}{2} [\ln(s+1) - \ln(s-1)] \\ &= \frac{1}{2} \int_s^\infty \left(\frac{-du}{u+1} + \frac{du}{u-1} \right)\end{aligned}$$

But we know that

$$\frac{1}{2} L^{-1} \left\{ \frac{1}{s-1} - \frac{1}{s+1} \right\} = \frac{e^t - e^{-t}}{2} = \sinh t$$

Thus applying I.L.T. of integrals

$$\begin{aligned}L^{-1} \left\{ \frac{1}{2} \ln \left(\frac{s+1}{s-1} \right) \right\} \\ &= L^{-1} \left\{ \int_s^\infty \frac{1}{2} \left(\frac{du}{u-1} - \frac{du}{u+1} \right) \right\} \\ &= \frac{f(t)}{t} = \frac{\sinh t}{t}\end{aligned}$$

Example 2: Evaluate

$$L^{-1} \left\{ \int_s^\infty \left(\frac{u}{u^2+a^2} - \frac{u}{u^2+b^2} \right) du \right\}$$

Solution: Consider $F(s) = \frac{s}{s^2+a^2} - \frac{s}{s^2+b^2}$

$$\begin{aligned}f(t) &= L^{-1}\{F(s)\} = L^{-1} \left\{ \frac{s}{s^2+a^2} - \frac{s}{s^2+b^2} \right\} \\ &= \cos at - \cos bt\end{aligned}$$

By I.L.T. of Integral

$$\begin{aligned}L^{-1} \left\{ \int_s^\infty F(u) du \right\} \\ &= L^{-1} \left\{ \int_s^\infty \left(\frac{u}{u^2+a^2} - \frac{u}{u^2+b^2} \right) du \right\} = \frac{f(t)}{t} \\ &= \frac{\cos at - \cos bt}{t}.\end{aligned}$$

EXERCISE

Evaluate the following:

1. $L^{-1} \left\{ \int_s^\infty \left(\frac{1}{u} - \frac{1}{u+1} \right) du \right\}$

Hint: $L^{-1} \left\{ \frac{1}{s} - \frac{1}{s+1} \right\} = 1 - e^{-t}$.

Ans. $\frac{1-e^{-t}}{t}$

2. $L^{-1} \left\{ \int_s^\infty \ln \left(\frac{u+2}{u+1} \right) du \right\}$

Hint: $L^{-1} \left\{ \ln \left(\frac{s+2}{s+1} \right) \right\} = \frac{e^{-t} - e^{-2t}}{t}$.

Ans. $\frac{e^{-t} - e^{-2t}}{t^2}$

3. $L^{-1} \left\{ \int_s^\infty \tan^{-1} \left(\frac{2}{u^2} \right) du \right\}$

Hint: $L^{-1} \left\{ \tan^{-1} \frac{2}{s^2} \right\} = \frac{2 \sin t \sinh t}{t^2}$.

Ans. $\frac{2 \sin t \sinh t}{t^3}$

Multiplication by s

Book Work: If $L^{-1}\{F(s)\} = f(t)$ and $f(0) = 0$ then

$$L^{-1}\{sF(s)\} = \frac{df}{dt}.$$

Proof: We know that

$$L \left\{ \frac{df}{dt} \right\} = sF(s) - f(0) = sF(s)$$

Then $\frac{df}{dt} = L^{-1}\{sF(s)\}.$

Thus Multiplication by s amounts to differentiating $f(t)$ w.r.t. t .

WORKED OUT EXAMPLES

Example: $L^{-1} \left\{ \frac{s}{s^2-a^2} \right\}.$

Solution: We know that

$$\frac{1}{a} L^{-1} \left\{ \frac{a}{s^2-a^2} \right\} = \frac{\sinh at}{a}, \text{ and } \sinh 0 = 0$$

$$L^{-1} \left\{ s \cdot \frac{1}{s^2-a^2} \right\} = \frac{d}{dt} \frac{\sinh at}{a} = \frac{a \cosh at}{a}$$

$$L^{-1} \left\{ \frac{s}{s^2-a^2} \right\} = \cosh at.$$

EXERCISE

Find the inverse Laplace transform:

1. $\frac{s^2}{s^2+1}$ *Ans.* $\cos t$

2. $\frac{s}{(s^2+1)^2}$ **Hint:** $L^{-1} \left\{ \frac{1}{(s^2+1)^2} \right\} = \frac{\sin t - t \cos t}{2}$.

Ans. $\frac{1}{2} t \sin t$

Division by Powers of s

Integration of a function $f(t)$ amounts to division of transform $F(s)$ by s

Theorem: $L^{-1} \left\{ \frac{F(s)}{s} \right\} = \int_0^t f(u) du.$

Proof: Let $g(t) = \int_0^t f(u) du$. Then $g'(t) = f(t)$, $g(0) = 0$

$$\text{Thus} \quad L\{g'(t)\} = sL\{g(t)\} - g(0) = sL\{g(t)\}$$

$$\text{But since} \quad g'(t) = f(t)$$

$$F(s) = L\{f(t)\} = L\{g'(t)\} = sL\{g(t)\}$$

$$\therefore L\{g(t)\} = \frac{F(s)}{s}$$

$$\therefore L^{-1} \left\{ \frac{F(s)}{s} \right\} = g(t) = \int_0^t f(u) du$$

$$\text{Similarly, } L^{-1} \left\{ \frac{F(s)}{s^2} \right\} = \int_0^t \int_0^v f(u) du dv.$$

In general,

$$L^{-1} \left\{ \frac{F(s)}{s^n} \right\} = \int_0^t \int_0^t \dots \int_0^t f(t) dt^n.$$

WORKED OUT EXAMPLES

Find the inverse Laplace transform $f(t)$ of each of the following functions $F(s)$:

Example 1: $\frac{s+2}{s^2(s+3)}$

Solution:

$$\begin{aligned} L^{-1} \left\{ \frac{s+2}{s^2(s+3)} \right\} &= L^{-1} \left\{ \frac{1}{s(s+3)} \right\} \\ &\quad + L^{-1} \left\{ \frac{2}{s^2(s+3)} \right\} = R_1 + R_2 \end{aligned}$$

We know that $L^{-1} \left\{ \frac{1}{s+3} \right\} = e^{-3t}$. $L^{-1} \left\{ \frac{1}{s} \right\} = e^{-3t}$

$$\begin{aligned} R_1 &= L^{-1} \left\{ \frac{1}{s} \cdot \frac{1}{s+3} \right\} \\ &= \int_0^t e^{-3u} du \text{ by ILT of Integral} \\ &= \frac{e^{-3u}}{-3} \Big|_0^t = \frac{1}{3} [1 - e^{-3t}] \end{aligned}$$

$$\begin{aligned} R_2 &= 2L^{-1} \left\{ \frac{1}{s^2} \cdot \frac{1}{s+3} \right\} = 2L^{-1} \left\{ \frac{1}{s} \cdot \frac{1}{s(s+3)} \right\} \\ &= 2 \int_0^t \frac{1}{3} (1 - e^{-3u}) du = \frac{2}{3} \left[u - \frac{e^{-3u}}{-3} \right]_0^t \\ &= \frac{2}{3} \left[t + \frac{e^{-3t}}{3} - \frac{1}{3} \right] \end{aligned}$$

$$\begin{aligned} \therefore L^{-1} \left\{ \frac{s+2}{s^2(s+3)} \right\} &= \frac{1}{3} - \frac{1}{3} e^{-3t} + \frac{2}{3} t + \frac{2}{9} e^{-3t} - \frac{2}{9} \\ &= \frac{1}{9} + \frac{2}{3} t - \frac{1}{9} e^{-3t}. \end{aligned}$$

Example 2: $\frac{1}{s^3(s+1)}$

Solution: We know that

$$L^{-1} \left\{ \frac{1}{s+1} \right\} = e^{-t} L \left\{ \frac{1}{s} \right\} = e^{-t}$$

Applying I.L.T. of integrals

$$L^{-1} \left\{ \frac{1}{s} \cdot \frac{1}{s+1} \right\} = \int_0^t e^{-u} du = \frac{e^{-u}}{-1} \Big|_0^t = 1 - e^{-t}$$

Now consider

$$\begin{aligned} L^{-1} \left\{ \frac{1}{s} \cdot \frac{1}{s(s+1)} \right\} &= \int_0^t (1 - e^{-u}) du = u - \frac{e^{-u}}{-1} \Big|_0^t \\ &= t + e^{-t} - 1 \end{aligned}$$

$$\text{Finally } L^{-1} \left\{ \frac{1}{s} \cdot \frac{1}{s^2(s+1)} \right\} = \int_0^t (u + e^{-u} - 1) du$$

$$\begin{aligned} &= -u + \frac{u^2}{2} + \frac{e^{-u}}{-1} \Big|_0^t = -t + \frac{t^2}{2} - e^{-t} + 1 \\ &= 1 - t + \frac{1}{2} t^2 - e^{-t} \end{aligned}$$

Example 3: $\frac{1}{(s^2+a^2)^2}$

Solution: Rewrite

$$\frac{1}{(s^2+a^2)^2} = \frac{1}{s} \cdot \frac{s}{(s^2+a^2)^2}$$

We know that

$$L^{-1} \left\{ \frac{s}{(s^2+a^2)^2} \right\} = +t \frac{\sin at}{2a}$$

(Using I.L.T. for derivatives).

12.28 — HIGHER ENGINEERING MATHEMATICS—III

Now

$$L^{-1} \left\{ \frac{1}{(s^2 + a^2)^2} \right\} = L^{-1} \left\{ \frac{1}{s} \cdot \frac{s}{(s^2 + a^2)^2} \right\}$$

Using I.L.T. for integral $= \int_0^t -u \cdot \frac{\sin au}{2a} du.$

Integrating by parts

$$\begin{aligned} &= -\frac{1}{2a^2} t \cdot \cos at \Big|_0^t + \frac{1}{2a^2} \cdot \frac{\sin at}{a} \Big|_0^t \\ &= \frac{1}{2a^3} \{\sin at - at \cdot \cos at\}. \end{aligned}$$

Example 4: $\frac{s^2}{(s^2 + a^2)^2}$

Solution: Rewriting

$$\frac{s^2}{(s^2 + a^2)^2} = \frac{s^2 + a^2 - a^2}{(s^2 + a^2)^2} = \frac{1}{(s^2 + a^2)} - \frac{a^2}{(s^2 + a^2)^2}$$

$$\begin{aligned} L^{-1} \left\{ \frac{s^2}{(s^2 + a^2)^2} \right\} \\ &= L^{-1} \left\{ \frac{1}{s^2 + a^2} \right\} - a^2 L^{-1} \left\{ \frac{1}{(s^2 + a^2)^2} \right\} \end{aligned}$$

(use the result in Example 3 for second term in R.H.S.)

$$\begin{aligned} &= \frac{\sin at}{a} - a^2 \cdot \frac{1}{2a^3} \{\sin at - at \cos at\} \\ &= \frac{1}{2a} \{\sin at + at \cos at\}. \end{aligned}$$

EXERCISE

Given $F(s)$ find the inverse Laplace transform $f(t)$:

1. $\frac{1}{s^3(s^2+1)}$ *Ans.* $\frac{t^2}{2} + \cos t - 1$

2. $\frac{s}{(s-2)^3(s+1)}$

Ans. $e^{2t} \left(\frac{t^4}{36} + \frac{t^3}{54} - \frac{t^2}{54} + \frac{t}{81} - \frac{1}{243} \right) + \frac{e^{-t}}{243}$

3. $\frac{s^2}{(s^2-4s+5)^2}$ *Ans.* $te^{2t}(\cos t - \sin t)$

4. $\frac{1}{s} \left(\frac{s-a}{s+a} \right)$ *Ans.* $2e^{-at} - 1$

5. $\frac{1}{s^2} \left(\frac{s+1}{s^2+1} \right)$ *Ans.* $1 + t - \cos t - \sin t$

6. $\frac{1}{s^4-2s^3}$ *Ans.* $(e^{2t} - 1 - 2t - 2t^2)/8$

7. $\frac{1}{s(s^2+a^2)}$ *Ans.* $(1 - \cos at)/a^2$

8. $\frac{1}{s(s+a)^3}$

Ans. $-\frac{t^2 e^{-at}}{2a} - \frac{te^{-at}}{a^2} - \frac{1}{a^3}(e^{-at} - 1)$

9. $\frac{1}{s^2(s^2+a^2)}$ *Ans.* $\frac{1}{a^2} \left(t - \frac{\sin at}{a} \right).$

Second Shifting Theorem

If $L\{f(t)\} = F(s)$ then from second shifting theorem for L.T., we have

$$L\{f(t-a)u(t-a)\} = e^{-as}F(s).$$

Therefore

$$f(t-a)u(t-a) = L^{-1}\{e^{-as}F(s)\}.$$

WORKED OUT EXAMPLES

Find the inverse Laplace transform of the following:

Example 1: $\frac{e^{-s}}{\sqrt{s+1}}$

Solution: Let $F(s) = \frac{1}{\sqrt{s+1}}$ so that

$$\begin{aligned} f(t) &= L^{-1}\{F(s)\} = L^{-1} \left\{ \frac{1}{(s+1)^{\frac{1}{2}}} \right\} \\ &= e^{-t} L^{-1} \left\{ \frac{1}{s^{\frac{1}{2}}} \right\} = e^{-t} \cdot \frac{t^{-\frac{1}{2}}}{\sqrt{\pi}} \end{aligned}$$

Using t -shift

$$\begin{aligned} L^{-1} \left\{ \frac{e^{-s}}{\sqrt{s+1}} \right\} &= L^{-1}\{e^{-s} \cdot F(s)\} = f(t-1) \cdot u(t-1) \\ &= \left\{ e^{-(t-1)} \cdot \frac{(t-1)^{-\frac{1}{2}}}{\sqrt{\pi}} \right\} u(t-1) \\ &= \begin{cases} e^{-(t-1)} \cdot \frac{(t-1)^{-\frac{1}{2}}}{\sqrt{\pi}}, & t > 1 \\ 0, & 0 < t < 1 \end{cases} \end{aligned}$$

Example 2: $(5 - 3e^{-3s} - 2e^{-7s})/s$

Solution:

$$\begin{aligned} L^{-1} \left\{ \frac{5 - 3e^{-3s} - 2e^{-7s}}{s} \right\} \\ &= 5L^{-1} \left\{ \frac{1}{s} \right\} - 3L^{-1} \left\{ e^{-3s} \frac{1}{s} \right\} - 2L^{-1} \left\{ e^{-7s} \cdot \frac{1}{s} \right\} \end{aligned}$$

Applying the second shifting theorem

$$= 5.1 - 3 \cdot u(t - 3) - 2u(t - 7)$$

Since $L^{-1} \left\{ \frac{1}{s} \right\} = 1$

Also $u(t - 3) = 0, \quad 0 < t < 3$

$$= 1, \quad t > 3$$

and $u(t - 7) = 0, \quad 0 < t < 7$

$$= 1, \quad t > 7$$

Therefore

$$\begin{aligned} L^{-1} \left\{ \frac{5 - 3e^{-3s} - 2e^{-7s}}{s} \right\} \\ &= \begin{cases} 5 - 3 \cdot 0 - 2 \cdot 0, & 0 < t < 3 \\ 5 - 3 \cdot 1 - 2 \cdot 0, & 3 < t < 7 \\ 5 - 3 \cdot 1 - 2 \cdot 1, & t > 7 \end{cases} \\ &= \begin{cases} 5, & 0 < t < 3 \\ 2, & 3 < t < 7 \\ 0, & t > 7. \end{cases} \end{aligned}$$

Example 3: $(2 + 5s)/(s^2 e^{4s})$.

Solution: Take $F(s) = \frac{2+5s}{s^2} = \frac{2}{s^2} + \frac{5}{s}$. Then

$$\begin{aligned} f(t) &= L^{-1}\{F(s)\} = L^{-1} \left\{ \frac{2}{s^2} + \frac{5}{s} \right\} \\ &= 2L^{-1} \left\{ \frac{1}{s^2} \right\} + 5L^{-1} \left\{ \frac{1}{s} \right\} \\ &= 2t + 5 \end{aligned}$$

Using result

$$L^{-1}\{e^{-as}F(s)\} = f(t - a)u(t - a)$$

We get (with $a = 4$)

$$\begin{aligned} L^{-1} \left\{ e^{-4s} \left(\frac{2}{s^2} + \frac{5}{s} \right) \right\} &= f(t - 4) \cdot u(t - 4) \\ &= \begin{cases} 0, & 0 < t < 4 \\ f(t - 4), & t > 4 \end{cases} \end{aligned}$$

Since $f(t) = 2t + 5$,

$$\text{so } f(t - 4) = 2(t - 4) + 5 = 2t - 3$$

$$\therefore L^{-1} \left\{ e^{-4s} \left(\frac{2}{s^2} + \frac{5}{s} \right) \right\} = \begin{cases} 0, & 0 < t < 4 \\ 2t - 3, & t > 4 \end{cases}$$

Example 4: $\frac{1}{s^2 - e^{-as}}$

Solution:

$$\begin{aligned} \frac{1}{s^2 - e^{-as}} &= \frac{1}{s^2} \left[1 - \frac{e^{-as}}{s^2} \right]^{-1} = \frac{1}{s^2} \sum_{n=0}^{\infty} \left(\frac{e^{-as}}{s^2} \right)^n \\ &= \sum_{n=0}^{\infty} \frac{e^{-ans}}{s^{2n+2}} = \sum_{n=0}^{\infty} \frac{e^{-ans}}{s^{(2n+1)+1}} \end{aligned}$$

Since $L^{-1} \left\{ \frac{1}{s^{(2n+1)+1}} \right\} = \frac{t^{2n+1}}{(2n+1)!}$.

Therefore

$$\begin{aligned} \frac{1}{s^2 - e^{-as}} &= L^{-1} \left\{ \sum_{n=0}^{\infty} \frac{e^{-ans}}{s^{2n+2}} \right\} = \sum_{n=0}^{\infty} L^{-1} \left\{ \frac{e^{-ans}}{s^{2n+2}} \right\} \\ &= \sum_{n=0}^{\infty} \frac{(t - an)^{2n+1}}{(2n+1)!} u(t - an). \end{aligned}$$

EXERCISE

Using t -shift find the inverse Laplace transform $f(t)$ for each of the following functions $F(s)$:

1. $\frac{(s+1)e^{-\pi s}}{s^2 + s + 1}$

Ans. $\frac{e^{-\frac{1}{2}(t-\pi)}}{\sqrt{3}} \left\{ \sqrt{3} \cos \frac{\sqrt{3}}{2}(t - \pi) + \sin \frac{\sqrt{3}}{2}(t - \pi) \right\} \times u(t - \pi)$

2. $(e^{-4s} - e^{-7s})/s^2$

Ans. $\begin{cases} 0, & 0 < t < 4 \\ t - 4, & 4 < t < 7 \\ 3, & t > 7 \end{cases}$

3. $\frac{e^{4-3s}}{(s+4)^{\frac{5}{2}}}$

Ans. $\frac{4(t-3)^{\frac{3}{2}} e^{-4(t-4)}}{3\sqrt{\pi}} u(t - 3)$

4. $\frac{e^{-3s}}{s^2 - 2s + 5}$

Ans. $\frac{1}{2} e^{(t-3)} \sin 2(t - 3) \cdot u(t - 3)$

5. $\frac{e^{-s}}{(s+1)^3}$

Ans. $\frac{1}{2} \cdot e^{-(t-1)} \cdot (t - 1)^2 \cdot u(t - 1)$

6. $\frac{se^{-\frac{\pi}{2}} + \pi e^{-s}}{s^2 + \pi^2}$

Ans. $\sin \pi t \left\{ u \left(t - \frac{1}{2} \right) - u(t - 1) \right\}$

7. $\frac{s}{s^2 - 5s + 6} e^{-2s}$

12.30 — HIGHER ENGINEERING MATHEMATICS—III

Ans. $\{-2e^{2(t-2)} + 3e^{3(t-2)}\} u(t-2)$

8. $\frac{3}{s} - \frac{4e^{-s}}{s^2} + \frac{4e^{-3s}}{s^2}$

Ans. $3 - 4(t-1)u(t-1) + 4(t-3)u(t-3)$

9. $\frac{e^{-3s}}{(s+1)^3}$

Evaluate $f(2), f(5), f(7)$

Ans. $f(2) = 0, f(5) = 2e^{-2}, f(7) = 8e^{-4}$

10. $\frac{e^{-3s}}{(s-4)^2}$

Ans. $(t-3)e^{4(t-3)}u(t-3)$

11. $\frac{se^{-\pi s}}{s^2+9}$

Ans. $-\cos 3t \cdot u(t-\pi)$

12. $\frac{1}{s+e^{-s}}$

Ans. $\sum_{n=0}^{\infty} \frac{(-1)^n}{n!} (t-n)^n u(t-n).$

12.7 USE OF PARTIAL FRACTIONS TO FIND INVERSE L.T.

Application of L.T. to a D.E. results in a subsidiary (algebraic) equation which usually comes out as a rational function $Y(s) = \frac{P(s)}{Q(s)}$ where $P(s)$ and $Q(s)$ are polynomials in s . When the degree of $P(s) \leq$ degree of $Q(s)$, then the rational function $\frac{P(s)}{Q(s)}$ can be written as the *sum* of simpler rational functions, called partial fractions, depending on the nature of factors of the denominator $Q(s)$ as follows:

Factor in denominator	Corresponding partial fraction
a. Non-repeated linear factor $ax+b$ (occurring once)	$\frac{A}{ax+b}$ with $A \neq 0$
b. Repeated linear factor $(ax+b)^r$ (occurring r times)	$\frac{A_1}{ax+b} + \frac{A_2}{(ax+b)^2} + \dots + \frac{A_r}{(ax+b)^r}$ with $A_r \neq 0$
c. Non-repeated quadratic factor ax^2+bx+c	$\frac{Ax+B}{ax^2+bx+c}$ with at least one of A, B non-zero
d. Repeated quadratic factor $(ax^2+bx+c)^r$ (occurring r times)	$\frac{A_1x+B_1}{ax^2+bx+c} + \frac{A_2x+B_2}{(ax^2+bx+c)^2} + \dots + \frac{A_rx+B_r}{(ax^2+bx+c)^r}$ with at least one of A_r, B_r non-zero.

Here $A, B, A_1, B_1, \dots, A_r, B_r$ are all constants.

By finding the inverse L.T. of each of these partial fractions, $L^{-1}\{Y(s)\} = L^{-1}\left\{\frac{P(s)}{Q(s)}\right\}$ can be determined.

WORKED OUT EXAMPLES

Find the inverse Laplace transform $f(t)$ of each of the following functions $F(s)$:

Distinct non-repeated linear factors

Example 1: $\frac{3s+7}{s^2-2s-3}$

Solution: Using partial fractions, we have

Method 1:

$$\frac{3s+7}{s^2-2s-3} = \frac{3s+7}{(s-3)(s+1)} = \frac{A}{s-3} + \frac{B}{s+1}$$

Multiplying both sides by $(s-3)(s+1)$,

$$3s+7 = A(s+1) + B(s-3) = (A+B)s + A-3B$$

Equating the corresponding coefficients on both sides

$$A+B=3, A-3B=7 \quad \text{Then } A=4, B=-1$$

$$\text{Thus } \frac{3s+7}{(s-3)(s+1)} = \frac{4}{s-3} - \frac{1}{s+1}$$

$$L^{-1}\left\{\frac{3s+7}{(s-3)(s+1)}\right\} = 4L^{-1}\left\{\frac{1}{s-3}\right\} - L^{-1}\left\{\frac{1}{s+1}\right\} \\ = 4e^{3t} - e^{-t}.$$

Method 2:

$$\text{Put } s=3, 16=4A \quad \therefore A=4,$$

$$\text{Put } s=-1, 4=-4B \quad \therefore B=-1$$

Method 3: Multiplying by $(s-3)$ and taking the limit as s tends to 3

$$\lim_{s \rightarrow 3} \frac{3s+7}{s+1} = A + \lim_{s \rightarrow 3} \frac{B(s-3)}{(s+1)}, \quad \text{then } A=4.$$

Similarly, multiplying by $(s+1)$ and letting $s \rightarrow -1$, we get

$$\lim_{s \rightarrow -1} \frac{3s+7}{s-3} = \lim_{s \rightarrow -1} \frac{A(s+1)}{(s-3)} + B \quad \text{Then } B=-1$$

Applying inverse transform, we get the above result.

Linear repeated factors

Example 2: $\frac{s^3+6s^2+14s}{(s+2)^4}$ *Solution:*

$$\begin{aligned} & \frac{s^3+6s^2+14s}{(s+2)^4} \\ &= \frac{A}{(s+2)^4} + \frac{B}{(s+2)^3} + \frac{C}{(s+2)^2} + \frac{D}{(s+2)} \\ s^3+6s^2+14s &= A+B(s+2)+C(s+2)^2+D(s+2)^3 \\ &= Ds^3+(6D+C)s^2+(12D+4C+B)s \\ &\quad +(8D+4C+2B+A) \end{aligned}$$

Equating the coefficients of s

$$A = -12, B = 2, C = 0, D = 1$$

$$\begin{aligned} & L^{-1} \left\{ \frac{s^3+6s^2+14s}{(s+2)^4} \right\} \\ &= -12L^{-1} \left\{ \frac{1}{(s+2)^4} \right\} + 2L^{-1} \left\{ \frac{1}{(s+2)^3} \right\} \\ &\quad + L^{-1} \left\{ \frac{1}{s+2} \right\} \\ &= -12e^{2t} L^{-1} \left\{ \frac{1}{s^4} \right\} + 2e^{-2t} L^{-1} \left\{ \frac{1}{s^3} \right\} + e^{-2t} \\ &= -2e^{-2t} t^3 + e^{-2t} t^2 + e^{-2t} \\ &= e^{-2t} \{1 + t^2 - 2t^3\}. \end{aligned}$$

Non-repeated Quadratic Factors

Example 3: $\frac{s^2+2s+3}{(s^2+2s+2)(s^2+2s+5)}$ *Solution:***Method 1:**

$$\begin{aligned} & \frac{s^2+2s+3}{(s^2+2s+2)(s^2+2s+5)} \\ &= \frac{As+B}{s^2+2s+2} + \frac{Cs+D}{s^2+2s+5} \\ s^2+2s+3 &= (As+B)(s^2+2s+5) + (Cs+D)(s^2+2s+2) \\ &= (A+C)s^3 + (2A+B+2C+D)s^2 \\ &\quad +(5A+2B+2C+2D)s + 5B+2D \end{aligned}$$

Comparing coefficients of s on either side

$$A+C=0, 2A+B+2C+D=1,$$

$$5A+2B+2C+2D=2,$$

$$5B+2D=3$$

By solving these equations, we get

$$A=0, B=\frac{1}{3}, C=0, D=\frac{2}{3}$$

$$\begin{aligned} & L^{-1} \left\{ \frac{s^2+2s+3}{(s^2+2s+2)(s^2+2s+5)} \right\} \\ &= L^{-1} \left\{ \frac{\frac{1}{3}}{s^2+2s+2} \right\} + L^{-1} \left\{ \frac{\frac{2}{3}}{s^2+2s+5} \right\} \\ &= \frac{1}{3} L^{-1} \left\{ \frac{1}{(s+1)^2+1} \right\} + \frac{2}{3} L^{-1} \left\{ \frac{1}{(s+1)^2+4} \right\} \\ &= \frac{1}{3} e^{-t} \sin t + \frac{2}{3} \cdot \frac{1}{2} \cdot e^{-t} \cdot \sin 2t \\ &= \frac{1}{3} e^{-t} (\sin t + \sin 2t). \end{aligned}$$

Method 2: Reduction of non-repeated quadratic factors to non-repeated linear factors using complex numbers

$$\begin{aligned} & \frac{s^2+2s+3}{[(s^2+2s+2)][s^2+2s+5]} \\ &= \frac{s^2+2s+3}{[(s+1-i)(s+1+i)][(s+1-2i)(s+1+2i)]} \\ &= \frac{A}{s+1-i} + \frac{B}{s+1+i} + \frac{C}{s+1-2i} + \frac{D}{s+1+2i}. \end{aligned}$$

Solving $A = \frac{1}{6i}, B = -\frac{1}{6i}, C = \frac{1}{6i}, D = \frac{-1}{6i}$

$$\begin{aligned} & L^{-1} \left\{ \frac{s^2+2s+3}{(s^2+2s+2)(s^2+2s+5)} \right\} \\ &= \frac{e^{-(1-i)t}}{6i} - \frac{e^{-(1+i)t}}{6i} + \frac{e^{-(1-2i)t}}{6i} - \frac{e^{-(1+2i)t}}{6i} \\ &= \frac{1}{3} e^{-t} \left(\frac{e^{it} - e^{-it}}{2i} \right) + \frac{1}{3} e^{-t} \left(\frac{e^{2it} - e^{-2it}}{2i} \right) \\ &= \frac{1}{3} e^{-t} \cdot \sin t + \frac{1}{3} e^{-t} \sin 2t. \end{aligned}$$

Example 4: $\frac{a(s^2-2a^2)}{s^4+4a^4}$

12.32 — HIGHER ENGINEERING MATHEMATICS—III

Solution: Rewriting

$$\begin{aligned}
 s^4 + 4a^4 &= (s^2 + 2a^2)^2 - (2as)^2 \\
 &= (s^2 + 2as + 2a^2)(s^2 - 2as + 2a^2) \\
 \frac{a(s^2 - 2a^2)}{s^4 + 4a^4} &= \frac{a(s^2 - 2a^2)}{(s^2 + 2as + 2a^2)(s^2 - 2as + 2a^2)} \\
 &= \frac{1}{2} \frac{-(s+a)}{s^2 + 2as + 2a^2} + \frac{1}{2} \frac{s-a}{s^2 - 2as + 2a^2} \\
 &= \frac{1}{2} \left[\frac{-(s+a)}{(s+a)^2 + a^2} + \frac{s-a}{(s-a)^2 + a^2} \right] \\
 \therefore L^{-1} \left\{ \frac{a(s^2 - 2a^2)}{s^4 + 4a^4} \right\} \\
 &= \frac{1}{2} L^{-1} \left\{ \frac{-(s+a)}{(s+a)^2 + a^2} \right\} + \frac{1}{2} L^{-1} \left\{ \frac{s-a}{(s-a)^2 + a^2} \right\} \\
 &= \frac{-1}{2} e^{-at} \cos at + \frac{1}{2} e^{at} \cos at \\
 &= \cos at \left[\frac{-1}{2} e^{-at} + \frac{e^{at}}{2} \right] = \cos at \cdot \sinh at.
 \end{aligned}$$

Repeated quadratic factors

Example 5: $\frac{s^3 - 3s^2 + 6s - 4}{(s^2 - 2s + 2)^2}$

Solution:

$$\begin{aligned}
 \frac{s^3 - 3s^2 + 6s - 4}{(s^2 - 2s + 2)^2} &= \frac{As + B}{(s^2 - 2s + 2)^2} + \frac{Cs + D}{(s^2 - 2s + 2)} \\
 s^3 - 3s^2 + 6s - 4 &= As + B + (Cs + D)(s^2 - 2s + 2) \\
 &= Cs^3 + (D - 2C)s^2 \\
 &\quad + (A + 2C - 2D)s + B + 2D.
 \end{aligned}$$

Equating and solving $A = 2, B = -2, C = 1, D = -1$, and rewriting $s^2 - 2s + 2 = (s - 1)^2 + 1$

$$\begin{aligned}
 \text{I.T.} &= L^{-1} \left\{ \frac{2s - 2}{[(s - 1)^2 + 1]^2} \right\} + L^{-1} \left\{ \frac{s - 1}{(s - 1)^2 + 1} \right\} \\
 &= e^t L^{-1} \left\{ \frac{2s}{(s^2 + 1)^2} + \frac{s}{(s^2 + 1)} \right\} \\
 &= 2e^{-t} L^{-1} \left\{ \frac{s}{(s^2 + 1)^2} \right\} + e^{-t} \cdot \cos t \\
 &= 2e^t \cdot \frac{t}{2} \cdot \sin t + e^{-t} \cdot \cos t = e^t \{t \sin t + \cos t\}.
 \end{aligned}$$

EXERCISE

Find the inverse Laplace transform $f(t)$ of each of the following functions $F(s)$:

- $\frac{s-2}{s^2+5s+6}$ *Ans.* $-4e^{-2t} + 5e^{-3t}$
- $\frac{2s^2-4}{(s+1)(s-2)(s-3)}$ *Ans.* $\frac{-1}{6}e^{-t} - \frac{4}{3}e^{2t} + \frac{7}{2}e^{3t}$
- $\frac{s^2-7s+24}{s^3-7s^2+14s-8}$ *Ans.* $6e^t - 7e^{2t} + 2e^{4t}$
- $\frac{s+17}{(s-1)(s+3)}$ *Ans.* $\frac{9}{2}e^t - \frac{7}{2}e^{-3t}$
- $\frac{2s^2-6s+5}{s^3-6s^2+11s-6}$ *Ans.* $\frac{1}{2}e^t - e^{2t} + \frac{5}{2}e^{3t}$
- $\frac{5s}{s^2+4s+4}$ *Ans.* $5e^{-2t}(1 - 2t)$
- $\frac{5}{(s-2)^4}$ *Ans.* $\frac{5t^2e^{2t}}{6}$
- $\frac{7}{(2s+1)^3}$ *Ans.* $\frac{7}{16}t^2e^{-\frac{t}{2}}$
- $\frac{s+2}{s^2+4s+7}$ *Ans.* $e^{-2t} \cdot \cos \sqrt{3}t$
- $\frac{2s+12}{s^2+6s+13}$ *Ans.* $e^{-3t}(2 \cos 2t + 3 \sin 2t)$
- $\frac{s^2+9s-9}{s^3-9s}$ *Ans.* $1 + 3 \sinh 3t$
- $\frac{s}{(s^2-2s+2)(s^2+2s+2)}$ *Ans.* $\frac{1}{2} \sin t \cdot \sinh t$
- $\frac{3s^3-3s^2-40s+36}{(s^2-4)^2}$ *Ans.* $(5t + 3)e^{-2t} - 2te^{2t}$
- $\frac{2s^3-s^2-1}{(s+1)^2(s^2+1)^2}$ *Ans.* $\frac{1}{2} \sin t + \frac{1}{2}t \cos t - te^{-t}$
- $\frac{5s^2-7s+17}{(s-1)(s^2+4)}$ *Ans.* $3e^t + 2 \cos 2t - \frac{5}{2} \sin 2t$
- $\frac{2s^2+15s+7}{(s+1)^2(s-2)}$ *Ans.* $(2t - 3)e^{-t} + 5e^{2t}$
- $\frac{s+1}{(s^2+1)(s^2+4)}$ *Ans.* $\frac{1}{6}(2 \cos t - 2 \cos 2t + 2 \sin t - \sin 2t)$
- $\frac{10}{s(s^2-2s+5)}$ *Ans.* $2 - e^t(2 \cos 2t - \sin 2t)$
- $\frac{1}{s(s+1)^2}$ *Ans.* $1 - e^{-t} - te^{-t}$

$$20. \frac{s^2 + 8s + 27}{(s+1)(s^2 + 4s + 13)}$$

$$\text{Ans. } 2e^{-t} + e^{-2t}(\sin 3t - \cos 3t)$$

$$21. \frac{s}{s^4 + s^2 + 1}$$

$$\text{Hint: } s^4 + s^2 + 1 = (s^2 + s + 1)(s^2 - s + 1)$$

$$\text{Ans. } \frac{1}{\sqrt{3}} \left[e^{\frac{t}{2}} \sin \frac{\sqrt{3}}{2} t - e^{-\frac{t}{2}} \sin \frac{\sqrt{3}}{2} t \right]$$

$$22. \frac{s}{s^4 + 4a^4}$$

$$\text{Hint: } s^4 + 4a^4 = (s^2 + 2a^2)^2 - (2as)^2 \\ = (s^2 + 2as + 2a^2)(s^2 - 2as + 2a^2).$$

$$\text{Ans. } \frac{1}{2a^2} \sin at \cdot \sinh at$$

$$23. \frac{5s+3}{(s-1)(s^2+2s+5)}$$

$$\text{Ans. } e^t - e^{-t} \left(\cos 2t - \frac{3}{2} \sin 2t \right)$$

$$24. \frac{s^2}{s^4 + 4a^4}$$

$$\text{Hint: Use hint of above Example 22.}$$

$$\text{Ans. } \frac{1}{2a} [\sinh at \cos at + \cosh at \cdot \sin at].$$

12.8 CONVOLUTION

Convolution is used to find inverse Laplace transforms in solving differential equations and integral equations.

Suppose two Laplace transforms $F(s)$ and $G(s)$ are given. Let $f(t)$ and $g(t)$ be their inverse Laplace transforms respectively i.e., $f(t) = L^{-1}\{F(s)\}$ and $g(t) = L^{-1}\{G(s)\}$. Then the inverse $h(t)$ of the product of transforms $H(s) = F(s)G(s)$ can be calculated from the known inverse $f(t)$ and $g(t)$.

Convolution

$h(t)$ of $f(t)$ and $g(t)$, denoted by $(f * g)(t)$ is defined as

$$h(t) = (f * g)(t) = \int_0^t f(u)g(t-u)du$$

$f * g$ is called the convolution or *faltung** of f and g and can be regarded as a “generalized product” of these functions.

Result: Thus to find the inverse transform of product of transforms $H(s) = F(s)G(s)$, calculate $h(t) = f * g$ which is the convolution of f and g . Therefore one should tactfully rewrite $H(s)$ as a product of $F(s)$ and $G(s)$ in such a way that the

corresponding inverses $f(t)$ and $g(t)$ are readily known from transform tables or other means.

Convolution Theorem

Prove that

$$L\{h(t)\} = L\{f * g\} = H(s) = F(s) \cdot G(s)$$

$$\text{or } L^{-1}\{F(s) \cdot G(s)\} = h(t) = f * g.$$

Proof: From the definition of Laplace transform

$$\begin{aligned} L\{f * g\} &= \int_0^\infty e^{-st} (f * g) dt \\ &= \int_0^\infty e^{-st} \left[\int_0^t f(\tau)g(t-\tau) d\tau \right] dt \\ &= \int_0^\infty \int_0^t e^{-st} f(\tau)g(t-\tau) d\tau dt, \\ &= \int_R \int e^{-st} f(\tau)g(t-\tau) d\tau dt \end{aligned}$$

Fig. 12.10

where R is the 45° wedge bounded by the lines $\tau = 0$ and $t = \tau$ (see Fig. 12.10). Change the variables τ, t to the new variables u, v by the transformation

$$u = t - \tau$$

$$v = \tau$$

Fig. 12.11

* German for folding.

12.34 — HIGHER ENGINEERING MATHEMATICS—III

The Jacobian $J = 1$. Thus the double integral over R transforms to a double integral over D the first quadrant of the new uv -plane (i.e., $u > 0, v > 0$) (refer Fig. 12.11). Thus

$$\begin{aligned} L\{f * g\} &= \int_D \int e^{-s(u+v)} f(v)g(u) du dv \\ &= \int_0^\infty \int_0^\infty e^{-s(u+v)} f(v)g(u) du dv \\ &= \int_0^\infty e^{-sv} f(v) dv \int_0^\infty e^{-su} g(u) du \\ &= L\{f\} \cdot L\{g\} \end{aligned}$$

Valid Properties

1. $f * g = g * f$ Commutative
2. $(f * g) * v = f * (g * v)$ Associative
3. $f * (g_1 + g_2) = f * g_1 + f * g_2$ Distributive
4. $f * 0 = 0 * f = 0$.

WORKED OUT EXAMPLES

Use convolution theorem to find the inverse of the following:

Example 1: $\frac{1}{s^2(s^2+1)}$

Solution: Rewriting

$$\frac{1}{s^2(s^2+1)} = \frac{1}{s^2} \cdot \frac{1}{s^2+1} = F(s) \cdot G(s)$$

so that $f(t) = L^{-1}(F(s)) = L^{-1}\left(\frac{1}{s^2}\right) = t$

$$g(t) = L^{-1}(G(s)) = L^{-1}\left(\frac{1}{s^2+1}\right) = \sin t$$

$\therefore$ By convolution theorem

$$\begin{aligned} L^{-1}\left\{\frac{1}{s^2(s^2+1)}\right\} &= f * g = \int_0^t (t-u) \cdot \sin u du \\ &= -t \cos t + t + t \cos t - \sin t \\ &= t - \sin t. \end{aligned}$$

Example 2: $\frac{1}{(s^2+a^2)^2}$

Solution: Rewriting

$$\frac{1}{(s^2+a^2)^2} = \left(\frac{1}{s^2+a^2}\right) \left(\frac{1}{s^2+a^2}\right)$$

Here $f(t) = L^{-1}\left(\frac{1}{s^2+a^2}\right) = \frac{1}{a} \sin at$

Similarly, $g(t) = \frac{1}{a} \sin at$

$$\begin{aligned} \therefore L^{-1}\left\{\frac{1}{(s^2+a^2)^2}\right\} &= f * g \\ &= \int_0^t \frac{\sin au}{a} \cdot \frac{\sin a(t-u)}{a} du \\ &= \frac{1}{2a^2} \int_0^t [\cos a(2u-t) - \cos at] du \\ \therefore \sin A \cdot \sin B &= \frac{\cos(A-B) - \cos(A+B)}{2} \\ &= \frac{1}{2a^2} \left[\frac{\sin a(2u-t)}{2a} - \cos at \cdot u \right]_{u=0}^a \\ &= \frac{1}{2a^2} \left[\frac{\sin at}{2a} - t \cos at - \frac{\sin(-at)}{2a} \right] \\ &= \frac{1}{2a^3} [\sin at - at \cos at] \end{aligned}$$

Example 3: $\frac{16}{(s-2)(s+2)^2}$

Solution: Rewriting $\frac{1}{(s-2)} \cdot \frac{1}{(s+2)^2} = F(s) \cdot G(s)$

We know that $f(t) = L^{-1}\{F(s)\} = L^{-1}\left\{\frac{1}{s-2}\right\} = e^{2t}$

$$\begin{aligned} g(t) &= L^{-1}\{G(s)\} = L^{-1}\left\{\frac{1}{(s+2)^2}\right\} \\ &= e^{-2t} L^{-1}\left\{\frac{1}{s^2}\right\} = te^{-2t} \end{aligned}$$

Applying convolution theorem

$$\begin{aligned} L^{-1}\left\{\frac{16}{(s-2)(s+2)^2}\right\} &= 16 \cdot g * f = 16 \int_0^t ue^{-2u} e^{2(t-u)} du \\ &= 16e^{2t} \int_0^t ue^{-4u} du \\ &= 16e^{2t} \left[\frac{ue^{-4u}}{-4} - 1 \frac{e^{-4u}}{16} \right]_{u=0}^t \\ &= e^{2t} - e^{-2t} - 4te^{-2t}. \end{aligned}$$

Example 4: $\frac{1}{s(s+1)(s+2)}$

Solution: Rewriting

$$\frac{1}{s(s+1)(s+2)} = \frac{1}{s(s+1)} \cdot \frac{1}{s+2}$$

Consider

$$\frac{1}{s(s+1)} = \frac{1}{s} \cdot \frac{1}{s+1}$$

so that $f(t) = 1$, $g(t) = e^{-t}$

$$\begin{aligned} L^{-1} \left\{ \frac{1}{s} \cdot \frac{1}{s+1} \right\} &= f * g = \int_0^t 1 \cdot e^{-u} du \\ &= 1 - e^{-t} = h(t) \end{aligned}$$

Also $L^{-1} \left\{ \frac{1}{s+2} \right\} = J(t) = e^{-2t}$

$$\begin{aligned} \therefore L^{-1} \left\{ \frac{1}{s(s+1)} \cdot \frac{1}{s+2} \right\} &= h * J \\ &= \int_0^t e^{-2(t-u)} \cdot (1 - e^u) du \\ &= e^{-2t} \int_0^t (e^{2u} - e^u) du \\ &= e^{-2t} \left[\frac{e^{2u}}{2} \Big|_0^t - e^u \Big|_0^t \right] \\ &= e^{-2t} \left[\frac{e^{2t}}{2} - \frac{1}{2} - (e^t - 1) \right] \\ &= \frac{1}{2} + \frac{1}{2} e^{-2t} - e^{-t}. \end{aligned}$$

EXERCISE

Use convolution theorem to find inverse Laplace transform of the following:

- $\frac{1}{(s+a)(s+b)}$ *Ans.* $\frac{e^{-at} - e^{-bt}}{b-a}$
- $\frac{1}{s(s^2+9)}$ *Ans.* $(1 - \cos 3t)/9$
- $\frac{1}{s^2(s+3)}$ *Ans.* $(-1 + 3t + e^{-3t})/9$
- $\frac{s^2}{(s^2+a^2)^2}$ *Ans.* $\frac{1}{2a}(\sin at + at \cos at)$
- $\frac{s}{(s^2+a^2)^3}$ *Ans.* $\frac{t}{8a^3}(\sin at - at \cos at)$
- $\frac{s^2}{(s^2+a^2)(s^2+b^2)}$ *Ans.* $\frac{a \sin at - b \sin bt}{a^2 - b^2}$
- $\frac{1}{(s+1)(s^2+1)}$ *Ans.* $\frac{1}{2}(\sin t - \cos t + e^{-t})$

$$8. \frac{1}{(s+1)(s+9)^2} \quad \text{Ans. } \frac{e^{-t}}{64} [1 - e^{-8t}(1 + 8t)]$$

$$9. \frac{1}{s^2(s-a)} \quad \text{Ans. } \frac{1}{a^2}(e^{at} - at - 1)$$

$$10. \frac{s}{(s^2+a^2)^2} \quad \text{Ans. } \frac{t \sin at}{2a}$$

$$11. \frac{a}{s^2(s^2+a^2)} \quad \text{Ans. } (at - \sin at)/a^2$$

$$12. \frac{1}{(s^2+4)(s+1)^2} \quad \text{Ans. } \frac{e^{-t}}{50} [10e^{-t} - (3 \sin 2t + 4 \cos 2t)]$$

$$13. \frac{1}{s^3(s^2+1)} \quad \text{Ans. } \frac{t^2}{2} + \cos t - 1$$

$$14. \frac{1}{[s^2(s^2-a^2)]} \quad \text{Ans. } \frac{1}{a^2} \left[-t + \frac{\sinh at}{a} \right]$$

$$15. \frac{1}{(s+2)^2(s-2)} \quad \text{Ans. } \frac{1}{16} [e^{2t} - (4t + 1)e^{-2t}].$$

12.9 APPLICATION OF LAPLACE TRANSFORM TO DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

Laplace transform is especially suitable to obtain the solution of linear non-homogeneous ordinary differential equations with constant coefficients, when all the boundary conditions are specified for the unknown function and its derivatives at a single point.

Consider the initial value problem

$$\frac{d^2 y}{dt^2} + a \frac{dy}{dt} + by = r(t) \quad (1)$$

$$y(t=0) = k_0, \quad y'(t=0) = k_1 \quad (2)$$

where a, b, k_0, k_1 are all constants and $r(t)$ is a function of t .

Method of solution to D.E. by L.T.

Step I. Apply Laplace transform on both sides of the given differential Equation (1), resulting in a subsidiary equation

$$\begin{aligned} [s^2 Y - sy(0) - y'(0)] \\ + a[sY - y(0)] + bY = R(s) \end{aligned} \quad (3)$$

where $Y = L\{y(t)\}$ and $R(s) = L\{r(t)\}$.

Replace $y(0), y'(0)$ using given initial conditions (2).

Step II. Solve (3) algebraically for $Y(s)$, usually to a sum of partial fractions.

12.36 — HIGHER ENGINEERING MATHEMATICS—III

Step III. Apply inverse Laplace transform to $Y(s)$ obtained in step II. This yields the solution of O.D.E. (1) satisfying the initial conditions (2) as

$$y(t) = L^{-1}\{Y(s)\}.$$

WORKED OUT EXAMPLES

Homogeneous

Solve the following using Laplace transform:

Example 1: $y'' - 2y' - 8y = 0$, $y(0) = 3$, $y'(0) = 6$

Solution: Applying L.T.

$$(s^2 Y - 3s - 6) - 2(sY - 3) - 8Y = 0$$

Solving,

$$Y(s) = \frac{3s}{s^2 - 2s - 8} = \frac{3s}{(s - 4)(s + 2)}$$

Using partial fractions

$$Y(s) = \frac{2}{s - 4} + \frac{1}{s + 2}$$

Applying I.L.T.

$$\begin{aligned} y(t) &= L^{-1}(Y(s)) = 2L^{-1}\left(\frac{1}{s - 4}\right) + L^{-1}\left(\frac{1}{s + 2}\right) \\ &= 2e^{4t} + e^{-2t}. \end{aligned}$$

Non-homogeneous

Example 2: $y'' + 2y' + 5y = e^{-t} \sin t$, $y(0) = 0$, $y'(0) = 1$.

Solution: Using L.T.

$$\begin{aligned} [s^2 Y - 0 - 1] + 2[sY - 0] + 5Y &= L(e^{-t} \sin t) \\ &= \frac{1}{(s + 1)^2 + 1} \end{aligned}$$

$$\text{Solving } Y = \frac{s^2 + 2s + 3}{(s^2 + 2s + 5)(s^2 + 2s + 2)}$$

By partial fractions,

$$\begin{aligned} \frac{s^2 + 2s + 3}{(s^2 + 2s + 5)(s^2 + 2s + 2)} &= \frac{As + B}{s^2 + 2s + 5} + \frac{Cs + D}{s^2 + 2s + 2} \\ s^2 + 2s + 3 &= (As + B)(s^2 + 2s + 2) \\ &\quad + (Cs + D)(s^2 + 2s + 5) \\ &= s^3(A + C) + s^2(2A + 2C + B + D) \\ &\quad + s(2A + 5C + 2B + 2D) + 2B + 5D. \end{aligned}$$

Equating coefficients of s on either side

$$A + C = 0, \quad 2A + 2C + B + D = 1,$$

$$2A + 5C + 2B + 2D = 2, \quad 2B + 5D = 3$$

$$\therefore A = 0, B = \frac{1}{3}, C = 0, D = \frac{2}{3}$$

$$Y(s) = \frac{1}{3} \frac{1}{s^2 + 2s + 5} + \frac{2}{3} \frac{1}{s^2 + 2s + 2}$$

Rewriting

$$Y(s) = \frac{1}{3} \frac{1}{(s + 1)^2 + 2^2} + \frac{2}{3} \frac{1}{(s + 1)^2 + 1^2}.$$

Applying I.T.

$$\begin{aligned} y(t) &= L^{-1}(Y) = \frac{1}{3} L^{-1}\left(\frac{1}{(s + 1)^2 + 2^2}\right) \\ &\quad + \frac{2}{3} L^{-1}\left(\frac{1}{(s + 1)^2 + 1^2}\right) \end{aligned}$$

Using first shift theorem

$$= \frac{1}{3} e^{-t} L^{-1}\left(\frac{1}{s^2 + 1}\right) + \frac{2}{3} e^{-t} L^{-1}\left(\frac{1}{s^2 + 2^2}\right)$$

$$y(t) = \frac{e^{-t}}{3} [\sin t + \sin 2t].$$

Example 3: $y'' + n^2 y = a \sin(nt + 2)$, $y(0) = 0$, $y'(0) = 0$.

Solution:

$$y'' + n^2 y = a[\sin nt \cdot \cos 2 + \cos nt \cdot \sin 2]$$

$$\begin{aligned} \text{Applying L.T., } L(y'') + n^2 L(y) &= \\ a \cdot \cos 2 \cdot L(\sin nt) + a \sin 2 \cdot L(\cos nt). \end{aligned}$$

$$\begin{aligned} [s^2 Y - sy(0) - y'(0)] + n^2 Y &= \\ = \frac{n}{s^2 + n^2} \cdot a \cdot \cos 2 + \frac{s}{s^2 + n^2} \cdot a \sin 2 \end{aligned}$$

Solving for Y

$$Y(s) = \frac{n}{(s^2 + n^2)^2} \cdot a \cdot \cos 2 + \frac{s}{(s^2 + n^2)^2} \cdot a \cdot \sin 2.$$

Applying I.T.

$$y(t) = n \cdot a \cdot \cos 2 \cdot L^{-1} \left\{ \frac{1}{(s^2 + n^2)^2} \right\} + a \cdot \sin 2 \cdot L^{-1} \left\{ \frac{s}{(s^2 + n^2)^2} \right\} \quad (1)$$

From I.L.T. tables, we know that (2nd term in R.H.S.)

$$L^{-1} \left\{ \frac{s}{(s^2 + n^2)^2} \right\} = \frac{t \cdot \sin nt}{2n} \quad (2)$$

To find 1st term in R.H.S.

$$L^{-1} \left\{ \frac{1}{(s^2 + n^2)^2} \right\} = L^{-1} \left\{ \frac{1}{s} \cdot \frac{s}{(s^2 + n^2)^2} \right\} = \frac{1}{2n} \int_0^t t \cdot \sin nt \, dt$$

because

$$L^{-1} \left\{ \frac{F(s)}{s} \right\} = \int_0^t f(t) dt.$$

$$\therefore L^{-1} \left\{ \frac{1}{(s^2 + n^2)^2} \right\} = \frac{1}{2n} \int_0^t t \cdot \sin nt \, dt = \frac{1}{2n^3} [-nt \cos nt + \sin nt] \quad (3)$$

Thus substituting (2) and (3) in (1), we get

$$\begin{aligned} y(t) &= an \cdot \cos 2 \cdot \frac{1}{2n^3} [-nt \cos nt + \sin nt] \\ &\quad + a \sin 2 \frac{t}{2n} \sin nt \\ &= \frac{a}{2n^2} [-nt \cdot \cos 2 \cdot \cos nt + \cos 2 \cdot \sin nt \\ &\quad + nt \cdot \sin 2 \cdot \sin nt] \\ &= \frac{a}{2n^2} [\sin nt \cdot \cos 2 - nt(\cos nt \cdot \cos 2 \\ &\quad - \sin nt \cdot \sin 2)] \\ &= \frac{a}{2n^2} [\sin nt \cdot \cos 2 - nt \cos(nt + 2)]. \end{aligned}$$

Example 4: Solve $y''' - 3y'' + 3y' - y = t^2 e^t$, $y(0) = 1$, $y'(0) = 0$, $y''(0) = -2$.

Solution: Applying L.T. to D.E.

$$\begin{aligned} L(y''') - 3L(y'') + 3L(y') - L(y) &= L(t^2 e^t) \\ [s^3 Y - s^2 y(0) - s y'(0) - y''(0)] \\ - 3[s^2 Y - s y(0) - y'(0)] \\ + 3[s Y - y(0)] - Y &= \frac{2}{(s-1)^3} \end{aligned}$$

Using the initial condition $y(0) = 1$, $y'(0) = 0$, $y''(0) = -2$, and solving for Y

$$(s^3 - 3s^2 + 3s - 1)Y - s^2 + 3s - 1 = \frac{2}{(s-1)^3}$$

$$Y = \frac{s^2 - 3s + 1}{(s-1)^3} + \frac{2}{(s-1)^6}$$

$$= \frac{s^2 - 2s + 1 - s}{(s-1)^3} + \frac{2}{(s-1)^6}$$

$$= \frac{(s-1)^2 - (s-1) - 1}{(s-1)^3} + \frac{2}{(s-1)^6}$$

$$Y = \frac{1}{s-1} - \frac{1}{(s-1)^2} - \frac{1}{(s-1)^3} + \frac{2}{(s-1)^6}.$$

Applying I.L.T.

$$\begin{aligned} y(t) &= L^{-1}(Y) = L^{-1} \left(\frac{1}{s-1} \right) - L^{-1} \left(\frac{1}{(s-1)^2} \right) \\ &\quad - L^{-1} \left(\frac{1}{(s-1)^3} \right) + 2L^{-1} \left(\frac{1}{(s-1)^6} \right) \end{aligned}$$

$$y(t) = e^t - t e^t - \frac{t^2 e^t}{2} + \frac{t^5 e^t}{60}$$

where we have used the first shift theorem.

Example 5: Find the general solution of the D.E. in the above Example 4.

Solution: Since the initial conditions are arbitrary assume $y(0) = a$, $y'(0) = b$, $y''(0) = c$.

Then

$$\begin{aligned} (s^2 Y - a s^2 - b s - c) - 3(s^2 Y - a s - b) \\ + 3(s Y - a) - Y &= \frac{2}{(s-1)^3} \end{aligned}$$

$$Y = \frac{as^2 + (b-3a)s + (3a-3b+c)}{(s-1)^3} + \frac{2}{(s-1)^6}$$

12.38 — HIGHER ENGINEERING MATHEMATICS—III

By partial fractions

$$Y = \frac{c_1}{(s-1)^3} + \frac{c_2}{(s-1)^2} + \frac{c_3}{(s-1)^1} + \frac{2}{(s-1)^6}$$

where c_1, c_2, c_3 are constants depending on a, b, c .

Applying I.T., and using first shift theorem

$$y(t) = c_1 \frac{t^2}{2} e^t + c_2 t e^t + c_3 e^t + \frac{t^5}{60} e^t.$$

EXERCISE

Use L.T. to solve each of the following I.V.P. consisting of a D.E. with I.C:

1. $y' - y = 0$, general solution

Hint: Assume $y(0) = A = \text{constant}$

Ans. $y = Ae^t$

2. $y' - y = e^{3t}$, $y(0) = 2$

Ans. $y = (3e^t + e^{3t})/2$

3. $y'' + y' = 0$, general solution

Hint: Assume $y(0) = A, y'(0) = B$

Ans. $y = C + De^{-t}, C = A + B, D = -B$

4. $y'' + y = 2e^t$, $y(0) = 0, y'(0) = 2$

Ans. $y = e^t + \cos t + \sin t$

5. $y'' - 6y' + 9y = 0$, $y(0) = 2, y'(0) = 9$

Ans. $y = (3t + 2)e^{3t}$

6. $y'' + 4y = 9t$, $y(0) = 0, y'(0) = 7$

Ans. $y = \frac{9}{4}t + \frac{19}{8}\sin 2t$

7. $y'' + 7y' + 10y = 4e^{-3t}$, $y(0) = 0, y'(0) = -1$

Ans. $y = e^{-2t} - 2e^{-3t} + e^{-5t}$

8. $y'' - 8y' + 15y = 9te^{2t}$, $y(0) = 5, y'(0) = 10$

Ans. $y = 4e^{2t} + 3te^{2t} + 3e^{3t} - 2e^{5t}$

9. $y'' + y = t \cos 2t$, $y(0) = 0, y'(0) = 0$

Ans. $y = \frac{4}{9}\sin 2t - \frac{5}{9}\sin t - \frac{1}{3}t \cos 2t$

10. $y'' + n^2y = a \sin(nt + \theta)$, $y(0) = y'(0) = 0$

Ans. $y = \frac{a}{2n^2}[\sin nt \cos \theta - nt \cos(nt + \theta)]$

11. $y'' + y = \sin t \cdot \sin 2t$, $y(0) = 1, y'(0) = 0$

Ans. $y = \frac{15}{16}\cos t + \frac{t}{4}\sin t + \frac{1}{16}\cos 3t$

12. $y'' + y = e^{-2t} \sin t$, $y(0) = 0, y'(0) = 0$

Ans. $y = \frac{1}{8}(\sin t - \cos t) + \frac{e^{-2t}}{8}(\sin t + \cos t)$

13. $y''' + 4y'' + 5y' + 2y = 10 \cos t$

$y(0) = 0, y'(0) = 0, y''(0) = 3$

Ans. $y = -e^{-2t} + 2e^{-t} - 2te^{-t} - \cos t + 2 \sin t$

14. $y''' - y = e^t$

$y(0) = y'(0) = y''(0) = 0$

Ans. $y = \frac{t}{3}e^t + \frac{e^{2t}}{18} \left\{ 9 \cos \frac{\sqrt{3}}{2}t + \frac{5\sqrt{3}}{2} \sin \frac{\sqrt{3}}{2}t \right\} - \frac{e^t}{2}$

15. $y^{iv} - 16y = 30 \sin t$

$y''(0) = 0, y'''(0) = -18,$

$y''(\pi) = 0, y'''(\pi) = -18$

Ans. $y(t) = -\frac{1}{8}e^{2t} + \frac{1}{8}e^{-2t} + 7 \sin t - \frac{9}{2} \sin 2t.$

12.10 APPLICATION OF LAPLACE TRANSFORM TO SYSTEM OF SIMULTANEOUS DIFFERENTIAL EQUATIONS

Laplace Transform can also be used to solve a system (or family) of m simultaneous ordinary differential equations in m dependent variables which are functions of the independent variable t . Consider a family of two simultaneous D.E. in the 2 dependent variables x and y which are functions of t .

$$\begin{aligned} a_1 \frac{d^2x}{dt^2} + a_2 \frac{d^2y}{dt^2} + a_3 \frac{dx}{dt} + a_4 \frac{dy}{dt} + a_5x + a_6y \\ = R_1(t) \end{aligned} \quad (1)$$

$$\begin{aligned} b_1 \frac{d^2x}{dt^2} + b_2 \frac{d^2y}{dt^2} + b_3 \frac{dx}{dt} + b_4 \frac{dy}{dt} + b_5x + b_6y \\ = R_2(t) \end{aligned} \quad (2)$$

Initial conditions:

$$x(0) = c_1, y(0) = c_2, x'(0) = c_3, y'(0) = c_4 \quad (3)$$

Here $a_1, a_2, \dots, a_6, b_1, b_2, \dots, b_6, c_1, c_2, c_3, c_4$ are all constants and $R_1(t)$ and $R_2(t)$ are functions of t .

Method of solution to system of D.E

Step I. Apply Laplace transform on both sides of each of the two D.E. (1) and (2). This reduces (1) and (2) to two algebraic equations in $X(s)$ and $Y(s)$ where $X(s) = L\{x(t)\}$ and $Y(s) = L\{y(t)\}$.

$$\begin{aligned} a_1\{s^2X - sx(0) - x'(0)\} + a_2\{s^2Y - sy(0) - y'(0)\} \\ + a_3\{sX - x(0)\} + a_4\{sY - y(0)\} \\ + a_5X + a_6Y = Q_1(s) \end{aligned} \quad (4)$$

$$\begin{aligned} b_1\{s^2X - sx(0) - x'(0)\} + b_2\{s^2Y - sy(0) - y'(0)\} \\ + b_3\{sX - x(0)\} + b_4\{sY - y(0)\} \\ + b_5X + b_6Y = Q_2(s) \end{aligned} \quad (5)$$

Use the initial conditions (3) and substitute for $x(0)$, $x'(0)$, $y(0)$, $y'(0)$.

Step II. Solve (4) and (5) for $X(s)$ and $Y(s)$.

Step III. The required solution is obtained by taking the inverse Laplace transform of $X(s)$ and $Y(s)$ as

$$\begin{aligned} x(t) &= L^{-1}\{X(s)\} \quad \text{and} \\ y(t) &= L^{-1}\{Y(s)\}. \end{aligned}$$

WORKED OUT EXAMPLES

Example 1: $2\frac{dx}{dt} + \frac{dy}{dt} - x - y = e^{-t}$

$$\frac{dx}{dt} + \frac{dy}{dt} + 2x + y = e^t, \quad x(0) = 2, y(0) = 1$$

Solution: Taking L.T. of the given D.E., we get

$$2[sX(s) - x(0)] + sY(s) - y(0) - X(s) - Y(s) = \frac{1}{s+1}$$

$$sX(s) - x(0) + sY(s) - y(0) + 2X(s) + Y(s) = \frac{1}{s-1}$$

Using I.C. $x(0) = 2$, $y(0) = 1$,

$$(2s-1)X(s) + (s-1)Y(s) = \frac{5s+6}{s+1}$$

$$(s+2)X(s) + (s+1)Y(s) = \frac{3s-2}{s-1}$$

Solving

$$X(s) = \frac{2(s+4)}{s^2+1}$$

$$Y(s) = \frac{s^3 - 12s^2 - s + 14}{(s^2+1)(s^2-1^2)} = \frac{s-13}{s^2+1} + \frac{1}{s^2-1}$$

Taking inverse Laplace transform, we have

$$x(t) = L^{-1}\{X(s)\} = L^{-1}\left\{\frac{2s+8}{s^2+1}\right\} = 2\cos t + 8\sin t$$

$$\begin{aligned} y(t) &= L^{-1}\left\{\frac{s-13}{s^2+1} + \frac{1}{s^2-1}\right\} \\ &= \cos t - 13\sin t + \sinh t \end{aligned}$$

Example 2: $\frac{d^2x}{dt^2} - 3\frac{dx}{dt} - \frac{dy}{dt} + 2y = 14t + 3$
 $\frac{dx}{dt} - 3x + \frac{dy}{dt} = 1$
 $x(0) = 0, x'(0) = 0, y(0) = 6.5$

Solution: Taking L.T. of the given D.E., we have

$$[s^2X - sx(0) - x'(0)] - 3[sX - x(0)]$$

$$-[sY - y(0)] + 2Y = 14\frac{1}{s^2} + 3\frac{1}{s}$$

$$[sX - x(0)] - 3X + [sY - y(0)] = \frac{1}{s}$$

Use I.C.: $x(0) = 0, x'(0) = 0, y(0) = 6.5 = \frac{13}{2}$

$$s(s-3)X + (2-s)Y = \frac{28+6s-13s^2}{2s^2}$$

$$(s-3)X + sY = \frac{2+13s}{2s}$$

Solving

$$Y(s) = \frac{13s^3 + 15s^2 - 6s - 28}{2s^2(s^2 + s - 2)}$$

$$X(s) = \frac{4(7-6s)}{s(s-3)(s+2)(s-1)}$$

12.40 — HIGHER ENGINEERING MATHEMATICS—III

Taking inverse Laplace transform

$$\begin{aligned} y(t) &= L^{-1}\{Y(s)\} = L^{-1}\left\{\frac{13s^3 + 15s^2 - 6s - 28}{2s^2(s^2 + s - 2)}\right\} \\ &= L^{-1}\left\{\frac{A}{s^2} + \frac{B}{s} + \frac{C}{s-1} + \frac{D}{s+2}\right\} \\ &= L^{-1}\left\{\frac{7}{s^2} + \frac{5}{s} - \frac{1}{s-1} + \frac{5}{2} \frac{1}{s+2}\right\} \\ y(t) &= 7t + 5 - e^{+t} + \frac{5}{2}e^{-2t} \end{aligned}$$

Similarly,

$$\begin{aligned} x(t) &= L^{-1}\left\{\frac{4(7-6s)}{s(s-3)(s+2)(s-1)}\right\} \\ &= L^{-1}\left\{\frac{2}{s} - \frac{1}{2} \frac{1}{s-1} - \frac{1}{2} \frac{1}{s-3} - \frac{1}{s+2}\right\} \\ x(t) &= 2 - \frac{1}{2}e^t - \frac{1}{2}e^{3t} - e^{-2t} \end{aligned}$$

EXERCISE

Solve the following system of equations:

1. $\frac{dx}{dt} = 2x - 3y$; $\frac{dy}{dt} = y - 2x$, $x(0) = 8$, $y(0) = 3$

Ans. $x(t) = 5e^{-t} + 3e^{4t}$; $y(t) = 5e^{-t} - 2e^{4t}$

2. $\frac{dx}{dt} + y \sin t$; $\frac{dy}{dt} + x = \cos t$, $x(0) = 2$, $y(0) = 0$

Ans. $x(t) = e^t + e^{-t} = 2 \cosh t$,

$$y(t) = \sin t - 2 \sinh t$$

3. $\frac{dx}{dt} - 6x + 3y = 8e^t$; $\frac{dy}{dt} - 2x - y = 4e^t$, $x(0) = -1$, $y(0) = 0$

Ans. $x(t) = -2e^t + e^{4t}$; $y(t) = -\frac{2}{3}e^t + \frac{2}{3}e^{4t}$

4. $\frac{2dx}{dt} + \frac{4dy}{dt} + x - y = 3e^t$;

$$\frac{dx}{dt} + \frac{dy}{dt} + 2x + 2y = e^t, x(0) = 1, y(0) = 0$$

Ans. $x(t) = e^{-2t} - te^t$; $y(t) = \frac{e^t}{3} - \frac{e^{-2t}}{3} + te^t$

5. $\frac{dx}{dt} - \frac{dy}{dt} - 2x + 2y = 1 - 2t$

$$\frac{d^2x}{dt^2} + 2\dot{x} + x = 2, x(0) = y(0) = x'(0) = 0$$

Ans. $x = 2 - 2e^{-t}(1+t)$;

$$y(t) = 2 - t - 2(1+t)e^{-t}$$

6. $\frac{dx}{dt} + 2\frac{d^2y}{dt^2} = e^{-t}$

$$\frac{dx}{dt} + 2x - y = 1$$

$$x(0) = y(0) = y'(0) = 0$$

Ans. $x(t) = 1 + e^{-t} - e^{-at} - e^{-bt}$

$$y(t) = 1 + e^{-t} - be^{-at} - ae^{-bt}$$

where $a = \frac{1}{2}(2 - \sqrt{2})$, $b = \frac{1}{2}(2 + \sqrt{2})$.

7. $\frac{3dx}{dt} + \frac{dy}{dt} + 2x = 1$; $\frac{dx}{dt} + 4\frac{dy}{dt} + 3y = 0$

$$x(0) = 3, y(0) = 0$$

Ans. $x = (5 - 2e^{-t} - 3e^{-\frac{6t}{11}})/10$;

$$y(t) = (e^{-t} - e^{-\frac{6t}{11}})/5$$

8. $\frac{dx}{dt} = y + e^t$; $\frac{dy}{dt} = \sin t - x$,

$$x(0) = 1, y(0) = 0$$

Ans. $x(t) = (e^t + \cos t + 2 \sin t - t \cos t)/2$

$$y(t) = (t \sin t - e^t + \cos t - \sin t)/2$$

9. $\frac{d^2x}{dt^2} = 2x + 3y + e^{2t}$; $\frac{d^2y}{dt^2} = -x - 2y$

$$x(0) = y(0) = 1, x'(0) = y'(0) = 0$$

Ans. $x(t) = \frac{1}{4}(3e^t + 7e^{-t}) - \frac{1}{10}(19 \cos t - 2 \sin t) + \frac{2}{5}e^{2t}$

$$y(t) = \frac{-1}{12}(3e^t + 7e^{-t}) + \frac{1}{10}(19 \cos t - 2 \sin t) - \frac{1}{15}e^{2t}$$

10. $\frac{d^2x}{dt^2} + \frac{dy}{dt} + 3x = 15e^{-t}$

$$\frac{d^2y}{dt^2} - \frac{4dx}{dt} + 3y = 15 \sin 2t$$

$$x(0) = 35, x'(0) = -48, y(0) = 27,$$

$$y'(0) = -55$$

Ans. $x(t) = 30 \cos t - 15 \sin 3t + 3e^{-t} + 2 \cos 2t$

$$y(t) = 30 \cos 3t - 60 \sin t - 3e^{-t} + \sin 2t.$$

12.11 TABLE OF GENERAL PROPERTIES OF LAPLACE TRANSFORM

$$F(s) = \int_0^{\infty} e^{-st} f(t) dt$$

Chapter 13

Matrices

INTRODUCTION

The term matrix was apparently coined by Sylvester about 1850, but was introduced first by Cayley in 1860. By a ‘matrix’ we mean an “arrangement” or “rectangular array” of numbers. The elegant “short-hand” representation of an array of many numbers as a single object and perform calculations makes matrices very useful. Matrices (plural of matrix) find applications in solution of system of linear equations, probability, mathematical economics, quantum mechanics, electrical networks, curve fitting, transportation problems, frameworks in mechanics. Matrices are easily amenable for computers. A brief revision of matrices, types, properties is presented.

A matrix is a rectangular array of $m \cdot n$ numbers (or functions) arranged in m rows (horizontal lines) and n columns l (vertical lines). These numbers known as elements or entries are enclosed in brackets [] or () or $\parallel$.

The order of such matrix is $m \times n$ and is said to be a rectangular matrix.

Notation

Elements of a matrix are located by the double subscript ij where i denotes the row and j the column.

Null or Zero matrix is a matrix with all elements zero.

Equality

Two matrices A and B are equal if they are of the same order and $a_{ij} = b_{ij}$, for every i, j .

Sum (difference)

$C = A \pm B$ where $c_{ij} = a_{ij} \pm b_{ij}$ (and A and B are conformable i.e., of the same order). Scalar multiplication: $C = kA$ where $c_{ij} = ka_{ij}$ i.e., every element of A is multiplied by constant k .

Matrix multiplication:

$$C_{m \times n} = A_{m \times p} B_{p \times n} \text{ where } c_{ij} = \sum_{k=1}^p a_{ik} b_{kj}$$

Transpose of a matrix $A_{m \times n}$ is denoted by $A_{n \times m}^T$ obtained by interchanging rows and columns.

Result: $(AB)^T = B^T A^T$.

Square matrix

$A : m = n$, when the number of rows equals to the number of columns, known as n -square matrix.

The elements a_{ii} are known as diagonal elements

Trace: $\sum_{i=1}^n a_{ii}$ = sum of the diagonal elements.

Singular matrix: if $|A| = 0$

Non-singular matrix: if $|A| \neq 0$

Upper triangular matrix A : $a_{ij} = 0$ for $i > j$

Lower triangular matrix A : $a_{ij} = 0$ for $i < j$

Diagonal matrix A : $a_{ij} = 0$ when $i \neq j$

Scalar matrix A : a diagonal matrix with $a_{ii} = k$ for every i and k is a constant.

Identity matrix: is a scalar matrix with $k = 1$

i.e.,
$$I_3 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Note: All the above definitions are only for square matrices.

13.2 — HIGHER ENGINEERING MATHEMATICS—IV

Row matrix (vector) is a matrix having only one row.

Column matrix (vector) is a matrix having only one column.

Matrix addition and multiplication is associative but not (necessarily) commutative.

i.e., $A + (B + C) = (A + B) + C$ and $A(BC) = (AB)C$.

Distributive: $A(B + C) = AB + AC$.

Power of a matrix: A^n is a matrix obtained by multiplying A by itself n times.

13.1 INVERSE OF A MATRIX

Consider only square matrices.

Inverse of a n -square matrix A is denoted by A^{-1} and is defined such that

$$AA^{-1} = A^{-1}A = I$$

where I is $n \times n$ unit matrix.

Result 1: Inverse of A exists only if $|A| \neq 0$ i.e., A is non-singular.

Result 2: Inverse of a matrix is unique.

If B, C are two inverses of A then $(CA)B = C(AB)$, $IB = CI$ i.e., $B = C$, so inverse is unique.

Result 3: Inverse of a product is the product of inverses in the reverse order

i.e., $(AB)^{-1} = B^{-1}A^{-1}$

since $(AB)(B^{-1}A^{-1}) = A(BB^{-1})A^{-1} = AIA^{-1} = AA^{-1} = I$.

Result 4: For a diagonal matrix D with d_{ii} as diagonal elements, D^{-1} is a diagonal matrix with reciprocals $1/d_{ii}$ as the diagonal elements.

Result 5: Transposition and inverse are commutative i.e.,

$$(A^{-1})^T = (A^T)^{-1}.$$

Taking transpose of $AA^{-1} = A^{-1}A = I_n$

$$(A^{-1})^T A^T = A^T (A^{-1})^T = I^T = I \text{ i.e.,}$$

$(A^{-1})^T$ is the inverse of A^T or $(A^{-1})^T = (A^T)^{-1}$.

Result 6: $(A^{-1})^{-1} = A$.

Taking inverse of $(AA^{-1}) = I$,

$$(AA^{-1})^{-1} = (A^{-1})^{-1}A^{-1} = I^{-1} = I = A A^{-1}.$$

Thus $A = (A^{-1})^{-1}$.

Inverse by Adjoint Matrix

Minor M_{ij} of an element a_{ij} of a $n \times n$ square matrix A is the determinant of the $(n - 1)$ square matrix of

A obtained by deleting the i th row and j th column from A .

Cofactor A_{ij} of a_{ij} of A is a signed minor

$$\text{i.e., } A_{ij} = (-1)^{i+j} M_{ij}$$

Adjoint of a Matrix A

Adjoint of a matrix is denoted by $\text{adj } A$ is the transpose of a n -square matrix $[A_{ij}]$ where the elements A_{ij} are the cofactors of a_{ij} of A .

$$\text{i.e., } \text{adj } A = \begin{bmatrix} A_{11} & A_{12} & A_{13} \cdots A_{1n} \\ A_{21} & A_{22} & A_{23} \cdots A_{2n} \\ \dots & \dots & \dots \\ A_{n1} & A_{n2} & A_{n3} \cdots A_{nn} \end{bmatrix}^T =$$

$$\text{adj } A = \begin{bmatrix} A_{11} & A_{21} & A_{31} \cdots A_{n1} \\ A_{12} & A_{22} & A_{32} \cdots A_{n2} \\ \dots & \dots & \dots \\ A_{1n} & A_{2n} & A_{3n} \cdots A_{nn} \end{bmatrix}$$

Result: $\text{adj } (AB) = (\text{adj } A)(\text{adj } B)$

Inverse of a matrix can be calculated by several methods.

Inverse from the adjoint:

$$A^{-1} = \frac{\text{adj } A}{|A|}.$$

WORKED OUT EXAMPLES

Inverse of a matrix

Example: Find the adjoint and inverse of

$$A = \begin{bmatrix} 2 & 3 & 4 \\ 4 & 3 & 1 \\ 1 & 2 & 4 \end{bmatrix}.$$

Solution:

$$\text{Adjoint of } A = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{bmatrix}^T$$

where A_{ij} are the cofactors of the element a_{ij} . Thus minors of a_{ij} are

$$M_{11} = \begin{vmatrix} 3 & 1 \\ 2 & 4 \end{vmatrix} = 10, \quad M_{12} = \begin{vmatrix} 4 & 1 \\ 1 & 4 \end{vmatrix} = 15$$

Similarly,

$$M_{13} = \begin{vmatrix} 4 & 3 \\ 1 & 2 \end{vmatrix} = 5, \quad M_{21} = \begin{vmatrix} 3 & 4 \\ 2 & 4 \end{vmatrix} = 4,$$

$$M_{22} = \begin{vmatrix} 2 & 4 \\ 1 & 4 \end{vmatrix} = 4, \quad M_{23} = \begin{vmatrix} 2 & 3 \\ 1 & 2 \end{vmatrix} = 1,$$

$$M_{31} = \begin{vmatrix} 3 & 4 \\ 3 & 1 \end{vmatrix} = -9, \quad M_{32} = \begin{vmatrix} 2 & 4 \\ 4 & 1 \end{vmatrix} = 14$$

$$M_{33} = \begin{vmatrix} 2 & 3 \\ 4 & 3 \end{vmatrix} = -6.$$

Cofactors $A_{ij} = (-1)^{i+j} M_{ij}$

$$\text{Adjoint of } A = \begin{bmatrix} 10 & -15 & 5 \\ -4 & 4 & -1 \\ -9 & +14 & -6 \end{bmatrix}^T$$

$$= \begin{bmatrix} 10 & -4 & -9 \\ -15 & 4 & +14 \\ 5 & -1 & -6 \end{bmatrix}$$

$$|A| = 2(12 - 2) - 3(16 - 1) + 4(8 - 3)$$

$$= 20 - 45 + 20 = 40 - 45 = -5$$

$$A^{-1} = \frac{1}{|A|} \text{adj } A = \frac{1}{-5} \begin{bmatrix} 10 & -4 & -9 \\ -15 & 4 & 14 \\ 5 & -1 & -6 \end{bmatrix}$$

or

$$A^{-1} = \frac{1}{5} \begin{bmatrix} -10 & 4 & 9 \\ 15 & -4 & -14 \\ -5 & 1 & 6 \end{bmatrix}.$$

EXERCISE

Inverse of a matrix

Find the inverse of the matrix A , by adjoint matrix:

$$1. \begin{bmatrix} 1 & 1 & 3 \\ 1 & 3 & -3 \\ -2 & -4 & -4 \end{bmatrix}$$

Ans. $|A| = -8$

$$\text{adj } A = \begin{bmatrix} -24 & -8 & -12 \\ 10 & 2 & 6 \\ 2 & 2 & 2 \end{bmatrix}$$

$$A^{-1} = \frac{1}{4} \begin{bmatrix} 12 & 4 & 6 \\ -5 & -1 & -3 \\ -1 & -1 & -1 \end{bmatrix}$$

$$2. \begin{bmatrix} 1 & 2 & 3 \\ 1 & 3 & 4 \\ 1 & 4 & 3 \end{bmatrix}$$

Ans. $|A| = -2$

$$\text{adj } A = \begin{bmatrix} -7 & 6 & -1 \\ 1 & 0 & -1 \\ 1 & -2 & 1 \end{bmatrix}$$

$$A^{-1} = \frac{1}{2} \begin{bmatrix} 7 & -6 & 1 \\ -1 & 0 & 1 \\ -1 & 2 & -1 \end{bmatrix}$$

$$3. \begin{bmatrix} -1 & 1 & 2 \\ 3 & -1 & 1 \\ -1 & 3 & 4 \end{bmatrix}$$

Ans. $|A| = 10$

$$\text{adj } A = \begin{bmatrix} -7 & 2 & 3 \\ -13 & -2 & 7 \\ 8 & 2 & -2 \end{bmatrix}, \quad A^{-1} = \frac{1}{|A|} \text{adj } A$$

$$A^{-1} = \begin{bmatrix} -0.7 & 0.2 & 0.3 \\ -1.3 & -0.2 & 0.7 \\ 0.8 & 0.2 & -0.2 \end{bmatrix}$$

$$4. \begin{bmatrix} 7 & 6 & 2 \\ -1 & 2 & 4 \\ 3 & 3 & 8 \end{bmatrix}$$

Ans. $|A| = 130,$

$$\text{adj } A = \begin{bmatrix} 4 & -42 & 20 \\ 20 & 50 & -30 \\ -9 & -3 & 20 \end{bmatrix}$$

13.2 RANK OF A MATRIX

Let A be a rectangular matrix of order $m \times n$.

Submatrix

Submatrix of a matrix A is any matrix obtained from A by omitting some rows and columns in A .

A is a submatrix of itself (obtained by deleting zero rows and columns).

Rank

Rank of a matrix A is the positive integer r such that there exists at least one r -rowed square matrix with non-vanishing determinant while every $(r+1)$ or more rowed matrices have vanishing determinants.

Thus rank of a matrix is the largest order of a non-zero minor of matrix.

Rank of A is denoted by $r(A)$.

Result: Rank of A and A^T is same.

Note 1: Rank of a null matrix is zero.

Note 2: For a rectangular matrix A of order $m \times n$, rank of $A \leq \min(m, n)$ i.e., rank can not exceed the smaller of m and n .

Note 3: For a n -square matrix, if rank = n then $|A| \neq 0$ i.e., A is non-singular.

13.4 — HIGHER ENGINEERING MATHEMATICS—IV

Note 4: For any square matrix, if $\text{rank} < n$, then $|A| = 0$ i.e., A is singular.

Elementary Row Transformations (Operation) on a Matrix

1. R_{ij} : Interchange of the i th and j th rows.
2. $R_{i(k)}$: Multiplication of every element of i th row by a non-zero scalar k .
3. $R_{ij(k)}$: Addition to the elements of i th row, of k times the corresponding elements of the j th row.

In a similar way, elementary column transformations (operations) are denoted by C_{ij} , $C_{i(k)}$, $C_{ij(k)}$ where the row in the above definitions is replaced by column.

WORKED OUT EXAMPLES

Inverse by Gauss-Jordan

Example: Find the inverse of A by Gauss-Jordan method where

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix}.$$

Solution: Consider $A|I$ and apply elementary row operations on both A and I until A gets transformed to I .

$$\left[\begin{array}{ccc|ccc} 1 & 2 & 3 & 1 & 0 & 0 \\ 2 & 4 & 5 & 0 & 1 & 0 \\ 3 & 5 & 6 & 0 & 0 & 1 \end{array} \right] \xrightarrow{\substack{R_{21}(-2) \\ R_{31}(-3)}} \left[\begin{array}{ccc|ccc} 1 & 2 & 3 & 1 & 0 & 0 \\ 0 & 0 & -1 & -2 & 1 & 0 \\ 0 & -1 & -3 & -3 & 0 & 1 \end{array} \right]$$

$$\xrightarrow{\substack{R_{23} \\ R_{2(-1)} \\ R_{3(-1)}}} \left[\begin{array}{ccc|ccc} 1 & 2 & 3 & 1 & 0 & 0 \\ 0 & 1 & 3 & 3 & 0 & -1 \\ 0 & 0 & 1 & 2 & -1 & 0 \end{array} \right]$$

$$\xrightarrow{\substack{R_{23(-3)} \\ R_{13(-3)}}} \left[\begin{array}{ccc|ccc} 1 & 2 & 0 & -5 & 3 & 0 \\ 0 & 1 & 0 & -3 & 3 & -1 \\ 0 & 0 & 1 & 2 & -1 & 0 \end{array} \right]$$

$$\xrightarrow{R_{12}(-2)} \left[\begin{array}{ccc|ccc} 1 & 0 & 0 & 1 & -3 & 2 \\ 0 & 1 & 0 & -3 & 3 & -1 \\ 0 & 0 & 1 & 2 & -1 & 0 \end{array} \right] = [I|A^{-1}]$$

$$\text{Thus } A^{-1} = \begin{bmatrix} 1 & -3 & 2 \\ -3 & 3 & -1 \\ 2 & -1 & 0 \end{bmatrix}.$$

EXERCISE

By Gauss-Jordan elimination

$$1. \begin{bmatrix} 1 & 3 & 3 \\ 1 & 4 & 3 \\ 1 & 3 & 4 \end{bmatrix}$$

$$\text{Ans. } A^{-1} = \begin{bmatrix} 7 & -3 & -3 \\ -1 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix}$$

$$2. \begin{bmatrix} 2 & 4 & 3 & 2 \\ 3 & 6 & 5 & 2 \\ 2 & 5 & 2 & -3 \\ 4 & 5 & 14 & 14 \end{bmatrix}$$

$$\text{Ans. } A^{-1} = \begin{bmatrix} -23 & 29 & \frac{-64}{5} & \frac{-18}{5} \\ 10 & -12 & \frac{26}{5} & \frac{7}{5} \\ 1 & -2 & \frac{6}{5} & \frac{2}{5} \\ 2 & -2 & \frac{3}{5} & \frac{1}{5} \end{bmatrix}$$

$$3. \begin{bmatrix} 0 & 1 & 3 \\ 1 & 2 & 3 \\ 3 & 1 & 1 \end{bmatrix}$$

$$\text{Ans. } A^{-1} = \frac{1}{2} \begin{bmatrix} 1 & -1 & 1 \\ -8 & 6 & -2 \\ 5 & -3 & 1 \end{bmatrix}$$

$$4. \begin{bmatrix} 9 & 7 & 3 \\ 5 & -1 & 4 \\ 3 & 4 & 1 \end{bmatrix}$$

$$\text{Ans. } A^{-1} = -\frac{1}{35} \begin{bmatrix} -17 & 5 & 31 \\ 7 & 0 & -21 \\ 23 & -15 & -44 \end{bmatrix}$$

$$5. \begin{bmatrix} -1 & -3 & 3 & -1 \\ 1 & 1 & -1 & 0 \\ 2 & -5 & 2 & -3 \\ -1 & 1 & 0 & 1 \end{bmatrix}$$

$$\text{Ans. } A^{-1} = \begin{bmatrix} 0 & 2 & 1 & 3 \\ 1 & 1 & -1 & -2 \\ 1 & 2 & 0 & 1 \\ -1 & 1 & 2 & 6 \end{bmatrix}$$

$$6. \begin{bmatrix} 1 & 2 & -1 \\ -1 & 1 & 2 \\ 2 & -1 & 1 \end{bmatrix}$$

$$\text{Ans. } A^{-1} = \frac{1}{14} \begin{bmatrix} 3 & -1 & 5 \\ 5 & 3 & -1 \\ -1 & 5 & 3 \end{bmatrix}$$

$$7. \begin{bmatrix} 4 & -1 & 1 \\ 2 & 0 & -1 \\ 1 & -1 & 3 \end{bmatrix}$$

$$\text{Ans. } A^{-1} = \begin{bmatrix} -1 & 2 & 1 \\ -7 & 11 & 6 \\ -2 & 3 & 2 \end{bmatrix}$$

Equivalent matrices

Two matrices A and B are said to be equivalent, denoted by $A \sim B$, if one matrix say A can be obtained from B by a sequence of elementary transformations.

Row-equivalence

Two matrices A and B are said to be row-equivalent if A can be reduced to B by a sequence of elementary row transformations or vice versa.

Determination of Rank of a Matrix A

Let A be a rectangular matrix of order $m \times n$.

I. Enumeration: Evaluate all the minors such that a minor of r is non-zero and every minor of $(r + 1)$ or more is zero:

Note: This is impracticable for matrices of higher order.

II. Apply only **elementary row operations** on A . Then the number of non-zero rows is the rank of A .

III. Normal form N of a matrix A of rank r is one of the forms

$$N = I_r, \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}, \quad [I_r \quad 0], \begin{bmatrix} I_r \\ 0 \end{bmatrix}$$

where I_r is an identity matrix of order r . By the application of both elementary row and column operations, a matrix of rank r can be reduced to normal form. Then the rank of A is r .

IV. Echelon Form.* Row Reduced Echelon form:
The number of non-zero rows in an Echelon form is the rank.

Result: Equivalent matrices have the same order and same rank because elementary transformations do not alter (effect) its order and rank.

WORKED OUT EXAMPLES

Rank of a matrix

Determine the rank of the following matrices:

$$\text{Example 1: } A = \begin{bmatrix} 4 & 2 & 3 \\ 8 & 4 & 6 \\ -2 & -1 & -1.5 \end{bmatrix}$$

Solution: Rank of $A \leq 3$ since A is of 3rd order.
 $|A| = 4(-6 + 6) - 2(-12 + 12) + 3(-8 + 8) = 0$

Since $|A| = 0$, rank of $A < 3$ i.e., $r(A) \leq 2$

Consider the determinants of 2nd order submatrices

$$\begin{vmatrix} 4 & 2 \\ 8 & 4 \end{vmatrix} = 0, \quad \begin{vmatrix} 2 & 3 \\ 4 & 6 \end{vmatrix} = 0, \quad \begin{vmatrix} 4 & 3 \\ 8 & 6 \end{vmatrix} = 0,$$

$$\begin{vmatrix} 4 & 2 \\ -2 & -1 \end{vmatrix} = 0, \quad \begin{vmatrix} 2 & 3 \\ -1 & -1.5 \end{vmatrix} = 0, \quad \begin{vmatrix} 4 & 3 \\ -2 & -1.5 \end{vmatrix} = 0,$$

Since all 2nd order submatrices have zero determinants i.e., 2nd order minors are all zero. So $r(A) < 2$. Since A is a non-zero matrix $r(A) > 0$.

Thus the rank of A is one.

Aliter: Apply elementary row operations on A

$$\begin{matrix} R_{21}(-2) \\ R_{31}(\frac{1}{2}) \end{matrix} \sim \begin{bmatrix} 4 & 2 & 3 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

The number of non-zero rows is one. So the rank of A is one.

* A matrix $A = (a_{ij})$ is an echelon matrix or is said to be in echelon form, if the number of zeros preceding the first non-zero entry (known as distinguished elements) of a row increases row by row until only zero rows remain.

In row reduced echelon matrix, the distinguished elements are unity and are the only non-zero entry in their respective columns.

13.6 — HIGHER ENGINEERING MATHEMATICS—IV

Example 2: $A = \begin{bmatrix} 1 & 5 & 4 \\ 0 & 3 & 2 \\ 2 & 3 & 10 \end{bmatrix}, B = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}$

Find rank of A , rank of B , rank of $A + B$, rank of AB and rank of BA .

Solution: $A = \begin{bmatrix} 1 & 5 & 4 \\ 0 & 3 & 2 \\ 2 & 13 & 10 \end{bmatrix} \xrightarrow{R_{31}(-2)} \sim \begin{bmatrix} 1 & 5 & 4 \\ 0 & 3 & 2 \\ 0 & 3 & 2 \end{bmatrix}$

$$\xrightarrow{R_{32}(-1)} \sim \begin{bmatrix} 1 & 5 & 4 \\ 0 & 3 & 2 \\ 0 & 0 & 0 \end{bmatrix}$$

Rank of A is 2 since the number of non-zero rows is 2.

$$B = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix} \xrightarrow{\substack{R_{21}(-1) \\ R_{31}(-3)}} \sim \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

$$\therefore r(B) = 1$$

$$A + B = \begin{bmatrix} 2 & 6 & 5 \\ 2 & 5 & 4 \\ 5 & 16 & 13 \end{bmatrix} \xrightarrow{\substack{R_{21}(-2) \\ R_{31}(-\frac{5}{2})}} \sim \begin{bmatrix} 2 & 6 & 5 \\ 0 & -7 & -6 \\ 0 & -1 & \frac{1}{2} \end{bmatrix},$$

$$r(A + B) = 3$$

$$AB = \begin{bmatrix} 23 & 23 & 23 \\ 12 & 12 & 12 \\ 58 & 58 & 58 \end{bmatrix} \xrightarrow{\substack{R_{1(\frac{1}{23})} \\ R_{21}(-12) \\ R_{31}(-58)}} \sim \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

$$r(AB) = 1$$

$$BA = \begin{bmatrix} 3 & 21 & 16 \\ 6 & 42 & 32 \\ 9 & 63 & 48 \end{bmatrix} \xrightarrow{\substack{R_{21}(-2) \\ R_{31}(-3)}} \sim \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

$$r(BA) = 1.$$

Note: Rank of product $\leq$ rank of either.

Example 3:

$$A = \begin{bmatrix} 1 & 2 & -2 & 3 \\ 2 & 5 & -4 & 6 \\ -1 & -3 & 2 & -2 \\ 2 & 4 & -1 & 6 \end{bmatrix}_{4 \times 4}$$

$$\xrightarrow{\substack{R_{21}(-2) \\ R_{31(1)} \\ R_{41}(-2)}} \sim \begin{bmatrix} 1 & 2 & -2 & 3 \\ 0 & 1 & 0 & 0 \\ 0 & -1 & 0 & 1 \\ 0 & 0 & 3 & 0 \end{bmatrix}$$

$$\begin{matrix} R_{32(1)} \\ R_{34} \\ R_{3(\frac{1}{3})} \end{matrix} \sim \begin{bmatrix} 1 & 2 & -2 & 3 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$\therefore r(A) = 4$$

Example 4:

$$A = \begin{bmatrix} 3 & 4 & 5 & 6 & 7 \\ 4 & 5 & 6 & 7 & 8 \\ 5 & 6 & 7 & 8 & 9 \\ 10 & 11 & 12 & 13 & 14 \\ 15 & 16 & 17 & 18 & 19 \end{bmatrix}_{5 \times 5}$$

$$\xrightarrow{\substack{R_{12}(-1) \\ R_{1(-1)}}} \sim \begin{bmatrix} 1 & 1 & 1 & 1 & 1 \\ 4 & 5 & 6 & 7 & 8 \\ 5 & 6 & 7 & 8 & 9 \\ 10 & 11 & 12 & 13 & 14 \\ 15 & 16 & 17 & 18 & 19 \end{bmatrix}$$

$$\xrightarrow{\substack{R_{21}(-4) \\ R_{31}(-5) \\ R_{41}(-10) \\ R_{51}(-15)}} \sim \begin{bmatrix} 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 & 4 \\ 0 & 1 & 2 & 3 & 4 \\ 0 & 1 & 2 & 3 & 4 \\ 0 & 1 & 2 & 3 & 4 \end{bmatrix} \xrightarrow{\substack{R_{32}(-1) \\ R_{42}(-1) \\ R_{52}(-1)}} \sim \begin{bmatrix} 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 & 4 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

Rank of A is 2 since the number of non-zero rows is 2.

Example 5: Determine the values of b such that the rank of A is 3.

Solution:

$$A = \begin{bmatrix} 1 & 1 & -1 & 0 \\ 4 & 4 & -3 & 1 \\ b & 2 & 2 & 2 \\ 9 & 9 & b & 3 \end{bmatrix}$$

$$\xrightarrow{\substack{R_{21}(-4) \\ R_{31}(-2) \\ R_{41}(-9)}} \sim \begin{bmatrix} 1 & 1 & -1 & 0 \\ 0 & 0 & 1 & 1 \\ b-2 & 0 & 4 & 2 \\ 0 & 0 & b+9 & 3 \end{bmatrix}$$

$$\xrightarrow{\substack{R_{32}(-4) \\ R_{42}(-3)}} \sim \begin{bmatrix} 1 & 1 & -1 & 0 \\ 0 & 0 & 1 & 1 \\ b-2 & 0 & 0 & -2 \\ 0 & 0 & b+6 & 0 \end{bmatrix}$$

$$\xrightarrow{R_{43}} \sim \begin{bmatrix} 1 & 1 & -1 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & b+6 & 0 \\ b-2 & 0 & 0 & -2 \end{bmatrix}$$

Cases:

- i. If $b = 2$, $|A| = 1 \cdot 0 \cdot 8 \cdot (-2) = 0$, rank of $A = 3$
- ii. If $b = -6$, no. of non-zero rows is 3, rank of $A = 3$.

Echelon form

Example 6: Reduce A to Echelon form and then to its row canonical form (or row reduced Echelon form) where

$$A = \begin{pmatrix} 1 & 3 & -1 & 2 \\ 0 & 11 & -5 & 3 \\ 2 & -5 & 3 & 1 \\ 4 & 1 & 1 & 5 \end{pmatrix}$$

Hence find the rank of A .

Solution: Applying elementary row operations on A

$$\begin{matrix} R_{31}(-2) \\ R_{41}(-4) \end{matrix} \sim \begin{bmatrix} 1 & 3 & -1 & 2 \\ 0 & 11 & -5 & 3 \\ 0 & -11 & 5 & -3 \\ 0 & -11 & 5 & -3 \end{bmatrix}$$

$$\begin{matrix} R_{32}(1) \\ R_{42}(1) \\ \sim \end{matrix} \begin{bmatrix} 1 & 3 & -1 & 2 \\ 0 & 11 & -5 & 3 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad \text{This is Echelon form.}$$

$$\begin{matrix} R_{2(\frac{1}{11})} \\ \sim \end{matrix} \begin{bmatrix} 1 & 3 & -1 & 2 \\ 0 & 1 & -\frac{5}{11} & \frac{3}{11} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

$$R_{12}(-3) \begin{bmatrix} 1 & 0 & \frac{4}{11} & \frac{13}{11} \\ 0 & 1 & -\frac{5}{11} & \frac{3}{11} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

This is the row canonical or row reduced Echelon form.

Rank of A is 2 since there are two non-zero rows.

EXERCISE
Rank of a matrix

Find the rank of the matrix:

1. $\begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \\ 3 & 1 & 2 \end{bmatrix}$ Ans. 3

2. $\begin{bmatrix} 1 & 1 & -1 & 1 \\ 1 & -1 & 2 & -1 \\ 3 & 1 & 0 & 1 \end{bmatrix}$ Ans. 2

3. $\begin{bmatrix} 2 & 3 & -1 & -1 \\ 1 & -1 & -2 & -4 \\ 3 & 1 & 3 & -2 \\ 6 & 3 & 0 & -7 \end{bmatrix}$ Ans. 3

4. $\begin{bmatrix} 3 & -2 & 0 & -1 & -7 \\ 0 & 2 & 2 & 1 & -5 \\ 1 & -2 & -3 & -2 & 1 \\ 0 & 1 & 2 & 1 & -6 \end{bmatrix}$ Ans. 4

5. $\begin{bmatrix} 1 & 2 & 3 & 2 \\ 2 & 3 & 5 & 1 \\ 1 & 3 & 4 & 5 \end{bmatrix}$ Ans. 2

6. $\begin{bmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 3 & 4 & 5 & 6 \\ 3 & 4 & 5 & 6 & 7 \\ 4 & 5 & 6 & 7 & 8 \end{bmatrix}$ Ans. 2

7. $\begin{bmatrix} 1 & 2 & 1 & 2 \\ 1 & 3 & 2 & 2 \\ 2 & 4 & 3 & 4 \\ 3 & 7 & 4 & 6 \end{bmatrix}$ Ans. 3

8. $\begin{bmatrix} 1 & 2 & -3 & 4 & 9 \\ 1 & 0 & -1 & 1 & 1 \\ 3 & -1 & 1 & 0 & -1 \\ -1 & 1 & 0 & 2 & 9 \\ 3 & 1 & 0 & 3 & 9 \end{bmatrix}$ Ans. 4

9. $\begin{bmatrix} 1 & 2 & 3 \\ 1 & 4 & 2 \\ 2 & 6 & 5 \end{bmatrix}$ Ans. 2

10. $\begin{bmatrix} 0 & 1 & -3 & -1 \\ 0 & 0 & 1 & 1 \\ 3 & 1 & 0 & 2 \\ 1 & 1 & -2 & 0 \end{bmatrix}$ Ans. 2

11. $\begin{bmatrix} 3 & 0 & 2 & 2 \\ -6 & 42 & 24 & 54 \\ 21 & -21 & 0 & -15 \end{bmatrix}$ Ans. 2

13.8 — HIGHER ENGINEERING MATHEMATICS—IV

$$12. \begin{bmatrix} 1 & 2 & -1 & 4 \\ 2 & 4 & 3 & 5 \\ -1 & -2 & 6 & -7 \end{bmatrix} \quad \text{Ans. 2}$$

$$13. \begin{bmatrix} 1 & 2 & 3 & 0 \\ 2 & 4 & 3 & 2 \\ 3 & 2 & 1 & 3 \\ 6 & 8 & 7 & 5 \end{bmatrix} \quad \text{Ans. 3}$$

$$14. \begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \\ -2 & -3 & -1 \end{bmatrix} \quad \text{Ans. 2}$$

Echelon form

Find the Echelon form and row reduced echelon form of the matrix and hence find the rank:

$$17. \begin{bmatrix} 1 & -2 & 3 & -1 \\ 2 & -1 & 2 & 2 \\ 3 & 1 & 2 & 3 \end{bmatrix}$$

$$\text{Ans. } \begin{pmatrix} 1 & -2 & 3 & -1 \\ 0 & 3 & -4 & 4 \\ 0 & 0 & 7 & -10 \end{pmatrix},$$

$$\begin{pmatrix} 1 & 0 & 0 & \frac{15}{7} \\ 0 & 1 & 0 & -\frac{4}{7} \\ 0 & 0 & 1 & -\frac{10}{7} \end{pmatrix}, \text{ rank} = 3$$

$$18. \begin{bmatrix} 1 & 2 & -5 \\ -4 & 1 & -6 \\ 6 & 3 & -4 \end{bmatrix}$$

$$\text{Ans. } \begin{pmatrix} 1 & 2 & -5 \\ 0 & 9 & -26 \\ 0 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 7/9 \\ 0 & 1 & -26/9 \\ 0 & 0 & 0 \end{pmatrix}$$

rank = 2

$$19. \begin{bmatrix} 0 & 1 & 3 & -2 \\ 0 & 4 & -1 & 3 \\ 0 & 0 & 2 & 1 \\ 0 & 5 & -3 & 4 \end{bmatrix}$$

$$\text{Ans. } \begin{bmatrix} 0 & 1 & 3 & -2 \\ 0 & 0 & -13 & 11 \\ 0 & 0 & 0 & 35 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

rank = 3

$$20. \begin{bmatrix} 2 & 3 & -2 & 5 & 1 \\ 3 & -1 & 2 & 0 & 4 \\ 4 & -5 & 6 & -5 & 7 \end{bmatrix}$$

$$\text{Ans. } \begin{pmatrix} 2 & 3 & -2 & 5 & 1 \\ 0 & -11 & 10 & -15 & 5 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\begin{pmatrix} 1 & 0 & \frac{4}{11} & \frac{5}{11} & \frac{13}{11} \\ 0 & 1 & -\frac{10}{11} & \frac{15}{11} & -\frac{5}{11} \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \text{ rank} = 2$$

13.3 NORMAL FORM

Procedure to Obtain Normal Form

Consider

$$A_{m \times n} = I_{m \times m} A_{m \times n} I_{n \times n}$$

Apply elementary row operations on A and on the prefactor $I_{m \times m}$ and apply elementary column operations on A and on the postfactor $I_{n \times n}$, such that A on the L.H.S. reduces to normal form. Then $I_{m \times m}$ reduces to $P_{m \times m}$ and $I_{n \times n}$ reduces to $Q_{n \times n}$; resulting in $N = PAQ$.

Here P and Q are non-singular matrices.

Thus for any matrix of rank r , there exist non-singular matrices P and Q such that

$$PAQ = N = \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}.$$

WORKED OUT EXAMPLES

Example 1: Find the non-singular matrices P and Q such that the normal form of A is PAQ where

$$A = \begin{bmatrix} 1 & 3 & 6 & -1 \\ 1 & 4 & 5 & 1 \\ 1 & 5 & 4 & 3 \end{bmatrix}_{3 \times 4}$$

Hence find its rank.

Solution: Consider $A_{3 \times 4} = I_{3 \times 3} A_{3 \times 4} I_{4 \times 4}$

$$\begin{aligned} \begin{bmatrix} 1 & 3 & 6 & -1 \\ 1 & 4 & 5 & 1 \\ 1 & 5 & 4 & 3 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} A I_4 \\ R_{21(-1)} \quad R_{31(-1)} \quad \text{pre} \quad \begin{bmatrix} 1 & 3 & 6 & -1 \\ 0 & 1 & -1 & 2 \\ 0 & 2 & -2 & 4 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix} A I_4 \\ R_{32(-2)} \quad \text{pre} \quad \begin{bmatrix} 1 & 3 & 6 & -1 \\ 0 & 1 & -1 & 2 \\ 0 & 0 & 0 & 0 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 1 & -2 & 1 \end{bmatrix} A I_4 \\ C_{21(-3)} \quad C_{31(-6)} \quad C_{41(1)} \quad \text{post} \quad \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & -1 & 2 \\ 0 & 0 & 0 & 0 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 1 & -2 & 1 \end{bmatrix} \times \\ &\times A \begin{bmatrix} 1 & -3 & -6 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \\ C_{32(1)} \quad C_{42(-2)} \quad \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 1 & -2 & 1 \end{bmatrix} \times \\ &\times A \begin{bmatrix} 1 & -3 & -9 & 7 \\ 0 & 1 & 1 & -2 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \end{aligned}$$

Thus $I_2 = PAQ$ where

$$P = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 1 & -2 & 1 \end{bmatrix}, Q = \begin{bmatrix} 1 & -3 & -9 & 7 \\ 0 & 1 & 1 & -2 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Rank of A is 2.

Example 2: Find P and Q such that the normal form of

$$A = \begin{bmatrix} 1 & -1 & -1 \\ 1 & 1 & 1 \\ 3 & 1 & 1 \end{bmatrix}$$

is PAQ .

Hence find the rank of A .

Solution: Consider

$$A_{3 \times 3} = I_{3 \times 3} A_{3 \times 3} I_{3 \times 3}$$

$$\begin{aligned} \begin{bmatrix} 1 & -1 & -1 \\ 1 & 1 & 1 \\ 3 & 1 & 1 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} A \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ C_{21(1)} \quad C_{31(1)} \quad \text{post} \quad \begin{bmatrix} 1 & 0 & 0 \\ 1 & 2 & 2 \\ 3 & 4 & 4 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} A \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ R_{21(-1)} \quad R_{31(-3)} \quad \text{pre} \quad \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 2 \\ 0 & 4 & 4 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ -3 & 0 & 1 \end{bmatrix} A \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ R_{2(\frac{1}{2})} \quad R_{3(\frac{1}{4})} \quad \text{pre} \quad \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ -\frac{1}{2} & \frac{1}{2} & 0 \\ -\frac{3}{4} & 0 & \frac{1}{4} \end{bmatrix} A \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ R_{32(-1)} \quad \text{pre} \quad \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 0 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ -\frac{1}{2} & \frac{1}{2} & 0 \\ -\frac{1}{4} & -\frac{1}{2} & \frac{1}{4} \end{bmatrix} A \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ C_{32(-1)} \quad \text{post} \quad \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} &= \begin{bmatrix} 1 & 0 & 0 \\ -\frac{1}{2} & \frac{1}{2} & 0 \\ -\frac{1}{4} & -\frac{1}{2} & \frac{1}{4} \end{bmatrix} A \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix} \end{aligned}$$

Thus the L.H.S. is in the normal form $\begin{bmatrix} I_2 & 0 \\ 0 & 0 \end{bmatrix}$.

Hence

$$P_{3 \times 3} = \begin{bmatrix} 1 & 0 & 0 \\ -\frac{1}{2} & \frac{1}{2} & 0 \\ -\frac{1}{4} & -\frac{1}{2} & \frac{1}{4} \end{bmatrix} \text{ and } Q_{3 \times 3} = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix}$$

Rank of $A = 2$.

EXERCISE

Determine the non-singular matrices P and Q such that PAQ is in the normal form for A . Hence find the rank of A .

$$1. A = \begin{bmatrix} 1 & 1 & 2 \\ 1 & 2 & 3 \\ 0 & -1 & -1 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ -1 & 1 & 1 \end{bmatrix}, Q = \begin{bmatrix} 1 & -1 & -1 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix}$$

rank = 2

13.10 — HIGHER ENGINEERING MATHEMATICS—IV

$$2. A = \begin{bmatrix} 3 & 2 & -1 & 5 \\ 5 & 1 & 4 & -2 \\ 1 & -4 & 11 & -19 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 0 & 0 & 1 \\ 0 & \frac{1}{3} & -\frac{5}{3} \\ \frac{1}{2} & -\frac{1}{3} & \frac{1}{6} \end{bmatrix},$$

$$Q = \begin{bmatrix} 1 & \frac{4}{17} & \frac{9}{119} & \frac{9}{217} \\ 0 & \frac{1}{7} & -\frac{1}{7} & -\frac{1}{7} \\ 0 & 0 & -\frac{1}{17} & 0 \\ 0 & 0 & 0 & \frac{1}{31} \end{bmatrix}, \text{ rank} = 2$$

$$3. A = \begin{bmatrix} 1 & 2 & 3 \\ 2 & -1 & 0 \\ 3 & 1 & 2 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 0 & 0 \\ \frac{2}{5} & -\frac{1}{5} & 0 \\ 1 & 1 & -1 \end{bmatrix}, Q = \begin{bmatrix} 1 & -2 & -\frac{3}{5} \\ 0 & 1 & -\frac{6}{5} \\ 0 & 0 & 1 \end{bmatrix}$$

rank = 3

$$4. A = \begin{bmatrix} 1 & -1 & -1 & 2 \\ 4 & 2 & 2 & -1 \\ 2 & 2 & 0 & -2 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 0 & 0 \\ -\frac{2}{3} & \frac{1}{6} & 0 \\ -\frac{1}{3} & \frac{1}{3} & -\frac{1}{2} \end{bmatrix},$$

$$Q = \begin{bmatrix} 1 & 1 & 0 & -\frac{1}{2} \\ 0 & 1 & -1 & -\frac{3}{2} \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \text{ rank} = 3$$

$$5. A = \begin{bmatrix} 1 & 2 & 3 & -2 \\ 2 & -2 & 1 & 3 \\ 3 & 0 & 4 & 1 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ -1 & -1 & 1 \end{bmatrix},$$

$$Q = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{4}{3} & -\frac{1}{3} \\ 0 & -\frac{1}{6} & -\frac{5}{6} & \frac{7}{6} \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \text{ rank} = 2$$

$$6. A = \begin{bmatrix} 1 & -1 & 2 & -1 \\ 4 & 2 & -1 & 2 \\ 2 & 2 & -2 & 0 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 0 & 0 \\ -\frac{2}{3} & \frac{1}{6} & -\frac{1}{2} \\ -\frac{1}{3} & \frac{1}{3} & -\frac{1}{2} \end{bmatrix},$$

$$Q = \begin{bmatrix} 1 & 1 & 0 & -\frac{1}{2} \\ 0 & 1 & -1 & \frac{3}{2} \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}, \text{ rank} = 3.$$

13.4 SYSTEM OF LINEAR NON-HOMOGENEOUS EQUATIONS

A system (or family) of m linear algebraic equations in n unknowns $x_1, x_2, \dots, x_n$ is a set of equations of the form

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n &= b_2 \end{aligned} \quad (1)$$

$$\dots \dots \dots$$

$$a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n = b_m$$

The numbers a_{ij} are known as coefficients and b_i are known as (R.H.S.) constants of the system.

(1) can be represented as

$$\sum_{j=1}^n a_{ij}x_j = b_i; i = 1 \text{ to } m$$

Non-homogeneous system: When all b_i are not zero, i.e., at least one b_i is non-zero.

Homogeneous system: If $b_i = 0, i = 1 \text{ to } m$ (all R.H.S. constants are zero).

Solution of system (1) is a set of numbers $x_1, x_2, \dots, x_n$ which satisfy (simultaneously) all the equations of the system (1).

Trivial solution is a solution where all x_i are zero i.e., $x_1 = x_2 = \dots = x_n = 0$.

Matrix Representation

$$\text{Let } X = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}_{n \times 1}, B = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_m \end{bmatrix}_{m \times 1}$$

be two column vectors.

$$\text{Let } A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & a_{m3} & \cdots & a_{mn} \end{bmatrix}_{m \times n}$$

Here

A = Coefficient matrix of the system (1)

B = (R.H.S.) constant vector

X = Solution (vector)

Then the system (1) can be represented as

$$A_{m \times n} X_{n \times 1} = B_{m \times 1}$$

Augmented matrix $[A|B]$ or $\tilde{A}$ of system (1) is obtained by augmenting A by the column B

$$\text{i.e., } \tilde{A} = [A|B] = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} & b_1 \\ a_{21} & a_{22} & \cdots & a_{2n} & b_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} & b_m \end{bmatrix}$$

Consistent: System is said to be consistent if (1) has at least one solution.

Inconsistent if system has no solution at all.

Solution of System of Linear Equations

We consider two methods of obtaining solution of system of n linear equations in n unknowns. They are

- i. Cramer's rule ii. matrix inverse

Cramer's rule (Solution by determinants)

- a. If A is non-singular i.e., $D = \text{determinant of } A = |A| \neq 0$. Then system (1) has a unique solution given by

$$x_i = \frac{D_i}{D} \quad \text{for } i = 1, 2, \dots, n$$

where D_i is the determinant obtained from D by replacing the i th column in D by constant column vector B .

- b. For homogeneous system with $D \neq 0$, only trivial solution exists.
c. For homogeneous system with $D = 0$, non-trivial solutions exist.

Note: Cramer's rule is not suitable for computations.

Matrix inversion method

Consider the system of n equations in n unknowns represented by

$$AX = B$$

where A is n -square non-singular matrix. Premultiplying by A^{-1} on both sides, we get

$$A^{-1}AX = A^{-1}B$$

or

$$X = A^{-1}B$$

which is the required solution.

Here A^{-1} , the inverse of A is obtained by Gauss-Jordan method: (see Page 13.4)

Consider $A|I$

Apply *only* elementary row operations on both A and I such that A is reduced to an identity matrix I , then I gets transformed to A^{-1} i.e.,

$$\begin{array}{c|c} A^{-1} & A^{-1}I \\ \hline I & A^{-1} \end{array}$$

Consistency of System of Linear Equations

Consider m linear equations in n unknowns so that

$$A_{m \times n} X_{n \times 1} = B_{m \times 1}$$

Fundamental theorem

- I. If rank of A and rank of the augmented matrix $\tilde{A}$ are equal, then the system is consistent.

- a. If $r(A) = r(\tilde{A}) = n$

then unique solution exists.

- b. If $r(A) = r(\tilde{A}) < n$

then infinitely many solutions exist in terms of $(n - r)$ arbitrary constants.

- II. If rank of A is not equal to rank of $\tilde{A}$ then the system is inconsistent and has no solution at all.

Procedure

1. Determine $r(A)$ and $r(\tilde{A})$.
2. If $r(A) \neq r(\tilde{A})$, system inconsistent, no solutions.
3. If $r(A) = r(\tilde{A}) = n$

13.12 — HIGHER ENGINEERING MATHEMATICS—IV

Then the unique solution may be obtained by Cramer's rule or matrix inversion method.

4. If $r(A) = r(\tilde{A}) < n$

Then rewrite $x_1, \dots, x_r$ variables (whose coefficient submatrix has rank r) in terms $(n - r)$ variables and solve by Gaussian elimination or Gauss-Jordan elimination method.

WORKED OUT EXAMPLES

Example 1: Solve by Cramer's rule

$$\begin{aligned}x + y + z &= 11 \\2x - 6y - z &= 0 \\3x + 4y + 2z &= 0.\end{aligned}$$

Solution:

$$\begin{aligned}D &= \begin{vmatrix} 1 & 1 & 1 \\ 2 & -6 & -1 \\ 3 & 4 & 2 \end{vmatrix} = 11, \quad D_1 = \begin{vmatrix} 11 & 1 & 1 \\ 0 & -6 & -1 \\ 0 & 4 & 2 \end{vmatrix} = -88, \\D_2 &= \begin{vmatrix} 1 & 11 & 1 \\ 2 & 0 & -1 \\ 3 & 0 & 2 \end{vmatrix} = -77, \quad D_3 = \begin{vmatrix} 1 & 1 & 11 \\ 2 & -6 & 0 \\ 3 & 4 & 0 \end{vmatrix} = 286\end{aligned}$$

The unique solution $x = \frac{D_1}{D} = \frac{-88}{11} = -8$

$$y = \frac{D_2}{D} = \frac{-77}{11} = -7, \quad z = \frac{D_3}{D} = \frac{286}{11} = 26$$

Thus $x = -8, \quad y = -7, \quad z = 26.$

Example 2: Solve by calculating the inverse by adjoint method

$$\begin{aligned}x_1 + x_2 + 2x_3 &= 4 \\2x_1 + 5x_2 - 2x_3 &= 3 \\x_1 + 7x_2 - 7x_3 &= 5.\end{aligned}$$

Solution: The given system is written as $AX = B$ where

$$A = \begin{bmatrix} 1 & 1 & 2 \\ 2 & 5 & -2 \\ 1 & 7 & -7 \end{bmatrix}, \quad X = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}, \quad B = \begin{bmatrix} 4 \\ 3 \\ 5 \end{bmatrix}$$

Inverse by adjoint

$$|A| = \begin{vmatrix} 1 & 1 & 2 \\ 2 & 5 & -2 \\ 1 & 7 & -7 \end{vmatrix} = 9$$

$$A^{-1} = \frac{1}{|A|} \text{adj } A = \frac{1}{|A|} \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{bmatrix}^T$$

where A_{ij} are cofactor of the element a_{ij}

$$A^{-1} = \frac{1}{9} \begin{bmatrix} -21 & 12 & 9 \\ 21 & -9 & -6 \\ -12 & 6 & 3 \end{bmatrix}^T = \frac{1}{3} \begin{bmatrix} -7 & 7 & -4 \\ 4 & -3 & 2 \\ 3 & -2 & 1 \end{bmatrix}$$

The solution to the given system is

$$X = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = A^{-1}B = \frac{1}{3} \begin{bmatrix} -7 & 7 & -4 \\ 4 & -3 & 2 \\ 3 & -2 & 1 \end{bmatrix} \begin{bmatrix} 4 \\ 3 \\ 5 \end{bmatrix} = \frac{1}{3} \begin{bmatrix} -27 \\ 17 \\ 11 \end{bmatrix}$$

i.e., $x_1 = -27/3, \quad x_2 = 17/3, \quad x_3 = 11/3.$

Example 3: Solve by calculating the inverse by elementary row operations

$$\begin{aligned}x_1 + x_2 + x_3 + x_4 &= 0 \\x_1 + x_2 + x_3 - x_4 &= 4 \\x_1 + x_2 - x_3 + x_4 &= -4 \\x_1 - x_2 + x_3 + x_4 &= 2\end{aligned}$$

Solution: The system is written as $AX = B$ where

$$A = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & -1 \\ 1 & 1 & -1 & 1 \\ 1 & -1 & 1 & 1 \end{bmatrix}, \quad X = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 4 \\ -4 \\ 2 \end{bmatrix}$$

Inverse by elementary row operations

$$\begin{aligned}[A|I] &= \left[\begin{array}{cccc|cccc} 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & -1 & 0 & 1 & 0 & 0 \\ 1 & 1 & -1 & 1 & 0 & 0 & 1 & 0 \\ 1 & -1 & 1 & 1 & 0 & 0 & 0 & 1 \end{array} \right] \begin{array}{l} R_{21}(-1), R_{31}(-1), \\ R_{41}(-1) \text{ and} \\ R_{2}(-1), R_{3}(-1), \\ R_{4}(-1) \end{array} \\ &\sim \left[\begin{array}{cccc|cccc} 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 & 1 & -1 & 0 & 0 \\ 0 & 0 & 2 & 0 & 1 & 0 & -1 & 0 \\ 0 & 2 & 0 & 0 & 1 & 0 & 0 & -1 \end{array} \right] \begin{array}{l} R_{24} \\ R_{2(\frac{1}{2})} \\ R_{3(\frac{1}{2})} \\ R_{4(\frac{1}{2})} \end{array}\end{aligned}$$

$$\sim \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & \frac{1}{2} & 0 & 0 & -\frac{1}{2} \\ 0 & 0 & 1 & 0 & \frac{1}{2} & 0 & -\frac{1}{2} & 0 \\ 0 & 0 & 0 & 1 & \frac{1}{2} & -\frac{1}{2} & 0 & 0 \end{bmatrix} \begin{matrix} R_{14}(-1) \\ R_{13}(-1) \\ R_{12}(-1) \end{matrix}$$

$$\sim \begin{bmatrix} 1 & 0 & 0 & 0 & -\frac{1}{2} & \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \\ 0 & 1 & 0 & 0 & \frac{1}{2} & 0 & 0 & -\frac{1}{2} \\ 0 & 0 & 1 & 0 & \frac{1}{2} & 0 & -\frac{1}{2} & 0 \\ 0 & 0 & 0 & 1 & \frac{1}{2} & -\frac{1}{2} & 0 & 0 \end{bmatrix}$$

$$\text{Thus } A^{-1} = \frac{1}{2} \begin{bmatrix} -1 & 1 & 1 & 1 \\ 1 & 0 & 0 & -1 \\ 1 & 0 & -1 & 0 \\ 1 & -1 & 0 & 0 \end{bmatrix}$$

The required solution is

$$X = A^{-1}B = \frac{1}{2} \begin{bmatrix} -1 & 1 & 1 & 1 \\ 1 & 0 & 0 & -1 \\ 1 & 0 & -1 & 0 \\ 1 & -1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ 4 \\ -4 \\ 2 \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \\ 2 \\ -2 \end{bmatrix}$$

i.e., $x_1 = 1, x_2 = -1, x_3 = 2, x_4 = -2$.

Example 4: Solve

$$2x_1 - 2x_2 + 4x_3 + 3x_4 = 9$$

$$x_1 - x_2 + 2x_3 + 2x_4 = 6$$

$$2x_1 - 2x_2 + x_3 + 2x_4 = 3$$

$$x_1 - x_2 + x_4 = 2$$

Solution: Apply elementary row operation on $[A|B]$

$$[A|B] = \begin{bmatrix} 2 & -2 & 4 & 3 & 9 \\ 1 & -1 & 2 & 2 & 6 \\ 2 & -2 & 1 & 2 & 3 \\ 1 & -1 & 0 & 1 & 2 \end{bmatrix} \begin{matrix} R_{12} \\ R_{21}(-2) \\ R_{41}(-1) \\ R_{31}(-2) \\ R_{2}(-1) \\ R_{3}(-1) \\ R_{4}(-1) \end{matrix} \begin{bmatrix} 1 & -1 & 2 & 2 & 6 \\ 0 & 0 & 0 & 1 & 3 \\ 0 & 0 & 3 & 2 & 9 \\ 0 & 0 & 2 & 1 & 4 \end{bmatrix}$$

$$\sim \begin{bmatrix} 1 & -1 & 2 & 2 & 6 \\ 0 & 0 & 0 & 1 & 3 \\ 0 & 0 & 1 & 1 & 5 \\ 0 & 0 & 2 & 1 & 4 \end{bmatrix}$$

$$\sim \begin{bmatrix} 1 & -1 & 2 & 2 & 6 \\ 0 & 0 & 1 & 1 & 5 \\ 0 & 0 & 2 & 1 & 4 \\ 0 & 0 & 0 & 1 & 3 \end{bmatrix}$$

$$\sim \begin{bmatrix} 1 & -1 & 2 & 2 & 6 \\ 0 & 0 & 1 & 1 & 5 \\ 0 & 0 & 0 & 1 & 6 \\ 0 & 0 & 0 & 1 & 3 \end{bmatrix} \begin{matrix} R_{32}(-2) \\ R_{3}(-1) \end{matrix}$$

$$\sim \begin{bmatrix} 1 & -1 & 2 & 2 & 6 \\ 0 & 0 & 1 & 1 & 5 \\ 0 & 0 & 0 & 1 & 6 \\ 0 & 0 & 0 & 0 & 3 \end{bmatrix} \begin{matrix} R_{43}(-1) \\ R_{4}(-1) \end{matrix}$$

rank of $(A) = 3 \neq 4 = \text{rank of } [A|B]$

So the given system is inconsistent and therefore has no solution.

Example 5: Solve

$$3x + 3y + 2z = 1$$

$$x + 2y = 4$$

$$10y + 3z = -2$$

$$2x - 3y - z = 5.$$

Solution:

$$[A|B] = \begin{bmatrix} 3 & 3 & 2 & 1 \\ 1 & 2 & 0 & 4 \\ 0 & 10 & 3 & -2 \\ 2 & -3 & -1 & 5 \end{bmatrix} R_{12} \sim \begin{bmatrix} 1 & 2 & 0 & 4 \\ 3 & 3 & 2 & 1 \\ 0 & 10 & 3 & -2 \\ 2 & -3 & -1 & 5 \end{bmatrix}$$

$$\sim \begin{bmatrix} 1 & 2 & 0 & 4 \\ 0 & -3 & 2 & -11 \\ 0 & 10 & 3 & -2 \\ 0 & -7 & -1 & -3 \end{bmatrix} \begin{matrix} R_{21}(-3) \\ R_{41}(-2) \end{matrix}$$

$$\sim \begin{bmatrix} 1 & 2 & 0 & 4 \\ 0 & 1 & -\frac{2}{3} & \frac{11}{3} \\ 0 & 0 & \frac{29}{3} & -\frac{116}{3} \\ 0 & 0 & -\frac{17}{3} & \frac{68}{3} \end{bmatrix} \begin{matrix} R_{2}(-\frac{1}{3}) \\ R_{32}(-10) \\ R_{42}(7) \end{matrix}$$

$$\sim \begin{bmatrix} 1 & 2 & 0 & 4 \\ 0 & 1 & -\frac{2}{3} & \frac{11}{3} \\ 0 & 0 & 1 & -\frac{116}{29} \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{matrix} R_{3}(\frac{3}{29}) \\ R_{43}(\frac{17}{3}) \end{matrix}$$

$r(A) = 3 = r(A|B) = n = \text{number of variables}$.
The system is consistent and has unique solution.
Solving

$$z = -\frac{116}{29} = -4$$

$$y - \frac{2}{3}z = \frac{11}{3} \quad \text{or} \quad y = \frac{11}{3} + \frac{2}{3}(-4) = 1$$

$$x + 2y + 0 = 4 \quad \text{or} \quad x = 4 - 2 = 2$$

13.14 — HIGHER ENGINEERING MATHEMATICS—IV

i.e., $x = 2, y = 1, z = -4$.

Example 6: Solve

$$\begin{aligned}x_1 + x_2 - x_3 &= 0 \\2x_1 - x_2 + x_3 &= 3 \\4x_1 + 2x_2 - 2x_3 &= 2.\end{aligned}$$

Solution: By applying elementary row operations

$$\begin{aligned}[A|B] &= \left[\begin{array}{ccc|c} 1 & 1 & -1 & 0 \\ 2 & -1 & 1 & 3 \\ 4 & 2 & -2 & 2 \end{array} \right] \begin{array}{l} R_{21}(-2) \\ R_{31}(-4) \\ \sim \end{array} \left[\begin{array}{ccc|c} 1 & 1 & -1 & 0 \\ 0 & -3 & 3 & 3 \\ 0 & -2 & 2 & 2 \end{array} \right] \\ &\begin{array}{l} R_{2(-\frac{1}{3})} \\ \sim \\ R_{3(-\frac{1}{2})} \end{array} \left[\begin{array}{ccc|c} 1 & 1 & -1 & 0 \\ 0 & 1 & -1 & -1 \\ 0 & 1 & -1 & -1 \end{array} \right] \\ &\begin{array}{l} R_{32}(-1) \\ \sim \end{array} \left[\begin{array}{ccc|c} 1 & 1 & -1 & 0 \\ 0 & 1 & -1 & -1 \\ 0 & 0 & 0 & 0 \end{array} \right]\end{aligned}$$

$r(A) = 2 = r(A|B) < 3 = n$ = number of variables.

The system is consistent but has infinite number of solutions in terms of $n - r = 3 - 2 = 1$ variable. Choose $x_3 = k$ = arbitrary constant.

Solving $x_2 - x_3 = -1$ or $x_2 = x_3 - 1 = k - 1$.

$x_1 + x_2 - x_3 = 0$ or $x_1 = -x_2 + x_3 = -k + 1 + k = 1$

Thus the solutions are

$x_1 = 1, x_2 = k - 1, x_3 = k$, where k is arbitrary.

Example 7: Determine the values of a and b for which the system

$$\begin{aligned}x + 2y + 3z &= 6 \\x + 3y + 5z &= 9 \\2x + 5y + az &= b\end{aligned}$$

has (i) no solution (ii) unique solution (iii) infinite number of solutions. Find the solutions in case (ii) and (iii).

Solution:

$$\begin{aligned}[A|B] &= \left[\begin{array}{ccc|c} 1 & 2 & 3 & 6 \\ 1 & 3 & 5 & 9 \\ 2 & 5 & a & b \end{array} \right] \begin{array}{l} R_{21}(-1) \\ R_{31}(-2) \\ \sim \end{array} \left[\begin{array}{ccc|c} 1 & 2 & 3 & 6 \\ 0 & 1 & 2 & 3 \\ 0 & 1 & a-6 & b-12 \end{array} \right] \\ &\begin{array}{l} R_{32}(-1) \\ \sim \end{array} \left[\begin{array}{ccc|c} 1 & 2 & 3 & 6 \\ 0 & 1 & 2 & 3 \\ 0 & 0 & a-8 & b-15 \end{array} \right]\end{aligned}$$

Case 1: $a = 8, b \neq 15, r(A) = 2 \neq 3 = r(A|B)$, inconsistent, no solution.

Case 2: $a \neq 8, b$ any value, $r(A) = 3 = r(A|B) = n$ = number of variables, unique solution, $z = \frac{b-15}{a-8}$,

$$y = (3a - 2b + 6)/(a - 8), x = z = (b - 15)/(a - 8).$$

Case 3: $a = 8, b = 15, r(A) = 2 = r(A|B) < 3 = n$, infinite solutions with $n - r = 3 - 2 = 1$ arbitrary variable. $x = k, y = 3 - 2k, z = k$, with k arbitrary.

EXERCISE

Solve the following:

$$\begin{aligned}1. \quad &5x + 3y + 7z = 4, \\&3x + 26y + 2z = 9, \\&7x + 2y + 10z = 5.\end{aligned}$$

Ans. $x = (7 - 16k)/11, y = (3 + k)/11, z = k$, k arbitrary

$$\begin{aligned}2. \quad &x_1 + x_2 - 2x_3 + x_4 + 3x_5 = 1, \\&2x_1 - x_2 + 2x_3 + 2x_4 + 6x_5 = 2, \\&3x_1 + 2x_2 - 4x_3 - 3x_4 - 9x_5 = 3.\end{aligned}$$

Ans. $x_1 = 1, x_2 = 2a, x_3 = a, x_4 = -3b, x_5 = b$ where a and b are arbitrary constants

$$\begin{aligned}3. \quad &x_1 + x_2 + 2x_3 + x_4 = 5, \\&2x_1 + 3x_2 - x_3 - 2x_4 = 2, \\&4x_1 + 5x_2 + 3x_3 = 7.\end{aligned}$$

Ans. No solution, system inconsistent

4. Using A^{-1} (inverse of the coefficient matrix)

$$\begin{aligned}&2x_1 + x_2 + 5x_3 + x_4 = 5, \\&x_1 + x_2 - 3x_3 - 4x_4 = -1, \\&3x_1 + 6x_2 - 2x_3 + x_4 = 8, \\&2x_1 + 2x_2 + 2x_3 - 3x_4 = 2.\end{aligned}$$

Ans. $x_1 = 2, x_2 = 1/5, x_3 = 0, x_4 = 4/5$, unique solution

Hint.

$$A^{-1} = \frac{1}{120} \begin{bmatrix} 120 & 120 & 0 & -120 \\ -69 & -73 & 17 & 80 \\ -15 & -35 & -5 & 40 \\ 24 & 8 & 8 & -40 \end{bmatrix}$$

5. $2x_1 + 3x_2 - x_3 = 1$,
 $3x_1 - 4x_2 + 3x_3 = -1$,
 $2x_1 - x_2 + 2x_3 = -3$,
 $3x_1 + x_2 - 2x_3 = 4$.

Ans. Inconsistent, no solution

6. $3x_1 + 2x_2 + x_3 = 3$,
 $2x_1 + x_2 + x_3 = 0$,
 $6x_1 + 2x_2 + 4x_3 = 3$.

Ans. Inconsistent, no solution.

7. $-x_1 + x_2 + 2x_3 = 2$,
 $3x_1 - x_2 + x_3 = 6$,
 $-x_1 + 3x_2 + 4x_3 = 4$.

Ans. $x_1 = 1, x_2 = -1, x_3 = 2$, unique solution

8. $7x + 16y - 7z = 4$,
 $2x + 5y - 3z = -3$,
 $x + y + 2z = 4$.

Ans. Inconsistent, no solution

9. $x + y + z = 4$,
 $2x + 5y - 2z = 3$,
 $x + 7y - 7z = 5$.

Ans. Inconsistent, no solution

10. $2x + y - z = 0$,
 $2x + 5y + 7z = 52$,
 $x + y + z = 9$.

Ans. unique solution $x = 1, y = 3, z = 5$

Find the values of a and b for which the system has (i) no solution (ii) unique solution (iii) infinitely many solutions for:

11. $2x + 3y + 5z = 9$,
 $7x + 3y - 2z = 8$,
 $2x + 3y + az = b$.

Ans. i. no solution of $a = 5, b \neq 9$;

ii. unique solution $a \neq 5, b$ any value;

iii. infinitely many solutions $a = 5, b = 9$

12. $x + y + z = 6$,
 $x + 2y + 3z = 10$,
 $x + 2y + az = b$.

Ans. i. $a = 3, b \neq 10$ inconsistent

ii. $a \neq 3, b$ any value, unique solution

iii. $a = 3, b = 10$ infinite solutions

13. Test for consistency

$$\begin{aligned} -2x + y + z &= a, \\ x - 2y + z &= b, \\ x + y - 2z &= c. \end{aligned}$$

where a, b, c are constants

Ans. i. If $a + b + c \neq 0$, inconsistent

ii. If $a + b + c = 0$, infinite solutions

14. Solve the system

$$\begin{aligned} x + y + z &= 6, \\ 2x - 3y + 4z &= 8, \\ x - y + 2z &= 5 \end{aligned} \quad \text{by}$$

i. Cramer's rule

ii. Matrix inversion

iii. Gauss-Jordan.

Ans. i. $x_1 = 1, x_2 = 2, x_3 = 3, \Delta = -1$,
 $\Delta_1 = -1, \Delta_2 = -2, \Delta_3 = -3$

ii. $A^{-1} = \begin{bmatrix} 2 & 3 & -7 \\ 0 & -1 & 2 \\ -1 & -2 & 5 \end{bmatrix}$

iii. $\begin{bmatrix} 1 & 1 & 1 & 6 \\ 2 & -3 & 4 & 8 \\ 1 & -1 & 2 & 5 \end{bmatrix} \sim \begin{bmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 3 \end{bmatrix}$.

13.5 SYSTEM OF HOMOGENEOUS EQUATIONS

Solution to a System of m Homogeneous Equations in n Unknowns

Result 1: If $r < m$, omit $m - r$ equations such that the coefficient matrix of the remaining equations still has rank r . Rewrite r unknowns in terms of $n - r$ arbitrary unknowns and solve.

13.16 — HIGHER ENGINEERING MATHEMATICS—IV

Result 2: If $m < n$, system has non-trivial solutions.

Result 3: If $m = n$, system has non-trivial solutions if its coefficient determinant is zero.

Note: A homogeneous system always has a trivial solution since $r[A|B] = r[A|O] = r[A]$ for any A .

WORKED OUT EXAMPLES

Example 1: Determine b such that the system of homogeneous equations

$$2x + y + 2z = 0$$

$$x + y + 3z = 0$$

$$4x + 3y + bz = 0$$

has (i) Trivial solution (ii) non-trivial solution.

Find the non-trivial solution.

Solution: The coefficient matrix A is

$$A = \begin{bmatrix} 2 & 1 & 2 \\ 1 & 1 & 3 \\ 4 & 3 & b \end{bmatrix} \xrightarrow{R_{12}} \begin{bmatrix} 1 & 1 & 3 \\ 2 & 1 & 2 \\ 4 & 3 & b \end{bmatrix}$$

$$\sim \begin{matrix} R_{21(-2)} \\ R_{31(-4)} \end{matrix} \begin{bmatrix} 1 & 1 & 3 \\ 0 & -1 & -4 \\ 0 & -1 & b-12 \end{bmatrix}$$

$$R_{32(-1)} \sim \begin{bmatrix} 1 & 1 & 3 \\ 0 & 1 & 4 \\ 0 & 0 & b-8 \end{bmatrix}$$

Case 1: If $b \neq 8$ then $r(A) = r(A|B) = 3 =$ number of variables. i.e., $|A| \neq 0$. System has only trivial solution $x = 0, y = 0, z = 0$.

Case 2: If $b = 8$ then $r(A) = r(A|B) = 2 < 3 = n$. System has non-trivial solutions in terms of $n - r = 3 - 2 = 1$ arbitrary variable. Solving the system

$$x + y + 3z = 0$$

$$y + 4z = 0$$

Choose z as arbitrary say $z = k =$ arbitrary constant. Then $y = -4z = -4k$ and $x = -y - 3z = 4k - 3k = k$.

Thus the infinite number of non-trivial solutions are obtained for different values of k as

$$x = k, y = -4k, z = k.$$

Example 2: Solve

$$x + y - 2z + 3w = 0$$

$$x - 2y + z - w = 0$$

$$4x + y - 5z + 8w = 0$$

$$5x - 7y + 2z - w = 0.$$

Solution: The coefficient matrix A is

$$A = \begin{bmatrix} 1 & 1 & -2 & 3 \\ 1 & -2 & 1 & -1 \\ 4 & 1 & -5 & 8 \\ 5 & -7 & 2 & -1 \end{bmatrix}$$

$$\begin{matrix} R_{21(-1)} \\ R_{31(-4)} \\ R_{41(-5)} \end{matrix} \begin{bmatrix} 1 & 1 & -2 & 3 \\ 0 & -3 & 3 & -4 \\ 0 & -3 & 3 & -4 \\ 0 & -12 & 12 & -16 \end{bmatrix}$$

$$\sim \begin{matrix} R_{2(-1)} \\ R_{32(1)} \\ R_{42(4)} \end{matrix} \begin{bmatrix} 1 & 1 & -2 & 3 \\ 0 & 3 & -3 & 4 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

$r(A) = r(A|B) = 2 < 4 = n =$ number of variables.

Non-trivial solutions exist in terms of

$n - r = 4 - 2 = 2$ variables.

Choose $z = k_1$, and $w = k_2$. Then solving

$$x + y - 2z + 3w = 0$$

$$3y - 3z + 4w = 0$$

We get

$$y = \frac{1}{3}(3z - 4w) = z - \frac{4}{3}w = k_1 - \frac{4}{3}k_2$$

$$x = -y + 2z - 3w = -k_1 + \frac{4}{3}k_2 + 2k_1 - 3k_2$$

$$x = k_1 - \frac{5}{3}k_2$$

where k_1 and k_2 are arbitrary constants.

EXERCISE

Solve the system of homogeneous equations:

$$1. \quad x + 2y + 3z = 0,$$

$$3x + 4y + 4z = 0,$$

$$7x + 10y + 12z = 0.$$

Ans. Trivial solution $x = y = z = 0$ since $r(A) = 3 = n$

$$2. \quad 4x + 2y + z + 3w = 0,$$

$$6x + 3y + 4z + 7w = 0,$$

$$2x + y + w = 0.$$

Ans. $y = -2k_1 - k_2, z = -k_2, x = k_1, w = k_2$ where k_1 and k_2 are arbitrary constants, giving infinite number of solutions

$$3. \quad x + y - 3z + 2w = 0,$$

$$2x - y + 2z - 3w = 0,$$

$$3x - 2y + z - 4w = 0,$$

$$-4x + y - 3z + w = 0.$$

Ans. Trivial solution $x = y = z = 0$, since $r(A) = 4 = n$

$$4. \quad x_1 + x_2 + x_3 + x_4 = 0,$$

$$x_1 + 3x_2 + 2x_3 + 4x_4 = 0,$$

$$2x_1 + x_3 - x_4 = 0.$$

Ans. $x_1 = -\frac{1}{2}k_1 + \frac{1}{2}k_2, x_2 = -\frac{1}{2}k_1 - \frac{3}{2}k_2, x_3 = k_1, x_4 = k_2$ where k_1 and k_2 are arbitrary constants giving infinite number of solutions: $r(A) = 2, n = 4$

$$5. \quad 3x + 2y + z = 0,$$

$$2x + 3z = 0,$$

$$y + 5z = 0,$$

$$x + 2y + 3z = 0.$$

Ans. $x = 0 = y = z$ is the only (trivial) solution since $r(A) = 3 = n$

$$6. \quad 2x + 3y - 4z + w = 0,$$

$$x - y + z + 2w = 0,$$

$$5x - z + 7w = 0,$$

$$7x + 8y - 11z + 5w = 0.$$

Ans. $z = k_1, w = k_2, x = (k_1 - 7k_2)/5, y = (6k_1 + 3k_2)/5$ where k_1, k_2 are arbitrary constants

$$7. \quad x + 3y - 2z = 0,$$

$$2x - y + 4z = 0,$$

$$x - 11y + 14z = 0.$$

Ans. $z = k, x = -10k/7, y = 8k/7, k$ arbitrary

$$8. \quad x_1 + 3x_2 + 2x_3 = 0,$$

$$2x_1 - x_2 + 3x_3 = 0,$$

$$3x_1 - 5x_2 + 4x_3 = 0,$$

$$x_1 + 17x_2 + 4x_3 = 0.$$

Ans. $x_1 = 11k, x_2 = k, x_3 = -7k, k$ is arbitrary $r(A) = 2, n = 3$

9. Determine the values of b for which the system of equations has non-trivial solutions. Find them.

$$(b - 1)x + (4b - 2)y + (b + 3)z = 0,$$

$$(b - 1)x + (3b + 1)y + 2bz = 0,$$

$$2x + (3b + 1)y + 3(b - 1)z = 0.$$

Ans. i. $b = 0, x = y = z$

ii. $b = 3, x = -5k_1 - 3k_2, y = k_1, z = k_2$ where k_1 and k_2 are arbitrary

10. Find the values of b for which the system has non-trivial solutions. Find them

$$2x + 3by + (3b + 4)z = 0,$$

$$x + (b + 4)y + (4b + 2)z = 0,$$

$$x + 2(b + 1)y + (3b + 4)z = 0.$$

Ans. i. $b \neq \pm 2$, only trivial solution $x = y = z = 0$

ii. $b = 2, x = 0, z = k, y = -5k/3, k$ arbitrary

iii. $b = -2, x = 4k, y = z = k, k$ arbitrary.

13.6 GAUSSIAN ELIMINATION METHOD

Gaussian elimination method is an exact method which solves a given system of equations in n unknowns by transforming the coefficient matrix, into an upper triangular matrix and then solve for the unknowns by back substitution.

Consider a system of n equations in n unknowns

$$a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \cdots + a_{1n}x_n = a_{1,n+1} \quad (1)$$

$$a_{21}x_1 + a_{22}x_2 + a_{23}x_3 + \cdots + a_{2n}x_n = a_{2,n+1} \quad (2)$$

$$\dots\dots\dots$$

$$a_{n1}x_1 + a_{n2}x_2 + a_{n3}x_3 + \cdots + a_{nn}x_n = a_{n,n+1} \quad (n)$$

13.18 — HIGHER ENGINEERING MATHEMATICS—IV

Eliminate the unknown x_1 from the $(n - 1)$ equations namely (2), (3), $\dots$ $(n - 1)$, (n) by subtracting the multiple $\frac{a_{i1}}{a_{11}}$ of the first equation from the i th equation, for $i = 2, 3, 4, \dots, n$. Now eliminate x_2 from the $(n - 2)$ equations of the resultant system. By this procedure, we arrive at a derived system as follows:

$$a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = a_{1,n+1} \quad (1)$$

$$a_{22}^{(1)}x_2 + \dots + a_{2n}^{(1)}x_n = a_{2,n+1}^{(2)} \quad (2^*)$$

$$a_{33}^{(2)}x_3 + \dots + a_{3n}^{(2)}x_n = a_{3,n+1}^{(2)} \quad (3^*)$$

.....

$$a_{nn}^{(n-1)}x_n = a_{n,n+1}^{(n^*)} \quad (n^*)$$

In the forward elimination process, the coefficients are given by

$$a_{ij}^{(k)} = a_{ij}^{(k-1)} - \frac{a_{ik}^{(k-1)}}{a_{kk}^{(k-1)}} a_{kj}^{(k-1)}$$

where

$$k = 1, 2, \dots, n - 1$$

$$j = k + 1, \dots, n + 1$$

$$i = k + 1, \dots, n$$

and

$$a_{ij}^{(0)} = a_{ij}$$

Back substitution

Now the driven system (1), (2*), (3*) $\dots$ (n^*) is solved by back substitution. Solve equation (n^*) for the unknown x_n . Substituting this x_n in $(n^* - 1)$ equation, solve for x_{n-1} . Continuing this process, x_1 is solved from the first equation. Thus

$$x_i = \frac{1}{a_{ii}^{(i-1)}} \left[a_{i,n+1}^{(i-1)} - \sum_{j=i+1}^n a_{ij}^{(i-1)} x_j \right]$$

for $i = n, n - 1, n - 2, \dots, 3, 2, 1$.

Check sum

Initially, for the given system, write row sum, the sum of the coefficients in each row, in the $(n + 2)$ nd column. Perform the same operations on the elements of this column also. Now in the absence of computational errors, at any stage, the row sum element in $(n + 2)$ nd row, will be equal to the sum of the elements of the corresponding transformed row.

Gauss-Jordan elimination method

Apply elementary row operations on both A and B such that A reduces to the normal form I_r . Then the solution is obtained (without the necessity of back substitution).

WORKED OUT EXAMPLES

Example 1: Solve by Gaussian elimination method, the following system of equations:

$$\begin{aligned} 2x_1 + 2x_2 + x_3 + 2x_4 &= 7 \\ -x_1 + 2x_2 + x_4 &= -2 \\ -3x_1 + x_2 + 2x_3 + x_4 &= -3 \\ -x_1 + 2x_4 &= 0. \end{aligned}$$

Solution: Arranging in tabular form, we get

Table 13.1

Row No.	x_1	x_2	x_3	x_4	b	Check Sum	Explanation
[1]	2	2	1	2	7	14	Equation 1
[2]	-1	2	0	1	-2	0	Equation 2
[3]	-3	1	2	1	-3	-2	Equation 3
[4]	-1	0	0	2	0	1	Equation 4
[5]	1	1	$\frac{1}{2}$	1	$\frac{7}{2}$	7	$R_1 \left(\frac{1}{2} \right)$
[6]	0	3	$\frac{1}{2}$	2	$\frac{3}{2}$	7	$R_{25(1)}$
[7]	0	4	$\frac{7}{2}$	4	$\frac{15}{2}$	19	$R_{35(3)}$
[8]	0	1	$\frac{1}{2}$	3	$\frac{7}{2}$	8	$R_{45(1)}$
[9]	0	1	$\frac{1}{2}$	3	$\frac{7}{2}$	8	R_{86}
[10]	0	3	$\frac{1}{2}$	2	$\frac{3}{2}$	7	R_{78}
[11]	0	4	$\frac{7}{2}$	4	$\frac{15}{2}$	19	
[12]	0	0	-1	-7	-9	-17	$R_{10,9(-3)}$
[13]	0	0	$\frac{3}{2}$	-8	$\frac{-13}{2}$	-13	$R_{11,9(-4)}$
[14]	0	0	0	$\frac{-37}{2}$	-20	$\frac{-77}{2}$	$R_{13,12\left(\frac{3}{2}\right)}$

Here $R_{ij(k)}$ denotes a row operation in which the k th multiples of j th row are added to the corresponding elements of the i th row. Also, R_{ij} : interchange of i th and j th rows.

Check sum: The sum of the elements of any row must be equal to check sum (otherwise errors in operations). The given system of equations has reduced to an upper triangular matrix. Now using back substitution, solve [14] (row) equation

$$x_4 = \frac{40}{37} = 1.08.$$

Solve [13] equation

$$x_3 + 7x_4 = 9 \quad \text{or} \quad x_3 = 1.4324$$

Solve [9]: $x_2 = -0.4562$

Solve [5]: $x_1 = 2.1600$

The solution is ($x_1 = 2.16$, $x_2 = -0.4562$, $x_3 = 1.4324$, $x_4 = 1.08$).

Example 2: Solve the system by (i) Gaussian elimination method (ii) Gauss-Jordan method

$$\begin{aligned} 2x_1 + 5x_2 + 2x_3 - 3x_4 &= 3 \\ 3x_1 + 6x_2 + 5x_3 + 2x_4 &= 2 \\ 4x_1 + 5x_2 + 14x_3 + 14x_4 &= 11 \\ 5x_1 + 10x_2 + 8x_3 + 4x_4 &= 4 \end{aligned}$$

Solution: Consider the augmented matrix $[A|B]$

$$\begin{aligned} [A|B] &= \left[\begin{array}{cccc|c} 2 & 5 & 2 & -3 & 3 \\ 3 & 6 & 5 & 2 & 2 \\ 4 & 5 & 14 & 14 & 11 \\ 5 & 10 & 8 & 4 & 4 \end{array} \right] \begin{array}{l} R_{21}(-1) \\ R_{32}(-1) \\ R_{43}(-1) \end{array} \\ &\sim \left[\begin{array}{cccc|c} 2 & 5 & 2 & -3 & 3 \\ 1 & 1 & 3 & 5 & -1 \\ 1 & -1 & 9 & 12 & 9 \\ 1 & 5 & -6 & -10 & -7 \end{array} \right] \begin{array}{l} R_{41}, R_{23} \\ R_{21}(-1) \\ R_{31}(-1) \\ R_{41}(-2) \end{array} \\ &\sim \left[\begin{array}{cccc|c} 1 & 5 & -6 & -10 & -7 \\ 0 & -6 & 15 & 22 & 16 \\ 0 & -4 & 9 & 15 & 6 \\ 0 & -5 & 14 & 17 & 17 \end{array} \right] \begin{array}{l} R_{24}(-1) \\ R_{2(-1)}, R_{32}(-4) \\ R_{3(-1)} \quad R_{42}(-5) \\ R_{4(-1)} \end{array} \\ &\sim \left[\begin{array}{cccc|c} 1 & 5 & -6 & -10 & -7 \\ 0 & 1 & -1 & -5 & 1 \\ 0 & 0 & -5 & 5 & -10 \\ 0 & 0 & 9 & -8 & 22 \end{array} \right] \begin{array}{l} R_{3(-\frac{1}{5})} \\ R_{43}(-9) \end{array} \\ [A|B] &\sim \left[\begin{array}{cccc|c} 1 & 5 & -6 & -10 & -7 \\ 0 & 1 & -1 & -5 & 1 \\ 0 & 0 & 1 & -1 & 2 \\ 0 & 0 & 0 & 1 & 4 \end{array} \right] \end{aligned}$$

By back substitution: $x_4 = 4$

$$x_3 - x_4 = 2 \quad \text{or} \quad x_3 = 2 + x_4 = 2 + 4 = 6$$

$$x_2 - x_3 - 5x_4 = 1 \quad \text{or} \quad x_2 = 27$$

$$x_1 + 5x_2 - 6x_3 - 10x_4 = -7 \quad \text{or} \quad x_1 = -66$$

$$\text{Thus } x_1 = -66, x_2 = 27, x_3 = 6, x_4 = 4.$$

Gauss-Jordan method:

$$\begin{aligned} &\left[\begin{array}{cccc|c} 1 & 5 & -6 & -10 & -7 \\ 0 & 1 & -1 & -5 & 1 \\ 0 & 0 & 1 & -1 & 2 \\ 0 & 0 & 0 & 1 & 4 \end{array} \right] \begin{array}{l} R_{34(1)} \\ R_{24(5)} \\ R_{14(10)} \end{array} \sim \left[\begin{array}{cccc|c} 1 & 5 & -6 & 0 & 33 \\ 0 & 1 & -1 & 0 & 21 \\ 0 & 0 & 1 & 0 & 6 \\ 0 & 0 & 0 & 1 & 4 \end{array} \right] \\ &\begin{array}{l} R_{23(1)} \\ \sim \end{array} \left[\begin{array}{cccc|c} 1 & 5 & 0 & 0 & 69 \\ 0 & 1 & 0 & 0 & 27 \\ 0 & 0 & 1 & 0 & 6 \\ 0 & 0 & 0 & 1 & 4 \end{array} \right] \begin{array}{l} R_{12(-5)} \\ \sim \end{array} \left[\begin{array}{cccc|c} 1 & 0 & 0 & 0 & -66 \\ 0 & 1 & 0 & 0 & 27 \\ 0 & 0 & 1 & 0 & 6 \\ 0 & 0 & 0 & 1 & 4 \end{array} \right] \\ &\begin{array}{l} R_{13(6)} \\ \sim \end{array} \left[\begin{array}{cccc|c} 1 & 0 & 0 & 0 & -66 \\ 0 & 1 & 0 & 0 & 27 \\ 0 & 0 & 1 & 0 & 6 \\ 0 & 0 & 0 & 1 & 4 \end{array} \right] \end{aligned}$$

$$\therefore x_1 = -66, x_2 = 27, x_3 = 6, x_4 = 4.$$

EXERCISE

Solve the following system of equations by Gaussian elimination method.

$$\begin{aligned} 1. \quad &x_1 + 2x_2 - x_3 = 3, \quad 3x_1 - x_2 + 2x_3 = 1, \\ &2x_1 - 2x_2 + 3x_3 = 2, \quad x_1 - x_2 + x_3 = -1 \end{aligned}$$

$$\text{Ans. } x_1 = 1, x_2 = 4, x_3 = 4$$

$$\begin{aligned} 2. \quad &2x_1 + x_2 + 3x_3 = 1, \quad 4x_1 + 4x_2 + 7x_3 = 1, \\ &2x_1 + 5x_2 + 9x_3 = 3 \end{aligned}$$

$$\text{Ans. } x_1 = -\frac{1}{2}, x_2 = -1, x_3 = 1$$

$$\begin{aligned} 3. \quad &2x_1 - 7x_2 + 4x_3 = 9, \quad x_1 + 9x_2 - 6x_3 = 1, \\ &-3x_1 + 8x_2 + 5x_3 = 6 \end{aligned}$$

$$\text{Ans. } x_1 = 4, x_2 = 1, x_3 = 2$$

$$\begin{aligned} 4. \quad &2x_1 + 2x_2 + 4x_3 = 18, \quad x_1 + 3x_2 + 2x_3 = 13, \\ &3x_1 + x_2 + 3x_3 = 14 \end{aligned}$$

$$\text{Ans. } x_1 = 1, x_2 = 2, x_3 = 3$$

$$\begin{aligned} 5. \quad &2x_1 + x_2 + x_3 = 10, \quad 3x_1 + 2x_2 + 3x_3 = 18, \\ &x_1 + 4x_2 + 9x_3 = 16 \end{aligned}$$

$$\text{Ans. } x_1 = 7, x_2 = -9, x_3 = 5$$

$$\begin{aligned} 6. \quad &2x_1 + x_2 + 4x_3 = 12, \quad 8x_1 - 3x_2 + 2x_3 = 20, \\ &4x_1 + 11x_2 - x_3 = 33 \end{aligned}$$

$$\text{Ans. } x_1 = 3, x_2 = 2, x_3 = 1$$

13.20 — HIGHER ENGINEERING MATHEMATICS—IV

$$\begin{aligned} 7. \quad x_1 + 4x_2 - x_3 &= -5, \quad x_1 + x_2 - 6x_3 = -12, \\ 3x_1 - x_2 - x_3 &= 4 \end{aligned}$$

$$\text{Ans. } x_1 = \frac{117}{71}, x_2 = -\frac{81}{71}, x_3 = \frac{148}{71}$$

$$\begin{aligned} 8. \quad 10x_1 - 7x_2 + 3x_3 + 5x_4 &= 6, \\ -6x_1 + 8x_2 - x_3 - 4x_4 &= 5, \\ 3x_1 + x_2 + 4x_3 + 11x_4 &= 2, \\ 5x_1 - 9x_2 - 2x_3 + 4x_4 &= 7 \end{aligned}$$

$$\text{Ans. } x_1 = 5, x_2 = 4, x_3 = -7, x_4 = 1.$$

13.7 LU-DECOMPOSITIONS

The Gaussian elimination with back substitution, Gauss-Jordan elimination, computing A^{-1} then $x = A^{-1}B$ and Cramer's rule are some of the direct (non-iterative) methods for solving system of linear equations. Gauss-Jordan elimination produces both solution for one or more R.H.S. vector B and also A^{-1} . Its principal weakness is (i) it requires all RHS $\bar{B}$ to be stored and manipulated and (ii) when A^{-1} is not required. The usefulness of Gaussian elimination with back substitution is primarily pedagogical. It stands between full elimination schemes such as Gauss-Jordan and triangular decomposition. LU -decomposition or triangular decomposition (triangular factorization) is a different approach in which the coefficient matrix A is factored into the product of a lower triangular matrix L and an upper triangular matrix U i.e.,

$$A = LU.$$

Since a matrix that is either upper triangular or lower triangular is called "triangular", so LU -decomposition is also referred to as triangular factorization. LU method can be easily adopted to solve a system with new R.H.S. B with great economy of effort.

It is popular because storage of space can be economized and accumulates sums in double precision (Example: LINPAK (1979) computer program of Argonne National Labs).

Solution of Linear System by LU-Decomposition

A non singular matrix A is said to have a triangular factorization or LU -decomposition if A can be expressed as the product of a lower triangular matrix L with ones on its main diagonal and an upper triangular matrix U . i.e.,

$$A = LU$$

For $n = 4$, we have $A_{4 \times 4} = L_{4 \times 4}U_{4 \times 4}$

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ l_{21} & 1 & 0 & 0 \\ l_{31} & l_{32} & 1 & 0 \\ l_{41} & l_{42} & l_{43} & 1 \end{bmatrix} \begin{bmatrix} u_{11} & u_{12} & u_{13} & u_{14} \\ 0 & u_{22} & u_{23} & u_{24} \\ 0 & 0 & u_{33} & u_{34} \\ 0 & 0 & 0 & u_{44} \end{bmatrix}$$

The condition of non singularity of A implies that $u_{kk} \neq 0$ for all k . Now consider the system of equations

$$AX = B$$

or

$$LUX = B$$

Put $Y = UX$ then

$$LY = B$$

and

$$UX = Y$$

Solve first $LY = B$ for Y using forward substitution and then solve $UX = Y$ for X using backward substitution. Here X is the required solution vector.

LU -decomposition is also known as Doolittle's method. Another variation of LU -decomposition is crout's reduction or Cholosky's reduction in which the upper triangular matrix U has ones on its main diagonal (instead of L) in the triangular decomposition $A = LU$

Note that LU decomposition is not unique. Any matrix A with all non-zero diagonal elements (i.e., $a_{ii} \neq 0$ for $i = 1$ to n) can be factored in infinite number of ways.

Example 1:

$$\begin{bmatrix} 2 & -1 & -1 \\ 0 & -4 & 2 \\ 6 & -3 & 1 \end{bmatrix} = \begin{bmatrix} 2 & 0 & 0 \\ 0 & -4 & 0 \\ 6 & 0 & 4 \end{bmatrix} \begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & 1 & -\frac{1}{2} \\ 0 & 0 & 1 \end{bmatrix} = LU$$

or

$$= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 3 & 0 & 1 \end{bmatrix} \begin{bmatrix} 2 & -1 & -1 \\ 0 & -4 & 2 \\ 0 & 0 & 4 \end{bmatrix} = LU$$

or

$$= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 3 & 0 & 1 \end{bmatrix} \begin{bmatrix} 2 & -1 & -1 \\ 0 & -2 & 1 \\ 0 & 0 & 4 \end{bmatrix} = LU$$

and so on.

Example 2:

$$A = LU = \begin{bmatrix} l_{11} & 0 & 0 \\ l_{21} & l_{22} & 0 \\ l_{31} & l_{32} & l_{33} \end{bmatrix} \begin{bmatrix} 1 & u_{12} & u_{13} \\ 0 & 1 & u_{23} \\ 0 & 0 & 1 \end{bmatrix}$$

The non-zero diagonal entries in L can be shifted to U .

$$A = \begin{bmatrix} 1 & 0 & 0 \\ \frac{l_{21}}{l_{11}} & 1 & 0 \\ \frac{l_{31}}{l_{11}} & \frac{l_{32}}{l_{22}} & 1 \end{bmatrix} \begin{bmatrix} l_{11} & 0 & 0 \\ 0 & l_{22} & 0 \\ 0 & 0 & l_{33} \end{bmatrix} \begin{bmatrix} 1 & u_{12} & u_{13} \\ 0 & 1 & u_{23} \\ 0 & 0 & 1 \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 0 & 0 \\ \frac{l_{21}}{l_{11}} & 1 & 0 \\ \frac{l_{31}}{l_{11}} & \frac{l_{32}}{l_{22}} & 1 \end{bmatrix} \begin{bmatrix} l_{11} & l_{11}u_{12} & l_{11}u_{13} \\ 0 & l_{22} & l_{22}u_{23} \\ 0 & 0 & l_{33} \end{bmatrix}$$

which is another LU decomposition of A . However of the entire set of LU decompositions, choose the pair in which L has ones on its diagonal.

13.8 LU-DECOMPOSITION FROM GAUSSIAN ELIMINATION

Theorem: If A is a square matrix which can be reduced to echlon form U without using any row interchanges, then A has a LU decomposition and can be factored as $A = LU$ where L is a lower triangular matrix with ones on its main diagonal.

Explanation: In solving a system $AX = B$ of n equations in n unknowns, use the Gaussian elimination method to reduce A to an echlon form (upper triangular matrix) U . We assume that no row interchanges

are necessary in this process. Then the multipliers l_{ij} used in the Gaussian elimination process will form the subdiagonal entries in the lower triangular matrix L .

Step I: Use Gaussian elimination to reduce A to echolon form U , without using any row interchanges. Keep track of the multipliers used to introduce zeros below the leading diagonal elements of A .

Step II: In each position below the main diagonal (consisting of ones) of L , place the *negative* of the multiplier used to introduce zeros in that position in U .

The LU -decomposition can also be obtained by solving the equations in l_{ij} and u_{ij} as follows. Suppose

$$A = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} = LU =$$

$$= \begin{pmatrix} 1 & 0 & 0 \\ l_{21} & 1 & 0 \\ l_{31} & l_{32} & 1 \end{pmatrix} \cdot \begin{pmatrix} u_{11} & u_{12} & u_{13} \\ 0 & u_{22} & u_{23} \\ 0 & 0 & u_{33} \end{pmatrix}$$

From the first row elements.

$$u_{11} = a_{11}, u_{12} = a_{12}, u_{13} = a_{13}$$

From 2nd row elements:

$$l_{21}u_{11} = a_{21}, l_{21}u_{12} + u_{22} = a_{22},$$

$$l_{21}u_{13} + u_{23} = a_{23}$$

From 3rd row elements

$$l_{31}u_{11} = a_{31}, l_{31}u_{12} + l_{32}u_{22} = a_{32},$$

$$l_{31}u_{13} + l_{32}u_{23} + u_{33} = a_{33}.$$

Solving we get u_{11}, u_{12}, u_{13} , then l_{21}, u_{22}, u_{23} followed by l_{31}, l_{32}, u_{33} .

LU-Decomposition by Gaussian Elimination**WORKED OUT EXAMPLES**

Example 1: Solve $AX = B$ by LU -decomposition using Gaussian elimination where

13.22 — HIGHER ENGINEERING MATHEMATICS—IV

$$A = \begin{pmatrix} 2 & 4 & -6 \\ 1 & 5 & 3 \\ 1 & 3 & 2 \end{pmatrix}$$

and

$$(a) B^T = (-4, 10, 5), (b) B^T = (20, 49, 32)$$

Solution: Since A has all non-zero diagonal elements, we can factor A as LU . Use Gaussian elimination to reduce A to echelon form U , without using any row interchanges.

$$A = \begin{pmatrix} 2 & 4 & -6 \\ 1 & 5 & 3 \\ 1 & 3 & 2 \end{pmatrix}$$

Step I: The multiplier $(-\frac{1}{2})$ is used to reduce the element $a_{21} = 1$ to zero. The operation is $R_{21}(-\frac{1}{2})$. So $m_{21} = -\frac{1}{2}$. Similarly the multiplier $(-\frac{1}{2})$ is used to reduce the element $a_{31} = 1$ to zero i.e., $R_{31}(-\frac{1}{2})$. So $m_{31} = -\frac{1}{2}$. This results

$$A \sim \begin{pmatrix} 2 & 4 & -6 \\ 0 & 3 & 6 \\ 0 & 1 & 5 \end{pmatrix}$$

Use the multiplier $(-\frac{1}{3})$ to reduce the element $a_{32} = 1$ to zero i.e., $R_{32}(-\frac{1}{3})$. So the multiplier is $m_{32} = -\frac{1}{3}$. This yields the echelon form (or upper triangular matrix) U of A as

$$A \sim \begin{pmatrix} 2 & 4 & -6 \\ 0 & 3 & 6 \\ 0 & 0 & 3 \end{pmatrix}$$

Step II: The lower triangular matrix L is obtained by simply placing the *negative* of the multipliers used in introducing zeros in that position in U i.e., $l_{21} = -m_{21} = -(-\frac{1}{2}) = +\frac{1}{2}$, $l_{31} = -m_{31} = \frac{1}{2}$ and $l_{32} = -m_{32} = \frac{1}{3}$

$$L = \begin{pmatrix} 1 & 0 & 0 \\ l_{21} & 1 & 0 \\ l_{31} & l_{32} & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ \frac{1}{2} & \frac{1}{3} & 1 \end{pmatrix}$$

Thus the LU (factorization) decomposition of A by Gaussian elimination is

$$A = \begin{pmatrix} 2 & 4 & -6 \\ 1 & 5 & 3 \\ 1 & 3 & 2 \end{pmatrix} = LU = \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ \frac{1}{2} & \frac{1}{3} & 1 \end{pmatrix} \begin{pmatrix} 2 & 4 & -6 \\ 0 & 3 & 6 \\ 0 & 0 & 3 \end{pmatrix}$$

Now to solve $AX = B$, $LUX = B$ put $UX = Y$ so $LY = B$. First we solve $LY = B$ for Y by using forward substitution

$$(a) B^T = (-4, 10, 5)$$

$$\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ \frac{1}{2} & \frac{1}{3} & 1 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} -4 \\ 10 \\ 5 \end{pmatrix}$$

By forward substitution

$$y_1 = -4$$

$$\frac{1}{2}y_1 + y_2 = 10 \text{ so } y_2 = 10 - \frac{1}{2}y_1 = 12$$

$$\frac{1}{2}y_1 + \frac{1}{3}y_2 + y_3 = 5 \text{ so } y_3 = 5 - \frac{1}{2}y_1 - \frac{1}{3}y_2 = 3.$$

$$\text{Thus } Y^T = (-4, 12, 3).$$

Now solve $UX = Y$ using backward substitution.

$$\begin{pmatrix} 2 & 4 & -6 \\ 0 & 3 & 6 \\ 0 & 0 & 3 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} -4 \\ 12 \\ 3 \end{pmatrix}$$

$$\text{So } 3x_3 = 3 \text{ or } x_3 = 1$$

$$3x_2 + 6x_3 = 12 \text{ so } x_2 = \frac{12 - 6x_3}{3} = 2$$

$$2x_1 + 4x_2 - 6x_3 = -4 \text{ so } x_1 = \frac{-4 + 6x_3 - 4x_2}{2} = -3$$

$$\text{Solution: } X^T = (-3, 2, 1)$$

$$(b) B^T = (20, 49, 32)$$

$$LY = B$$

$$\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ \frac{1}{2} & \frac{1}{3} & 1 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} 20 \\ 49 \\ 32 \end{pmatrix}$$

$$\text{Solving } y_1 = 20$$

$$\frac{1}{2}y_1 + y_2 = 49 \quad \text{so} \quad y_2 = 49 - \frac{1}{2}y_1 = 39$$

$$\frac{1}{2}y_1 + \frac{1}{3}y_2 + y_3 = 32 \quad \text{so} \quad y_3 = 32 - \frac{1}{2}y_1 - \frac{1}{3}y_2 = 9$$

Thus $Y^T = (20, 39, 9)$

Now solve $UX = Y$

$$\begin{pmatrix} 2 & 4 & -6 \\ 0 & 3 & 6 \\ 0 & 0 & 3 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} 20 \\ 39 \\ 9 \end{pmatrix}$$

Solving $3x_3 = 9$ so $x_3 = 3$

$$3x_2 + 6x_3 = 39 \quad \text{so} \quad x_2 = \frac{39 - 6x_3}{3} = 7$$

$$2x_1 + 4x_2 - 6x_3 = 20 \quad \text{so} \quad x_1 = \frac{20 + 6x_3 - 4x_2}{2} = 5$$

Solution: $X^T = (5, 7, 3)$.

Example 2: Solve the system

$$3x_1 - 6x_2 - 3x_3 = -3$$

$$2x_1 + 6x_3 = -22$$

$$-4x_1 + 7x_2 + 4x_3 = 3$$

Solution: $A = \begin{bmatrix} 3 & -6 & -3 \\ 2 & 0 & 6 \\ -4 & 7 & 4 \end{bmatrix}, B = \begin{bmatrix} -3 \\ -22 \\ 3 \end{bmatrix}$

consider

$$A = \begin{bmatrix} 3 & -6 & -3 \\ 2 & 0 & 6 \\ -4 & 7 & 4 \end{bmatrix} = LU =$$

$$= \begin{bmatrix} 1 & 0 & 0 \\ l_{21} & 1 & 0 \\ l_{31} & l_{32} & 1 \end{bmatrix} \begin{bmatrix} u_{11} & u_{12} & u_{13} \\ 0 & u_{22} & u_{23} \\ 0 & 0 & u_{33} \end{bmatrix}$$

From first row: $u_{11} = 3, u_{12} = -6, u_{13} = -3$

First 2nd row: $l_{21}u_{11} = 2, l_{21} \cdot 3 = 2, l_{21} = \frac{2}{3}$

$$l_{21}u_{12} + u_{22} = 0, u_{22} = -l_{21}u_{12} = -\frac{2}{3} \cdot (-6) = 4$$

$$l_{21}u_{13} + u_{23} = 6, u_{23} = 6 - l_{21}u_{13}$$

$$= 6 - \frac{2}{3}(-3) = 8$$

From 3rd row: $l_{31}u_{11} = -4, l_{31} = -\frac{4}{3}$

$$l_{31}u_{12} + l_{32}u_{22} = 7, l_{32} = \frac{7 - l_{31}u_{12}}{u_{22}} = \frac{7 - (-\frac{4}{3})(-6)}{4}$$

$$\text{so } l_{32} = -\frac{1}{4}$$

$$l_{31}u_{13} + l_{32}u_{23} + u_{33} = 4$$

$$\text{so } u_{33} = 4 - l_{31}u_{13} - l_{32}u_{23}$$

$$u_{33} = 4 - \left(-\frac{4}{3}\right) \cdot (-3) - \left(-\frac{1}{4}\right) \cdot 8 = 0 + 2 = +2$$

$$A = \begin{bmatrix} 1 & 0 & 0 \\ \frac{2}{3} & 1 & 0 \\ -\frac{4}{3} & -\frac{1}{4} & 1 \end{bmatrix} \begin{bmatrix} 3 & -6 & 3 \\ 0 & 4 & 8 \\ 0 & 0 & +2 \end{bmatrix}$$

$$LY = B$$

$$\begin{bmatrix} 1 & 0 & 0 \\ \frac{2}{3} & 1 & 0 \\ -\frac{4}{3} & -\frac{1}{4} & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} -3 \\ -22 \\ 3 \end{bmatrix}$$

Solving $y_1 = -3, \frac{2}{3}y_1 + y_2 = -22$

$$y_2 = -22 - \frac{2}{3}y_1 = -20$$

So $-\frac{4}{3}y_1 - \frac{1}{4}y_2 + y_3 = 3$

$$y_3 = 3 + \frac{4}{3}y_1 + \frac{1}{4}y_2 = 3 - 4 - 5 = -6$$

$$UX = Y$$

$$\begin{bmatrix} 3 & -6 & -3 \\ 0 & 4 & 8 \\ 0 & 0 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} -3 \\ -20 \\ -6 \end{bmatrix}$$

solving $2x_3 = -6$ or $x_3 = -3$

$$4x_2 + 8x_3 = -20 \quad \text{or} \quad x_2 = \frac{-20 - 8x_3}{4} = 1$$

$$3x_1 - 6x_2 - 3x_3 = -3 \quad \text{or} \quad x_1 = \frac{-3 + 6x_2 + 3x_3}{3} = -2$$

solution $X^T = [-2, 1, -3]$.

EXERCISE

1. Let $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$. If $a \neq 0$ find LU decomposition.

Ans. $\begin{bmatrix} 1 & 0 \\ \frac{c}{a} & 1 \end{bmatrix} \begin{bmatrix} a & b \\ 0 & \frac{ad-bc}{a} \end{bmatrix}$

2. Let $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$. Show that A has no LU -decomposition.

13.24 — HIGHER ENGINEERING MATHEMATICS—IV

Hint: Since $a_{11} = 0$, $a_{21} = 1$ can not be made zero.

Solve the following system of equations by LU -decomposition.

3. $3x_1 - 6x_2 = 0$, $-2x_1 + 5x_2 = 1$

Ans. $x_1 = 2$, $x_2 = 1$

Hint: $L = \begin{pmatrix} 1 & 0 \\ -\frac{2}{3} & 1 \end{pmatrix}$, $U = \begin{pmatrix} 3 & -6 \\ 0 & 1 \end{pmatrix}$

4. $2x_1 + 8x_2 = -2$, $-x_1 - x_2 = -2$

Ans. $x_1 = 3$, $x_2 = -1$

Hint: $L = \begin{pmatrix} 1 & 0 \\ -\frac{1}{2} & 1 \end{pmatrix}$, $U = \begin{pmatrix} 2 & 8 \\ 0 & 3 \end{pmatrix}$

5. $-5x_1 - 10x_2 = -10$, $6x_1 + 5x_2 = 19$

Ans. $x_1 = 4$, $x_2 = -1$

Hint: $L = \begin{pmatrix} 1 & 0 \\ -\frac{6}{5} & 1 \end{pmatrix}$, $U = \begin{pmatrix} -5 & -10 \\ 0 & -7 \end{pmatrix}$

6. $2x_1 - 2x_2 - 2x_3 = -4$

$-2x_2 + 2x_3 = -2$

$-x_1 + 5x_2 + 2x_3 = 6$

Ans. $x_1 = -1$, $x_2 = 1$, $x_3 = 0$

Hint: $L = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -\frac{1}{2} & -2 & 1 \end{pmatrix}$,

Ans. $x_1 = -3$, $x_2 = 1$, $x_3 = 2$, $x_4 = 1$

Hint: $L = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -2 & 1 & 0 & 0 \\ 0 & -\frac{1}{3} & 1 & 0 \\ 0 & 0 & \frac{1}{2} & 1 \end{bmatrix}$,

$U = \begin{bmatrix} -1 & 0 & 1 & 0 \\ 0 & 3 & 0 & 6 \\ 0 & 0 & 2 & 2 \\ 0 & 0 & 0 & 4 \end{bmatrix}$

8. Solve $\begin{bmatrix} 4 & 8 & 4 & 0 \\ 1 & 5 & 4 & -3 \\ 1 & 4 & 7 & 2 \\ 1 & 3 & 0 & -2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ b_4 \end{bmatrix}$

(a) $B^T = [8, -4, 10, -4]$

(b) $B^T = [28, 13, 23, 4]$

Ans. (a) $Y^T = [8, -6, 12, 2]$, $X^T = [3, -1, 1, 2]$

(b) $Y^T = [28, 6, 12, 1]$, $X^T = [3, 1, 2, 1]$

Hint: $L = \begin{bmatrix} 1 & 0 & 0 & 0 \\ \frac{1}{4} & 1 & 0 & 0 \\ \frac{1}{4} & \frac{2}{3} & 1 & 0 \\ \frac{1}{4} & \frac{1}{3} & -\frac{1}{2} & 1 \end{bmatrix}$,

$U = \begin{bmatrix} 4 & 8 & 4 & 0 \\ 0 & 3 & 3 & -3 \\ 0 & 0 & 4 & 4 \\ 0 & 0 & 0 & 1 \end{bmatrix}$

Find LU decomposition (triangular factorization) $A = LU$

9. $\begin{bmatrix} 4 & 3 & -1 \\ -2 & -4 & 5 \\ 1 & 2 & 6 \end{bmatrix}$

Ans. $L = \begin{bmatrix} 1 & 0 & 0 \\ -0.5 & 1 & 0 \\ 0.25 & -0.5 & 1 \end{bmatrix}$

$U = \begin{bmatrix} 4 & 3 & 1 \\ 0 & -2.5 & 4.5 \\ 0 & 0 & 8.5 \end{bmatrix}$

10. $\begin{bmatrix} -5 & 2 & -1 \\ 1 & 0 & 3 \\ 3 & 1 & 6 \end{bmatrix}$

Ans. $L = \begin{bmatrix} 1 & 0 & 0 \\ -0.2 & 1 & 0 \\ -0.6 & 5.5 & 1 \end{bmatrix}$

$U = \begin{bmatrix} -5 & 2 & -1 \\ 0 & 0.4 & 2.8 \\ 0 & 0 & -10 \end{bmatrix}$

11. $\begin{bmatrix} 1 & 1 & 0 & 4 \\ 2 & -1 & 5 & 0 \\ 5 & 2 & 1 & 2 \\ -3 & 0 & 2 & 6 \end{bmatrix}$

$$\text{Ans. } L = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 2 & 1 & 0 & 0 \\ 5 & 1 & 1 & 0 \\ -3 & -1 & -1.75 & 1 \end{bmatrix}$$

$$U = \begin{bmatrix} 1 & 1 & 0 & 4 \\ 0 & -3 & 5 & -8 \\ 0 & 0 & -4 & -10 \\ 0 & 0 & 0 & -7.5 \end{bmatrix}$$

13.9 SOLUTION TO TRIDIAGONAL SYSTEMS

Band matrix is a $n \times n$ square matrix A with the property that $a_{ij} = 0$ whenever $i + p \leq j$ or $j + q \leq i$ for integers p and q with $p > 1$ and $q < n$. The *band width* of such matrix is defined to be $w = p + q - 1$.

Example:

$$A = \begin{bmatrix} 8 & 3 & 0 \\ 2 & 6 & -1 \\ 0 & 6 & -9 \end{bmatrix}$$

A is band matrix with $p = 2, q = 2$ and band width 3.

In band matrices, all the non-zero entries are concentrated about the diagonal.

Tridiagonal matrix is a band matrix of width 3 with $p = q = 2$. Thus *tridiagonal* matrices are those that have non-zero elements *only* on the diagonal a_{ii} or super diagonal $a_{i,i+1}$ or subdiagonal $a_{i+1,i}$. So $a_{ij} = 0$ if $|i - j| > 1$.

Example:

$$B = \begin{bmatrix} -4 & 2 & 0 & 0 & 0 \\ 1 & -4 & 1 & 0 & 0 \\ 0 & 1 & -4 & 1 & 0 \\ 0 & 0 & 1 & -4 & 1 \\ 0 & 0 & 0 & 2 & -4 \end{bmatrix}$$

Note: Non-zero elements (entries) occur only on the diagonal and in the positions adjacent to the diagonal.

Most often tridiagonal matrices occur in cubic spline interpolation and numerical solution (crank-Nicolson method) of PDE involving heat equation.

13.10 CROUT REDUCTION FOR TRIDIAGONAL LINEAR SYSTEMS

Consider a tridiagonal linear system of n equations in n unknowns.

$$a_{11}x_1 + a_{12}x_2 \cdots = b_1$$

$$a_{21}x_1 + a_{22}x_2 + a_{23}x_3 \cdots = b_2$$

$$\dots$$

$$a_{n-1,n-2}x_{n-2} + a_{n-1,n-1}x_{n-1} + a_{n-1,n}x_n = b_{n-1}$$

$$a_{n,n-1}x_{n-1} + a_{nn}x_n = b_n$$

with the tridiagonal coefficient matrix

$$A = \begin{bmatrix} a_{11} & a_{12} & 0 & \cdots & 0 \\ a_{21} & a_{22} & a_{23} & \ddots & \vdots \\ 0 & a_{32} & a_{33} & a_{34} & 0 \\ & \ddots & \ddots & \ddots & \\ 0 & \ddots & \ddots & \ddots & a_{n-1,n} \\ 0 & \cdots & 0 & a_{n,n-1} & a_{nn} \end{bmatrix}$$

In the case of tridiagonal matrix A having large number of zeros in regular patterns, the computational effort is reduced due to the structure of A . Using Crout or Doolittle factorization algorithm, A can be factored into L and U where L is lower triangular matrix and U is an upper triangular matrix with one's on its main diagonal.

Here

$$L = \begin{bmatrix} l_{11} & 0 & \cdots & \cdots & 0 \\ l_{21} & l_{22} & \ddots & & \vdots \\ 0 & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & l_{n,n-1} & l_{nn} \end{bmatrix},$$

$$U = \begin{bmatrix} 1 & u_{12} & 0 & \cdots & 0 \\ 0 & 1 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & 0 \\ 0 & & \ddots & \ddots & u_{n-1,n} \\ 0 & \cdots & \cdots & 0 & 1 \end{bmatrix}$$

Since A has only $(3n - 2)$ non-zero entries, there are only $(3n - 2)$ conditions to be applied to determine the entries of L and U . There are $(2n - 1)$ un-

13.26 — HIGHER ENGINEERING MATHEMATICS—IV

determined entries in L and $(n - 1)$ undetermined entries of U , which totals the number of conditions $(3n - 2)$.

Carrying out the multiplication LU , we get

$$a_{11} = l_{11}$$

$$a_{i,i-1} = l_{i,i-1} \quad \text{for } i = 2, 3, \dots, n \quad (1)$$

$$a_{ii} = l_{i,i-1}u_{i-1,i} + l_{ii} \quad \text{for } i = 2, 3, \dots, n \quad (2)$$

$$a_{i,i+1} = l_{ii}u_{i,i+1} \quad \text{for } i = 1, 2, \dots, n-1 \quad (3)$$

From (2), non-zero off-diagonal terms in L are calculated first. Then using (3) and (2) obtain alternately the remainder of the entries in U and L .

Thus the tridiagonal system can be solved by LU decomposition followed by forward and backward substitution. The LU decomposition can be obtained using Gaussian elimination as is done in the earlier section (without tedious calculations of l_{ii} and u_{ii} see W.E.2).

If A is a symmetric ($a_{ij} = a_{ji}$) and positive definite (i.e., $V^T A V > 0$ for all $V \neq 0$). Then by Cholesky decomposition we can factorize A as

$$A = LL^T$$

This factorization is sometimes referred to as taking the square root of the matrix A . Instead of seeking arbitrary lower triangular matrix L and upper triangular matrix U , Cholesky decomposition constructs a lower triangular matrix L whose transpose L^T can itself serve as upper triangular matrix U .

WORKED OUT EXAMPLES

Example 1: Solve the following tridiagonal system.

$$\begin{aligned} x_1 - x_2 &= 0 \\ -2x_1 + 4x_2 - 2x_3 &= -1 \\ -x_2 + 2x_3 &= 1.5 \end{aligned}$$

Solution: The tridiagonal matrix is

$$A = \begin{bmatrix} 1 & -1 & 0 \\ -2 & 4 & -2 \\ 0 & -1 & 2 \end{bmatrix}$$

LU -decomposition:

$$\begin{bmatrix} 1 & -1 & 0 \\ -2 & 4 & -2 \\ 0 & -1 & 2 \end{bmatrix} = \begin{bmatrix} l_{11} & 0 & 0 \\ l_{21} & l_{22} & 0 \\ l_{31} & l_{32} & l_{33} \end{bmatrix} \begin{bmatrix} 1 & u_{12} & u_{13} \\ 0 & 1 & u_{23} \\ 0 & 0 & 1 \end{bmatrix}$$

From first column: $l_{11} = a_{11} = 1$, $l_{21} = a_{21} = -2$, $l_{31} = 0$

From 2nd column: $l_{11}u_{12} = -1$, $u_{12} = \frac{-1}{l_{11}} = \frac{-1}{1} = -1$

$l_{21}u_{12} + l_{22} = 4$, $l_{22} = 4 - l_{21}u_{12} = 4 - (-2)(-1) = 2$, $l_{21}u_{13} + l_{22}u_{23} = -2$,

Also $l_{11}u_{13} = 0$ so $u_{13} = 0$

$$0 + 2 \cdot u_{23} = -2 \quad \text{so} \quad u_{23} = -1$$

From 3rd row: $l_{31} = 0$

$$l_{31}u_{12} + l_{32} = -1 \quad \therefore \quad l_{32} = -1$$

$$l_{31}u_{13} + l_{32}u_{23} + l_{33} = 2$$

$$0 - 1 \cdot (-1) + l_{33} = 2 \quad \therefore \quad l_{33} = 1$$

Thus

$$\begin{bmatrix} 1 & -1 & 0 \\ -2 & 4 & -2 \\ 0 & -1 & 2 \end{bmatrix} = A = LU = \begin{bmatrix} 1 & 0 & 0 \\ -2 & 2 & 0 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix}$$

Now $AX = LUX = B$

Put $UX = Y$ so $LY = B$

$$\begin{bmatrix} 1 & 0 & 0 \\ -2 & 2 & 0 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = B = \begin{bmatrix} 0 \\ -1 \\ \frac{3}{2} \end{bmatrix}$$

solving $y_1 = 0$, $y_2 = -\frac{1}{2}$, $y_3 = 1$

From $UX = Y$, we have

$$\begin{bmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

solving $x_3 = 1$, $x_2 = x_1 = \frac{1}{2}$

Example 2: Solve

$$\begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 1 & 2 & 1 & 0 & 0 \\ 0 & 1 & 2 & 1 & 0 \\ 0 & 0 & 1 & 2 & 1 \\ 0 & 0 & 0 & 1 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ b_4 \\ b_5 \end{bmatrix}$$

Also solve when $b_1 = 1, b_2 = 0, b_3 = 2, b_4 = 3, b_5 = -1$

Solution: Assume $A = LU$ where

$$L = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ l_{21} & 1 & 0 & 0 & 0 \\ l_{31} & l_{32} & 1 & 0 & 0 \\ l_{41} & l_{42} & l_{43} & 1 & 0 \\ l_{51} & l_{52} & l_{53} & l_{54} & 0 \end{bmatrix}, \quad U = \begin{bmatrix} u_{11} & u_{12} & u_{13} & u_{14} & u_{15} \\ 0 & u_{22} & u_{23} & u_{24} & u_{25} \\ 0 & 0 & u_{33} & u_{34} & u_{35} \\ 0 & 0 & 0 & u_{44} & u_{45} \\ 0 & 0 & 0 & 0 & u_{55} \end{bmatrix}$$

Now we reduce the tridiagonal matrix A to echolon form using Gaussian elimination method without any row interchanges.

$$\begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 1 & 2 & 1 & 0 & 0 \\ 0 & 1 & 2 & 1 & 0 \\ 0 & 0 & 1 & 2 & 1 \\ 0 & 0 & 0 & 1 & 2 \end{bmatrix} \xrightarrow{R_{21} \left(-\frac{1}{2}\right)} \begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 0 & \frac{3}{2} & 1 & 0 & 0 \\ 0 & 1 & 2 & 1 & 0 \\ 0 & 0 & 1 & 2 & 1 \\ 0 & 0 & 0 & 1 & 2 \end{bmatrix} \xrightarrow{R_{32} \left(-\frac{2}{3}\right)} \begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 0 & \frac{3}{2} & 1 & 0 & 0 \\ 0 & 0 & \frac{4}{3} & 1 & 0 \\ 0 & 0 & 1 & 2 & 1 \\ 0 & 0 & 0 & 1 & 2 \end{bmatrix} \xrightarrow{R_{43} \left(-\frac{3}{4}\right)} \begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 0 & \frac{3}{2} & 1 & 0 & 0 \\ 0 & 0 & \frac{4}{3} & 1 & 0 \\ 0 & 0 & 0 & \frac{5}{4} & 1 \\ 0 & 0 & 0 & 1 & 2 \end{bmatrix} \xrightarrow{R_{54} \left(-\frac{4}{5}\right)} \begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 0 & \frac{3}{2} & 1 & 0 & 0 \\ 0 & 0 & \frac{4}{3} & 1 & 0 \\ 0 & 0 & 0 & \frac{5}{4} & 1 \\ 0 & 0 & 0 & 0 & \frac{6}{5} \end{bmatrix}$$

$$U = \begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 0 & \frac{3}{2} & 1 & 0 & 0 \\ 0 & 0 & \frac{4}{3} & 1 & 0 \\ 0 & 0 & 0 & \frac{5}{4} & 1 \\ 0 & 0 & 0 & 0 & \frac{6}{5} \end{bmatrix}$$

Then multipliers are $-\frac{1}{2}, -\frac{2}{3}, -\frac{3}{4}, -\frac{4}{5}$ so

$$L = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ \frac{1}{2} & 1 & 0 & 0 & 0 \\ 0 & \frac{2}{3} & 1 & 0 & 0 \\ 0 & 0 & \frac{3}{4} & 1 & 0 \\ 0 & 0 & 0 & \frac{4}{5} & 1 \end{bmatrix}$$

Now solve by forward substitution

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ \frac{1}{2} & 1 & 0 & 0 & 0 \\ 0 & \frac{2}{3} & 1 & 0 & 0 \\ 0 & 0 & \frac{3}{4} & 1 & 0 \\ 0 & 0 & 0 & \frac{4}{5} & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ b_4 \\ b_5 \end{bmatrix}$$

Solving $y_1 = b_1, y_2 = b_2 - \frac{1}{2}b_1$

$$y_3 = b_3 - \frac{2}{3}b_2 + \frac{1}{3}b_1$$

$$y_4 = b_4 - \frac{3}{4}b_3 + \frac{1}{2}b_2 - \frac{1}{4}b_1$$

$$y_5 = b_5 - \frac{4}{5}b_4 + \frac{3}{5}b_3 - \frac{2}{5}b_2 + \frac{1}{5}b_1$$

For $b_1 = 1, b_2 = 0, b_3 = 2, b_4 = 3, b_5 = -1$,

$$y_1 = 1, y_2 = -\frac{1}{2}, y_3 = \frac{7}{3}, y_4 = \frac{21}{4}, y_5 = 0.$$

Now solve by backward substitution

$$\begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 0 & \frac{3}{2} & 1 & 0 & 0 \\ 0 & 0 & \frac{4}{3} & 1 & 0 \\ 0 & 0 & 0 & \frac{5}{4} & 1 \\ 0 & 0 & 0 & 0 & \frac{6}{5} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = B = \begin{bmatrix} 1 \\ -\frac{1}{2} \\ \frac{7}{3} \\ \frac{21}{4} \\ 0 \end{bmatrix}$$

solving $x_5 = 0, x_4 = \frac{21}{5}, x_3 = -\frac{13}{10},$

$$x_2 = \frac{8}{15}, x_1 = \frac{7}{30}$$

Thus the solution is

$$X^T = \left[\frac{7}{30}, \frac{8}{15}, -\frac{13}{10}, \frac{21}{5}, 0 \right]$$

Note the amount of simplification in calculation of L and U .

EXERCISE

Solve the tridiagonal systems.

$$1. \quad \begin{aligned} 3x_1 + x_2 &= -1 \\ 2x_1 + 4x_2 + x_3 &= 7 \\ 2x_2 + 5x_3 &= 9 \end{aligned}$$

Ans. $x_1 = -0.999995, x_2 = 1.999999, x_3 = 1$

13.28 — HIGHER ENGINEERING MATHEMATICS—IV

$$\begin{aligned} 2. \quad & 2x_1 - x_2 = 3 \\ & -x_1 + 2x_2 - x_3 = -3 \\ & -x_2 + 2x_3 = 1 \end{aligned}$$

Ans. $x_1 = 1, x_2 = -1, x_3 = 0$

$$\begin{aligned} 3. \quad & 0.5x_1 + 0.25x_2 = 0.35 \\ & 0.35x_1 + 0.8x_2 + 0.4x_3 = 0.77 \\ & 0.25x_2 + x_3 + 0.5x_4 = -0.5 \\ & x_3 - 2x_4 = -2.25 \end{aligned}$$

Ans. $x_1 = -0.09357762, x_2 = 1.587155$
 $x_3 = -1.16743, x_4 = 0.5412842$

$$\begin{aligned} 4. \quad & 2x_1 - x_2 = 1 \\ & -x_1 + 2x_2 - x_3 = 0 \\ & -x_2 + 2x_3 - x_4 = 0 \\ & -x_3 + 2x_4 = 1 \end{aligned}$$

Ans. $x_1 = x_2 = x_3 = x_4 = 1$

Hint:

$$L = \begin{bmatrix} 2 & 0 & 0 & 0 \\ -1 & \frac{3}{2} & 0 & 0 \\ 0 & -1 & \frac{4}{3} & 0 \\ 0 & 0 & -1 & \frac{5}{4} \end{bmatrix}, U = \begin{bmatrix} 1 & -\frac{1}{2} & 0 & 0 \\ 0 & 1 & -\frac{2}{3} & 0 \\ 0 & 0 & 1 & -\frac{3}{4} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$\begin{aligned} 5. \quad & 2x_1 + x_2 = 1 \\ & x_{i-1} + 2x_i + x_{i+1} = 0, 2 \leq i \leq n-1 \\ & x_{n-1} + 2x_n = (-1)^{n+1} \\ & \text{for } n = 10. \end{aligned}$$

Ans. $x_i = (-1)^{i-1}$ for $1 \leq i \leq 10$

Chapter 14

Eigen Values and Eigen Vectors

INTRODUCTION

Suppose A is a 2×2 matrix and X is a non-zero vector such that AX is a scalar multiple of X say $AX = \lambda X$. Then geometrically each vector on the line through the origin determined by X gets mapped back onto the same line under multiplication by A . The algebraic eigen value problem consists of determination of such vectors X , known as eigen vectors, such scalars λ , known as eigen values. Thus the finding of non zero vectors that get mapped into scalar multiples of themselves under a linear operator are most important in the study of vibrations of beams, probability (Markov process), Economics (Leontief model), genetics, quantum mechanics, population dynamics and geometry. For example in a mechanical system, they represent the normal modes of vibration. EISPACK is a package of programs in FORTRAN for solving eigen value problems [Smith et. al (1976) in "Matrix Eigen-system routines-EISPACK guide", Lecture notes in computer science, vol. 6, Springer-Verlag, New York].

14.1 LINEAR TRANSFORMATION

Consider a set of n linear equations

[illegible]

Let $y=[y_1, y_2, y_3, \dots, y_n]^T$, $X=[x_1, x_2, x_3, \dots, x_n]^T$

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & a_{nn} \end{bmatrix}_{n \times n}$$

Then set of n equations (1) can be represented as

$$Y = AX \quad (2)$$

which transforms the set of n variables $(x_1, x_2, \dots, x_n)$ to the set of n variables $(y, y_2, \dots, y_n)$. Thus (2) is a transformation which transforms X into Y . Here A is known as the matrix of the transformation.

Linear transformation

(2) is said to be linear if it is additive and homogeneous i.e.,

$$\begin{aligned} A(c_1X_1 + c_2X_2) &= c_1AX_1 + c_2AX_2 \\ &= c_1Y_1 + c_2Y_2 \end{aligned}$$

where c_1 and c_2 are constants. Inverse transformation of (2) is $X = A^{-1}Y$.

14.2 EIGEN VALUES AND EIGEN VECTORS

Only square matrices are considered in this chapter.

Let A be a $n \times n$ matrix. Suppose the linear transformation $Y = AX$ transforms X into a scalar multiple of itself i.e.,

$$AX = Y = \lambda X$$

i.e., X is an invariant vector.

14.2 — HIGHER ENGINEERING MATHEMATICS—IV

Then the unknown scalar λ is known as an eigen value of the matrix A and the corresponding non zero vector X as eigen vector. Thus eigen values or characteristic values or latent or proper values are scalars λ which satisfy the equation

$$AX = \lambda X \quad (3)$$

for an $X \neq 0$

$$\text{or} \quad AX - \lambda IX = 0$$

$$(A - \lambda I)X = 0 \quad (4)$$

(4) represents a system of n homogeneous equations in the n variables $x_1, x_2, \dots, x_n$. (4) has non-trivial solutions if the coefficient matrix $(A - \lambda I)$ is singular i.e.,

$$|A - \lambda I| = 0 \quad (5)$$

or

$$\begin{vmatrix} a_{11} - \lambda & a_{12} & a_{13} \cdots a_{1n} \\ a_{21} & a_{22} - \lambda & a_{23} \cdots a_{2n} \\ \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & a_{n3} \cdots a_{nn} - \lambda \end{vmatrix} = 0 \quad (6)$$

Expansion of the determinant gives a n th degree polynomial $P_n(\lambda)$ known as the **characteristic polynomial** of A . (6) is known as the **characteristic equation** of A . Thus eigen values of n -square matrix A are the roots of the characteristic Equation (6). Hence A can have at least one and at most n eigen values.

Degree of characteristic polynomial = order of matrix A .

Spectrum of A is the set of all eigen values of A .

The eigen vector X corresponding to an eigen value λ is obtained by solving the homogeneous system (4) with this known eigen value λ . However eigen vector X is not unique, since kX is also an eigen vector where $k \neq 0$ constant ($AX = \lambda X$, multiplying by k , $kAX = k\lambda X$ or $A(kX) = \lambda(kX)$. Thus kX is an eigen vector of A).

Note 1: If all the n eigen values of A are distinct, then there correspond n distinct linearly independent eigen vectors.

Note 2: For an eigen value of A , repeated (twice or more), there may correspond one or several linearly independent eigen vectors. Thus the set of eigen vectors may or may not form a set of n linearly independent vectors.

Note 3: Algebraic multiplicity of an eigen value λ is the order of the eigen value as a root of the characteristic polynomial (i.e., if λ is a double root then algebraic multiplicity is 2).

Note 4: Geometric multiplicity of λ is the number of linearly independent eigen vectors corresponding to λ .

Procedure to Obtain Eigen Values and Eigen Vectors

1. Solve the characteristic equation $|A - \lambda I| = 0$ for eigen values λ_i . If A is of n th order, the number of eigen values are n or less than n (with repeated real roots or complex conjugate pairs).
2. For a specific eigen value λ_i , solve the homogeneous system of equations $(A - \lambda_i I)X = 0$.

Observation: See Note 1 and Note 2 above.

14.3 PROPERTIES OF EIGEN VALUES AND EIGEN VECTORS

1. **Real and complex eigen values:** If A is real, its eigen values are real or complex conjugates in pairs.

Proof: Expanding the characteristic equation

$$|A - \lambda I| = \begin{vmatrix} a_{11} - \lambda & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} - \lambda & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} - \lambda \end{vmatrix} = 0$$

we get an n th degree polynomial in λ

$$|A - \lambda I| = (-1)^n \left[\lambda^n - \sigma_1 \lambda^{n-1} + \sigma_2 \lambda^{n-2} \cdots + (-1)^{n-1} \sigma_{n-1} \lambda + (-1)^n \sigma_n \right] = 0$$

Since A is real, the roots of the characteristic polynomial will be real or complex conjugate pairs.

Let $\lambda_1, \lambda_2, \dots, \lambda_n$ be the roots of the characteristic equation.

2. **Trace:** σ_1 = sum of the diagonal elements of A = trace of A = sum of the roots of the polynomial equation = $\lambda_1 + \lambda_2 + \cdots + \lambda_n$.

Thus, trace of A = sum of the eigen values of A .

- 3. Determinant of $A = \sigma_n = |A|$**

$$= \lambda_1 \cdot \lambda_2 \cdot \lambda_3 \cdots \lambda_n.$$

Thus, the determinant of $A =$ product of eigen values of A .

- 4. Transpose:** A and A^T has same eigen values. Since the diagonal elements in the determinants of A and A^T are same, the determinant $|A - \lambda I|$ and $|A^T - \lambda I|$ are equal; hence have the same eigen values.

$$\begin{aligned} |A| &= |A^T|, |A - \lambda I| = |(A - \lambda I)^T| \\ &= |A^T - (\lambda I)^T| = |A^T - \lambda I| \end{aligned}$$

- 5. Non-zero eigen values:** If all the eigen values are non-zero, then $|A| \neq 0$ since $|A| =$ product of the eigen values. i.e., A is non singular.
- 6. Singular matrix:** $|A| = 0$. If at least one eigen value is zero then $|A| =$ product of eigen values $= \lambda_1, \lambda_2, \dots, \lambda_n = 0$ i.e., A is singular.
- 7. Inverse:** A^{-1} exists iff 0 is not an eigen value of A .
 Eigen values of A^{-1} are $\frac{1}{\lambda_1}, \frac{1}{\lambda_2}, \dots, \frac{1}{\lambda_n}$,

i.e., the reciprocals of the eigen values of A :

$$\begin{aligned} AX &= \lambda X, \text{ premultiply by } A^{-1}, \\ A^{-1}AX &= A^{-1}\lambda X = \lambda A^{-1}X \\ \therefore X &= \lambda A^{-1}X \text{ or } A^{-1}X = \frac{1}{\lambda}X \end{aligned}$$

- 8. "Spectral shift":** $A \mp kI$ has eigen values $\lambda_i \pm k$ and has the same eigen vectors of A : characteristic polynomial of $A \mp kI$ is $|A \mp kI - \lambda I| = |A - (\lambda \mp k)I|$ which has $\lambda \mp k$ as the eigen values.
- 9. Scalar multiples:** kA has eigen values $k\lambda_i$. Multiplying $(A - \lambda I)X = 0$ by k , $k(A - \lambda I)X = 0$, characteristic equation is $|k(A - \lambda I)| = |kA - k\lambda I| = 0$, thus kA has eigen values $k\lambda$.
- 10. Powers:** A^m has eigen values λ^m .

$$\begin{aligned} \text{By induction : } X &= A^0 X = \lambda^0 X = X, m = 0 \\ AX &= \lambda X, m = 1 \text{ true} \end{aligned}$$

$$\text{Suppose } A^k X_j = \lambda_j^k X_j \text{ is true}$$

$$\text{premultiplying by } A, AA^k X_j = A\lambda_j^k X_j$$

$$A^{k+1} X_j = \lambda_j^k AX_j = \lambda_j^k \lambda_j X_j = \lambda_j^{k+1} X_j$$

true for $k + 1$, hence by induction A^m has λ^m as eigen value.

- 11. Spectral mapping theorem:** The polynomial matrix $P(A) = k_m A^m + k_{m-1} A^{m-1} + \dots + k_1 A + k_0 I$ has the eigen values $P(\lambda_j) = k_m \lambda_j^m + k_{m-1} \lambda_j^{m-1} + \dots + k_1 \lambda_j + k_0$

From 9, 10 kA^m has eigen value $k\lambda^m$.

To prove additive:

$$\begin{aligned} (k_2 A^2 + k_1 A + k_0 I)X &= k_2 A^2 X + k_1 A X + k_0 I X \\ &= k_2 \lambda^2 X + k_1 \lambda X + k_0 I X \\ &= (k_0 \lambda^2 + k_1 \lambda + k_0)X \end{aligned}$$

Thus $k_0 \lambda^2 + k_1 \lambda + k_0$ is the eigen value of $k_2 A^2 + k_1 A + k_0 I$.

- 12. Characteristic Vector cannot correspond to two distinct characteristic values:** Suppose X_1 corresponds to λ_1 and λ_2 where $\lambda_1 \neq \lambda_2$. Then $(A - \lambda_1 I)X_1 = 0$, $(A - \lambda_2 I)X_1 = 0$, subtracting $(\lambda_1 - \lambda_2)IX_1 = 0$, which implies $X_1 = 0$ since $\lambda_1 \neq \lambda_2$. But $X_1 \neq 0$ (eigen vectors are chosen to be non-zero). Hence a contradiction.
- 13. Eigen values of diagonal,** upper triangular or lower triangular matrices are the principal diagonal elements since the characteristic polynomial becomes the product of diagonal elements namely

$$|D - \lambda I| = (a_{11} - \lambda)(a_{22} - \lambda)(a_{33} - \lambda) \cdots (a_{nn} - \lambda).$$

Thus characteristic values are the diagonal elements a_{ii} .

- 14.** If λ is an eigen value of an orthogonal matrix A then $\frac{1}{\lambda}$ is also an eigen value of A . By definition of orthogonal matrix, $A^T = A^{-1}$. But A and A^T have same eigen values. Also eigen values of A^{-1} are reciprocals of eigen values of A . Thus if λ is an eigen value of A then $\frac{1}{\lambda}$ is eigen value of $A^{-1} = A^T$. Since A and A^T has same eigen values, λ and $\frac{1}{\lambda}$ are eigen values of A .
- 15. Orthogonal:** Two vectors X and Y are said to be orthogonal if $X^T Y = Y^T X = 0$.

WORKED OUT EXAMPLES

Find the eigen values and eigen vectors of:

Example 1: $A = \begin{pmatrix} 8 & -4 \\ 2 & 2 \end{pmatrix}$

Solution: The eigen values are the roots of the characteristic equation

$$\begin{vmatrix} 8-\lambda & -4 \\ 2 & 2-\lambda \end{vmatrix} = 0$$

i.e., $(8-\lambda)(2-\lambda) + 8 = 0$
or $\lambda^2 - 10\lambda + 24 = 0$,
 $(\lambda - 4)(\lambda - 6) = 0$

The two distinct eigen values are $\lambda = 4, 6$.

Eigen vector corresponding to eigen value $\lambda = 4$:

$$(A - \lambda I)X = 0$$

$$\begin{pmatrix} 18-4 & -4 \\ 2 & 2-4 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 4 & -4 \\ 2 & -2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = 0$$

$$4x_1 - 4x_2 = 0$$

$$2x_1 - 2x_2 = 0 \quad \therefore x_1 = x_2$$

$$\bar{X}_1 = C_1 \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

$\bar{X}_2$ corresponding to $\lambda = 6$

$$\begin{pmatrix} 8-6 & -4 \\ 2 & 2-6 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 2 & -4 \\ 2 & -4 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = 0$$

$$2x_1 - 4x_2 = 0 \quad \therefore x_1 = 2x_2$$

$$\bar{X}_2 = C_2 \begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

Example 2: $A^T = \begin{pmatrix} 8 & 2 \\ -4 & 2 \end{pmatrix}$

Solution: Characteristic equation is $\begin{vmatrix} 8-\lambda & 2 \\ -4 & 2-\lambda \end{vmatrix} = 0$
characteristic equation is $\lambda^2 - 10\lambda + 24 = 0$ same as the ch. equation of A . Thus the eigen values of A and A^T are same. However the eigen vectors are not the same.

For $\lambda = 4$,

$$\begin{pmatrix} 8-4 & 2 \\ -4 & 2-4 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = 0$$

$$4x_1 + 2x_2 = 0 \quad \text{or} \quad x_2 = -2x_1$$

$$X_1 = C_1 \begin{pmatrix} -2 \\ 1 \end{pmatrix}$$

For $\lambda = 6$,

$$\begin{pmatrix} 8-6 & 2 \\ -4 & 2-6 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = 0$$

$$2x_1 + 2x_2 = 0$$

$$X_2 = C_2 \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Example 3: $A^{-1} = \frac{1}{24} \begin{bmatrix} 2 & 4 \\ -2 & 8 \end{bmatrix}$.

Solution: Characteristic equation is $|A^{-1} - \lambda I| = 0$

$$\begin{vmatrix} \frac{1}{12} - \lambda & \frac{1}{6} \\ -\frac{1}{12} & \frac{1}{3} - \lambda \end{vmatrix} = \left(\frac{1}{12} - \lambda \right) \left(\frac{1}{3} - \lambda \right) + \frac{1}{12} \cdot \frac{1}{6} = 0$$

$$24\lambda^2 - 10\lambda + 1 = 0, \quad \left(\lambda - \frac{1}{4} \right) \left(\lambda - \frac{1}{6} \right) = 0$$

The eigen values of A^{-1} are $\frac{1}{4}, \frac{1}{6}$ which are the reciprocals of the eigen values 4, 6 of A . Also the eigen vectors of A^{-1} and A are same.

For $\lambda = \frac{1}{4}$,

$$\begin{pmatrix} \frac{1}{12} - \frac{1}{4} & \frac{1}{6} \\ -\frac{1}{12} & \frac{1}{3} - \frac{1}{4} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = 0$$

$$-2x_1 + x_2 = 0 \quad \therefore x_1 = x_2$$

$$X_1 = C_1 \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

For $\lambda = \frac{1}{6}$,

$$\begin{pmatrix} \frac{1}{12} - \frac{1}{6} & \frac{1}{6} \\ -\frac{1}{12} & \frac{1}{3} - \frac{1}{6} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = 0$$

$$-x_1 + 2x_2 = 0 \quad \therefore x_1 = 2x_2$$

$$X_2 = C_2 \begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

Example 4: $B = kA$ where $k = -\frac{1}{2}$

Solution: $B = -\frac{1}{2}A = \begin{pmatrix} -4 & +2 \\ -1 & -1 \end{pmatrix}$

Characteristic equation of B is

$$|B - \lambda I| = \begin{vmatrix} -4-\lambda & 2 \\ -1 & -1-\lambda \end{vmatrix} = 0$$

$$(4 + \lambda)(1 + \lambda) + 2 = 0 \quad \text{or} \quad \lambda^2 + 5\lambda + 6 = 0$$

So the eigen values of B are $-2, -3$ which are $-\frac{1}{2}$ times of eigen values 4, 6 of A . Also the eigen vectors of B and A are same.

For $\lambda = -2$,

$$\begin{bmatrix} -4+2 & 2 \\ -1 & -1+2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 0 \quad \therefore x_1 = x_2$$

$$X_1 = C_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

For $\lambda = -3$,

$$\begin{bmatrix} -4+3 & 2 \\ -1 & -1+3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 0,$$

$$-x_1 + 2x_2 = 0$$

$$X_2 = C_2 \begin{bmatrix} 1 \\ 2 \end{bmatrix}.$$

Example 5: $A^2 = \begin{pmatrix} 56 & -40 \\ 20 & -4 \end{pmatrix}$

Solution: Characteristic equation of A^2 is

$$\begin{vmatrix} 56-\lambda & -40 \\ 20 & -4-\lambda \end{vmatrix} = 0$$

$$\lambda^2 - 52\lambda + 576 = (\lambda - 16)(\lambda - 36) = 0$$

So eigen values of A^2 are 16, 36 which are square of the eigen values 4, 6 of A . Also the eigen vectors of A and A^2 are same

For $\lambda = 16$,

$$\begin{bmatrix} 56-16 & -40 \\ 20 & -4-16 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 0$$

$$x_1 - x_2 = 0 \quad \text{i.e., } x_1 = x_2$$

$$X_1 = C_1 \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

For $\lambda = 36$,

$$\begin{bmatrix} 56-36 & -40 \\ 20 & -4-36 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 0,$$

$$x_1 - 2x_2 = 0 \quad \text{i.e., } x_1 = 2x_2$$

$$X_2 = C \begin{pmatrix} 1 \\ 2 \end{pmatrix}.$$

Example 6:

$$\begin{aligned} B &= A \pm kI = \begin{pmatrix} 8 & -4 \\ 2 & 2 \end{pmatrix} \pm k \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 8 \pm k & -4 \\ 2 & 2 \pm k \end{pmatrix} \end{aligned}$$

Solution: Characteristic equation of B is

$$|B - \lambda I| = 0$$

$$\begin{vmatrix} 8 \pm k - \lambda & -4 \\ 2 & 2 \pm k - \lambda \end{vmatrix} = 0$$

$$\text{i.e., } (8 \pm k - \lambda)(2 \pm k - \lambda) + 8 = 0$$

$$\lambda^2 - (10 \pm 2k)\lambda + (k^2 \pm 10k + 24) = 0$$

roots are $\frac{10 \pm 2}{2} \pm k$ i.e., $4 \pm k$ and $6 \pm k$ which are 4, 6 of A with $\pm k$.

Eigen vectors of B and A are same

For $\lambda = 4 \pm k$,

$$\begin{bmatrix} 8 \pm k - (4 \pm k) & -4 \\ 2 & 2 \pm k - (4 \pm k) \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 0$$

$$4x_1 - 4x_2 = 0 \quad \text{or } x_1 = x_2 \text{ etc.}$$

Example 7: $D = 2A^2 - \frac{1}{2}A + 3I$

Solution:

$$\begin{aligned} D &= 2 \begin{pmatrix} 56 & -40 \\ 20 & -4 \end{pmatrix} - \frac{1}{2} \begin{pmatrix} 8 & -4 \\ 2 & 2 \end{pmatrix} + 3 \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 111 & -78 \\ 39 & -6 \end{pmatrix} \end{aligned}$$

$$\text{ch. eq. of } D \text{ is } \begin{bmatrix} 111-\lambda & -78 \\ 39 & -6-\lambda \end{bmatrix} = 0$$

$$\text{or } \lambda^2 - 105\lambda + 2376 = (\lambda - 33)(\lambda - 72) = 0$$

Thus the eigen values of D are 33 and 72.

Note that $33 = 2 \cdot 16 - \frac{1}{2} \cdot 4 + 3$ and $72 = 2 \cdot 36 - \frac{1}{2} \cdot 6 + 3$ i.e., eigen value of D is $2\lambda^2 - \frac{1}{2}\lambda + 3$ where λ is the eigen value of A . The eigen vectors of D and A are same.

For $\lambda = 33$,

$$\begin{bmatrix} 111-33 & -78 \\ 39 & -6-33 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 0$$

$$\text{i.e., } 78x_1 - 78x_2 = 0$$

$$\text{i.e., } x_1 = x_2 \text{ etc.}$$

Example 8: Find the sum and product of eigen values of A .

Solution: Sum of eigen values of $A = 4 + 6 = 10 = \text{trace of } A = a_{11} + a_{22} = 8 + 2 = 10$.

Product of eigen values of $A = 4 \cdot 6 = 24 = |A| = 16 + 8 = 24$.

Example 9: Find the eigen values and eigen vectors of

$$A = \begin{pmatrix} 3 & 1 & 4 \\ 0 & 2 & 6 \\ 0 & 0 & 5 \end{pmatrix}$$

14.6 — HIGHER ENGINEERING MATHEMATICS—IV

Solution: For upper triangular, lower triangular and diagonal matrices, the eigen values are given by the diagonal elements.

The characteristic eq.

$$|A - \lambda I| = \begin{vmatrix} 3 - \lambda & 1 & 4 \\ 0 & 2 - \lambda & 6 \\ 0 & 0 & 5 - \lambda \end{vmatrix} = 0$$

i.e., $(3 - \lambda)(2 - \lambda)(5 - \lambda) = 0$

So eigen values of A are 3, 2, 5 which are the diagonal elements of A .

Eigen vector X_1 for $\lambda = 3$

$$\begin{bmatrix} 0 & 1 & 4 \\ 0 & -1 & 6 \\ 0 & 0 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = 0$$

i.e., $x_2 + 4x_3 = 0, -x_2 + 6x_3 = 0, 2x_3 = 0$

$x_2 = 0, x_3 = 0, x_1 = \text{arbitrary},$

$$X_1 = C_1 \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}.$$

Eigen vector X_2 for $\lambda = 2$,

$x_1 + x_2 + 4x_3 = 0, 6x_3 = 0, 3x_3 = 0$

$\therefore x_3 = 0, x_1 = -x_2, X_2 = C_1 \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}$

For $\lambda = 5$,

$-2x_1 + x_2 + 4x_3 = 0$

$-3x_2 + 6x_3 = 0$

i.e., $x_1 = 3x_3, x_2 = 2x_3$

$$X_3 = C_2 \begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}.$$

Find the eigen values and eigen vectors of:

Example 10:

$$A = \begin{bmatrix} 1 & 0 & -1 \\ 1 & 2 & 1 \\ 2 & 2 & 3 \end{bmatrix}$$

Determine whether the eigen vectors are orthogonal.

Solution:

Characteristic equation is $\begin{vmatrix} 1 - \lambda & 0 & -1 \\ 1 & 2 - \lambda & 1 \\ 2 & 2 & 3 - \lambda \end{vmatrix}$

$$= \lambda^3 - 6\lambda^2 + 11\lambda - 6 = 0$$

$$(\lambda - 1)(\lambda - 2)(\lambda - 3) = 0$$

So $\lambda = 1, 2, 3$ are three distinct eigen values of A

For $\lambda = 1$,

$$\begin{bmatrix} 0 & 0 & -1 \\ 1 & 1 & 1 \\ 2 & 2 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = 0, \quad \begin{matrix} x_3 = 0 \\ x_1 + x_2 = 0, \end{matrix}$$

$$X_1 = C_1 \begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix}$$

For $\lambda = 2$,

$$\begin{bmatrix} -1 & 0 & -1 \\ 1 & 0 & 1 \\ 2 & 2 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = 0, \quad \begin{matrix} x_1 + x_3 = 0 \\ 2x_1 + 2x_2 + x_3 = 0 \end{matrix}$$

$$x_1 = -x_3, \quad x_2 = \frac{1}{2}x_3, \quad X_2 = C \begin{bmatrix} 2 \\ -1 \\ -2 \end{bmatrix}$$

For $\lambda = 3$,

$$\begin{bmatrix} -2 & 0 & -1 \\ 1 & -1 & 1 \\ 2 & 2 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = 0, \quad \begin{matrix} x_1 = -x_2 \\ x_1 = -\frac{1}{2}x_3, \end{matrix}$$

$$X_3 = C \begin{bmatrix} 1 \\ 1 \\ -2 \end{bmatrix}$$

Thus there are three linearly independent eigen vectors X_1, X_2, X_3 corresponding to the three distinct eigen values. Since $X_1^T X_2 = 3 \neq 0, X_2^T X_3 = 5 \neq 0, X_3^T X_1 = 0$.

Therefore only X_1 and X_3 are orthogonal.

Example 11:

$$A = \begin{bmatrix} 1 & 2 & 2 \\ 0 & 2 & 1 \\ -1 & 2 & 2 \end{bmatrix}$$

Determine the algebraic and geometric multiplicity.

Solution:

Characteristic equation is $\begin{vmatrix} 1 - \lambda & 2 & 2 \\ 0 & 2 - \lambda & 1 \\ -1 & 2 & 2 - \lambda \end{vmatrix} = 0$

$$\lambda^3 - 5\lambda^2 + 8\lambda - 4 = (\lambda - 1)(\lambda - 2)^2 = 0$$

So $\lambda = 1, 2, 2$ are eigen values with $\lambda = 2$ repeated twice (double root) of multiplicity 2.

The algebraic multiplicity of the eigen value $\lambda = 2$ is 2.

For $\lambda = 1$,

$$\begin{bmatrix} 0 & 2 & 2 \\ 0 & 1 & 1 \\ -1 & 2 & 1 \end{bmatrix}, \quad \begin{matrix} x_2 = -x_3 \\ x_1 = -x_3 \end{matrix}$$

$$X_1 = C \begin{bmatrix} 1 \\ 1 \\ -1 \end{bmatrix}$$

For $\lambda = 2$,

$$\begin{bmatrix} -1 & 2 & 2 \\ 0 & 0 & 1 \\ -1 & 2 & 0 \end{bmatrix}, \quad \begin{matrix} x_3 = 0 \\ x_1 = 2x_2 \end{matrix}$$

$$X_2 = C \begin{bmatrix} 2 \\ 1 \\ 0 \end{bmatrix}$$

Thus only one eigen vector X_2 corresponds to the repeated eigen value $\lambda = 2$.

The geometric multiplicity of eigen value $\lambda = 2$ is one.

Example 12: $A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -3 & 3 \end{bmatrix}$

Determine the algebraic and geometric multiplicity.

Solution: Characteristic equation is

$$\lambda^3 - 3\lambda^2 + 3\lambda - 1 = (\lambda - 1)^3 = 0$$

$\lambda = 1, 1, 1$ is an eigen value of algebraic multiplicity 3.

For $\lambda = 1$,

$$\begin{matrix} -x_1 + x_2 = 0 & \therefore x_1 = x_2 \\ -x_2 + x_3 = 0 & x_2 = x_3 \\ x_1 - 3x_2 + 2x_3 = 0 \end{matrix}$$

$$X = C \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Thus only one eigen value X corresponds to the thrice repeated eigen value $\lambda = 1$, so geometric

multiplicity is one.

Example 13: $A = \begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 0 & 0 & 1 \end{bmatrix}$

Determine the algebraic and geometric multiplicity.

Solution: Characteristic equation is

$$\begin{vmatrix} 2-\lambda & 1 & 1 \\ 1 & 2-\lambda & 1 \\ 0 & 0 & 1-\lambda \end{vmatrix} = (1-\lambda)(\lambda-1)(\lambda-3) = 0$$

Thus $\lambda = 1, 1, 3$ are the eigen values of A . So the algebraic multiplicity of eigen value $\lambda = 1$ is two.

For $\lambda = 3$,

$$\begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 0 & 0 & -2 \end{bmatrix} \sim \begin{matrix} x_3 = 0 \\ x_1 = x_2 \end{matrix}, \quad X_1 = C \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$$

For $\lambda = 1$,

$$\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 0 & 0 & 0 \end{bmatrix} \sim \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad \begin{matrix} n = 3 \\ r = 1 \end{matrix}$$

$$n - r = 3 - 1 = 2 \quad \text{arbitrary}$$

$$x_1 + x_2 + x_3 = 0 \quad \text{or} \quad x_1 = -x_2 - x_3$$

where x_2 and x_3 are arbitrary

For a choice of $x_2 = 0$, $x_3 = \text{arbitrary}$.

$$X_2 = C \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}$$

For a choice of $x_2 \neq 0$, $x_3 = 0$

$$X_3 = C \begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix}$$

Thus for the repeated eigen value $\lambda = 1$, there corresponds two linearly independent eigen vectors X_2 and X_3 . So the geometric multiplicity of eigen value $\lambda = 1$ is 2.

Example 14: Find the eigen values of the orthogonal matrix

$$B = \frac{1}{3} \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ 2 & -2 & 1 \end{bmatrix}$$

14.8 — HIGHER ENGINEERING MATHEMATICS—IV

Solution: The characteristic equation of

$$A = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ 2 & -2 & 1 \end{bmatrix} \text{ is}$$

$$\begin{vmatrix} 1-\lambda & 2 & 2 \\ 2 & 1-\lambda & -2 \\ 2 & -2 & 1-\lambda \end{vmatrix} = \lambda^3 - 3\lambda^2 - 9\lambda + 27 = 0$$

or $(\lambda - 3)^2(\lambda + 3) = 0$

The eigen values of A are 3, 3, -3, so the eigen values of $B = \frac{1}{3}A$ are 1, 1, -1.

Note that $\lambda = 1$ is an eigen value of B then its reciprocal $\frac{1}{\lambda} = \frac{1}{1} = 1$ is also an eigen value of B .

Example 15: Find the inverse transformation of

$$y_1 = x_1 + 2x_2 + 5x_3$$

$$y_2 = -x_2 + 2x_3$$

$$y_3 = 2x_1 + 4x_2 + 11x_3$$

Solution: With $Y = [y_1 \ y_2 \ y_3]^T$, $X = [x_1 \ x_2 \ x_3]^T$, the coefficient matrix

$$A = \begin{bmatrix} 1 & 2 & 5 \\ 0 & -1 & 2 \\ 2 & 4 & 11 \end{bmatrix}. \text{ Its } |A| = -1$$

$$\text{Adj } A = \begin{bmatrix} -19 & -2 & 9 \\ 4 & 1 & -2 \\ 2 & 0 & -1 \end{bmatrix}$$

Thus the inverse transformation is

$$\begin{aligned} X = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} &= A^{-1}Y = \begin{bmatrix} 19 & 2 & -9 \\ -4 & -1 & 2 \\ -2 & 0 & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} \\ &= \begin{bmatrix} 19y_1 & +2y_2 & -9y_3 \\ -4y_1 & -y_2 & +2y_3 \\ -2y_1 & & +y_3 \end{bmatrix} \end{aligned}$$

EXERCISE

Find the eigen values and eigen vectors of:

1. $\begin{bmatrix} -5 & 2 \\ 2 & -2 \end{bmatrix}$

Ans. $\lambda^2 + 7\lambda + 6 = 0$, $\lambda = -1, -6$, $\begin{bmatrix} 1 \\ 2 \end{bmatrix}$, $\begin{bmatrix} 2 \\ -1 \end{bmatrix}$

2. $\begin{bmatrix} 6 & 8 \\ 8 & -6 \end{bmatrix}$

Ans. 10, -10, $\begin{bmatrix} 2 \\ 1 \end{bmatrix}$, $\begin{bmatrix} 1 \\ -2 \end{bmatrix}$

3. $\begin{bmatrix} 1 & 2 \\ 1 & 0 \end{bmatrix}$

Ans. 2, -1, $\begin{bmatrix} 2 \\ 1 \end{bmatrix}$, $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$

4. $\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix}$

Ans. 4, -1, $\begin{bmatrix} 2 \\ 3 \end{bmatrix}$, $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$

5. $\begin{bmatrix} -2 & 2 & -3 \\ 2 & 1 & -6 \\ -1 & -2 & 0 \end{bmatrix}$

Ans. 5, -3, -3, $\begin{bmatrix} 1 \\ 2 \\ -1 \end{bmatrix}$, $\begin{bmatrix} -2 \\ 1 \\ 0 \end{bmatrix}$, $\begin{bmatrix} 3 \\ 0 \\ 1 \end{bmatrix}$

6. $\begin{bmatrix} 1 & 1 & 3 \\ 1 & 5 & 1 \\ 3 & 1 & 1 \end{bmatrix}$

Ans. $\lambda^3 - 7\lambda^2 + 36 = 0$, $\lambda = -2, 3, 6$, $\begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$, $\begin{bmatrix} +1 \\ -1 \\ 1 \end{bmatrix}$, $\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$

7. $\begin{bmatrix} -3 & -7 & -5 \\ 2 & 4 & 3 \\ 1 & 2 & 2 \end{bmatrix}$

Ans. $(\lambda - 1)^3 = 0$, $\lambda = 1, 1, 1$, $\begin{bmatrix} -3 \\ 1 \\ 1 \end{bmatrix}$

8. $\begin{bmatrix} 8 & -6 & 2 \\ -6 & 7 & -4 \\ 2 & -4 & 3 \end{bmatrix}$

Ans. $\lambda^3 - 18\lambda^2 + 45\lambda = 0$, $\lambda = 0, 3, 15$, $\begin{bmatrix} 1 \\ 2 \\ 2 \end{bmatrix}$, $\begin{bmatrix} 2 \\ 1 \\ -2 \end{bmatrix}$, $\begin{bmatrix} 2 \\ -2 \\ 1 \end{bmatrix}$

9. $\begin{bmatrix} 2 & 2 & 1 \\ 1 & 3 & 1 \\ 1 & 2 & 2 \end{bmatrix}$

Ans. $\lambda^3 - 7\lambda^2 + 11\lambda - 5 = 0$ $\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$, $\begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}$, $\begin{bmatrix} 2 \\ -1 \\ 0 \end{bmatrix}$
 $\lambda = 5, 1, 1,$

10. $\begin{bmatrix} 3 & 10 & 5 \\ -2 & -3 & -4 \\ 3 & 5 & 7 \end{bmatrix}$

Ans. $\lambda^3 - 7\lambda^2 + 16\lambda - 12 = 0$, for $\lambda = 2$, $\begin{bmatrix} 5 \\ 2 \\ -3 \end{bmatrix}$,
 $\lambda = 2, 2, 3$

For $\lambda = 3$, $\begin{bmatrix} 1 \\ 1 \\ -2 \end{bmatrix}$

11. $\begin{bmatrix} 6 & -2 & 2 \\ -2 & 3 & -1 \\ 2 & -1 & 3 \end{bmatrix}$

Ans. $\lambda^3 - 12\lambda^2 + 36\lambda - 32 = 0$, $\begin{bmatrix} -1 \\ 0 \\ 2 \end{bmatrix}$, $\begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix}$,
 $\lambda = 2, 2, 8$

For $\lambda = 8$, $\begin{bmatrix} 2 \\ -1 \\ 1 \end{bmatrix}$

12. $\begin{bmatrix} 2 & 1 & 0 \\ 0 & 2 & 1 \\ 0 & 0 & 2 \end{bmatrix}$

Ans. $(\lambda - 2)^3 = 0$, $\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$
 $\lambda = 2, 2, 2$

13. $\begin{bmatrix} 1 & -4 & -1 & -4 \\ 2 & 0 & 5 & -4 \\ -1 & 1 & -2 & 3 \\ -1 & 4 & -1 & 6 \end{bmatrix}$

Ans. $\lambda^4 - 5\lambda^3 + 9\lambda^2 - 7\lambda + 2 = 0$
 $\lambda = 2, 1, 1, 1,$

For $\lambda = 2$, $\begin{bmatrix} 2 \\ 3 \\ -2 \\ -3 \end{bmatrix}$, for $\lambda = 1$, $\begin{bmatrix} 3 \\ 6 \\ -4 \\ -5 \end{bmatrix}$

14. $\begin{bmatrix} 2 & -2 & 2 \\ 1 & 1 & 1 \\ 1 & 3 & -1 \end{bmatrix}$

$$\lambda^3 - 2\lambda^2 - 4\lambda + 8 = 0$$

Ans. $\lambda = 2, 2, -2$
 For $\lambda = 2$, $[0 \ 1 \ 1]^T$
 For $\lambda = -2$, $[-4 \ -1 \ 7]^T$

15. $\begin{bmatrix} 3 & -2 & -5 \\ 4 & -1 & -5 \\ -2 & -1 & -3 \end{bmatrix}$

$$(\lambda + 5)(\lambda - 2)^2 = 0, \lambda = 5, 2, 2$$

Ans. For $\lambda = 5$, $X_1 = [3 \ 2 \ 4]^T$
 For $\lambda = 2$, $X_2 = [1 \ 3 \ -1]$

16. Find the sum and product of the eigen values of

$$A = \begin{bmatrix} 2 & 3 & -2 \\ -2 & 1 & 1 \\ 1 & 0 & 2 \end{bmatrix}$$

Ans. sum = trace = $2 + 1 + 2 = 5$
 product = $|A| = 21$.

14.4 CAYLEY-HAMILTON THEOREM

Every square matrix satisfies its own characteristic equation.

Proof: Let A be an n -square matrix. Let $D(\lambda)$ be the characteristic polynomial of A , given by

$$D(\lambda) = |\lambda I - A| = \lambda^n + C_{n-1}\lambda^{n-1} + C_{n-2}\lambda^{n-2} + \dots + C_1\lambda + C_0 \quad (1)$$

Let $B(\lambda)$ be the adjoint of $(\lambda I - A)$. The elements of $B(\lambda)$ are cofactors of the matrix $(\lambda I - A)$ and are polynomials in λ of degree not exceeding $n - 1$. Thus

$$B(\lambda) = B_{n-1}\lambda^{n-1} + B_{n-2}\lambda^{n-2} + \dots + B_1\lambda + B_0 \quad (2)$$

where B_i are n -square matrices whose elements are functions of the elements of A and independent of λ . We know that

$$(\lambda I - A) \cdot \text{adj}(\lambda I - A) = |\lambda I - A|I$$

$$(\lambda I - A) \cdot B(\lambda) = |\lambda I - A|I$$

From (1) and (2), we have

$$(\lambda I - A)(B_{n-1}\lambda^{n-1} + B_{n-2}\lambda^{n-2} + \dots + B_1\lambda + B_0)$$

14.10 — HIGHER ENGINEERING MATHEMATICS—IV

$$= I(\lambda^n + C_{n-1}\lambda^{n-1} + \dots + C_1\lambda + C_0) \quad (3)$$

Equating the like powers of λ on both sides of (3), we get

$$\begin{aligned} B_{n-1} &= I \\ B_{n-2} - AB_{n-1} &= C_{n-1}I \\ B_{n-3} - AB_{n-2} &= C_{n-2}I \\ &\dots\dots\dots \\ B_0 - AB_1 &= C_1I \\ -AB_0 &= C_0I \end{aligned}$$

Multiplying both sides of the above matrix equations by $A^n, A^{n-1}, A^{n-2}, \dots, A, I$ respectively, we have

$$\begin{aligned} A^n B_{n-1} &= A^n \\ A^{n-1} B_{n-2} - A^n B_{n-1} &= C_{n-1} A^{n-1} \\ A^{n-2} B_{n-3} - A^{n-1} B_{n-2} &= C_{n-2} A^{n-2} \\ &\dots\dots\dots \\ AB_0 - A^2 B_1 &= C_1 A \\ -AB_0 &= C_0 I \end{aligned}$$

By adding all the above equations, we get

$$\begin{aligned} 0 &= A^n + C_{n-1}A^{n-1} + C_{n-2}A^{n-2} + \dots \\ &\quad + C_1A + C_0I \end{aligned} \quad (4)$$

since all the terms on the L.H.S. cancel each other. Thus A satisfies its own characteristic equation.

Inverse by Cayley-Hamilton Theorem

Multiplying (4) by A^{-1}

$$\begin{aligned} 0 &= A^{n-1} + C_{n-1}A^{n-2} + C_{n-2}A^{n-3} + \dots \\ &\quad + C_1I + C_0A^{-1} \end{aligned}$$

Solving for A^{-1} , we get

$$\begin{aligned} A^{-1} &= \frac{-1}{C_0} [A^{n-1} + C_{n-1}A^{n-2} \\ &\quad + C_{n-2}A^{n-3} + \dots + C_1I]. \end{aligned}$$

Note: A^{-1} exists only if $C_0 =$ determinant of A is not equals to zero.

WORKED OUT EXAMPLES

Example 1: Verify Cayley-Hamilton theorem for the matrix $A = \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}$. Find A^{-1} . Determine A^8 .

Solution: The characteristic equation is

$$|A - \lambda I| = \begin{vmatrix} 1 - \lambda & 2 \\ 2 & -1 - \lambda \end{vmatrix} = 0$$

$$\text{or} \quad (\lambda - 1)(1 + \lambda) - 4 = 0$$

$$\text{so} \quad \lambda^2 - 5 = 0$$

$$A^2 = A \cdot A = \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix} = \begin{bmatrix} 5 & 0 \\ 0 & 5 \end{bmatrix} = 5I$$

$$\text{or} \quad A^2 - 5I = 0$$

Thus A satisfies the characteristic equation. To find A^{-1} , multiply $A^2 - 5I = 0$ by A^{-1} .

$$A^{-1} \cdot A^2 - 5A^{-1}I = 0$$

$$\text{or} \quad A - 5A^{-1} = 0$$

$$\text{So} \quad A^{-1} = \frac{1}{5}A = \frac{1}{5} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}$$

To find A^8 , multiply $A^2 - 5I = 0$ by A^6

$$A^6 \cdot A^2 - 5I \cdot A^6 = 0$$

$$A^8 = 5A^6 = 5 \cdot A^2 \cdot A^2 \cdot A^2 = 5 \cdot (5I)(5I)(5I)$$

$$A^8 = 625I$$

Example 2: Verify Cayley-Hamilton theorem for the matrix

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix}$$

and hence find the inverse of A . Find A^4 . Express $B = A^8 - 11A^7 - 4A^6 + A^5 + A^4 - 11A^3 - 3A^2 + 2A + I$ as a quadratic polynomial in A . Find B .

Solution: The characteristic equation of A is

$$|A - \lambda I| = \begin{vmatrix} 1 - \lambda & 2 & 3 \\ 2 & 4 - \lambda & 5 \\ 3 & 5 & 6 - \lambda \end{vmatrix}$$

$$= (1 - \lambda)[(4 - \lambda)(6 - \lambda) - 25]$$

$$-2[2(6 - \lambda) - 15]$$

$$+3[10 - 3(4 - \lambda)] = 0,$$

$$\lambda^3 - 11\lambda^2 - 4\lambda + 1 = 0.$$

Cayley-Hamilton theorem is verified if A satisfies the above characteristic equation i.e.,

$$A^3 - 11A^2 - 4A + I = 0$$

$$A^2 = A \cdot A = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix} \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix}$$

$$= \begin{bmatrix} 14 & 25 & 31 \\ 25 & 45 & 56 \\ 31 & 56 & 70 \end{bmatrix}$$

$$A^3 = A \cdot A^2 = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix} \begin{bmatrix} 14 & 25 & 31 \\ 25 & 45 & 56 \\ 31 & 56 & 70 \end{bmatrix}$$

$$= \begin{bmatrix} 157 & 283 & 353 \\ 283 & 510 & 636 \\ 353 & 636 & 793 \end{bmatrix}$$

verification

$$A^3 - 11A^2 - 4A + I$$

$$= \begin{bmatrix} 157 & 283 & 353 \\ 283 & 510 & 636 \\ 353 & 636 & 793 \end{bmatrix} - 11 \begin{bmatrix} 14 & 25 & 31 \\ 25 & 45 & 56 \\ 31 & 56 & 70 \end{bmatrix}$$

$$-4 \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

To find A^{-1} : From characteristic equation $A^{-1} = -A^2 + 11A + 4I$. So

$$A^{-1} = - \begin{bmatrix} 14 & 25 & 31 \\ 25 & 45 & 56 \\ 31 & 56 & 70 \end{bmatrix} + 11 \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix} +$$

$$+4 \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & -3 & 2 \\ -3 & 3 & -1 \\ 2 & -1 & 0 \end{bmatrix}$$

To find A^4 : From Cayley-Hamilton theorem

$$A^3 - 11A^2 - 4A + I = 0$$

$$\text{or } A^3 = 11A^2 + 4A - I$$

Multiplying both sides by A

$$A^4 = A \cdot A^3 = A(11A^2 + 4A - I) = 11A^3 + 4A^2 - A$$

$$= 11 \begin{bmatrix} 157 & 283 & 353 \\ 283 & 510 & 636 \\ 353 & 636 & 793 \end{bmatrix} + 4 \begin{bmatrix} 14 & 25 & 31 \\ 25 & 45 & 56 \\ 31 & 56 & 70 \end{bmatrix}$$

$$- \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix}$$

$$= \begin{bmatrix} 1782 & 3211 & 4004 \\ 3211 & 5786 & 7215 \\ 4004 & 7215 & 8997 \end{bmatrix}$$

To find B: Rewrite

$$B = A^8 - 11A^7 - 4A^6 + A^5 + A^4 - 11A^3$$

$$-3A^2 + 2A + I$$

$$= A^5(A^3 - 11A^2 - 4A + I)$$

$$+ A(A^3 - 11A^2 - 4A + I) + A^2 + A + I$$

$$= A^5(0) + A(0) + A^2 + A + I$$

since A satisfies the characteristic equation.

Thus

$$B = A^2 + A + I = \begin{bmatrix} 14 & 25 & 31 \\ 25 & 45 & 56 \\ 31 & 56 & 70 \end{bmatrix} + \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$B = \begin{bmatrix} 16 & 27 & 34 \\ 27 & 50 & 61 \\ 34 & 61 & 77 \end{bmatrix}$$

Example 3: Determine A^{-1} , A^{-2} , A^{-3} if

$$A = \begin{bmatrix} 4 & 6 & 6 \\ 1 & 3 & 2 \\ -1 & -4 & -3 \end{bmatrix}$$

Solution: The characteristic equation of A is

$$|A - \lambda I| = \begin{vmatrix} 4 - \lambda & 6 & 6 \\ 1 & 3 - \lambda & 2 \\ -1 & -4 & -3 - \lambda \end{vmatrix}$$

$$= \lambda^3 - 4\lambda^2 - \lambda + 4 = 0$$

It follows from Cayley-Hamilton theorem that

14.12 — HIGHER ENGINEERING MATHEMATICS—IV

$$A^3 - 4A^2 - A + 4I = 0$$

Multiplying by A^{-1} ,

$$A^{-1}A^3 - 4A^{-1}A^2 - A^{-1} \cdot A + A^{-1}4I = 0$$

$$\text{Solving } A^{-1} = \frac{1}{4}[I + 4A - A^2]$$

$$A^2 = A \cdot A = \begin{bmatrix} 16 & 18 & 18 \\ 5 & 7 & 6 \\ -5 & -6 & -5 \end{bmatrix}$$

$$A^{-1} = \frac{1}{4} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} + 4 \begin{bmatrix} 4 & 6 & 6 \\ 1 & 3 & 2 \\ -1 & -4 & -3 \end{bmatrix}$$

$$- \frac{1}{4} \begin{bmatrix} 16 & 18 & 18 \\ 5 & 7 & 6 \\ -5 & -6 & -5 \end{bmatrix}$$

$$A^{-1} = \frac{1}{4} \begin{bmatrix} 1 & 6 & 6 \\ -1 & 6 & 2 \\ 1 & -10 & -6 \end{bmatrix}$$

Multiplying A^{-1} by A^{-1} , we have

$$A^{-2} = A^{-1}A^{-1} = A^{-1} \frac{1}{4}[I + 4A - A^2] = \frac{1}{4}[A^{-1} + 4I - A]$$

$$A^{-2} = \frac{1}{4} \begin{bmatrix} \frac{1}{4} & -\frac{9}{2} & -\frac{9}{2} \\ -\frac{5}{4} & \frac{5}{2} & -\frac{3}{2} \\ \frac{5}{4} & \frac{3}{2} & \frac{11}{2} \end{bmatrix}$$

Similarly,

$$\begin{aligned} A^{-3} &= A^{-1}A^{-2} = A^{-1}[A^{-1} + 4I - A] \frac{1}{4} \\ &= \frac{1}{4}[A^{-2} + 4A^{-1} - I] = \frac{1}{64} \begin{bmatrix} 1 & 78 & 78 \\ -21 & 90 & 26 \\ 21 & -154 & -90 \end{bmatrix} \end{aligned}$$

EXERCISE

Verify Cayley-Hamilton theorem for the matrix:

$$1. \begin{bmatrix} 2 & 5 \\ 1 & -3 \end{bmatrix}$$

Ans. Characteristic polynomial: $\lambda^2 + \lambda - 11$

$$2. \begin{bmatrix} 2 & -3 \\ 7 & -4 \end{bmatrix}$$

Ans. Characteristic polynomial: $\lambda^2 + 2\lambda + 13$

$$3. \begin{bmatrix} 1 & 4 & -3 \\ 0 & 3 & 1 \\ 0 & 2 & -1 \end{bmatrix}$$

Ans. Characteristic equation: $\lambda^3 - 3\lambda^2 - 3\lambda + 5 = 0$

4. Verify Cayley-Hamilton theorem for

$$A = \begin{bmatrix} 1 & 4 \\ 2 & 3 \end{bmatrix}. \text{ Find } A^{-1}.$$

$$\text{Find } B = A^5 - 4A^4 - 7A^3 + 11A^2 - A - 10I$$

Ans. Characteristic equation: $\lambda^2 - 4\lambda - 5 = 0$,

$$A^{-1} = \frac{1}{5} \begin{bmatrix} -3 & 4 \\ 2 & -1 \end{bmatrix}, B = A + 5I = \begin{bmatrix} 6 & 4 \\ 2 & 8 \end{bmatrix}$$

5. Use Cayley-Hamilton theorem to find A^{-1} if

$$A = \begin{bmatrix} 1 & 1 & 3 \\ 1 & 3 & -3 \\ -2 & -4 & -4 \end{bmatrix}$$

Ans. Characteristic equation: $\lambda^3 - 20\lambda + 8 = 0$

$$A^{-1} = \frac{1}{4} \begin{bmatrix} 12 & 4 & 6 \\ -5 & -1 & -3 \\ -1 & -1 & -1 \end{bmatrix}$$

6. Find A^{-1} and A^4 if

$$A = \begin{bmatrix} 1 & 0 & 3 \\ 2 & 1 & -1 \\ 1 & -1 & 1 \end{bmatrix}$$

Ans. Characteristic equation: $\lambda^3 - 3\lambda^2 - \lambda + 9 = 0$,

$$A^{-1} = \frac{1}{9} \begin{bmatrix} 0 & 3 & 3 \\ 3 & 2 & -7 \\ 3 & -1 & -1 \end{bmatrix}$$

$$A^4 = \begin{bmatrix} 7 & -30 & 42 \\ 18 & -13 & 46 \\ -6 & -14 & 17 \end{bmatrix}$$

7. Find A^{-1} for

$$A = \begin{bmatrix} 2 & -1 & 1 \\ -1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix}$$

Ans. Characteristic equation: $\lambda^3 - 6\lambda^2 + 9\lambda - 4 = 0$,

$$A^{-1} = \frac{1}{4} \begin{bmatrix} 3 & 1 & -1 \\ 1 & 3 & 1 \\ -1 & 1 & 3 \end{bmatrix}$$

8. Compute A^{-1} , A^{-2} , A^3 and A^4 if

$$A = \begin{bmatrix} 1 & 1 & 2 \\ 3 & 1 & 1 \\ 2 & 3 & 1 \end{bmatrix}$$

Ans. Characteristic equation: $\lambda^3 - 3\lambda^2 - 7\lambda - 11 = 0$

$$A^{-1} = \frac{1}{11} \begin{bmatrix} -2 & 5 & -1 \\ -1 & -3 & 5 \\ 7 & -1 & -2 \end{bmatrix},$$

$$A^{-2} = \frac{1}{121} \begin{bmatrix} -8 & -24 & 29 \\ 40 & -1 & -24 \\ -27 & 40 & -8 \end{bmatrix}$$

$$A^3 = \begin{bmatrix} 42 & 31 & 29 \\ 45 & 39 & 31 \\ 53 & 45 & 42 \end{bmatrix},$$

$$A^4 = \begin{bmatrix} 193 & 160 & 144 \\ 224 & 177 & 160 \\ 272 & 224 & 193 \end{bmatrix}$$

9. If $A = \begin{bmatrix} 2 & 1 & 1 \\ 0 & 1 & 0 \\ 1 & 1 & 2 \end{bmatrix}$ find A^{-1} . Find $B =$

$$A^8 - 5A^7 + 7A^6 - 3A^5 - 5A^3 + 8A^2 - 2A + I$$

Ans. Characteristic equation:

$$\lambda^3 - 5\lambda^2 + 7\lambda - 3 = 0$$

$$A^{-1} = \frac{1}{3} \begin{bmatrix} 2 & -1 & -1 \\ 0 & 3 & 0 \\ -1 & -1 & 2 \end{bmatrix}, B = \begin{bmatrix} 8 & 5 & 5 \\ 0 & 3 & 0 \\ 5 & 5 & 8 \end{bmatrix}$$

10. Verify Cayley-Hamilton theorem and hence find A^{-1} for

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

Ans. Characteristic equation: $\lambda^4 - \lambda^3 - \lambda + 1 = 0$

$$A^{-1} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$$

11. Find $B = A^6 - 4A^5 + 8A^4 - 12A^3 + 14A^2$ if $A = \begin{bmatrix} 1 & 2 \\ -1 & 3 \end{bmatrix}$

Ans. Characteristic equation: $\lambda^2 - 4\lambda + 5 = 0$,

$$B = 5I - 4A = \begin{bmatrix} +1 & -8 \\ 4 & -7 \end{bmatrix}$$

12. Find A^{-1} if $A = \begin{bmatrix} 7 & 2 & -2 \\ -6 & -1 & 2 \\ 6 & 2 & -1 \end{bmatrix}$

Ans. Characteristic equation: $\lambda^3 - 5\lambda^2 + 7\lambda - 3 = 0$,

$$A^{-1} = \frac{1}{3} \begin{bmatrix} -3 & -2 & 2 \\ 6 & 5 & -2 \\ -6 & -2 & 5 \end{bmatrix}.$$

14.5 DIAGONALIZATION POWERS OF A MATRIX

Consider only square matrices of order n .

Similar matrix

A is said to be similar to B if there exists a non-singular matrix P such that

$$B = P^{-1}AP$$

This transformation of A to B is known as similarity transformation.

Invariant Eigen Values

1. Similar matrices A and B have same eigen values
2. Further if X is an eigen vector of A then $Y = P^{-1}X$ is an eigen vector of the matrix B .

Proof:

1. Suppose B is similar to A i.e., $B = P^{-1}AP$.

14.14 — HIGHER ENGINEERING MATHEMATICS—IV

Consider the characteristic polynomial of B

$$\begin{aligned}|B - \lambda I| &= |P^{-1}AP - \lambda I| = |P^{-1}AP - \lambda P^{-1}IP| \\ &= |P^{-1}(A - \lambda I)P| = |P^{-1}||A - \lambda I||P| \\ &= |A - \lambda I|\end{aligned}$$

since $|P^{-1}||P| = |P^{-1}P| = |I| = 1$.

Thus A and B have the same characteristic polynomial and therefore has the same eigen values.

2. Let X be an eigen vector of A so that $AX = \lambda X$.
Consider

$$B = P^{-1}AP$$

Post multiplying by P^{-1}

$$BP^{-1} = (P^{-1}AP)P^{-1} = (P^{-1}A)(PP^{-1}) = P^{-1}A$$

Post multiply by X

$$\begin{aligned}B(P^{-1}X) &= P^{-1}AX = P^{-1}(\lambda X) \\ &= P^{-1}\lambda X = \lambda(P^{-1}X)\end{aligned}$$

Thus $P^{-1}X$ is an eigen vector of B corresponding to the eigen value λ .

Diagonalization

A n -square matrix A with n linearly independent eigen vectors is similar to a diagonal matrix D whose diagonal elements are the eigen values of A .

Proof: Let $X_1, X_2, \dots, X_n$ be the n linearly independent eigen vectors of A corresponding to n eigen values $\lambda_1, \lambda_2, \dots, \lambda_n$. Construct P , known as **modal matrix**, having $X_1, X_2, \dots, X_n$ as the n column vectors i.e.,

$$P_{n \times n} = [X_1 X_2 \dots X_n].$$

Since $X_1, X_2, \dots, X_n$ are linearly independent, P^{-1} exists.

Consider

$$\begin{aligned}AP &= A[X_1 X_2 \dots X_n] = [AX_1 \ AX_2 \dots \ AX_n] \\ &= [\lambda_1 X_1 \ \lambda_2 X_2 \dots \lambda_n X_n] \\ &= [X_1 X_2 \dots X_n] \begin{bmatrix} \lambda_1 & 0 & 0 \dots 0 \\ 0 & \lambda_2 & 0 \dots 0 \\ \vdots & & \\ 0 & 0 & \dots \lambda_n \end{bmatrix}\end{aligned}$$

$$AP = PD$$

where D is the diagonal matrix with eigen values of A as the principal diagonal elements. D is known as **spectral matrix**.

Pre multiplying by P^{-1} on both sides

$$B = P^{-1}AP = P^{-1}PD = (P^{-1}P)D = ID = D.$$

Powers of a Matrix A

Consider $D = P^{-1}AP$

$$\begin{aligned}\text{Then } D^2 &= (P^{-1}AP)(P^{-1}AP) \\ &= P^{-1}A(PP^{-1})AP \\ &= P^{-1}A \cdot IAP = P^{-1}AAP \\ &= P^{-1}A^2P\end{aligned}$$

$$\text{Similarly, } D^3 = P^{-1}A^3P$$

$$\text{Thus } D^n = P^{-1}A^nP$$

To obtain A^n , pre-multiply by P and post-multiply by P^{-1} ,

$$\begin{aligned}PD^nP^{-1} &= P(P^{-1}A^nP)P^{-1} = (PP^{-1})A^n(PP^{-1}) \\ &= IA^nI = A^n \\ \therefore A^n &= PD^nP^{-1}.\end{aligned}$$

WORKED OUT EXAMPLES

Example 1: Find a matrix P which diagonalizes the matrix

$$A = \begin{bmatrix} 4 & 1 \\ 2 & 3 \end{bmatrix}. \text{ Verify that } P^{-1}AP = D$$

where D is the diagonal matrix. Hence find A^6 .

Solution: A is diagonalizable by P whose columns are the linearly independent eigen vectors of A .

The characteristic equation of A is

$$|A - \lambda I| = \begin{vmatrix} 4 - \lambda & 1 \\ 2 & 3 - \lambda \end{vmatrix} = 0$$

$$\begin{aligned}(4 - \lambda)(3 - \lambda) - 2 &= \lambda^2 - 7\lambda + 10 \\ &= (\lambda - 2)(\lambda - 5) = 0,\end{aligned}$$

so $\lambda = 2, 5$ are two distinct eigen values of A .

$$\text{For } \lambda = 2, 2x_1 + x_2 = 0, x_2 = -2x_1, X_1 = \begin{bmatrix} 1 \\ -2 \end{bmatrix}$$

$$\text{For } \lambda = 5, -x_1 + x_2 = 0, x_2 = x_1, X_2 = [1, 1]^T$$

Thus the matrix P which diagonalizes A is

$$P = [X_1, X_2] = \begin{bmatrix} 1 & 1 \\ -2 & 1 \end{bmatrix}$$

Verification:

$$P^{-1} = \frac{1}{3} \begin{bmatrix} 1 & -1 \\ 2 & 1 \end{bmatrix}$$

$$\begin{aligned} P^{-1}AP &= \frac{1}{3} \begin{bmatrix} 1 & -1 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} 4 & 1 \\ 2 & 3 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ -2 & 1 \end{bmatrix} \\ &= \frac{1}{3} \begin{bmatrix} 2 & -2 \\ 10 & 5 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ -2 & 1 \end{bmatrix} \end{aligned}$$

$$P^{-1}AP = \frac{1}{3} \begin{bmatrix} 6 & 0 \\ 0 & 15 \end{bmatrix} = \begin{bmatrix} 2 & 0 \\ 0 & 5 \end{bmatrix} = D = \text{diagonal matrix}$$

D contains eigen values 2, 5 as diagonal elements.

To find A^6 :

$$A^6 = PD^6P^{-1} = \begin{bmatrix} 1 & 1 \\ -2 & 1 \end{bmatrix} \begin{bmatrix} 2^6 & 0 \\ 0 & 5^6 \end{bmatrix} \frac{1}{3} \begin{bmatrix} 1 & -1 \\ 2 & 1 \end{bmatrix}$$

$$A^6 = \frac{1}{3} \begin{bmatrix} 64 & 15625 \\ -128 & 15625 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 2 & 1 \end{bmatrix}$$

$$= \frac{1}{3} \begin{bmatrix} 31314 & 15561 \\ 31122 & 15753 \end{bmatrix}$$

$$\therefore A^6 = \begin{bmatrix} 10438 & 5187 \\ 10374 & 5251 \end{bmatrix}$$

Example 2: Diagonalize

$$A = \begin{bmatrix} 1 & 6 & 1 \\ 1 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$$

and hence find A^8 . Find the modal matrix.

Solution: The non-singular square matrix P containing eigen vectors of A as columns, diagonalizes A .

$$\begin{aligned} \text{The ch. eq. of } A \text{ is } \begin{vmatrix} 1-\lambda & 6 & 1 \\ 1 & 2-\lambda & 0 \\ 0 & 0 & 3-\lambda \end{vmatrix} &= 0 \\ \text{i.e., } (\lambda + 1)(\lambda - 3)(\lambda - 4) &= 0 \end{aligned}$$

so eigen values of A are $\lambda = -1, 3, 4$

For $\lambda = -1$,

$$\begin{aligned} 2x_1 + 6x_2 + x_3 &= 0 \\ x_1 + 3x_2 + 0 &= 0 \\ 4x_3 &= 0 \end{aligned} \quad \therefore \begin{aligned} x_3 &= 0 \\ x_1 &= -3x_2 \end{aligned}$$

$$X_1 = \begin{bmatrix} -3 \\ 1 \\ 0 \end{bmatrix}$$

For $\lambda = 3$,

$$\begin{aligned} -2x_1 + 6x_2 + x_3 &= 0 \\ x_1 - 2x_2 &= 0 \end{aligned} \quad \therefore \begin{aligned} x_1 &= x_2 \\ x_3 &= -4x_2 \end{aligned}$$

$$X_2 = \begin{bmatrix} 1 \\ 1 \\ -4 \end{bmatrix}$$

For $\lambda = 4$,

$$\begin{aligned} -3x_1 + 6x_2 + x_3 &= 0 \\ x_1 - 2x_2 &= 0 \\ -x_3 &= 0 \end{aligned} \quad \therefore \begin{aligned} x_3 &= 0 \\ x_2 &= 2x_1 \end{aligned}$$

$$X_3 = \begin{bmatrix} 2 \\ 1 \\ 0 \end{bmatrix}$$

Thus

$$P = \begin{bmatrix} -3 & 1 & 2 \\ 1 & 1 & 1 \\ 0 & -4 & 0 \end{bmatrix}$$

is the modal matrix.

To find P^{-1} :

$$\begin{bmatrix} -3 & 1 & 2 & | & 1 & 0 & 0 \\ 1 & 1 & 1 & | & 0 & 1 & 0 \\ 0 & -4 & 0 & | & 0 & 0 & 1 \end{bmatrix}$$

$$\begin{aligned} R_{12} &\sim \begin{bmatrix} 1 & 1 & 1 & | & 0 & 1 & 0 \\ 0 & 4 & 5 & | & 1 & 3 & 0 \\ 0 & -4 & 0 & | & 0 & 0 & 1 \end{bmatrix} \\ R_{21(3)} &\sim \begin{bmatrix} 1 & 1 & 1 & | & 0 & 1 & 0 \\ 0 & 4 & 5 & | & 1 & 3 & 0 \\ 0 & -4 & 0 & | & 0 & 0 & 1 \end{bmatrix} \end{aligned}$$

$$\begin{aligned} R_{32(1)} &\sim \begin{bmatrix} 1 & 1 & 1 & | & 0 & 1 & 0 \\ 0 & 4 & 5 & | & 1 & 3 & 0 \\ 0 & 0 & 5 & | & 1 & 3 & 1 \end{bmatrix} \\ &\sim \begin{bmatrix} 1 & 1 & 1 & | & 0 & 1 & 0 \\ 0 & 4 & 5 & | & 1 & 3 & 0 \\ 0 & 0 & 1 & | & \frac{1}{5} & \frac{3}{5} & \frac{1}{5} \end{bmatrix} \end{aligned}$$

$$\begin{aligned} R_{2\left(\frac{1}{4}\right)} &\sim \begin{bmatrix} 1 & 1 & 1 & | & 0 & 1 & 0 \\ 0 & 1 & \frac{5}{4} & | & \frac{1}{4} & \frac{3}{4} & 0 \\ 0 & 0 & 1 & | & \frac{1}{5} & \frac{3}{5} & \frac{1}{5} \end{bmatrix} \\ R_{3\left(\frac{1}{5}\right)} &\sim \begin{bmatrix} 1 & 1 & 1 & | & 0 & 1 & 0 \\ 0 & 1 & \frac{5}{4} & | & \frac{1}{4} & \frac{3}{4} & 0 \\ 0 & 0 & 1 & | & \frac{1}{5} & \frac{3}{5} & \frac{1}{5} \end{bmatrix} \end{aligned}$$

$$\begin{aligned} R_{23\left(-\frac{5}{4}\right)} &\sim \begin{bmatrix} 1 & 1 & 0 & | & -\frac{1}{5} & \frac{2}{5} & -\frac{1}{5} \\ 0 & 1 & 0 & | & 0 & 0 & -\frac{1}{4} \\ 0 & 0 & 1 & | & \frac{1}{5} & \frac{3}{5} & \frac{1}{5} \end{bmatrix} \\ R_{13(-1)} &\sim \begin{bmatrix} 1 & 1 & 0 & | & -\frac{1}{5} & \frac{2}{5} & -\frac{1}{5} \\ 0 & 1 & 0 & | & 0 & 0 & -\frac{1}{4} \\ 0 & 0 & 1 & | & \frac{1}{5} & \frac{3}{5} & \frac{1}{5} \end{bmatrix} \end{aligned}$$

$$\sim R_{12(-1)} \left[\begin{array}{ccc|ccc} 1 & 0 & 0 & -\frac{1}{5} & \frac{2}{5} & \frac{1}{20} \\ 0 & 1 & 0 & 0 & 0 & -\frac{1}{4} \\ 0 & 0 & 1 & \frac{1}{5} & \frac{3}{5} & \frac{1}{5} \end{array} \right]$$

Thus

$$P^{-1} = \frac{1}{20} \begin{bmatrix} -4 & 8 & 1 \\ 0 & 0 & -5 \\ 4 & 12 & 4 \end{bmatrix}$$

Diagonalization:

$$\begin{aligned} D &= P^{-1}AP \\ &= \frac{1}{20} \begin{bmatrix} -4 & 8 & 1 \\ 0 & 0 & -5 \\ 4 & 12 & 4 \end{bmatrix} \begin{bmatrix} 1 & 6 & 1 \\ 1 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix} \begin{bmatrix} -3 & 1 & 2 \\ 1 & 1 & 1 \\ 0 & -4 & 0 \end{bmatrix} \\ &= \frac{1}{20} \begin{bmatrix} 4 & -8 & -1 \\ 0 & 0 & -15 \\ 16 & 48 & 16 \end{bmatrix} \begin{bmatrix} -3 & 1 & 2 \\ 1 & 1 & 1 \\ 0 & -4 & 0 \end{bmatrix} \\ &= \frac{1}{20} \begin{bmatrix} -20 & 0 & 0 \\ 0 & 60 & 0 \\ 0 & 0 & 80 \end{bmatrix} = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 4 \end{bmatrix} \end{aligned}$$

To find A^8 :

$$\begin{aligned} A^8 &= PD^8P^{-1} \\ &= \begin{bmatrix} -3 & 1 & 2 \\ 1 & 1 & 1 \\ 0 & -4 & 0 \end{bmatrix} \begin{bmatrix} (-1)^8 & 0 & 0 \\ 0 & 3^8 & 0 \\ 0 & 0 & 4^8 \end{bmatrix} \frac{1}{20} \begin{bmatrix} -4 & 8 & 1 \\ 0 & 0 & -5 \\ 4 & 12 & 4 \end{bmatrix} \\ &= \begin{bmatrix} -3 & 1 & 2 \\ 1 & 1 & 1 \\ 0 & -4 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 6561 & 0 \\ 0 & 0 & 65536 \end{bmatrix} \begin{bmatrix} -4 & 8 & 1 \\ 0 & 0 & 5 \\ 4 & 12 & 4 \end{bmatrix} \frac{1}{20} \\ &= \frac{1}{20} \begin{bmatrix} -3 & 6561 & 131072 \\ 1 & 6561 & 65536 \\ 0 & -26244 & 0 \end{bmatrix} \begin{bmatrix} -4 & 8 & 1 \\ 0 & 0 & 5 \\ 4 & 12 & 4 \end{bmatrix} \\ &= \frac{1}{20} \begin{bmatrix} 524300 & 1572840 & 491480 \\ 262140 & 786440 & 229340 \\ 0 & 0 & 131220 \end{bmatrix} \\ \therefore A^8 &= \begin{bmatrix} 26215 & 78642 & 24574 \\ 13107 & 39322 & 11467 \\ 0 & 0 & 6561 \end{bmatrix} \end{aligned}$$

EXERCISE

Diagonalize the following matrices. Find the modal

matrix P which diagonalizes (transforms) A

$$1. \begin{bmatrix} 5 & 3 \\ 3 & 5 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}, D = \begin{bmatrix} 8 & 0 \\ 0 & 2 \end{bmatrix}$$

$$2. \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$$

Ans. not diagonalizable since only one eigen vector $\begin{bmatrix} k \\ 0 \end{bmatrix}$ exists.

$$3. \begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 4 & 1 \\ 1 & -1 \end{bmatrix}, D = \begin{bmatrix} 6 & 0 \\ 0 & 1 \end{bmatrix}$$

$$4. \begin{bmatrix} 2 & -2 \\ -2 & 5 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 2 \\ -2 & 1 \end{bmatrix}, D = \begin{bmatrix} 6 & 0 \\ 0 & 1 \end{bmatrix}$$

$$5. \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}, D = \begin{bmatrix} 3 & 0 \\ 0 & -1 \end{bmatrix}$$

$$6. \begin{bmatrix} 1 & 2 \\ 5 & 4 \end{bmatrix}$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 2 \\ -1 & 5 \end{bmatrix}, D = \begin{bmatrix} -1 & 0 \\ 0 & 6 \end{bmatrix}$$

$$7. \begin{bmatrix} 4 & 1 \\ 3 & 2 \end{bmatrix} \text{ hence find } A^5$$

$$\text{Ans. } P = \begin{bmatrix} 1 & 1 \\ -3 & 1 \end{bmatrix}, D = \begin{bmatrix} 1 & 0 \\ 0 & 5 \end{bmatrix},$$

$$A^5 = \begin{bmatrix} 2344 & 781 \\ 2343 & 782 \end{bmatrix}$$

$$8. \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}$$

Ans. no real eigen values, $\lambda = 1 \pm i$ so not diagonalizable over real.

Modal matrix over complex

$$\begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix}, D = \begin{pmatrix} 1+i & 0 \\ 0 & 1-i \end{pmatrix}.$$

$$9. \begin{bmatrix} 7.3 & 0.2 & -3.7 \\ -11.5 & 1.0 & 5.5 \\ 17.7 & 1.8 & -9.3 \end{bmatrix}$$

Ans. characteristic equation $\lambda^3 + \lambda^2 - 12\lambda = 0$
eigen values 3, -4, 0.

$$\text{Modal matrix} = \begin{bmatrix} -1 & 1 & 2 \\ 3 & -1 & 1 \\ -1 & 3 & 4 \end{bmatrix},$$

$$D = \begin{bmatrix} 3 & 0 & 0 \\ 0 & -4 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

$$10. \begin{bmatrix} 1 & 1 & 3 \\ 1 & 5 & 1 \\ 3 & 1 & 1 \end{bmatrix} \text{ hence find } A^4.$$

Ans. characteristic equation
 $(\lambda + 2)(\lambda - 3)(\lambda - 6) = 0, \lambda = -2, 3, 6$

$$\text{Modal matrix } P = \begin{bmatrix} -1 & 1 & 1 \\ 0 & -1 & 2 \\ 1 & 1 & 1 \end{bmatrix},$$

$$D = \begin{bmatrix} -2 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 6 \end{bmatrix},$$

$$A^4 = \begin{bmatrix} 251 & 485 & 235 \\ 485 & 1051 & 485 \\ 235 & 485 & 251 \end{bmatrix}.$$

$$11. \begin{bmatrix} 8 & -6 & 2 \\ -6 & 7 & -4 \\ 2 & -4 & 3 \end{bmatrix}$$

Ans. $\lambda^3 - 18\lambda^2 + 45\lambda = 0, \lambda = 0, 3, 15$

$$P = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ 2 & -2 & 1 \end{bmatrix}, \quad D = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 15 \end{bmatrix}$$

$$12. \text{ Find } A^8 \text{ for } A = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 2 & 1 \\ -4 & 4 & 3 \end{bmatrix}$$

Ans. $(1 - \lambda)(\lambda - 2)(\lambda - 3) = 0, \lambda = 1, 2, 3,$

$$P = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 1 & 1 \\ -2 & 0 & 1 \end{bmatrix}$$

$$A^8 = \begin{bmatrix} -12099 & 12355 & 6305 \\ -12100 & 12356 & 6305 \\ -13120 & 13120 & 6561 \end{bmatrix}$$

$$13. \text{ Find } A^5 \text{ for } A = \begin{bmatrix} 11 & -4 & -7 \\ 7 & -2 & -5 \\ 10 & -4 & -6 \end{bmatrix}$$

Ans. $\lambda = 0, 1, 2$

$$P = \begin{bmatrix} 1 & 1 & -2 \\ 1 & -1 & -1 \\ 1 & 2 & -2 \end{bmatrix}, A^5 = \begin{bmatrix} 191 & -64 & -127 \\ 97 & -32 & -65 \\ 190 & -64 & -126 \end{bmatrix}$$

$$14. \text{ Find } A^4 \text{ for } A = \begin{bmatrix} 3 & -1 & 1 \\ -1 & 5 & -1 \\ v1 & -1 & 3 \end{bmatrix}$$

Ans. $\lambda = 2, 3, 6,$

$$P = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & -2 \\ -1 & 1 & 1 \end{bmatrix}, A^4 = \begin{bmatrix} 251 & -405 & 235 \\ -405 & 891 & -405 \\ 235 & -405 & 251 \end{bmatrix}$$

$$15. \begin{bmatrix} 7 & -2 & 1 \\ -2 & 10 & -2 \\ 1 & -2 & 7 \end{bmatrix}$$

Ans. $\lambda^3 - 24\lambda^2 + 180\lambda - 432 = 0, \lambda = 6, 6, 12$

$$P = \begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{6}} \\ 0 & \frac{1}{\sqrt{3}} & -\frac{2}{\sqrt{6}} \\ -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{6}} \end{bmatrix}$$

$$16. \begin{bmatrix} +1 & -3 & 2 \\ -3 & 7 & -5 \\ 2 & -5 & 8 \end{bmatrix}$$

Ans. $\lambda = 1, -2, 18,$

$$P = \begin{bmatrix} 1 & 3 & -1 \\ 0 & 1 & 1 \\ 0 & 0 & 2 \end{bmatrix}$$

$$\begin{aligned} C^T &= \frac{1}{2}(A - A^T)^T = \frac{1}{2}(A^T - A^{TT}) \\ &= \frac{1}{2}(A^T - A) = -(A - A^T) = -C \end{aligned}$$

Now

$$A = (B + C) = \frac{1}{2} [(A + A^T) + (A - A^T)] = A.$$

Example 2: Show that

$$A = \frac{1}{2} \begin{bmatrix} -1 & 1 & 1 & 1 \\ 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & -1 \end{bmatrix} \text{ is orthogonal.}$$

Solution: Consider $A \cdot A^T$

$$\begin{aligned} AA^T &= \frac{1}{2} \begin{bmatrix} -1 & 1 & 1 & 1 \\ 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & -1 \end{bmatrix} \frac{1}{2} \begin{bmatrix} -1 & 1 & 1 & 1 \\ 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & -1 \end{bmatrix} \\ &= \frac{1}{4} \begin{bmatrix} 4 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 4 \end{bmatrix} = I \end{aligned}$$

i.e., $A^T = A^{-1} \therefore A$ is orthogonal.

Example 3: Determine a, b, c so that A is orthogonal, where

$$A = \begin{bmatrix} 0 & 2b & c \\ a & b & -c \\ a & -b & c \end{bmatrix}$$

Solution: For orthogonal matrix $AA^T = I$ so

$$\begin{aligned} AA^T &= \begin{bmatrix} 0 & 2b & c \\ a & b & -c \\ a & -b & c \end{bmatrix} \begin{bmatrix} 0 & a & a \\ 2b & b & -b \\ c & -c & c \end{bmatrix} \\ &= \begin{bmatrix} 4b^2 + c^2 & 2b^2 - c^2 & -2b^2 + c^2 \\ 2b^2 - c^2 & a^2 + b^2 + c^2 & a^2 - b^2 - c^2 \\ -2b^2 + c^2 & a^2 - b^2 - c^2 & a^2 + b^2 + c^2 \end{bmatrix} = I \end{aligned}$$

Solving $2b^2 - c^2 = 0$, $a^2 - b^2 - c^2 = 0$ (non-diagonal elements of I)

$$c = \pm\sqrt{2}b, a^2 = b^2 + c^2 = b^2 + 2b^2 = 3b^2, a = \pm\sqrt{3}b$$

From diagonal elements of I ,

$$\begin{aligned} 4b^2 + c^2 &= 1, \quad 4b^2 + 2b^2 = 1 \\ \therefore b &= \pm\frac{1}{\sqrt{6}}, \quad c = \pm\frac{1}{\sqrt{3}}, \quad a = \pm\frac{1}{\sqrt{2}} \end{aligned}$$

Example 4: If $X_1 = \frac{1}{3}[2 \ -1 \ 2]^T$

and $X_2 = k[3 \ -4 \ -5]^T$

where $k = \frac{1}{\sqrt{50}}$, construct an orthogonal matrix

$$A = [X_1 \ X_2 \ X_3]$$

Solution: Let $X_3 = [a_1 \ a_2 \ a_3]^T$ be the undetermined vector. Since A is orthogonal, the columns vectors of A form an orthonormal system $X_i^T X_j = \delta_{ij}$

$$\begin{aligned} X_1^T X_2 &= \begin{bmatrix} \frac{2}{3} & -\frac{1}{3} & \frac{2}{3} \end{bmatrix} \begin{bmatrix} 3k \\ -4k \\ -5k \end{bmatrix} \\ &= 2k + \frac{4}{3} - \frac{10}{3}k = 0, \text{ true} \\ \therefore X_1 \text{ and } X_2 \text{ are orthogonal.} \end{aligned}$$

$$\begin{aligned} X_1^T X_3 &= \begin{bmatrix} \frac{2}{3} & -\frac{1}{3} & \frac{2}{3} \end{bmatrix} \begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix} \\ &= \frac{1}{3}[2a_1 - a_2 + 2a_3] = 0 \end{aligned} \quad (1)$$

$$\begin{aligned} X_2^T X_3 &= [3k \ -4k \ -5k] \begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix} \\ &= (3a_1 - 4a_2 - 5a_3)k = 0 \end{aligned} \quad (2)$$

Since X_3 should be normalized

$$\begin{aligned} X_3^T X_3 &= [a_1 \ a_2 \ a_3] \begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix} \\ &= a_1^2 + a_2^2 + a_3^2 \\ 1 &= \|X_3\| = \sqrt{X_3^T X_3} = \sqrt{a_1^2 + a_2^2 + a_3^2} \end{aligned} \quad (3)$$

Solving (1) (2) (3), we get a_1, a_2, a_3

$$2a_1 - a_2 + 2a_3 = 0$$

$$3a_1 - 4a_2 + 5a_3 = 0$$

$$a_1^2 + a_2^2 + a_3^2 = 1$$

$$\begin{aligned} \text{So } a_1 &= -\frac{13}{5}a_3, \quad a_2 = -\frac{16}{5}a_3, \\ a_3^2 &= \frac{25}{550}, \quad a_3 = \frac{1}{\sqrt{22}} \end{aligned}$$

14.20 — HIGHER ENGINEERING MATHEMATICS—IV

$$\therefore a_1 = -\frac{13}{5}k_1, \quad a_2 = -\frac{16}{5}k_1, \quad a_3 = k_1$$

$$\text{where } k_1 = \frac{1}{\sqrt{22}}$$

Thus the required orthogonal matrix A is

$$A = \begin{bmatrix} \frac{2}{3} & 3k & -\frac{13}{5}k_1 \\ -\frac{1}{3} & -4k & -\frac{16}{5}k_1 \\ \frac{2}{3} & -5k & k_1 \end{bmatrix}.$$

Example 5: Find a real symmetric matrix C of the quadratic form $Q = x_1^2 + 3x_2^2 + 2x_3^2 + 2x_1x_2 + 6x_2x_3$

Solution: The coefficient matrix of Q is

$$A = \begin{bmatrix} 1 & 2 & 0 \\ 0 & 3 & 6 \\ 0 & 0 & 2 \end{bmatrix}, \text{ so } C = \text{symmetric matrix} = \frac{1}{2}[A + A^T]$$

$$C = \frac{1}{2} \left\{ \begin{bmatrix} 1 & 2 & 0 \\ 0 & 3 & 6 \\ 0 & 0 & 2 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 6 & 2 \end{bmatrix} \right\} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 3 & 3 \\ 0 & 3 & 2 \end{bmatrix}$$

Notes : The simplest of way writing C is

1. Put coefficients of square terms as the diagonal elements.
2. Place $\frac{1}{2}$ of a_{ij} , the coefficient of $x_i x_j$ at c_{ij} and the remaining $\frac{1}{2}$ of a_{ij} at c_{ji} i.e., $c_{ij} = c_{ji} = \frac{1}{2}a_{ij}$ such that $c_{ij} + c_{ji} = \frac{1}{2}(a_{ij} + a_{ji}) = a_{ij}$. For example 6, coefficient of $x_2 x_3$ is equidistributed as 3 and 3 to c_{23} and c_{32} .

EXERCISE

1. Express A as the sum of a symmetric and skew-symmetric matrix where

$$A = \begin{bmatrix} 4 & 2 & -3 \\ 1 & 3 & -6 \\ -5 & 0 & -7 \end{bmatrix}$$

$$\text{Ans. } A + A^T = \frac{1}{2} \begin{bmatrix} 8 & 3 & -8 \\ 3 & 6 & -6 \\ -8 & -6 & -14 \end{bmatrix} \text{ symmetric,}$$

$$A - A^T = \frac{1}{2} \begin{bmatrix} 0 & 1 & 2 \\ -1 & 0 & -6 \\ -2 & 6 & 0 \end{bmatrix} \text{ skew-symmetric}$$

2. If A and B are square matrices of the same order and A is symmetric, then prove that $B^T A B$ is also symmetric.

Hint: $(B^T A B)^T = B^T A^T B^{TT}$ but $A^T = A$, $= B^T A B$.

3. Prove that the inverse of a non-singular symmetric matrix A is symmetric.

Hint: $(A^{-1})^T = (A^T)^{-1} = A^{-1}$ (since $(A^T)^{-1} = (A^{-1})^T$ and $A = A^T$ by symmetry).

4. Write $A = \begin{bmatrix} 3 & -4 & -1 \\ 6 & 0 & -1 \\ -3 & 13 & -4 \end{bmatrix}$ as the sum of a symmetric R and skew-symmetric S .

$$\text{Ans. } R = \frac{1}{2}[A + A^T] = \begin{bmatrix} 3 & 1 & -2 \\ 1 & 0 & 6 \\ -2 & 6 & -4 \end{bmatrix},$$

$$S = \frac{1}{2}[A - A^T] = \begin{bmatrix} 0 & -5 & 1 \\ 5 & 0 & -7 \\ -1 & 7 & 0 \end{bmatrix}$$

5. Show that the eigen values of the skew-symmetric matrix

$$A = \begin{bmatrix} 0 & 9 & -12 \\ -9 & 0 & 20 \\ 12 & -20 & 0 \end{bmatrix}$$

are purely imaginary or zero.

Ans. eigen values are $0, -25i, 25i$ (see Page 14.27)

Find real symmetric matrix C such that $Q = X^T C X$ where

$$6. Q = 6x_1^2 - 4x_1x_2 + 2x_2^2$$

$$\text{Ans. } \begin{pmatrix} 6 & -2 \\ -2 & 2 \end{pmatrix}$$

$$7. Q = 2(x_1 - x_2)^2$$

Ans. $\begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}$

8. $Q = (x_1 + x_2 + x_3)^2$

Ans. $\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$

9. $Q = 4x_1x_3 + 2x_2x_3 + x_3^2$

Ans. $\begin{bmatrix} 0 & 0 & 2 \\ 0 & 0 & 1 \\ 2 & 1 & 1 \end{bmatrix}$

Verify that the following matrices are orthogonal:

10. $\frac{1}{3} \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ 2 & -2 & 1 \end{bmatrix}$

Hint: Show that $AA^T = I$.

11. $\begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

12. Prove that the product AB of two symmetric matrices A and B is symmetric if $AB = BA$.

Hint: $(AB)^T = B^T A^T = BA$ since $A = A^T, B = B^T$, so $(AB)^T = BA = AB$ then AB is symmetric. Provided $AB = BA$.

14.7 CANONICAL FORM: or SUM OF THE SQUARES FORM

Of a real quadratic form $Q = X^T A X$ is $Y^T D Y$ or

$$\lambda_1 y_1^2 + \lambda_2 y_2^2 + \cdots + \lambda_n y_n^2 \quad (1)$$

which is obtained by an orthogonal transformation $X = P Y$. Here P is known as **modal** matrix. D is known as **spectral** matrix. D is a diagonal matrix with the eigen values of A as the diagonal elements.

Let r be the rank of A and n be the number of variables $x_1, x_2, \dots, x_n$ in the quadratic form. Then:

Index S of a quadratic form is the number of positive square terms in the canonical form.

Signature of a quadratic form is the difference between the number of positive and negative square terms in the canonical form.

Definiteness A real nonsingular quadratic form $Q = X^T A X$ (with $|A| \neq 0$) is said to be

Positive definite: If rank and index are equal i.e., $r = n, s = n$ or if all the eigen values of A are positive

Negative definite: If index equals to zero i.e., $r = n, s = 0$ or if all the eigen values of A are negative.

Positive semi-definite: If rank and index are equal but less than n

i.e., $s = r < n, (|A| = 0)$

or all eigen values of A are non-negative (≥ 0) and at least one eigen value is zero.

Negative semi definite: If index zero

i.e., $s = 0, r < n, (|A| = 0)$

or all eigen values of A are non-positive (≤ 0) and at least one eigen value is zero.

Indefinite: Quadratic form is said to be indefinite in any other case or some eigen values are positive and some eigen values are negative.

Note: If Q is negative definite (semi-definite) then $-Q$ is positive definite (semi-definite).

WORKED OUT EXAMPLES

Example 1: Determine the nature, index and signature of the quadratic form $2x_1^2 + 2x_2^2 + 3x_3^2 + 2x_1x_2 - 4x_1x_3 - 4x_2x_3$.

Solution: The real symmetric matrix A associated with the Q.F. is

$$A = \begin{bmatrix} 2 & 1 & -2 \\ 1 & 2 & -2 \\ -2 & -2 & 3 \end{bmatrix}$$

Its characteristic equation is

$$\begin{vmatrix} 2-\lambda & 1 & -2 \\ 1 & 2-\lambda & -2 \\ -2 & -2 & 3-\lambda \end{vmatrix} \\ = \lambda^3 - 7\lambda^2 + 7\lambda - 1 = 0 \\ = (\lambda - 1)(\lambda - (3 + \sqrt{8}))(\lambda - (3 - \sqrt{8})) = 0$$

14.22 — HIGHER ENGINEERING MATHEMATICS—IV

The eigen values are $\lambda = 1, 0.1715, 3.1715$ which are all positive. So Q.F. is positive definite.

Index: 3, Signature : $3 - 0 = 3$.

Example 2: Find the nature, index and signature of Q.F.

$$2x_1x_2 + 2x_1x_3 + 2x_2x_3$$

Solution: $A = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}$

Characteristic equation is

$$\begin{vmatrix} -\lambda & 1 & 1 \\ 1 & -\lambda & 1 \\ 1 & 1 & -\lambda \end{vmatrix} = 0$$

$$\lambda^3 - 3\lambda - 2 = 0 \quad \text{or} \quad (\lambda + 1)^2(\lambda - 2) = 0$$

The eigen values are 2, -1, -1, some are positive and some are negative. So the Q.F. is indefinite.

Index: 1, Signature: $1 - 2 = -1$.

Example 3: Identify the nature, index and signature of the Q.F.

$$x_1^2 + 4x_2^2 + x_3^2 - 4x_1x_2 + 2x_3x_1 - 4x_2x_3$$

Solution: $A = \begin{bmatrix} 1 & -2 & 1 \\ -2 & 4 & -2 \\ 1 & -2 & 1 \end{bmatrix}$

Characteristic equation is

$$|A - \lambda I| = \begin{vmatrix} 1-\lambda & -2 & 1 \\ -2 & 4-\lambda & -2 \\ 1 & -2 & 1-\lambda \end{vmatrix} = \lambda^2(\lambda - 6) = 0$$

Eigen values are $\lambda = 0, 0, 6$. So Q.F. is positive semi definite.

Index: 3, Signature: 3.

Example 4: Classify the Q.F. and find the index and signature of

$$-3x_1^2 - 3x_2^2 - 3x_3^2 - 2x_1x_2 - 2x_1x_3 + 2x_2x_3$$

Solution: $A = \begin{bmatrix} -3 & -1 & -1 \\ -1 & -3 & 1 \\ -1 & 1 & -3 \end{bmatrix}$

Characteristic equation is

$$\begin{vmatrix} -3-\lambda & -1 & -1 \\ -1 & -3-\lambda & 1 \\ -1 & 1 & -3-\lambda \end{vmatrix} = 0$$

$$\lambda^3 + 9\lambda^2 + 24\lambda + 16 = (\lambda + 1)(\lambda + 4)^2 = 0$$

All the eigen values -1, -4, -4, are negative. So Q.F. is negative definite.

Index: 0, Signature: $0 - 3 = -3$.

Note:

$$Q = 3x_1^2 + 3x_2^2 + 3x_3^2 + 2x_1x_2 + 2x_1x_3 - 2x_2x_3$$

is positive definite.

EXERCISE

Determine the nature, index and signature of the quadratic form:

1. $x_1^2 + 2x_2^2 + 3x_3^2 + 2x_2x_3 - 2x_3x_1 + 2x_1x_2$

Ans. indefinite (eigen value: 1, 1, -2), index: 2, signature: 1

2. $5x_1^2 + 26x_2^2 + 10x_3^2 + 4x_2x_3 + 14x_3x_1 + 6x_1x_2$

Ans. positive semi definite (eigen value: 5, 0, 5), index: 3, signature: 3

3. $x_1^2 + 5x_2^2 + x_3^2 + 2x_1x_2 + 2x_2x_3 + 6x_3x_1$

Ans. indefinite (eigen value: -2, 3, 6), index: 2, signature: 1

4. $3x_1^2 + 5x_2^2 + 3x_3^2 - 2x_2x_3 + 2x_3x_1 - 2x_1x_2$

Ans. positive definite (eigen value: 2, 3, 6), index: 3, signature: 3

5. $8x_1^2 + 7x_2^2 + 3x_3^2 - 12x_1x_2 - 8x_2x_3 + 4x_3x_2$

Ans. positive semi definite (eigen value: 3, 0, 15), index: 3, signature: 3

6. $6x_1^2 + 3x_2^2 + 3x_3^2 - 4x_1x_2 - 2x_2x_3 + 4x_1x_3$

Ans. positive definite (eigen value: 8, 2, 2), index: 3, signature: 3

7. $-4x_1^2 - 2x_2^2 - 13x_3^2 - 4x_1x_2 - 8x_2x_3 - 4x_1x_3$

Ans. negative definite, index: 0, signature: -3

8. $-3x_1^2 - 3x_2^2 - 7x_3^2 - 6x_1x_2 - 6x_2x_3 - 6x_3x_1$

Ans. negative definite, index: 0, signature -3.

14.8 TRANSFORMATION (REDUCTION) OF QUADRATIC FORM TO CANONICAL FORM

Let Q be the quadratic form given by

$$Q = X^T A X = \sum_{i=1}^n \sum_{j=1}^n a_{ij} x_i x_j \quad (1)$$

The coefficient matrix A is real symmetric therefore has n linearly independent orthonormal set of eigen vectors corresponding n eigen values (which need not necessarily be distinct). Let $\hat{P}$ be normalized modal matrix of A . Then $\hat{P}$ is an orthogonal matrix.

Thus the transformation

$$X = \hat{P} Y \quad (2)$$

is an orthogonal transformation. This transfers the quadratic form Q to canonical form, as follows:

We know that P diagonalizes A . Thus

$$\begin{aligned} \hat{P}^{-1} A \hat{P} &= D \\ A &= \hat{P} D \hat{P}^{-1} = \hat{P} D \hat{P}^T \end{aligned} \quad (3)$$

since $\hat{P}^{-1} = \hat{P}^T$ by virtue of orthogonality
Substituting (3) in (1)

$$Q = X^T A X = X^T \hat{P} D \hat{P}^T X = (X^T \hat{P})(D)(\hat{P}^T X) \quad (4)$$

Pre-multiplying (2) by $\hat{P}^{-1}$, we get

$$\hat{P}^{-1} X = \hat{P}^{-1} \hat{P} Y = Y$$

$$\text{So} \quad Y = \hat{P}^{-1} X = \hat{P}^T X \quad (5)$$

since $\hat{P}^{-1} = \hat{P}^T$

Taking transpose of this equation

$$Y^T = (\hat{P}^T X)^T = X^T \hat{P} \quad (6)$$

Using (5) and (6) in (4), we have

$$Q = X^T A X = Y^T D Y$$

$$\begin{aligned} &= [y_1, y_2 \dots y_n] \begin{bmatrix} \lambda_1 & 0 & 0 & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \vdots & & & \\ 0 & \dots & \dots & \lambda_n \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} \\ Q &= \lambda_1 y_1^2 + \lambda_2 y_2^2 + \dots + \lambda_n y_n^2 \end{aligned} \quad (7)$$

(7) is known as the *canonical form* or “*sum of the squares form*” or “*principal axes form*”.

Procedure to Reduce Quadratic Form to Canonical Form

1. Identify the real symmetric matrix associated with the quadratic form Q .
2. Determine the eigen values of A .
3. The required canonical form is given by (7)
4. Form the modal matrix containing the n eigen vectors of A as n column vectors. Normalize. Then

$$X = \hat{P} Y$$

is the required orthogonal transformation which reduces Q.F. to C.F.

WORKED OUT EXAMPLES

Example 1: Find the orthogonal transformation which transforms the quadratic form

$$x_1^2 + 3x_2^2 + 3x_3^2 - 2x_2x_3$$

to canonical form (or “sum of squares form” or “principal axes form”). Determine the index, signature and nature of the quadratic form.

Solution: Let $X = [x_1 x_2 x_3]^T$, $Y = [y_1 y_2 y_3]^T$. Let P be the non-singular orthogonal matrix, containing the (three) eigen vectors of the coefficient matrix A of the given quadratic form. Then $X = \hat{P} Y$ is the required non-singular linear transformation that transforms (reduces) the given quadratics form to canonical form. Here $\hat{P}$ is the normalized modal matrix P . The coefficient matrix A of the given quadratic form is

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 3 & -1 \\ 0 & -1 & 3 \end{bmatrix}$$

The characteristic equation of A is

$$\begin{aligned} |A - \lambda I| &= \begin{vmatrix} 1 - \lambda & 0 & 0 \\ 0 & 3 - \lambda & -1 \\ 0 & -1 & 3 - \lambda \end{vmatrix} = \lambda^3 - 7\lambda^2 + 14\lambda - 8 \\ &= (\lambda - 1)(\lambda - 2)(\lambda - 4) = 0 \end{aligned}$$

So there are three distinct real eigen values $\lambda = 1, 2, 4$ of A .

14.24 — HIGHER ENGINEERING MATHEMATICS—IV

For $\lambda = 1$,

$$\begin{array}{ccc|c} 0 & 0 & 0 & 2x_2 = x_3 \\ 0 & 2 & -1 & x_2 = 2x_3 \\ 0 & -1 & 2 & \end{array}$$

$\therefore x_2 = x_3 = 0, x_1 = \text{arbitrary},$

The eigen vector X_1 associated with $\lambda = 1$ is

$$X_1 = [1 \ 0 \ 0]^T$$

For $\lambda = 2$,

$$\begin{array}{ccc|c} -x_1 + 0 + 0 = 0 & & & x_1 = 0 \\ x_2 - x_3 = 0 & \therefore & & x_2 = x_3 \\ -x_2 + x_3 = 0 & & & \end{array}$$

$$X_2 = [0 \ 1 \ 1]^T$$

For $\lambda = 3$,

$$\begin{array}{ccc|c} -3 & 0 & 0 & x_1 = 0 \\ 0 & -1 & -1 & x_2 = -x_3 \\ 0 & -1 & -1 & \end{array}$$

$$X_3 = [0 \ 1 \ -1]^T$$

Thus the modal matrix P is

$$P = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix}$$

The norm of the eigen vector X_1 is

$$\|X_1\| = \sqrt{1^2 + 0 + 0} = 1,$$

$$\|X_2\| = \sqrt{0 + 1^2 + 1^2} = \sqrt{2},$$

$$\|X_3\| = \sqrt{1^2 + 1^2} = \sqrt{2}.$$

Then the normalized modal matrix $\hat{P}$ is

$$\hat{P} = \begin{bmatrix} \frac{1}{1} & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ 0 & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix}$$

To find inverse of P :

$$\begin{array}{c} \left[\begin{array}{ccc|ccc} 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & -1 & 0 & 0 & 1 \end{array} \right] \\ \sim \begin{array}{c} R_{32(-1)} \\ R_{3(-\frac{1}{2})} \\ R_{23(-1)} \end{array} \left[\begin{array}{ccc|ccc} 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & \frac{1}{2} & \frac{1}{2} \\ 0 & 0 & 1 & 0 & \frac{1}{2} & -\frac{1}{2} \end{array} \right] \end{array}$$

Thus

$$P^{-1} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} \\ 0 & \frac{1}{2} & -\frac{1}{2} \end{bmatrix}$$

and the normalized P^{-1} is

$$\hat{P}^{-1} = \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix}$$

Diagonalization:

$$\begin{aligned} \hat{P}^{-1} A \hat{P} &= \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 3 & -1 \\ 0 & -1 & 3 \end{bmatrix} \\ &\times \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix} \\ &= \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 2 & 2 \\ 0 & 4 & -4 \end{bmatrix} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix} \\ &= \frac{1}{2} \begin{bmatrix} 2 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 8 \end{bmatrix} \end{aligned}$$

Then

$$\hat{P}^{-1} A \hat{P} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{bmatrix} = D = \text{diagonal matrix}$$

with the eigen values of A as the diagonal elements.

Transformation (reduction) to canonical form:

Quadratic form (Q.F.)

$$Q = x_1^2 + 3x_2^2 + 3x_3^2 - 2x_2x_3$$

$$= [x_1 \ x_2 \ x_3] \begin{bmatrix} 1 & 0 & 0 \\ 0 & 3 & -1 \\ 0 & -1 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = X^T A X$$

Put $X = \hat{P}Y$ and $X^T = (\hat{P}Y)^T = Y^T \hat{P}^T$.

So $Q = X^T A X = Y^T \hat{P}^T A \hat{P} Y = Y^T (\hat{P}^T A \hat{P}) Y$

But we know that $\hat{P}$ is an orthogonal matrix because

$$\begin{aligned} \hat{P} \hat{P}^T &= \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix} \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix} \\ &= \frac{1}{2} \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = I \end{aligned}$$

Thus

$$\hat{P}^T = \hat{P}^{-1}$$

So
$$\text{Q.F.} = X^T A X = Y^T (\hat{P}^{-1} A \hat{P}) Y$$

But through diagonalization

$$\hat{P}^{-1} A \hat{P} = D$$

Therefore

$$\begin{aligned} Q &= X^T A X = Y^T D Y \\ &= [y_1 \quad y_2 \quad y_3] \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} \\ &= [y_1 \quad 2 \cdot y_2 \quad 4y_3] \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} \\ &= y_1^2 + 2y_2^2 + 4y_3^2 \end{aligned}$$

This is the required canonical form (or sum of squares form).

Orthogonal transformation:

$$X = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \hat{P} Y = \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2} & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix}$$

so $x_1 = y_1$; $x_2 = \frac{1}{\sqrt{2}}(y_2 + y_3)$, $x_3 = \frac{1}{\sqrt{2}}(y_2 - y_3)$ is the orthogonal transformation which reduces the Q.F. to canonical form.

Index is 3 for the Q.F. since the number of positive terms in the canonical form is 3. i.e., $S = 3$, rank r is 3. The number of variables is $n = 3$.

Signature of Q.F. is $2s - r = 6 - 3 = 3$ (difference between number of positive and negative terms in C.F.).

The given Q.F. is *positive definite* because $r = 3 = n$ and $s = 3 = n$.

Example 2: By **Lagrange's reduction** transform the quadratic form $X^T A X$ to sum of the squares form for

$$A = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 6 & -2 \\ 4 & -2 & 18 \end{bmatrix}$$

Solution:

$$\text{Q.F.} = X^T A X = [x_1 \quad x_2 \quad x_3] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 6 & -2 \\ 4 & -2 & 18 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$$

$$\text{Q.F.} = [x_1 + 2x_2 + 4x_3 \quad 2x_1 + 6x_2 - 2x_3 \quad 4x_1 - 2x_2 + 18x_3] \times \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$$

$$\begin{aligned} &= x_1^2 + 6x_2^2 + 18x_3^2 + 4x_1x_2 + 8x_1x_3 - 4x_2x_3 \\ &= [x_1^2 + 4x_1(x_2 + 2x_3)] + 6x_2^2 + 18x_3^2 - 4x_2x_3 \\ &= [x_1^2 + 4x_1(x_2 + 2x_3) + 2^2(x_2 + 2x_3)^2] \\ &\quad - 2^2(x_2 + 2x_3)^2 + 6x_2^2 + 18x_3^2 - 4x_2x_3 \\ &= [x_1 + 2(x_2 + 2x_3)]^2 + 2x_2^2 + 2x_3^2 - 20x_2x_3 \\ &= [x_1 + 2(x_2 + 2x_3)]^2 + 2[x_2^2 - 10x_2x_3] + 2x_3^2 \\ &= [x_1 + 2(x_2 + 2x_3)]^2 \\ &\quad + 2[x_2^2 - 10x_2x_3 + 5^2x_3^2] - 2 \cdot 5^2x_3^2 + 2x_3^2 \\ &= [x_1 + 2(x_2 + 2x_3)]^2 + 2[x_2 - 5x_3]^2 - 48x_3^2 \end{aligned}$$

$$\text{Q.F.} = y_1^2 + 2y_2^2 - 48y_3^2$$

where

$$\begin{aligned} y_1 &= x_1 + 2(x_2 + 2x_3), \\ y_2 &= x_2 - 5x_3, \\ y_3 &= x_3. \end{aligned}$$

Index: $S = 2$, ($n = 3$, $r = 3$),

Signature: $2s - r = 2 \cdot 2 - 3 = 1$ (or $2 - 1 = 1$).

EXERCISE

Transform (reduce) the quadratic form to canonical form (or “sum of squares form” or “principal axes form”) by orthogonal transformation.

State matrix for transformation (i.e., modal matrix).

$$1. \quad 17x_1^2 - 30x_1x_2 + 17x_2^2$$

$$\text{Ans. } A = \begin{bmatrix} 17 & -15 \\ -15 & 17 \end{bmatrix}, \lambda = 2, 32,$$

$$P = \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix} \frac{1}{\sqrt{2}}, \text{ C.F.: } 2y_1^2 + 32y_2^2$$

14.26 — HIGHER ENGINEERING MATHEMATICS—IV

2. $3x_1^2 + 5x_2^2 + 3x_3^2 - 2x_2x_3 + 2x_1x_3 - 2x_1x_2$

Ans. $A = \begin{bmatrix} 3 & -1 & 1 \\ -1 & 5 & -1 \\ 1 & -1 & 3 \end{bmatrix}$, $\lambda = 2, 3, 6$,

$P = \begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{6}} \\ 0 & \frac{1}{\sqrt{3}} & -\frac{2}{\sqrt{6}} \\ -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{6}} \end{bmatrix}$, C.F.: $2y_1^2 + 3y_2^2 + 6y_3^2$

3. $5x_1^2 + 26x_2^2 + 10x_3^2 + 4x_2x_3 + 6x_1x_2 + 14x_1x_3$

Ans. $A = \begin{bmatrix} 5 & 3 & 7 \\ 3 & 26 & 2 \\ 7 & 2 & 10 \end{bmatrix}$, $\lambda = 5, \frac{121}{3}, 0$,

$P = \begin{bmatrix} 1 & -\frac{3}{5} & -\frac{16}{11} \\ 0 & 1 & \frac{1}{11} \\ 0 & 0 & 1 \end{bmatrix}$, C.F.: $5y_1^2 + \frac{121}{3}y_2^2$

4. $2(x_1x_2 + x_2x_3 + x_3x_1)$; nature of Q.F.

Ans. $A = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & +1 \\ 1 & +1 & 0 \end{bmatrix}$, $\lambda = 2, -1, -1$,

$P = \begin{bmatrix} \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} \\ \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} \\ \frac{1}{\sqrt{3}} & 0 & -\frac{2}{\sqrt{6}} \end{bmatrix}$,

C.F.: $2y_1^2 - y_2^2 - y_3^2$

Nature: Indefinite

5. $2(x_1^2 + x_1x_2 + x_2^2)$

Ans. $A = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}$, $\lambda = 1, 3$,

$P = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}$, C.F.: $y_1^2 + 3y_2^2$

6. $2x_1^2 + x_2^2 - 3x_3^2 - 8x_2x_3 - 4x_3x_1 + 12x_1x_2$,
find index

Ans. $A = \begin{bmatrix} 2 & 6 & -2 \\ 6 & 1 & -4 \\ -2 & -4 & -3 \end{bmatrix}$, $\lambda = 1, -1, -1$,

$P = \begin{bmatrix} a & -3b & \frac{11c}{17} \\ 0 & b & \frac{2b}{17} \\ 0 & 0 & c \end{bmatrix}$

where $a = 1/\sqrt{2}$, $b = 1/\sqrt{17}$, $c = \sqrt{(17/81)}$,

C.F.: $y_1^2 - y_2^2 - y_3^2$, Index = 1

7. $3x_1^2 - 2x_2^2 - x_3^2 - 4x_1x_2 + 12x_2x_3 + 8x_1x_3$

Ans. $A = \begin{bmatrix} 3 & -2 & 4 \\ -2 & -2 & 6 \\ 4 & 6 & -1 \end{bmatrix}$, $\lambda = 3, 6, -9$,

$P = \frac{1}{3} \begin{bmatrix} 2 & 2 & 1 \\ -2 & 1 & 2 \\ -1 & 2 & 2 \end{bmatrix}$, C.F.: $3y_1^2 + 6y_2^2 - 9y_3^2$

8. $8x_1^2 + 7x_2^2 + 3x_3^2 + 12x_1x_2 + 4x_1x_3 - 8x_2x_3$,
find the rank, index, signature and nature.

Ans. $A = \begin{bmatrix} 8 & -6 & 2 \\ -6 & 7 & -4 \\ 2 & -4 & 3 \end{bmatrix}$, $\lambda = 3, 0, 15$,

$P = \frac{1}{3} \begin{bmatrix} 2 & 1 & 2 \\ 1 & 2 & -2 \\ -2 & 2 & 1 \end{bmatrix}$, C.F.: $3y_1^2 + 15y_2^2$

rank of Q.F.: 2, index: 2, signature 2, positive definite.

Lagrange's reduction

9. $x_1^2 + 2x_2^2 - 7x_3^2 - 4x_1x_2 + 8x_1x_3$

Ans. $(x_1 - 2x_2 + 4x_3)^2 - 2(x_2 - 4x_3)^2 + 9x_3^2$

10. $2x_1^2 + 5x_2^2 + 19x_3^2 - 24x_4^2 + 8x_1x_2 + 12x_1x_3 + 8x_1x_4 + 18x_2x_3 - 8x_2x_4 - 16x_3x_4$

Ans. $2(x_1 + 2x_2 + 3x_3 + 2x_4)^2 - 3(x_2 + x_3 + 4x_4)^2 + 4(x_3 - 2x_4)^2$

11. $2x_1^2 + 7x_2^2 + 5x_3^2 - 8x_1x_2 - 10x_2x_3 + 4x_1x_3$

Ans. $2(x_1 - 2x_2 - x_3)^2 - (x_2 + x_3)^2 + 4x_3^2$

12. Coefficient matrix $A = \begin{bmatrix} 1 & -1 & 0 & 2 \\ -1 & 4 & 6 & 4 \\ 0 & 6 & 11 & 8 \\ 2 & 4 & 8 & 8 \end{bmatrix}$

Hint: QF: $x_1^2 + 4x_2^2 + 11x_3^2 + 8x_4^2 - 2x_1x_2 + 4x_1x_4 + 12x_2x_3 + 8x_2x_4 + 16x_3x_4$

Ans. $(x_1 - x_2 + 2x_3)^2 + 3(x_2 + 2x_3 + 2x_4)^2 - (x_3 + 4x_4)^2 + 8x_4^2$.

14.9 COMPLEX MATRICES: HERMITIAN, SKEW-HERMITIAN, UNITARY MATRICES

In a complex matrix A , the elements are complex or real.

$\bar{A} = (\bar{a}_{ij})$ is matrix obtained by replacing each a_{ij} of A by its complex conjugate $\bar{a}_{ij}$. A complex square matrix A is said to be

a. Hermitian if $\bar{A}^T = A$ i.e., $\bar{a}_{ji} = a_{ij}$

b. Skew-Hermitian if $\bar{A}^T = -A$ i.e., $\bar{a}_{ji} = -a_{ij}$

c. Unitary if $\bar{A}^T = A^{-1}$

Thus the Hermitian, Skew-Hermitian and Unitary matrices are respectively the natural generalization of the real symmetric, Skew-symmetric and orthogonal matrices to complex matrices.

It follows from the definition, that the diagonal elements of a Hermitian matrix are always real because $\bar{a}_{ji} = a_{ji}$ means a_{ji} must be real. Similarly, for a Skew-Hermitian matrix $\bar{a}_{ii} = -a_{ii}$ means that the diagonal elements are purely imaginary or zero.

Unitary system

of row and column vectors

$$\bar{X}_i^T X_j = \delta_{ij} = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$$

which is a direct analog of orthonormal system. Hermitian form H (generalization of the real quadratic form) is given by

$$H = \bar{X}^T A X = \sum_{i=1}^n \sum_{j=1}^n a_{ij} \bar{x}_i x_j$$

where A is Hermitian matrix.

Similarly, Skew-Hermitian form S is given by $S = \bar{X}^T A X$ where A is Skew-Hermitian matrix.

Theorem: For any X , Hermitian form is real.

Proof: $\bar{H} = \overline{(\bar{X}^T A X)} = X^T \bar{A} \bar{X} = X^T A^T \bar{X}$ since A is Hermitian i.e., $\bar{A} = A^T$. As the R.H.S. is a scalar, transposition does not change its values. Thus $\bar{H} = X^T A^T \bar{X} = (X^T A^T \bar{X})^T = \bar{X}^T A X = H$, so H is real.

Similarly,

Theorem: For any X , Skew-Hermitian is purely imaginary or zero.

Proof: $\bar{S} = \overline{(\bar{X}^T A X)} = X^T \bar{A} \bar{X} = -X^T A^T \bar{X}$ since A is Skew-Hermitian i.e., $\bar{A} = -A^T$. Taking transpose of R.H.S., we have

$$\bar{S} = -(X^T A^T \bar{X})^T = -\bar{X}^T A X = -S$$

So S is purely imaginary or zero.

Theorem: The column (and also row) vectors of a unitary matrix form a unitary system.

Proof: Let $c_1, c_2, \dots, c_n$ be the n column vectors of a n -squared unitary matrix A . Consider

$$I = A^{-1} A = \bar{A}^T A = \begin{bmatrix} \bar{c}_1^T \\ \bar{c}_2^T \\ \vdots \\ \bar{c}_n^T \end{bmatrix}_{n \times 1} [c_1, c_2, \dots, c_n]_{1 \times n}$$

since for a unitary matrix $A^{-1} = \bar{A}^T$. Then

$$I_{n \times n} = \begin{bmatrix} \bar{c}_1^T c_1 & \bar{c}_1^T c_2 & \dots & \bar{c}_1^T c_n \\ \bar{c}_2^T c_1 & \bar{c}_2^T c_2 & \dots & \bar{c}_2^T c_n \\ \dots & \dots & \dots & \dots \\ \bar{c}_n^T c_1 & \bar{c}_n^T c_2 & \dots & \bar{c}_n^T c_n \end{bmatrix}_{n \times n}$$

Thus

$$\bar{c}_i^T c_j = \delta_{ij} = \begin{cases} 0 & \text{for } i \neq j \\ 1 & \text{for } i = j \end{cases}$$

Hence the column vectors (in a similar way row vectors) of a unitary matrix A form a unitary system.

Corollary 1: If A is real orthogonal matrix, it follows that

$$c_i^T c_j = \begin{cases} 0 & \text{for } i \neq j \\ 1 & \text{for } i = j \end{cases}$$

Thus the column (and also the row) vectors of an orthogonal matrix form an orthonormal system (of vectors).

Theorem: Prove that the eigen values of

- Hermitian matrix A are real
- Skew-Hermitian S are purely imaginary or zero
- Unitary matrix U have absolute value 1.

14.28 — HIGHER ENGINEERING MATHEMATICS—IV

Proof: Let λ be an eigen value and $X (\neq 0)$ be the corresponding eigen vector. Then

$$\bar{X}^T X = \bar{x}_1 x_1 + \bar{x}_2 x_2 + \cdots + \bar{x}_n x_n = |x_1|^2 + \cdots + |x_n|^2$$

is real and not equals to zero.

a. Let A be Hermitian

$$AX = \lambda X$$

Pre-multiplying by $\bar{X}^T$, we have

$$\bar{X}^T AX = \bar{X}^T \lambda X = \lambda \bar{X}^T X$$

$$\lambda = \frac{\bar{X}^T AX}{\bar{X}^T X}$$

Fig. 14.1

Hence λ the eigen value of a Hermitian matrix is real because the numerator $\bar{X}^T AX$ is a Hermitian form which is always a real (and $\bar{X}^T X$ the denominator is also real).

b. Let S be Skew-Hermitian (refer Fig. 14.1)

$$SX = \lambda X$$

pre multiplying by $\bar{X}^T$, we have

$$\bar{X}^T SX = \bar{X}^T \lambda X = \lambda \bar{X}^T X$$

$$\lambda = \frac{\bar{X}^T SX}{\bar{X}^T X}$$

Since the numerator $\bar{X}^T SX$ is a Skew-Hermitian form which is purely imaginary or zero, therefore λ the eigen value of the Skew-Hermitian matrix is purely imaginary or zero.

c. Let U be a unitary matrix

$$UX = \lambda X \quad (1)$$

Taking conjugate transpose of (1)

$$(\bar{U} \bar{X})^T = (\bar{U} \bar{X})^T = \bar{X}^T \bar{U}^T$$

$$= \bar{X}^T U^{-1} = (\bar{\lambda} \bar{X})^T = \bar{\lambda} \bar{X}^T$$

$$\text{i.e., } \bar{X}^T U^{-1} = \bar{\lambda} \bar{X}^T \quad (2)$$

since $\bar{U}^T = U^{-1}$ for unitary matrix U and transposition on R.H.S. does not affect the scalar λ . Post multiplying, R.H.S. of (2) by R.H.S. of (1) and L.H.S. of (2) by L.H.S. of (1), we get

$$(\bar{X}^T U^{-1})(UX) = (\bar{\lambda} \bar{X}^T)(\lambda X)$$

$$\bar{X}^T (U^{-1}U)X = (\bar{\lambda} \bar{X}^T)(\lambda X)$$

$$\bar{X}^T X = (\bar{\lambda} \lambda) \bar{X}^T X$$

Since $U^{-1}U = I$. Thus

$$\lambda \bar{\lambda} = |\lambda|^2 = 1$$

Since $\bar{X}^T X \neq 0$. Hence eigen values of unitary matrix are of absolute value 1.

Corollary 2: Eigen values of (a) real symmetric matrix are real (b) Skew-symmetric are purely imaginary or zero (c) orthogonal matrix real or complex conjugates in pairs and have absolute value 1.

Properties of Unitary Matrix

1. Product of two unitary matrices is unitary.

Proof: Let A and B be unitary matrices so that $A^T = \bar{A}^{-1}$, $B^T = \bar{B}^{-1}$.

$$\text{Consider } (\overline{AB})^{-1} = (\overline{AB})^{-1} = \bar{B}^{-1} \bar{A}^{-1}$$

$$= B^T A^T \text{ Since } A, B \text{ are unitary}$$

$$= (AB)^T \text{ by transposition rule}$$

$$\text{Thus } (\overline{AB})^{-1} = (AB)^T \therefore AB \text{ is unitary.}$$

Corollary 1: Product of two orthogonal matrices is orthogonal.

2. Inverse of a unitary matrix is unitary.

Proof: For a unitary matrix A , $\bar{A}^T = A^{-1}$

$$\text{or } \bar{A}^T = \bar{A}^T = A^{-1}$$

$$A^T = \overline{A^{-1}}$$

$$((A^{-1})^{-1})^T = \overline{A^{-1}}$$

Denote A^{-1} by B then

$$(B^{-1})^T = \bar{B}$$

or

$$B^{-1} = \bar{B}^T$$

So B is unitary i.e., A^{-1} is unitary.

Corollary 2: Inverse of an orthogonal matrix is orthogonal.

3. Transpose of a unitary matrix is unitary.

Proof: For unitary matrix A , $\bar{A}^T = A^{-1}$

or

$$(\bar{A}^T) = A^{-1}$$

Taking transpose on both sides

$$(\bar{A}^T)^T = (A^{-1})^T = (A^T)^{-1}$$

since transposition and inverse taking are commutative. Taking $B = A^T$

$$\bar{B}^T = B^{-1}$$

Thus $B = A^T$ is also unitary.

Corollary 3: Transpose of an orthogonal matrix is orthogonal.

Properties of Hermitian and Skew-Hermitian Matrices

Book Work:

1. Show that any square matrix A can be written as the sum of a Hermitian and Skew-Hermitian matrices.

Proof: Choose $B = \frac{1}{2}(A + \bar{A}^T)$ and $C = \frac{1}{2}(A - \bar{A}^T)$. Then

$$B^T = \frac{1}{2}(A + \bar{A}^T)^T = \frac{1}{2}(A^T + \bar{A})$$

$$\bar{B} = \frac{1}{2}\overline{(A + \bar{A}^T)} = \frac{1}{2}(\bar{A} + \overline{\bar{A}^T}) = \frac{1}{2}(\bar{A} + A^T)$$

$$\therefore B^T = \bar{B}$$

Thus B is Hermitian. Now

$$\bar{C} = \frac{1}{2}\overline{(A - \bar{A}^T)} = \frac{1}{2}(\bar{A} - \overline{\bar{A}^T}) = \frac{1}{2}(\bar{A} - A^T)$$

$$C^T = \frac{1}{2}(A - \bar{A}^T)^T = \frac{1}{2}(A^T - \bar{A}) = -\bar{C}$$

Therefore C is Skew-Hermitian. Thus

$A = B + C = \frac{1}{2}(A + \bar{A}^T) + \frac{1}{2}(A - \bar{A}^T) = A$ is expressed as sum of Hermitian and Skew-Hermitian matrices.

2. If A, B are Hermitian, prove that $AB - BA$ Skew-Hermitian.

Proof:

$$\begin{aligned} \overline{(AB - BA)}^T &= (\overline{AB} - \overline{BA})^T = (\overline{AB} - \overline{BA})^T \\ &= (\overline{AB})^T - (\overline{BA})^T = \bar{B}^T \bar{A}^T - \bar{A}^T \bar{B}^T \\ &= BA - AB = -(AB - BA), \end{aligned}$$

since A, B are Hermitian, $\bar{A}^T = A$ and $\bar{B}^T = B$.

Thus $\overline{(AB - BA)}^T = -(AB - BA)$

Therefore $AB - BA$ is Skew-Hermitian.

3. If A is Hermitian (Skew-Hermitian) then (iA) is Skew-Hermitian (Hermitian).

Proof: Suppose A is Hermitian. Then

$$(\bar{iA})^T = (\bar{i} \bar{A})^T = (-i \bar{A})^T = -i \bar{A}^T$$

since transposition does not effect scalar i . Thus

$$(\bar{iA})^T = -i \bar{A}^T = -iA$$

since for Hermitian A , $\bar{A}^T = A$. Hence iA is Skew-Hermitian. [Similarly let A be Skew-Hermitian.

$$(\bar{iA})^T = (\bar{i} \bar{A})^T = (-i \bar{A})^T = -i \bar{A}^T = iA$$

since $-\bar{A}^T = A$ for a Skew-Hermitian. Thus iA is Hermitian.]

WORKED OUT EXAMPLES

Example 1: If

$$A = \begin{bmatrix} 2 & 3+2i & -4 \\ 3-2i & 5 & 6i \\ -4 & -6i & 3 \end{bmatrix}$$

Then show that A is Hermitian and iA is Skew-Hermitian.

Solution:

$$\bar{A} = \begin{bmatrix} 2 & 3-2i & -4 \\ 3+2i & 5 & -6i \\ -4 & 6i & 3 \end{bmatrix}$$

14.30 — HIGHER ENGINEERING MATHEMATICS—IV

$$\bar{A}^T = \begin{bmatrix} 2 & 3+2i & -4 \\ 3-2i & 5 & 6i \\ -4 & -6i & 3 \end{bmatrix} = A$$

Thus A is Hermitian.

Let

$$\begin{aligned} B &= iA = i \begin{bmatrix} 2 & 3+2i & -4 \\ 3-2i & 5 & 6i \\ -4 & -6i & 3 \end{bmatrix} \\ &= \begin{bmatrix} 2i & -2+3i & -4i \\ 2+3i & 5i & -6 \\ -4i & 6 & 3i \end{bmatrix} \end{aligned}$$

$$\bar{B} = \begin{bmatrix} -2i & -2-3i & 4i \\ 2-3i & -5i & -6 \\ 4i & 6 & -3i \end{bmatrix},$$

$$B^T = \begin{bmatrix} 2i & 2+3i & -4i \\ -2+3i & 5i & 6 \\ -4i & -6 & 3i \end{bmatrix}$$

Thus $\bar{B} = -B^T$ or B is Skew-Hermitian.

Note: From Book Work 3, (Page 450) it follows that for A Hermitian, iA is Skew-Hermitian.

Example 2: Show that

$$A = \begin{bmatrix} 2 & 3+4i \\ 3-4i & 2 \end{bmatrix}$$

is Hermitian. Find its eigen values and eigen vectors.

Solution:

$$\bar{A} = \begin{bmatrix} 2 & 3-4i \\ 3+4i & 2 \end{bmatrix}, \bar{A}^T = \begin{bmatrix} 2 & 3+4i \\ 3-4i & 2 \end{bmatrix} = A$$

Thus A is Hermitian.

(Note that the diagonal elements of A are real.)

The characteristic equation for A is

$$|A - \lambda I| = \begin{vmatrix} 2-\lambda & 3+4i \\ 3-4i & 2-\lambda \end{vmatrix} = 0$$

or

$$\begin{aligned} (2-\lambda)^2 - (3+4i)(3-4i) &= 4 + \lambda^2 - 4\lambda - [9 + 16] \\ &= 0 \end{aligned}$$

$$\text{i.e., } \lambda^4 - 4\lambda - 21 = (\lambda + 3)(\lambda - 7) = 0$$

Eigen values of A , Hermitian matrix are real $-3, 7$.

For $\lambda = -3$,

$$\begin{bmatrix} 5 & 3+4i \\ 3-4i & 5 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 0$$

$$x_1 = -\left(\frac{3+4i}{5}\right)x_2$$

The eigen vector corresponding to $\lambda = -3$ is

$$X_1 = \begin{bmatrix} -3-4i \\ 5 \end{bmatrix}$$

For $\lambda = 7$,

$$\begin{bmatrix} -5 & 3+4i \\ 3-4i & -5 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 0$$

$$x_1 = \frac{3+4i}{5}x_2$$

The eigen vector corresponding to $\lambda = 7$ is

$$X_2 = \begin{bmatrix} 3+4i \\ 5 \end{bmatrix}$$

Example 3: Show that

$$A = \begin{bmatrix} i & 0 & 0 \\ 0 & 0 & i \\ 0 & i & 0 \end{bmatrix}$$

is Skew-Hermitian and also unitary. Find the eigen values and eigen vectors.

Solution:

$$\bar{A} = \begin{bmatrix} -i & 0 & 0 \\ 0 & 0 & -i \\ 0 & -i & 0 \end{bmatrix}, \bar{A}^T = \begin{bmatrix} -i & 0 & 0 \\ 0 & 0 & -i \\ 0 & -i & 0 \end{bmatrix} = -A$$

Thus A is Skew-Hermitian.

Consider

$$A\bar{A}^T = \begin{bmatrix} i & 0 & 0 \\ 0 & 0 & i \\ 0 & i & 0 \end{bmatrix} \begin{bmatrix} -i & 0 & 0 \\ 0 & 0 & -i \\ 0 & -i & 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = I$$

Thus $\bar{A}^T = A^{-1}$, i.e., A is unitary matrix also. The characteristic equation of A is

$$|A - \lambda I| = \begin{vmatrix} i-\lambda & 0 & 0 \\ 0 & 0-\lambda & i \\ 0 & i & 0-\lambda \end{vmatrix} = (i-\lambda)(\lambda^2 + 1) = \lambda^3 - i\lambda^2 + \lambda - i = 0$$

$$= (\lambda + i)(\lambda - i)^2 = 0$$

The eigen values of A are $\lambda = -i, i, i$ which are purely imaginary (for Skew-Hermitian) and are of absolute value unity (i.e., $|-i| = |i| = 1$)

For $\lambda = -i$,

$$\begin{bmatrix} 2i & 0 & 0 \\ 0 & i & i \\ 0 & i & i \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = 0$$

Solving

$$x_1 = 0, \quad x_2 = -x_3,$$

eigen vector corresponding to $\lambda = -i$ is

$$X_1 = \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix}$$

For $\lambda = i$

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & -i & i \\ 0 & i & -i \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = 0$$

Solving

$$x_1 = \text{arbitrary}, \quad x_2 = x_3$$

Choose x_1 , so that two linearly independent eigen vectors are obtained (with $x_1 = 0, x_2 = 1$ and $x_1 = 1, x_2 = 0$)

$$X_2 = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} \quad \text{and} \quad X_3 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

Example 4: Find the Hermitian form H for

$$A = \begin{bmatrix} 0 & i & 0 \\ -i & 1 & -2i \\ 0 & 2i & 2 \end{bmatrix} \quad \text{with} \quad X = \begin{bmatrix} i \\ 1 \\ -i \end{bmatrix}$$

Solution:

$$\begin{aligned} H = \bar{X}^T A X &= [-i \quad 1 \quad i] \begin{bmatrix} 0 & i & 0 \\ -i & 1 & -2i \\ 0 & 2i & 2 \end{bmatrix} \begin{bmatrix} i \\ 1 \\ -i \end{bmatrix} \\ &= [-i \quad 1 + 1 - 2 \quad 0] \begin{bmatrix} i \\ 1 \\ -i \end{bmatrix} = 1, \text{ real.} \end{aligned}$$

Example 5: Determine the Skew-Hermitian form S for

$$A = \begin{pmatrix} 2i & 3i \\ 3i & 0 \end{pmatrix} \quad \text{with} \quad X = \begin{bmatrix} 4i \\ -5 \end{bmatrix}$$

Solution:

$$\begin{aligned} S &= \bar{X}^T A X = [-4i \quad -5] \begin{bmatrix} 2i & 3i \\ 3i & 0 \end{bmatrix} \begin{bmatrix} 4i \\ -5 \end{bmatrix} \\ &= (8 - 15i \quad 12) \begin{pmatrix} 4i \\ -5 \end{pmatrix} = 32i + 60 - 60 \\ &= 32i, \quad \text{purely imaginary.} \end{aligned}$$

EXERCISE

1. Determine for what values of the numbers a and b , $c = aA + bB$ is Skew-Hermitian given that A and B are Skew-Hermitian.

Ans. Both a and b must be real.

2. Show that the eigen vectors X_i, X_j corresponding to two distinct eigen values λ_i, λ_j of a Hermitian matrix H are orthogonal i.e., $\bar{X}_i^T X_j = 0$.

Hint: $HX_i = \lambda_i X_i, HX_j = \lambda_j X_j$ (1), $\bar{X}_i^T \bar{H}^T = \bar{\lambda}_i \bar{X}_i^T$ or $\bar{X}_i^T H = \lambda_i \bar{X}_i^T$ (2) since $\bar{H}^T = H, \bar{\lambda}_i = \lambda_i$, pre multiply (1) by $\bar{X}_i^T$ and post multiply (2) by X_j and subtract.

3. Prove that $A = \begin{bmatrix} 4 & 1 - 3i \\ 1 + 3i & 7 \end{bmatrix}$ is Hermitian matrix. Find its eigen values.

Ans. characteristic equation: $\lambda^2 - 11\lambda + 18 = 0$, eigen values 9, 2.

4. Show that $B = \begin{bmatrix} 3i & 2 + i \\ -2 + i & -i \end{bmatrix}$ is Skew-Hermitian. Find its eigen values.

Ans. characteristic equation: $\lambda^2 - 2i\lambda + 8 = 0$, eigen values $4i, -2i$.

5. Prove that $C = \begin{bmatrix} \frac{i}{2} & \frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & \frac{i}{2} \end{bmatrix}$ is unitary matrix. Find its eigen values.

Ans. $\lambda^2 - i\lambda - 1 = 0, \lambda = (\sqrt{3} + i)/2, (-\sqrt{3} + i)/2$

14.32 — HIGHER ENGINEERING MATHEMATICS—IV

6. If $A = \begin{bmatrix} 0 & 1+2i \\ -1+2i & 0 \end{bmatrix}$

show that $(I - A)(I + A)^{-1}$ is a unitary matrix.

Hint: $I - A = \begin{bmatrix} 1 & -1-2i \\ 1-2i & 1 \end{bmatrix}$,

$(I + A)^{-1} = \begin{bmatrix} 1 & -1-2i \\ 1-2i & 1 \end{bmatrix}$

7. Find the eigen vectors of the Hermitian matrix

$$A = \begin{pmatrix} a & b+ic \\ b-ic & k \end{pmatrix}.$$

Ans. $\lambda_{1,2} = [(a+k) \pm (a-k)^2 + 4(b^2 + c^2)]/2$

eigen vectors: $\begin{bmatrix} \frac{-(b^2 + c^2)}{(a-\lambda)(b-ic)} & 1 \end{bmatrix}^T$ at $\lambda = \lambda_1, \lambda_2$

8. Find the eigen vectors of the Skew-Hermitian matrix $A = \begin{bmatrix} 2i & 3i \\ 3i & 0 \end{bmatrix}$

Ans. $\lambda_{1,2} = (1 \pm \sqrt{10})i$, eigen vectors: $\begin{pmatrix} 1 \pm \frac{\sqrt{10}-1}{3} \end{pmatrix}^T$

9. Show that $A = \begin{bmatrix} a+ic & -b+id \\ b+id & a-ic \end{bmatrix}$ is unitary matrix if $a^2 + b^2 + c^2 + d^2 = 1$.

Hint: $|A| = (a^2 + c^2) + (b^2 + d^2)$

10. Find the Hermitian form of

$$A = \begin{bmatrix} 3 & 2-i \\ 2+i & 4 \end{bmatrix} \quad \text{with} \quad X = \begin{bmatrix} 1+i \\ 2i \end{bmatrix}$$

Ans. 34

11. Find the Skew-Hermitian form for

a. $A = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}$ with $X = \begin{pmatrix} 1 \\ i \end{pmatrix}$,

Ans. 0

b. $A = \begin{pmatrix} 2i & 4 \\ -4 & 0 \end{pmatrix}$ with $X = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$

Ans. $2i|x_1|^2 + 8i \operatorname{Im}(\bar{x}_1 x_2)$

12. Find the Hermitian form of $A = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}$,

$$X = \begin{pmatrix} 1 \\ i \end{pmatrix}$$

Ans. -2

13. Show that the column (and also row) vectors of the unitary matrix

$$A = \frac{1}{2} \begin{bmatrix} 1+i & -1+i \\ 1+i & 1-i \end{bmatrix}$$

form an orthonormal system.

14. Determine the eigen values and eigen vectors of the unitary matrix $\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & i \\ -i & -1 \end{bmatrix}$.

Ans. eigen values 1, -1, eigen vectors $[1 \pm i\sqrt{2}]^T$

15. Find the Skew-Hermitian form for

$$A = \begin{bmatrix} -i & 1 & 2+i \\ -1 & 0 & 3i \\ -2+i & 3i & i \end{bmatrix} \quad \text{with} \quad X = \begin{bmatrix} 0 \\ 1 \\ 2 \end{bmatrix}$$

Ans. $16i$.

14.10 SYLVESTER'S LAW OF INERTIA

Let $Q(x_1, x_2, \dots, x_n) = \sum_{i=1}^n \sum_{j=1}^n a_{ij} x_i x_j = X^T A X$ be any real quadratic form with the coefficient matrix A

given by $A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{bmatrix}$

Let 'r' be the rank of A .

Sylvester's law of inertia states that any real quadratic form $Q(x_1, x_2, \dots, x_n)$ can be transformed by a regular linear transformation (substitution) into the form

$$Q^*(y_1, y_2, \dots, y_n) = y_1^2 + y_2^2 + \dots + y_{s_1}^2 - y_{s_1+1}^2 - y_{s_1+2}^2 - \dots - y_{s_1+s_2}^2$$

where $s_1 + s_2 = r$. While the substitution which transforms $Q(x_1, x_2, \dots, x_n)$ to $Q^*(y_1, y_2, \dots, y_n)$ is not unique, however the number of positive terms (signs) s_1 as well as the number of negative terms (signs) $s_2 = r - s_1$ in the resulting term $Q^*(y_1, y_2, \dots, y_n)$ is always the same. Here s_1 is

¹ James Joseph Sylvester (1814–1897), British mathematician who in 1850 introduced for the first time the word "matrix" (in the sense of "The mother of determinants").

$$\begin{aligned} Q^*(y_1, y_2, \dots, y_n) &= y_1^2 + y_2^2 + \dots + y_{s_1}^2 \\ &\quad - y_{s_1+1}^2 - y_{s_1+2}^2 \dots - y_{s_1+s_2}^2 \\ &= Y^T S Y \end{aligned}$$

WORKED OUT EXAMPLES

$$S = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

EXERCISE

$$1. \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}$$
$$2. \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

3. $\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$

$$4. \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}$$

Ans. $r = 4, s_1 = \text{index} = 3, s_2 = 1,$
signature $= 3 - 1 = 2$

Chapter 15

Vector Differential Calculus: Gradient, Divergence and Curl

INTRODUCTION

Principal application of vector functions is the analysis of motion in space. The gradient defines the normal to the tangent plane, the directional derivative gives the rate of change in any given direction. If $\vec{F}$ is the velocity field of a fluid flow, then divergence of $\vec{F}$ at a point $P(x, y, z)$ (flux density) is the rate at which fluid is (diverging) piped in or drained away at P , and the curl $\vec{F}$ (or circulation density) is the vector of greatest circulation in flow. We express grad, div and curl in general curvilinear coordinates and in cylindrical and spherical coordinates which are useful in engineering, physics or geometry involving a cylinder or cone or a sphere.

In this Chapter 15, vector differential calculus is considered, which extends the basic concepts of (ordinary) differential calculus to vector functions, by introducing derivative of a vector function and the new concepts of gradient, divergence and curl.

15.1 VECTOR DIFFERENTIATION

Definitions

Scalar function

Scalar function of a scalar variable t is a function $F = F(t)$ which uniquely associates a scalar $F(t)$ for every value of the scalar t in an interval $[a, b]$.

Scalar field

Scalar field is a region in space such that for every point P in this region, the scalar function f associates a scalar $f(P)$.

Scalar function of a vector variable $\vec{u}$ is a function $F = F(\vec{u})$ which uniquely associates a scalar $F(\vec{u})$ for every vector $\vec{u}$.

Vector function

Vector function of a scalar variable t is a function $\vec{F} = \vec{F}(t)$ which uniquely associates a vector $\vec{F}$ for each scalar t .

Vector field

Vector field is a region in space such that with every point P in that region, the vector function $\vec{V}$ associates a vector $\vec{V}(P)$.

Vector function

Vector function of a vector variable $\vec{u}$ is $\vec{F} = \vec{F}(\vec{u})$ if for every $\vec{u}$ a unique vector $\vec{F}(\vec{u})$ is associated.

Derivative

Derivative of a vector function $\vec{F}(u)$ with respect to a scalar variable u is denoted by and is defined as

$$\frac{d\vec{F}}{du} = \lim_{\Delta u \rightarrow 0} \frac{\vec{F}(u + \Delta u) - \vec{F}(u)}{\Delta u}.$$

Let $\vec{i}, \vec{j}, \vec{k}$ be three mutually orthogonal unit vectors in the direction of the x, y, z -coordinate axes such that $\vec{i}, \vec{j}, \vec{k}$ form a right handed triad (i.e., $\vec{i} \cdot \vec{i} = 1, \vec{i} \cdot \vec{j} = 0, \vec{i} \cdot \vec{k} = 0, \vec{j} \cdot \vec{j} = 1, \dots$ etc.).

Derivative in the Component Form

Let $\vec{F}(u) = F_1(u)\vec{i} + F_2(u)\vec{j} + F_3(u)\vec{k}$ in the component form with $F_1(u), F_2(u)$ and $F_3(u)$ as

15.2 — HIGHER ENGINEERING MATHEMATICS—IV

components of $\vec{r}$ in the x, y, z -coordinate axes.
Then

$$\frac{d\vec{r}}{du} = \frac{dF_1}{du}\vec{i} + \frac{dF_2}{du}\vec{j} + \frac{dF_3}{du}\vec{k}.$$

Thus the derivative of a vector function $\vec{r}$ with respect to a scalar variable u is the vector whose components are the derivatives of the components F_1, F_2, F_3 of $\vec{r}$ with respect to u .

Results: Most of the basic rules of differentiation that are true for a scalar function of a scalar variable hold good for vector function of a scalar variable, provided the order of factors in vector products is maintained.

1. $\frac{d\vec{C}}{du} = 0$ ($\vec{C}$ = constant vector)
2. $\frac{d}{du}[\vec{F}(u) \pm \vec{G}(u)] = \frac{d\vec{F}}{du} \pm \frac{d\vec{G}}{du}$
3. $\frac{d}{du}[\alpha(u)\vec{F}(u)] = \alpha(u)\frac{d\vec{F}}{du} + \vec{F}\frac{d\alpha}{du}$
4. $\frac{d}{du}[\vec{F}(u) \cdot \vec{G}(u)] = \frac{d\vec{F}}{du} \cdot \vec{G} + \vec{F} \cdot \frac{d\vec{G}}{du}$
5. $\frac{d}{du}[\vec{F}(u) \times \vec{G}(u)] = \frac{d\vec{F}}{du} \times \vec{G} + \vec{F} \times \frac{d\vec{G}}{du}$
6. $\frac{d}{du}[\vec{A}(u) \cdot \vec{B}(u) \times \vec{C}(u)] = \vec{A} \cdot \vec{B} \times \frac{d\vec{C}}{du} + \vec{A} \cdot \frac{d\vec{B}}{du} \times \vec{C} + \frac{d\vec{A}}{du} \cdot \vec{B} \times \vec{C}$
7. $\frac{d}{du}[\vec{A} \times (\vec{B} \times \vec{C})] = \vec{A} \times \left(\vec{B} \times \frac{d\vec{C}}{du} \right) + \vec{A} \times \left(\frac{d\vec{B}}{du} \times \vec{C} \right) + \frac{d\vec{A}}{du} \times (\vec{B} \times \vec{C})$

Velocity and Acceleration

Let $\vec{r}$ be the position vector of a point P ($x(t), y(t), z(t)$) in space where t is the scalar time. Then $\vec{r}$ in the component form is

$$\vec{r} = r(t)\vec{i} + y(t)\vec{j} + z(t)\vec{k}$$

Derivative of $\vec{r}$ denoted by $\dot{\vec{r}}$ is defined as

$$\frac{d\vec{r}}{dt} = \dot{\vec{r}} = \lim_{\Delta t \rightarrow 0} \frac{\vec{r}(t + \Delta t) - \vec{r}(t)}{\Delta t} = \frac{dx}{dt}\vec{i} + \frac{dy}{dt}\vec{j} + \frac{dz}{dt}\vec{k}$$

$\dot{\vec{r}}$ and $\ddot{\vec{r}}$ denote the velocity and acceleration of a particle with position vector $\vec{r}$.

Unit Tangent Vector

Let s be the arc length reckoned (measured) from a fixed point M_0 of a space curve c whose equation is $\vec{r} = \vec{r}(s)$. Then the unit tangent vector of c is

$$\frac{d\vec{r}}{ds} = \frac{dx}{ds}\vec{i} + \frac{dy}{ds}\vec{j} + \frac{dz}{ds}\vec{k}$$

such that

$$\left| \frac{d\vec{r}}{ds} \right| = \sqrt{\left(\frac{dx}{ds} \right)^2 + \left(\frac{dy}{ds} \right)^2 + \left(\frac{dz}{ds} \right)^2} = 1.$$

Partial Derivatives of a Vector Function $\vec{r}$

which depends on more than one scalar variables u, v, w : The partial derivative of $\vec{r}$ with respect to u is

$$\frac{\partial \vec{r}}{\partial u} = \lim_{\Delta u \rightarrow 0} \frac{\vec{r}(u + \Delta u, v, w) - \vec{r}(u, v, w)}{\Delta u}$$

In the component form, if

$\vec{r}(u, v, w) = F_1(u, v, w)\vec{i} + F_2(u, v, w)\vec{j} + F_3(u, v, w)\vec{k}$ then the partial derivative of $\vec{r}$ with respect to say u is obtained by taking the partial derivatives of the components F_1, F_2, F_3 of $\vec{r}$ with respect to u . i.e.,

$$\frac{\partial \vec{r}}{\partial u} = \frac{\partial F_1}{\partial u}\vec{i} + \frac{\partial F_2}{\partial u}\vec{j} + \frac{\partial F_3}{\partial u}\vec{k}$$

Higher order partial derivatives can be obtained similarly.

WORKED OUT EXAMPLES

Example 1: Find the magnitude of the velocity and acceleration of a particle which moves along the curve $x = 2 \sin 3t$, $y = 2 \cos 3t$, $z = 8t$ at any time $t > 0$. Find unit tangent vector to the curve.

Solution: The position vector $\vec{r}$ of the particle is

$$\vec{r}(t) = x(t)\vec{i} + y(t)\vec{j} + z(t)\vec{k}$$

$$\vec{r}(t) = 2 \sin 3t \vec{i} + 2 \cos 3t \vec{j} + 8t \vec{k}$$

$$\text{Velocity} = \vec{V} = \frac{d\vec{r}}{dt} = 6 \cos 3t \vec{i} - 6 \sin 3t \vec{j} + 8 \vec{k}$$

$$\text{Acceleration} = \vec{a} = \ddot{\vec{r}} = \frac{d\vec{V}}{dt}$$

$$= -18 \sin 3t \vec{i} - 18 \cos 3t \vec{j} + 0$$

$$|\vec{V}| = \sqrt{36 \cos^2 3t + 36 \sin^2 3t + 64}$$

$$= \sqrt{36 + 64} = 10$$

$$|\vec{a}| = \sqrt{18^2 \sin^2 3t + 18^2 \cos^2 3t} = 18.$$

$$\begin{aligned} \text{Unit tangent vector} &= \frac{\frac{d\vec{r}}{dt}}{\left| \frac{d\vec{r}}{dt} \right|} \\ &= \frac{1}{10} [6 \cos 3t \vec{i} - 6 \sin 3t \vec{j} + 8 \vec{k}] \end{aligned}$$

Example 2: If $\bar{A} = t^2\bar{i} - t\bar{j} + (2t + 1)\bar{k}$,
 $\bar{B} = (2t - 3)\bar{i} + \bar{j} - t\bar{k}$ find (a) $\frac{d}{dt}(\bar{A} \cdot \bar{B})$

(b) $\frac{d}{dt}(\bar{A} \times \bar{B})$ (c) $\frac{d}{dt}|\bar{A} + \bar{B}|$ (d) $\frac{d}{dt}\left(\bar{A} \times \frac{d\bar{B}}{dt}\right)$

at $t = 1$.

Solution:

a. $\bar{A} \cdot \bar{B} = t^2(2t - 3) - t + (2t + 1)(-t)$

$$\frac{d}{dt}(\bar{A} \cdot \bar{B}) = 6t^2 - 6t - 1 - 4t - 1 \Big|_{t=1} = -6$$

b. $\bar{A} \times \bar{B} = \begin{vmatrix} \bar{i} & \bar{j} & \bar{k} \\ t^2 & -t & (2t + 1) \\ 2t - 3 & 1 & -t \end{vmatrix}$

$$\bar{A} \times \bar{B} = i(t^2 - 2t - 1) + j(t^3 + 4t^2 - 4t - 3) + \bar{k}(3t^2 - 3t)$$

$$\frac{d}{dt}(\bar{A} \times \bar{B}) = (2t - 2)\bar{i} + (3t^2 + 8t - 4)\bar{j} + (6t - 3)\bar{k}$$

$$\text{At } t = 1, \frac{d}{dt}(\bar{A} \times \bar{B}) = 7\bar{j} + 3\bar{k}$$

c. $\bar{A} + \bar{B} = (t^2 + 2t - 3)\bar{i} + (1 - t)\bar{j} + (t + 1)\bar{k}$

$$|\bar{A} + \bar{B}| = \sqrt{(t^2 + 2t - 3)^2 + (1 - t)^2 + (t + 1)^2}$$

$$= \sqrt{t^4 + 4t^3 - 12t + 11}$$

$$\frac{d}{dt}|\bar{A} + \bar{B}| = \frac{4t^3 + 12t^2 - 12}{2\sqrt{t^4 + 4t^3 - 12t + 11}} \text{ at } t = 1 \text{ is } 1.$$

d. $\frac{d\bar{B}}{dt} = 2\bar{i} + 0 - \bar{k}$

$$\bar{A} \times \frac{d\bar{B}}{dt} = \begin{vmatrix} \bar{i} & \bar{j} & \bar{k} \\ t^2 & -t & (2t + 1) \\ 2 & 0 & -1 \end{vmatrix}$$

$$= t\bar{i} + (t^2 + 4t - 2)\bar{j} + 2t\bar{k}$$

$$\frac{d}{dt}\left(\bar{A} \times \frac{d\bar{B}}{dt}\right) = i + (2t + 4)\bar{j} + 2\bar{k} \text{ at } t = 1$$

$$\text{is } \bar{i} + 6\bar{j} + 2\bar{k}$$

Aliter : $\frac{d}{dt}\left(\bar{A} \times \frac{d\bar{B}}{dt}\right) = \frac{d\bar{A}}{dt} \times \frac{d\bar{B}}{dt} + \bar{A} \times \frac{d^2\bar{B}}{dt^2}$

$$\frac{d\bar{A}}{dt} = 2t\bar{i} - \bar{j} + 2\bar{k}$$

$$\frac{d\bar{A}}{dt} \times \frac{d\bar{B}}{dt} = \begin{vmatrix} \bar{i} & \bar{j} & \bar{k} \\ 2t & -1 & 2 \\ 2 & 0 & -1 \end{vmatrix}$$

$$= i + (2t + 4)\bar{j} + 2\bar{k}$$

Also $\frac{d^2\bar{B}}{dt^2} = 0 + 0 + 0$

so that $\bar{A} \times \frac{d^2\bar{B}}{dt^2} = 0$

Thus $\frac{d}{dt}\left(\bar{A} \times \frac{d\bar{B}}{dt}\right) = i + (2t + 4)\bar{j} + 2\bar{k} \text{ at } t = 1$
 is $i + 6\bar{j} + 2\bar{k}$.

Example 3: If $\bar{A} = \cos xy \bar{i} + (3xy - 2x^2)\bar{j} - (3x + 2y)\bar{k}$ find

$$\frac{\partial \bar{A}}{\partial x}, \frac{\partial \bar{A}}{\partial y}, \frac{\partial^2 \bar{A}}{\partial x^2}, \frac{\partial^2 \bar{A}}{\partial y^2}, \frac{\partial^2 \bar{A}}{\partial x \partial y}, \frac{\partial^2 \bar{A}}{\partial y \partial x}.$$

Solution:

$$\frac{\partial \bar{A}}{\partial x} = -y \sin xy \bar{i} + (3y - 4x)\bar{j} - (3\bar{k})$$

$$\frac{\partial \bar{A}}{\partial y} = -x \sin xy \bar{i} + (3x\bar{j}) - 2\bar{k}$$

$$\frac{\partial^2 \bar{A}}{\partial x^2} = -y^2 \cos xy \bar{i} - 4\bar{j}$$

$$\frac{\partial^2 \bar{A}}{\partial y^2} = -x^2 \cos xy \bar{i}$$

$$\frac{\partial^2 \bar{A}}{\partial x \partial y} = (-\sin xy - xy \cos xy)\bar{i} + 3\bar{j}.$$

Example 4: Prove that $\bar{A} \cdot \frac{d\bar{A}}{dt} = 0$ if $\bar{A}$ is a constant vector.

Solution: For any vector $\bar{A}$, $\bar{A} \cdot \bar{A} = A^2$.
 Differentiating w.r.t., t

$$\frac{d}{dt}(\bar{A} \cdot \bar{A}) = \bar{A} \cdot \frac{d\bar{A}}{dt} + \frac{d\bar{A}}{dt} \cdot \bar{A} = 2\bar{A} \cdot \frac{d\bar{A}}{dt}$$

$$2\bar{A} \cdot \frac{d\bar{A}}{dt} = 2\bar{A} \cdot \frac{d\bar{A}}{dt}$$

If $\bar{A}$ is a vector of constant magnitude $\frac{dA}{dt} = 0$ so that

$$\bar{A} \cdot \frac{d\bar{A}}{dt} = 0.$$

EXERCISE

1. If $\bar{A} = 5t^2\bar{i} + t\bar{j} - t^3\bar{k}$ and $\bar{B} = \sin t\bar{i} - \cos t\bar{j}$, find (a) $\frac{d}{dt}(\bar{A} \cdot \bar{B})$, (b) $\frac{d}{dt}(\bar{A} \times \bar{B})$ (c) $\frac{d}{dt}(\bar{A} \cdot \bar{A})$.

15.4 — HIGHER ENGINEERING MATHEMATICS—IV

- Ans. a. $(5t^2 - 1)\cos t + 11t \sin t$
 b. $(t^3 \sin t - 3t^2 \cos t)i - (t^3 \cos t + 3t^2 \sin t)j + (5t^2 \sin t - 11t \cos t - \sin t)k$
 c. $100t^3 + 2t + 6t^5$

2. Find (a) $\frac{d}{du}(\bar{A} \cdot \bar{B})$ (b) $\frac{d}{du}(\bar{A} \times \bar{B})$ if $\bar{A}(u) = 2ui - 3u^2j + u^3k$, $\bar{B}(u) = \sin ui - uk$.

- Ans. $2 \sin u + 2u \cos u - 4u^3$; $9u^2i + (u^3 \cos u + 3u^2 \sin u + 4u)j + (3u^2 \cos u + 6u \sin u)k$

3. If $\bar{A} = 2ti - t^2j + t^3k$, $\bar{B} = -ti + t^2k$ and $\bar{C} = t^3j - 2tk$ find $\frac{d}{dt}(\bar{A} \cdot \bar{B} \times \bar{C})$ at $t = 1$.

- Ans. $-12t^5 + 8t^3 - 7t^6, -11$

4. If $\bar{A} = \sin ui + \cos uj + uk$, $\bar{B} = \cos ui - \sin uj - 3k$ and $\bar{C} = 2i + 3j - k$ find $\frac{d}{du}(\bar{A} \times (\bar{B} \times \bar{C}))$ at $u = 0$.

- Ans. $7i + 6j - 6k$

5. If $\bar{A} = (2x^2y - x^4)i + (e^{xy} - y \sin x)j + (x^2 \cos y)k$ find (a) $\frac{\partial \bar{A}}{\partial x}$, (b) $\frac{\partial \bar{A}}{\partial y}$, (c) $\frac{\partial^2 \bar{A}}{\partial x^2}$, (d) $\frac{\partial^2 \bar{A}}{\partial y^2}$, (e) $\frac{\partial^2 \bar{A}}{\partial x \partial y}$, (f) $\frac{\partial^2 \bar{A}}{\partial y \partial x}$.

- Ans. a. $(4xy - 4x^3)i + (ye^{xy} - y \cos x)j + 2x \cos yk$

b. $2x^2i + (xe^{xy} - \sin x)j - x^2 \sin yk$

c. $(4y - 12x^2)i + (y^2e^{xy} + y \sin x)j + 2 \cos yk$

d. $0 + x^2e^{xy}j - x^2 \cos yk$

e, f. $4xi + (xye^{xy} + e^{xy} - \cos x)j - 2x \sin yk$

6. Find $\frac{\partial^3}{\partial x^2 \partial z}(f\bar{A})$ at the point $(2, -1, 1)$ if

$$f = xy^2z, \bar{A} = xzi - xy^2j + yz^2k.$$

- Ans. $4y^2zi - 2y^4j; 4i - 2j$

7. Find $\frac{\partial^2(\bar{A} \times \bar{B})}{\partial x \partial y}$ at $(1, 0, -2)$ if $\bar{A} = x^2yzi - 2xz^3j + xz^2k$, $\bar{B} = 2zi + yj - x^2k$.

- Ans. $-4i - 8j$

8. Prove that $\bar{A} \times \frac{d\bar{A}}{dt} = 0$ if $\bar{A}(t)$ has constant (fixed) direction.

Hint: Take $\bar{A} = a(t)\bar{B}(t)$ where $a(t) = |\bar{A}|$ and $\bar{B}(t)$ is a unit vector in the direction of $\bar{A}$ so that $\frac{d\bar{B}}{dt} = 0$.

9. Given the curve $x = t^2 + 2$, $y = 4t - 5$, $z = 2t^2 - 6t$ find the unit tangent vector at the point $t = 2$.

- Ans. $ti + 2j + (2t - 3)k / (\sqrt{5t^2 - 12t + 13})$;
 $(2i + 2j + k)/3$

10. Find the angle between the tangents to the curve $\bar{r} = t^2i + 2tj - t^3k$ at the points $t = \pm 1$.

Hint: $\bar{T}_1 \cdot \bar{T}_2 = T_1 T_2 \cos \theta$.

- Ans. $\theta = \cos^{-1}(9/17)$

11. Determine the magnitude of velocity and acceleration at $t = 0$ of a particle moving along a curve whose parametric equations are $x = e^{-t}$, $y = 2 \cos 3t$, $z = 2 \sin 3t$; where t is the time.

Ans. $\bar{V} = -e^{-t}i - 6 \sin 3tj + 6 \cos 3tk$

$$\bar{a} = e^{-t}i - 18 \cos 3tj - 18 \sin 3tk$$

$$|\bar{V}| \text{ at } t = 0 \text{ is } \sqrt{37}; |\bar{a}| \text{ at } t = 0 \text{ is } \sqrt{325}$$

12. A particle moves along the curve $x = 2t^2$, $y = t^2 - 4t$, $z = 3t - 5$ where t is the time. Find the components of its velocity and acceleration at time $t = 1$ in the direction $\bar{i} - 3\bar{j} + 2\bar{k}$.

Hint: Component of $\bar{V}$ = dot product of $\bar{V}$ with unit vector in the direction of $\bar{i} - 3\bar{j} + 2\bar{k}$.

- Ans. $8\sqrt{14}/7; -\sqrt{14}/7$

13. If a, b, w are constants show that the acceleration of a particle with displacement vector $\bar{r} = a \cos wt + b \sin wt$ is always directed towards the origin.

Hint: $\bar{a} = \ddot{\bar{r}} = -w^2\bar{r}$.

14. Find the angle between the directions of the velocity and acceleration vectors at time t of a particle with position vector $\bar{r} = (t^2 + 1)i - 2tj + (t^2 - 1)k$.

- Ans. $\arccos t\sqrt{2}/\sqrt{2t^2 + 1}$

15. Prove that $\frac{d}{du}(\bar{A} \times \bar{B}) = \bar{C} \times (\bar{A} \times \bar{B})$ if

$$\frac{d\bar{A}}{du} = \bar{C} \times \bar{A} \quad \text{and} \quad \frac{d\bar{B}}{du} = \bar{C} \times \bar{B}$$

Hint:

$$\begin{aligned} \frac{d}{du}(\bar{A} \times \bar{B}) &= \bar{A} \times \frac{d\bar{B}}{du} + \frac{d\bar{A}}{du} \times \bar{B} \\ &= \bar{A} \times (\bar{C} \times \bar{B}) + (\bar{C} \times \bar{A}) \times \bar{B} \end{aligned}$$

$$\begin{aligned}
 &= (A \cdot B)C - (A \cdot C)B - (\bar{B} \cdot \bar{A})C \\
 &\quad + (B \cdot C)A \\
 &= \bar{C} \times (\bar{A} \times \bar{B}).
 \end{aligned}$$

15.2 DIRECTIONAL DERIVATIVE, GRADIENT OF A SCALAR FUNCTION AND CONSERVATIVE FIELD

In vector differential calculus, it is very convenient to introduce the symbolic linear vector differential “Hamiltonian” operator **del** defined and denoted as

$$\nabla = \bar{i} \frac{\partial}{\partial x} + \bar{j} \frac{\partial}{\partial y} + \bar{k} \frac{\partial}{\partial z} \quad (1)$$

This operator read as del (or nabla) is *not* a vector (neither has magnitude nor direction) but combines both differential and vectorial properties analogous to those of ordinary vectors.

Directional Derivative

If $f = f(x, y, z)$ then the partial derivatives $\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}$ are the derivatives (rates of change) of f in the “direction” of the coordinate axes OX, OY, OZ respectively. This concept can be extended to define a derivative of f in a “given” direction $\overrightarrow{PQ}$ (Fig. 15.1).

Fig. 15.1

Let P be a point in space and $\bar{b}$ be a unit vector from P in the given direction. Let s be the arc lengths measured from P to another point Q along the ray C in the direction of $\bar{b}$. Now consider

$$f(s) = f(x, y, z) = f((s), y(s), z(s))$$

$$\text{Then} \quad \frac{df}{ds} = \frac{\partial f}{\partial x} \frac{dx}{ds} + \frac{\partial f}{\partial y} \frac{dy}{ds} + \frac{\partial f}{\partial z} \frac{dz}{ds} \quad (2)$$

The *directional derivative* of f at the point P in the given direction $\bar{b}$ is $\frac{df}{ds}$ given by (2). $\frac{df}{ds}$ gives the rate of change of f in the direction of $\bar{b}$.

$$\text{Since} \quad \frac{dx}{ds} \bar{i} + \frac{dy}{ds} \bar{j} + \frac{dz}{ds} \bar{k} = \bar{b} = \text{unit vector} \quad (3)$$

Using the del operator defined by (1) $\frac{df}{ds}$ given by (2) can be rewritten as

$$\begin{aligned}
 \frac{df}{ds} &= \left(\bar{i} \frac{\partial f}{\partial x} + \bar{j} \frac{\partial f}{\partial y} + \bar{k} \frac{\partial f}{\partial z} \right) \cdot \left(\frac{dx}{ds} \bar{i} + \frac{dy}{ds} \bar{j} + \frac{dz}{ds} \bar{k} \right) \\
 \frac{df}{ds} &= \left[\left(\bar{i} \frac{\partial}{\partial x} + \bar{j} \frac{\partial}{\partial y} + \bar{k} \frac{\partial}{\partial z} \right) f \right] \cdot \bar{b} = \nabla f \cdot \bar{b} \quad (4)
 \end{aligned}$$

Thus the directional derivative of f at P is the component (dot product) of ∇f in the direction of (with) unit vector $\bar{b}$.

The directional derivative in the direction of any (non unit) vector $\bar{a}$ is

$$\frac{df}{ds} = \nabla f \cdot \left(\frac{\bar{a}}{|\bar{a}|} \right) \quad (5)$$

Equation (4) introduces the vector quantity, the **gradient of a scalar function** $f(x, y, z)$ or gradient f denoted by ∇f and defined as

$$\begin{aligned}
 \nabla f &= \left(\bar{i} \frac{\partial}{\partial x} + \bar{j} \frac{\partial}{\partial y} + \bar{k} \frac{\partial}{\partial z} \right) f \\
 &= \bar{i} \frac{\partial f}{\partial x} + \bar{j} \frac{\partial f}{\partial y} + \bar{k} \frac{\partial f}{\partial z} = \text{grad } f = \text{vector} \\
 \nabla f &= \left[\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right].
 \end{aligned}$$

Properties of gradient

1. Projection of ∇f in any direction is equal to the derivative of f in that direction.
2. The gradient of f is in the direction of the normal to the level surface $f(x, y, z) = C = \text{constant}$. So, the angle between any two surfaces $f(x, y, z) = C_1$ and $g(x, y, z) = C_2$ is the angle between their corresponding normals given by ∇f and ∇g respectively.
3. The gradient at P is in the direction of maximum increase of f at P .
4. The modulus of the gradient is equal to the largest directional derivative at a given point P .

$$\begin{aligned}
 \text{i.e., } \max \left. \frac{df}{ds} \right|_P &= \left| \nabla f \right|_P \\
 &= \sqrt{\left(\frac{\partial f}{\partial x} \right)^2 + \left(\frac{\partial f}{\partial y} \right)^2 + \left(\frac{\partial f}{\partial z} \right)^2} \Big|_{\text{at } P}.
 \end{aligned}$$

15.6 — HIGHER ENGINEERING MATHEMATICS—IV

These properties thus state that the vector gradient ∇f indicates the direction and magnitude of maximum change of a scalar function f at a given point.

Normal derivative

$\frac{df}{dn} = \nabla f \cdot \bar{n}$ where $\bar{n}$ is the unit normal to the surface $f = \text{constant}$.

Conservative

A vector function $\bar{A}$ is said to be a conservative vector field if $\bar{A} = \nabla f$ i.e., $\bar{A}$ is the gradient of a scalar function f . In this case f is known as the *potential function* of $\bar{A}$.

Instead of applying (operating) on a scalar function f , if ∇ is applied to a vector function $\bar{A}$, we get divergence and curl: (see Sections 15.3, 15.4)

WORKED OUT EXAMPLES

Example 1: If $\bar{A} = 2x^2\bar{i} - 3yz\bar{j} + xz^2\bar{k}$ and $f = 2z - x^3y$ find (i) $\bar{A} \cdot \nabla f$ and (ii) $\bar{A} \times \nabla f$ at the point $(1, -1, 1)$.

Solution: Here $\frac{\partial f}{\partial x} = -3x^2y$, $\frac{\partial f}{\partial y} = -x^3$, $\frac{\partial f}{\partial z} = 2$ so that

$$\nabla f = \frac{\partial f}{\partial x}\bar{i} + \frac{\partial f}{\partial y}\bar{j} + \frac{\partial f}{\partial z}\bar{k}$$

$$\nabla f = -3x^2y\bar{i} - x^3\bar{j} + 2\bar{k}$$

$$\begin{aligned} \text{i.} \quad \bar{A} \cdot \nabla f &= (2x^2\bar{i} - 3yz\bar{j} + xz^2\bar{k}) \cdot (-3x^2y\bar{i} - x^3\bar{j} + 2\bar{k}) \\ &= -6x^4y + 3x^3yz + 2xz^2 \end{aligned}$$

$$\bar{A} \cdot \nabla f \Big|_{1,-1,1} = 6 - 3 + 2 = 5$$

$$\text{ii.} \quad \bar{A} \times \nabla f = \begin{vmatrix} \bar{i} & \bar{j} & \bar{k} \\ 2x^2 & -3yz & xz^2 \\ -3x^2y & -x^3 & 2 \end{vmatrix}$$

Expanding the determinant

$$\begin{aligned} \bar{A} \times \nabla f &= (-6yz + x^4z^2)\bar{i} - j(4x^2 + 3x^3yz^2) \\ &\quad + (-2x^5 - 9x^2y^2z)\bar{k} \end{aligned}$$

$$\bar{A} \times \nabla f \Big|_{1,-1,1} = 7\bar{i} - \bar{j} - 11\bar{k}.$$

Example 2: Evaluate

- | | |
|--|-----------------------|
| i. ∇r^n | iv. ∇r |
| ii. $\nabla \bar{r} ^3$ | v. $\nabla (\ln r)$ |
| iii. $\nabla (3r^2 - 4\sqrt{r} + 6r^{-\frac{1}{3}})$ | vi. $\nabla (r^{-1})$ |

Solution:

$$\text{i.} \quad \nabla r^n = \bar{i} \frac{\partial r^n}{\partial x} + \bar{j} \frac{\partial r^n}{\partial y} + \bar{k} \frac{\partial r^n}{\partial z}$$

$$\frac{\partial r^n}{\partial x} = nr^{n-1} \frac{\partial r}{\partial x} = nr^{n-1} \frac{x}{r}$$

$$\frac{\partial r^n}{\partial x} = nr^{n-2}x$$

$$\text{Similarly, } \frac{\partial r^n}{\partial y} = nr^{n-2}y, \text{ and}$$

$$\frac{\partial r^n}{\partial z} = nr^{n-2}z.$$

$$\text{Then } \nabla r^n = nr^{n-2}(xi + yj + zk) = nr^{n-2}\bar{r}$$

ii. Put $n = 3$ in the result (i) above

$$\nabla r^3 = 3r^{3-2}\bar{r} = 3r\bar{r}$$

iii. $\nabla (3r^2 - 4\sqrt{r} + 6r^{-\frac{1}{3}})$

$$= 3\nabla r^2 - 4\nabla r^{\frac{1}{2}} + 6\nabla r^{-\frac{1}{3}}$$

Applying result (i) above with $n = 2, \frac{1}{2}, -\frac{1}{3}$, we get

$$\begin{aligned} &= 3(2r^{2-2}\bar{r}) - 4\left(\frac{1}{2}r^{\frac{1}{2}-2}\bar{r}\right) + 6\left(-\frac{1}{3}r^{-\frac{1}{3}-2}\bar{r}\right) \\ &= \left(6 - 2r^{-\frac{3}{2}} - 2r^{-\frac{7}{2}}\right)\bar{r} \end{aligned}$$

$$\text{iv.} \quad \nabla r = 1r^{1-2}\bar{r} = \frac{\bar{r}}{r}$$

$$\text{v.} \quad \nabla f = \nabla \ln r = \frac{1}{r}\nabla r = \frac{1}{r}\frac{\bar{r}}{r} = \frac{\bar{r}}{r^2}$$

$$\text{vi.} \quad \nabla (r^{-1}) = -1 \cdot r^{-1-2}\bar{r} = -\bar{r}/r^3.$$

Example 3: Find the directional derivative of $f(x, y, z) = 4e^{2x-y+z}$ at the point $(1, 1, -1)$ in the direction toward the point $(-3, 5, 6)$.

Solution:

$$\nabla f = 4e^{2x-y+z}(2\bar{i} - \bar{j} + \bar{k})$$

$$\nabla f \Big|_{(1,1,-1)} = 4(2i - j + k)$$

A unit vector $\hat{a}$ from the point $(1, 1, -1)$ in the direction toward the point $(-3, 5, 6)$ is

$$\begin{aligned}\hat{a} &= \frac{-4i + 4j + 7k}{\sqrt{16 + 16 + 49}} \\ &= \frac{-4i + 4j + 7k}{9}\end{aligned}$$

The required directional derivative is

$$\begin{aligned}\nabla f \Big|_{(1,1,-1)} \cdot \hat{a} &= 4(2i - j + k) \cdot \frac{(-4i + 4j + 7k)}{9} \\ &= -\frac{20}{9}.\end{aligned}$$

Example 4: Find the values of the constants a, b, c so that the directional derivative of $f = axy^2 + byz + cz^2x^3$ at $(1, 2, -1)$ has a maximum of magnitude 64 in a direction parallel to the z -axis.

Solution: Since $\bar{k}$ is a unit vector parallel to the z -axis, the maximum of magnitude of the directional derivative of f at $(1, 2, -1)$ in the direction parallel to z -axis is given by

$$\nabla f_{\text{at } (1,2,-1)} \cdot \bar{k}$$

$$\begin{aligned}\text{Here } \nabla f &= (ay^2 + 3x^2cz^2)i + (2axy + bz)j \\ &\quad + (by + 2czx^3)k\end{aligned}$$

So that

$$\nabla f_{\text{at } (1,2,-1)} = (4a + 3c)i + (4a - b)\bar{j} + (2b - 2c)\bar{k}$$

$$\begin{aligned}\text{Maximum} &= \nabla f_{\text{at } (1,2,-1)} \cdot k \\ &= [(4a + 3c)i + (4a - b)j + (2b - 2c)k] \cdot k \\ &= (2b - 2c)\end{aligned}$$

It is given in the problem that this maximum is 64. Thus

$$2b - 2c = 64$$

$$\text{or } b - c = 32 \quad (1)$$

Since ∇f is in the direction of z -axis, it is perpendicular to the x and y -axes
Thus

$$\begin{aligned}\nabla f \Big|_{(1,2,-1)} \cdot i &= [(4a + 3c)i + (4a - b)j \\ &\quad + (2b - 2c)k] \cdot i\end{aligned}$$

$$= 4a + 3c = 0 \quad (2)$$

Similarly,

$$\nabla f \cdot j = 4a - b = 0 \quad (3)$$

Solving the Equations (1), (2), (3), we get

$$a = 6, b = 24, c = -8.$$

Example 5: Find the constants a and b so that the surface $ax^2 - byz = (a + 2)x$ will be orthogonal to the surface $4x^2y + z^3 = 4$ at the point $(1, -1, 2)$.

Solution: The given surfaces

$$f = ax^2 - byz - (a + 2)x = 0 \quad (1)$$

$$\text{and } g = 4x^2y + z^3 = 4 \quad (2)$$

are orthogonal at the point $P(1, -1, 2)$ provided the normals to (1) and (2) at P are at right angles. The normal to surface (1) is given by ∇f ,

$$\begin{aligned}\nabla f \Big|_{1,-1,2} &= \{2ax - (a + 2)\}\bar{i} - bz\bar{j} - by\bar{k} \Big|_{1,-1,2} \\ \nabla f &= (a - 2)i - 2bj + bk\end{aligned} \quad (3)$$

and normal to surface (2) by ∇g ,

$$\begin{aligned}\nabla g \Big|_{1,-1,2} &= 8xyi + 4x^2j + 3z^2k \Big|_{1,-1,2} \\ \nabla g &= -8i + 4j + 12k\end{aligned} \quad (4)$$

The orthogonality condition is

$$\begin{aligned}0 &= \nabla f \cdot \nabla g = [(a - 2)i - 2bj + bk] \cdot [-8i + 4j + 12k] \\ 0 &= -2a + 4 + b\end{aligned} \quad (5)$$

Since $(1, -1, 2)$ lies on the surface (1), we have

$$a + 2b - (a + 2) = 0$$

$$\text{i.e., } b = 1.$$

So from (5), $a = \frac{5}{2}$.

Example 6: If $\nabla f = (y^2 - 2xyz^3)i + (3 + 2xy - x^2z^3)j + (6z^3 - 3x^2yz^2)\bar{k}$, find f if $f(1, 0, 1) = 8$.

Solution: Since

$$\begin{aligned}\frac{\partial f}{\partial x}i + \frac{\partial f}{\partial y}j + \frac{\partial f}{\partial z}k &= \nabla f = (y^2 - 2xyz^3)i \\ &\quad + (3 + 2xy - x^2z^3)j \\ &\quad + (6z^3 - 3x^2yz^2)k\end{aligned}$$

15.8 — HIGHER ENGINEERING MATHEMATICS—IV

We have

$$\frac{\partial f}{\partial x} = y^2 - 2xyz^3 \quad (1)$$

$$\frac{\partial f}{\partial y} = 3 + 2xy - x^2z^3 \quad (2)$$

$$\frac{\partial f}{\partial z} = 6z^3 - 3x^2yz^2 \quad (3)$$

Integrating (1), (2), (3) partially w.r.t., x, y, z respectively, we get

$$f = xy^2 - x^2yz^3 + c_1(y, z) \quad (4)$$

$$f = 3y + xy^2 - x^2yz^3 + c_2(x, z) \quad (5)$$

$$f = \frac{6}{4}z^4 - x^2yz^3 + c_3(x, y) \quad (6)$$

where c_1, c_2, c_3 arbitrary functions of the variables indicated.

To find $c_1(y, z)$, differentiate (4) partially w.r.t. z and equate it with (3). Thus

$$0 - 3x^2yz^2 + \frac{\partial c_1}{\partial z} = \frac{\partial f}{\partial z} = 6z^3 - 3x^2yz^2$$

$$\text{So} \quad \frac{\partial c_1}{\partial z} = 6z^3 \quad (7)$$

Integrating (7) partially w.r.t. ' z ', we get

$$c_1(y, z) = \frac{6}{4}z^4 + c_4(y) \quad (8)$$

where c_4 is a function of y alone.

Substituting (8) in (4), we have

$$f = xy^2 - x^2yz^3 + \frac{3}{2}z^4 + c_4(y) \quad (9)$$

To find c_4 , differentiate (9) partially w.r.t. y and equate it with (2), we get

$$2xy - x^2z^3 + 0 + \frac{dc_4}{dy} = \frac{\partial f}{\partial y} = 3 + 2xy - x^2z^3$$

$$\text{So} \quad \frac{dc_4}{dy} = 3 \quad (10)$$

Integrating (10) w.r.t. y , we have

$$c_4(y) = 3y + c_5 \quad (11)$$

where c_5 is a pure arbitrary constant.

Substituting (11) in (9), we get the required

$$f(x, y, z) = xy^2 - x^2yz^3 + \frac{3}{2}z^4 + 3y + c_5$$

$$\text{Since } 8 = f(1, 0, 1) = 1 - 0 + 0 + 3 + c_5$$

$$\therefore c_5 = 4.$$

$$\text{Hence } f = xy^2 - x^2yz^3 + \frac{3}{2}z^4 + 3y + 4.$$

Similar result can be obtained by starting from (5) or (6).

Example 7: Find $f(r)$ such that $\nabla f = \frac{\vec{r}}{r^5}$ and $f(1) = 0$.

Solution: It is given that

$$\frac{\partial f}{\partial x}i + \frac{\partial f}{\partial y}j + \frac{\partial f}{\partial z}k = \nabla f = \frac{\vec{r}}{r^5} = \frac{xi + yj + zk}{r^5}$$

$$\text{so } \frac{\partial f}{\partial x} = \frac{x}{r^5}, \frac{\partial f}{\partial y} = \frac{y}{r^5}, \text{ and } \frac{\partial f}{\partial z} = \frac{z}{r^5}$$

We know that

$$df = \frac{\partial f}{\partial x}dx + \frac{\partial f}{\partial y}dy + \frac{\partial f}{\partial z}dz = \frac{x}{r^5}dx + \frac{y}{r^5}dy + \frac{z}{r^5}dz$$

$$df = \frac{xdx + ydy + zdz}{r^5} = \frac{rdr}{r^5} = r^{-4}dr$$

$$\text{Integrating } f(r) = \frac{r^{-3}}{-3} + c$$

$$\text{Since } 0 = f(1) = -\frac{1}{3} + c$$

$$\text{so } c = \frac{1}{3}$$

$$\text{Thus } f(r) = \frac{1}{3} - \frac{1}{3} \frac{1}{r^3}.$$

EXERCISE

1. Find ∇f if $f = \ln(x^2 + y^2 + z^2)$.

Ans. $2(xi + yj + zk)/(x^2 + y^2 + z^2)$

2. If $f(x, y, z) = 3x^2y - y^3z^2$, find ∇f and $|\nabla f|$ at $(1, -2, -1)$.

Ans. $\nabla f = -12i - 9j - 16k, |\nabla f| = \sqrt{481}$

3. If $f = 2xz^4 - x^2y$, find ∇f and $|\nabla f|$ at $(2, -2, -1)$.

Ans. $10i - 4j - 16k, 2\sqrt{93}$

4. Find ∇f when

$$f = (x^2 + y^2 + z^2) e^{-\sqrt{x^2 + y^2 + z^2}}.$$

Ans. $(2 - r)e^{-r}\vec{r}$

5. If $U = 3x^2y$, $V = xz^2 - 2y$ evaluate $\nabla[\nabla U \cdot \nabla V]$.
 Ans. $(6yz^2 - 12x)\bar{i} + 6xz^2\bar{j} + 12xyz\bar{k}$
6. Find a unit normal to the surface $x^2y + 2xz = 4$ at the point $(2, -2, 3)$.
 Ans. $\pm \frac{1}{3}(i - 2j - 2k)$
7. Find the unit outward drawn normal to the surface $(x - 1)^2 + y^2 + (z + 2)^2 = 9$ at the point $(3, 1, -4)$.
 Ans. $(2i + j - 2k)/3$
8. Determine a unit vector normal to the surface $xy^3z^2 = 4$ at the point $(-1, -1, 2)$.
 Ans. $\pm(\bar{i} + 3\bar{j} - \bar{k})/\sqrt{11}$
9. What is the directional derivative of $f = xy^2 + yz^3$ at the point $(2, -1, 1)$ in the direction of the normal to the surface $x \ln z - y^2 = -4$ at $(-1, 2, 1)$.
 Ans. $\frac{15}{\sqrt{17}}$
10. Find the directional derivative of $f = x^2yz + 4xz^2$ at $(1, -2, -1)$ in the direction $2\bar{i} - \bar{j} - 2\bar{k}$.
 Ans. $\frac{37}{3}$
11. Find the directional derivative of $f = xy + yz + zx$ in the direction of vector $i + 2j + 2k$ at the point $(1, 2, 0)$.
 Ans. $\frac{10}{3}$
12. Determine the directional derivative of $f = xy^2 + yz^3$ at the point $(2, -1, 1)$ in the direction of the vector $i + 2j + 2k$.
 Ans. $-\frac{11}{3}$
13. Find the maximal directional derivative of x^3y^2z at $(1, -2, 3)$.
 Ans. $4\sqrt{91}$
14. **a.** In what direction from the point $(2, 1, -1)$ is the directional derivative of $f = x^2yz^3$ a maximum?
b. What is the magnitude of this maximum?
 Ans. **a.** The directional derivative is a maximum in the direction of $\nabla f = -4i - 4j + 12k$.
b. The magnitude of this maximum is $4\sqrt{11}$.
15. Find the direction in which temperature changes most rapidly with distance from the point $(1, 1, 1)$ and determine the maximum rate of change if the temperature at any point is given by $f(x, y, z) = xy + yz + zx$.
 Ans. Maximum direction is $2i + 2j + 2k$, maximum: $2\sqrt{3}$.
16. In what direction from $(3, 1, -2)$ is the directional derivative of $f = x^2y^2z^4$ maximum. Find also the magnitude of the maximum.
 Ans. $96(\bar{i} + 3\bar{j} - 3\bar{k}); 96\sqrt{19}$
17. Find the angle between the surfaces $x^2 + y^2 + z^2 = 9$ and $z = x^2 + y^2 - 3$ at the point $(2, -1, 2)$.
 Ans. The acute angle $= \cos^{-1}\left(\frac{8\sqrt{21}}{63}\right) = 54^\circ \cdot 25$.
18. Find the angle of intersection of the spheres $x^2 + y^2 + z^2 = 29$ and $x^2 + y^2 + z^2 + 4x - 6y - 8z = 47$ at $(4, -3, 2)$.
 Ans. $\theta = \cos^{-1}(19/29)$
19. Determine the angle between the normals to the surface $xy = z^2$ at the points $(4, 1, 2)$ and $(3, 3, -3)$.
 Ans. $\cos^{-1}(1/\sqrt{22})$
20. Calculate the angle between the normals to the surface $2x^2 + 3y^2 = 5z$ at the points $(2, -2, 4)$ and $(-1, -1, 1)$.
 Ans. $\theta = \cos^{-1}(65/(\sqrt{233}\sqrt{77}))$
21. If $\nabla f = 2xyz^3\bar{i} + x^2z^3\bar{j} + 3x^2yz^2\bar{k}$, find $f(x, y, z)$ if $f(1, -2, 2) = 4$.
 Ans. $f = x^2yz^3 + 20$
22. Find f given $\nabla f = 2xi + 4yj + 8z\bar{k}$.
 Ans. $f = x^2 + 2y^2 + 4z^2$
23. **a.** Determine f when $\nabla f = (zy\bar{i} + xz\bar{j} - xy\bar{k})/z^2$.
b. If $\nabla f = xy\bar{i} + 2xy\bar{j}$ find f .
 Ans. **a.** $f = xy/z$
b. f does not exist
24. Prove that $\nabla(f/g) = (g\nabla f - f\nabla g)/g^2$.
Hint: Use quotient formula for derivative of f/g .

15.3 DIVERGENCE

Divergence of a vector function $\vec{A}(x, y, z)$ is written as divergence of $\vec{A}$ or div of $\vec{A}$ and denoted by $\nabla \cdot \vec{A}$ is defined as

$$\nabla \cdot \vec{A} = \left(i \frac{\partial}{\partial x} + j \frac{\partial}{\partial y} + k \frac{\partial}{\partial z} \right) \cdot (\vec{A})$$

If $\vec{A} = A_1 i + A_2 j + A_3 k$, then

$$\nabla \cdot \vec{A} = \left(i \frac{\partial}{\partial x} + j \frac{\partial}{\partial y} + k \frac{\partial}{\partial z} \right) \cdot (A_1 i + A_2 j + A_3 k)$$

$$\nabla \cdot \vec{A} = \frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} = \text{a scalar quantity}$$

Note that $\nabla \cdot \vec{A} \neq \vec{A} \cdot \nabla$ because L.H.S. $\nabla \cdot \vec{A}$ is a scalar quantity, whereas the R.H.S. $\vec{A} \cdot \nabla = A_1 \frac{\partial}{\partial x} + A_2 \frac{\partial}{\partial y} + A_3 \frac{\partial}{\partial z}$ is a scalar differential operator.

Physically the divergence of $\vec{A}$ at point P constitutes the volume density of the flux of $\vec{A}$ at P. i.e., divergence measures outflow minus inflow.

A point P in a vector field $\vec{A}$ is said to be a source (sink) if divergence $\vec{A} > (<)0$.

Solenoidal Function

$\vec{A}$ is said to be solenoidal if divergence $\vec{A} = 0$ (at all points of function).

WORKED OUT EXAMPLES

Example 1: Evaluate divergence of $(2x^2z\vec{i} - xy^2z\vec{j} + 3yz^2\vec{k})$ at the point $(1, 1, 1)$.

Solution: Divergence of $\vec{A}$

$$\begin{aligned} &= \text{div } \vec{A} = \nabla \cdot \vec{A} \\ &= \frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \end{aligned}$$

$$\text{Here } \vec{A} = 2x^2z\vec{i} - xy^2z\vec{j} + 3yz^2\vec{k}$$

$$= A_1 i + A_2 j + A_3 k$$

$$\text{so that } \frac{\partial A_1}{\partial x} = \frac{\partial}{\partial x}(2x^2z) = 4xz$$

$$\frac{\partial A_2}{\partial y} = \frac{\partial}{\partial y}(-xy^2z) = -2xyz$$

$$\frac{\partial A_3}{\partial z} = \frac{\partial}{\partial z}(3yz^2) = 6yz$$

$$\text{Thus } \nabla \cdot \vec{A} = 4xz - 2xyz + 6yz,$$

$$\nabla \cdot \vec{A} \Big|_{(1,1,1)} = 8.$$

Example 2: Determine the constant b such that

$\vec{A} = (bx + 4y^2z)\vec{i} + (x^3 \sin z - 3y)\vec{j} - (e^x + 4 \cos x^2 y)\vec{k}$ is solenoidal.

Solution: $\nabla \cdot \vec{A} = b - 3 = 0 \quad \therefore b = 3.$

Example 3: Find the directional derivative of $\nabla \cdot \vec{U}$ at the point $(4, 4, 2)$ in the direction of the corresponding outer normal of the sphere $x^2 + y^2 + z^2 = 36$ where $\vec{U} = x^4\vec{i} + y^4\vec{j} + z^4\vec{k}$.

Solution: Let $f = \nabla \cdot \vec{U} = \nabla \cdot (x^4\vec{i} + y^4\vec{j} + z^4\vec{k}) = 4(x^3 + y^3 + z^3)$

$$\begin{aligned} \nabla f \Big|_{(4,4,2)} &= 12(x^2\vec{i} + y^2\vec{j} + z^2\vec{k}) \Big|_{4,4,2} \\ &= 48(4\vec{i} + 4\vec{j} + 2\vec{k}) \end{aligned}$$

Normal to the sphere $g = x^2 + y^2 + z^2 = 36$ is

$$\nabla g \Big|_{4,4,2} = 2(xi + yj + zk) \Big|_{4,4,2} = 4(2i + 2j + k)$$

$$\begin{aligned} \vec{a} = \text{unit normal} &= \frac{\nabla g}{|\nabla g|} = \frac{4(2i + 2j + k)}{\sqrt{64 + 64 + 16}} \\ &= \frac{2i + 2j + k}{3} \end{aligned}$$

The required directional derivative is

$$\begin{aligned} \nabla f \cdot \vec{a} &= 48(4i + 4j + 2k) \cdot \frac{(2i + 2j + k)}{3} \\ &= 16(8 + 8 + 1) = 272. \end{aligned}$$

Example 4: $\nabla \cdot (r^3 \vec{r})$.

Solution: Since $\nabla \cdot (f \vec{A}) = f \nabla \cdot \vec{A} + \nabla f \cdot \vec{A}$

$$\begin{aligned} \nabla \cdot (r^3 \vec{r}) &= r^3 \nabla \cdot \vec{r} + \vec{r} \cdot \nabla r^3 \\ &= 3r^3 + \vec{r} \cdot [3r^{3-2}\vec{r}] \\ &= 3r^3 + 3r\vec{r} \cdot \vec{r} \\ &= 3r^3 + 3r^2 = 6r^3. \end{aligned}$$

Example 5: If f and g are solutions of the Laplace equation show that

$$\nabla \cdot (f \nabla g - g \nabla f) = 0$$

Solution:

$$\begin{aligned} \nabla \cdot (f \nabla g - g \nabla f) &= \nabla \cdot (f \nabla g) - \nabla \cdot (g \nabla f) \\ &= f \nabla \cdot \nabla g + \nabla f \cdot \nabla g \end{aligned}$$

$$\begin{aligned}
 & -g \nabla \cdot \nabla f - \nabla g \cdot \nabla f \\
 & = f \nabla^2 g + \nabla f \cdot \nabla g \\
 & -g \nabla^2 f - \nabla g \cdot \nabla f = 0
 \end{aligned}$$

Note that $\nabla \cdot \nabla f = \nabla^2 f$.

Since f and g satisfy Laplace's equation we have $\nabla^2 f = 0$ and $\nabla^2 g = 0$, and also $\nabla f \cdot \nabla g = \nabla g \cdot \nabla f$ by commutative property.

Example 6: Find $\nabla(\nabla \cdot \bar{A})$ where $\bar{A} = \bar{r}/r$.

Solution: Consider

$$\begin{aligned}
 \nabla \cdot \bar{A} &= \nabla \cdot \left(\frac{\bar{r}}{r} \right) = r^{-1} \nabla \cdot \bar{r} + \bar{r} \cdot \nabla r^{-1} \\
 &= 3r^{-1} + \bar{r} \cdot (-r^{-1-2} \bar{r}) \\
 &= 3r^{-1} - r^{-3} \bar{r} \cdot \bar{r} \\
 &= 3r^{-1} - r^{-3} r^2 = 2r^{-1}
 \end{aligned}$$

$$\begin{aligned}
 \text{So } \nabla(\nabla \cdot \bar{A}) &= \nabla \left(\nabla \cdot \frac{\bar{r}}{r} \right) = \nabla(2r^{-1}) = 2 \nabla r^{-1} \\
 &= 2(-1)r^{-1-2} \bar{r} = -2r^{-3} \bar{r}.
 \end{aligned}$$

EXERCISE

1. Prove that $\nabla \cdot \bar{r} = 3$.
2. Find $\nabla \cdot \bar{A}$ when $\bar{A} = (x\bar{i} + y\bar{j} + z\bar{k})/r$ where $r = \sqrt{x^2 + y^2 + z^2}$.

Ans. $2/r$

3. Calculate $\nabla \cdot (3x^2\bar{i} + 5xy^2\bar{j} + xyz^3\bar{k})$ at the point $(1, 2, 3)$.

Ans. 80

4. If $\bar{A} = 3xyz^2\bar{i} + 2xy^3\bar{j} - x^2yz\bar{k}$ and $f = 3x^2 - yz$ find (i) $\nabla \cdot \bar{A}$ (ii) $\bar{A} \cdot \nabla f$ (iii) $\nabla \cdot (f\bar{A})$ (iv) $\nabla \cdot \nabla f$.

Ans. (i) 4 (ii) -15 (iii) 1 (iv) 6

5. Find $\nabla \cdot [(e^y \sin x \cos z)\bar{i} + e^{-x} \sin y \cos z \bar{j} + z^2 e^z \bar{k}]$.

Ans. $e^y \cos x \cdot \cos z + e^{-x} \cdot \cos y \cos z + (z^2 + 2z)e^z$

6. Show that $\bar{A} = 3y^4 z^2 \bar{i} + 4x^3 z^2 \bar{j} - 3x^2 y^2 \bar{k}$ is solenoidal.

7. Prove that $\bar{A} = (2x^2 + 8xy^2z)\bar{i} + (3x^3y - 3xy^3)\bar{j} - (4y^2z^2 + 2x^3z)\bar{k}$ is not solenoidal but $\bar{B} = xyz^2\bar{A}$ is solenoidal.

8. Determine the constant b such that $\bar{A} = (bx^2y + yz)\bar{i} + (xy^2 - xz^2)\bar{j} + (2xyz - 2x^2y^2)\bar{k}$ has zero divergence (i.e., $\nabla \cdot \bar{A} = 0$).

Ans. $b = -2$

9. Evaluate $\nabla \cdot [r \nabla(1/r^3)]$.

Ans. $3r^{-4}$

10. Find most general $f(r)$ such that $f(r)\bar{r}$ is solenoidal.

Ans. $f(r) = c/r^3$ where c is an arbitrary constant

11. Show that $\nabla f \times \nabla g$ is solenoidal.

Hint: $\nabla \cdot (\nabla f \times \nabla g) = \nabla g \cdot (\nabla \times \nabla f) - \nabla f \cdot (\nabla \times \nabla g) = 0$.

12. Prove that $\bar{A} = (y^2 - z^2 + 3yz - 2x)\bar{i} + (3xz + 2xy)\bar{j} + (3xy - 2xz + 2z)\bar{k}$ is both solenoidal and irrotational.

13. Show that $\nabla \cdot (f\bar{A}) = 5f$ where $f = x^2 + y^2 + z^2$ and $\bar{A} = x\bar{i} + y\bar{j} + z\bar{k}$.

14. Find the directional derivative of $\nabla \cdot \bar{U}$ at the point $(4, 4, 2)$ in the direction of the corresponding outer normal of the sphere $x^2 + y^2 + z^2 = 36$ where $\bar{U} = xz\bar{i} + yx\bar{j} + zy\bar{k}$.

Ans. $5/3$

15. Show that the vector field $\bar{V} = \frac{a(xi+yj)}{x^2+y^2}$ is a "source" or "sink" field according as $a > 0$ or $a < 0$.

Hint: If $\nabla \cdot \bar{V} > 0$ then $\bar{V}$ is a source field and if $\nabla \cdot \bar{V} < 0$ it is a sink field.

16. If $f = x^2yz$ and $g = xy - 3z^2$, calculate $\nabla(f \cdot \nabla g)$.

Ans. $2(y^3 + 3x^2y - 6xy^2)z\bar{i} + 2(3xy^2 + x^3 - 6x^2y)z\bar{j} + 2(xy^2 + x^3 - 3x^2y)y\bar{k}$.

15.4 CURL

Curl of $\bar{A}$, denoted by $\nabla \times \bar{A}$ also known as rotation $\bar{V}$ or rot of $\bar{V}$ is defined as

$$\begin{aligned}
 \text{curl of } \bar{A} &= \nabla \times \bar{A} = \left(i \frac{\partial}{\partial x} + j \frac{\partial}{\partial y} + k \frac{\partial}{\partial z} \right) \\
 &\quad \times (A_1\bar{i} + A_2\bar{j} + A_3\bar{k}) \\
 &= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ A_1 & A_2 & A_3 \end{vmatrix}
 \end{aligned}$$

15.12 — HIGHER ENGINEERING MATHEMATICS—IV

$$= i \left(\frac{\partial A_3}{\partial y} - \frac{\partial A_2}{\partial z} \right) + j \left(\frac{\partial A_1}{\partial z} - \frac{\partial A_3}{\partial x} \right) + k \left(\frac{\partial A_2}{\partial x} - \frac{\partial A_1}{\partial y} \right)$$

$\nabla \times \bar{A}$ = a vector quantity.

Irrotational Field

A vector point function $\bar{A}$ is said to be irrotational, if curl of $\bar{A}$ is zero at every point where $\bar{A}$ is defined. Otherwise it is said to be rotational. The curl of any vector point function, in general, gives the measure of the angular velocity at any point of the vector field.

WORKED OUT EXAMPLES

Example 1: Find the curl of $\bar{V} = e^{xyz}(\bar{i} + \bar{j} + \bar{k})$ at the point (1, 2, 3).

Solution: Curl of $\bar{V}$

$$\begin{aligned} \nabla \times \bar{V} &= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ e^{xyz} & e^{xyz} & e^{xyz} \end{vmatrix} \\ &= e^{xyz} [(xz - xy)\bar{i} - (yz - xy)\bar{j} + (yz - xz)\bar{k}] \end{aligned}$$

$$\nabla \times \bar{V} \Big|_{1,2,3} = e^6 [\bar{i} - 4\bar{j} + 3\bar{k}].$$

Example 2: Prove that $\nabla \times \nabla f = 0$ for any $f(x, y, z)$.

Solution:

$$\begin{aligned} \nabla \times \nabla f &= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{\partial f}{\partial x} & \frac{\partial f}{\partial y} & \frac{\partial f}{\partial z} \end{vmatrix} \\ &= i \left(\frac{\partial^2 f}{\partial y \partial z} - \frac{\partial^2 f}{\partial z \partial y} \right) - j \left(\frac{\partial^2 f}{\partial x \partial z} - \frac{\partial^2 f}{\partial z \partial x} \right) \\ &\quad + k \left(\frac{\partial^2 f}{\partial x \partial y} - \frac{\partial^2 f}{\partial y \partial x} \right) = 0 \end{aligned}$$

since $f_{yz} = f_{zy}$, $f_{xz} = f_{zx}$ and $f_{yx} = f_{xy}$.

Note: Since $\bar{V} = \nabla \phi$ for a conservative field, $\nabla \times \bar{V} = \nabla \times \nabla \phi = 0$. Thus for a conservative field $\bar{V}$, we have $\nabla \times \bar{V} = 0$.

Example 3: If $f(r)$ is differentiable and $r = \sqrt{x^2 + y^2 + z^2}$ show that $f(r)\bar{r}$ is irrotational. Hence deduce that (i) $r^n \bar{r}$ is irrotational (ii) $\nabla \times \bar{r} = 0$.

Solution: Here $f(r)\bar{r} = f(r)[xi + yj + zk]$

$$\begin{aligned} \nabla \times (f(r)\bar{r}) &= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ xf(r) & yf(r) & zf(r) \end{vmatrix} \\ &= i \left(\frac{z \partial f}{\partial y} - \frac{y \partial f}{\partial z} \right) - j \left(\frac{z \partial f}{\partial x} - \frac{x \partial f}{\partial z} \right) \\ &\quad + k \left(\frac{y \partial f}{\partial x} - \frac{x \partial f}{\partial y} \right) \end{aligned}$$

$$\text{Here } \frac{\partial f(r)}{\partial y} = \frac{\partial}{\partial r} f(r) \cdot \frac{\partial r}{\partial y} = f'(r) \cdot \frac{y}{r}$$

$$\begin{aligned} \text{since } \frac{\partial r}{\partial y} &= \frac{\partial}{\partial y} \sqrt{x^2 + y^2 + z^2} \\ &= \frac{1}{2} \frac{2y}{\sqrt{x^2 + y^2 + z^2}} = \frac{y}{r} \end{aligned}$$

$$\text{Similarly, } \frac{\partial f}{\partial x} = f' \frac{x}{r} \text{ and } \frac{\partial f}{\partial z} = f' \frac{z}{r}$$

Substituting these values

$$\begin{aligned} \nabla \times (f\bar{r}) &= i \left[zf' \frac{y}{r} - yf' \frac{z}{r} \right] - j \left[zf' \frac{x}{r} - xf' \frac{z}{r} \right] \\ &\quad + k \left[yf' \frac{x}{r} - xf' \frac{y}{r} \right] \\ &= 0 \end{aligned}$$

i. with $f(r) = r^n$.

$$\nabla \times (r^n \bar{r}) = \nabla (f(r)\bar{r}) = 0$$

follows from the above result.

ii. with $n = 0$, $\nabla \times \bar{r} = 0$ from above result (i).

Example 4: Prove that $\bar{A} = (6xy + z^3)\bar{i} + (3x^2 - z)\bar{j} + (3xz^2 - y)\bar{k}$ is irrotational. Find a scalar function $f(x, y, z)$ such that $\bar{A} = \nabla f$.

Solution:

$$\begin{aligned} \nabla \times \bar{A} &= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 6xy + z^3 & 3x^2 - z & 3xz^2 - y \end{vmatrix} \\ &= i[-1 - (-1)] - j[3z^2 - 3z^2] + k[6x - 6x] = 0 \end{aligned}$$

Therefore $\bar{A}$ is irrotational.

$$\text{To find } f : \bar{A} = \nabla f = \frac{\partial f}{\partial x}i + \frac{\partial f}{\partial y}j + \frac{\partial f}{\partial z}k$$

comparing components of i, j, k on either side

$$\frac{\partial f}{\partial x} = 6xy + z^3 \quad (1)$$

$$\frac{\partial f}{\partial y} = 3x^2 - z \quad (2)$$

$$\frac{\partial f}{\partial z} = 3xz^2 - y \quad (3)$$

Integrating (1) partially w.r.t. x , we get

$$f = 3x^2y + xz^3 + c_1(y, z) \quad (4)$$

Differentiating (4) partially w.r.t. y and equating it with (2), we get

$$3x^2 + 0 + \frac{\partial c_1}{\partial y} = \frac{\partial f}{\partial y} = 3x^2 - z$$

$$\text{i.e.,} \quad \frac{\partial c_1}{\partial y} = -z \quad (5)$$

Integrating (5) partially w.r.t. y , we have

$$c_1(y, z) = -zy + c_2(z) \quad (6)$$

Substituting (6) in (4)

$$f = 3x^2y + xz^3 - zy + c_2(z) \quad (7)$$

Differentiating (7) partially w.r.t. z and equating it with (3), we get

$$0 + 3xz^2 - y + \frac{dc_2}{dz} = 3xz^2 - y$$

$$\text{So} \quad \frac{dc_2}{dz} = 0$$

i.e., c_2 = a pure constant (independent of z)

Thus the required scalar function

$$f = 3x^2y + xz^3 - zy + c_2.$$

Example 5: Find curl curl of $\bar{A} = x^2y\bar{i} - 2xzj + 2yz\bar{k}$ at the point $(1, 0, 2)$.

Solution:

$$\nabla \times \bar{A} = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x^2y & -2xz & 2yz \end{vmatrix}$$

$$\nabla \times \bar{A} = i[2z + 2x] - j[0 - 0] + k[-2z - x^2]$$

$$\begin{aligned} \text{Now } \nabla \times (\nabla \times \bar{A}) &= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 2(z+x) & 0 & -(2z+x^2) \end{vmatrix} \\ &= i[0 - 0] - j[-2x - 2] + k[0 - 0] \\ &= 2(x+1)\bar{j} \\ \nabla \times (\nabla \times \bar{A}) \Big|_{\text{at } (1,0,2)} &= 2(1+i)\bar{j} = 4\bar{j}. \end{aligned}$$

EXERCISE

1. Prove that $\nabla \times \bar{r} = 0$.

2. Find the curl of $yz\bar{i} + 3zx\bar{j} + z\bar{k}$ at $(2, 3, 4)$.

Ans. $-6\bar{i} + 3\bar{j} + 8\bar{k}$

3. Find $\nabla \times [(yz - 2x^2y)\bar{i} + x(y^2 - z^2)\bar{j} + 2xy(z - xy)\bar{k}]$ at the point $(1, 1, 1)$.

Ans. $4x(z - xy)\bar{i} + (y - 2yz + 4xy^2)\bar{j} + (2x^2 + y^2 - z^2 - z)\bar{k}; 3\bar{j} + \bar{k}$

4. If $f = x^2yz$, $g = xy - 3z^2$, calculate $\nabla \cdot (\nabla f \times \nabla g)$.

Ans. zero

5. Determine curl of $xyz^2\bar{i} + yzx^2\bar{j} + zxy^2\bar{k}$ at the point $(1, 2, 3)$.

Ans. $xy(2z - x)\bar{i} + yz(2x - y)\bar{j} + zx(2y - z)\bar{k}; 10\bar{i} + 3\bar{k}$

6. If $\bar{A}$ and $\bar{B}$ are irrotational show that $\nabla \cdot (\bar{A} \times \bar{B}) = 0$.

7. Determine the constants a and b such that curl of $(2xy + 3yz)\bar{i} + (x^2 + axz - 4z^2)\bar{j} + (3xy + 2byz)\bar{k} = 0$.

Ans. $a = 3, b = 4$.

8. Find the value of constant b such that

$$\bar{A} = (bxy - z^3)\bar{i} + (b - 2)x^2\bar{j} + (1 - b)xz^2\bar{k}$$

has its curl identically equal to zero.

Ans. $b = 4$

9. Evaluate $\nabla \times (\bar{r}r^{-2})$. Find f such that $\bar{r}r^{-2} = -\nabla f$ with $f(a) = 0$ where $a > 0$.

Ans. $f = \ln(a/r)$

15.14 — HIGHER ENGINEERING MATHEMATICS—IV

10. Determine the constants a, b, c so that

$$\bar{A} = (x + 2y + az)i + (bx - 3y - z)j + (4x + cy + 2z)k$$

is irrotational. Find a scalar function $f(x, y, z)$ such that $\bar{A} = \nabla f$.

Ans. i. $a = 4, b = 2, c = -1$

ii. $f = \frac{x^2}{2} - \frac{3y^2}{2} + z^2 + 2xy + 4xz - yz$

11. Prove that $\bar{A} = (x^2 - yz)i + (y^2 - zx)j + (z^2 - xy)k$ is irrotational and find the scalar potential f such that $\bar{A} = \nabla f$.

Ans. $f(x, y, z) = \frac{x^3 + y^3 + z^3}{3} - xyz$

12. Show that $\nabla \times (\nabla \times (\nabla \times (\nabla \times \bar{A}))) = \nabla^4 \bar{A}$ where $\bar{A}$ is a solenoidal vector.

13. Prove that $(y^2 - z^2 + 3yz - 2x)i + (3xz + 2xy)j + (3xy - 2xz + 2z)$ is both solenoidal and irrotational.

14. Prove that $\nabla \cdot (\nabla \times \bar{A}) = 0$.

15.5 RELATED PROPERTIES OF GRADIENT, DIVERGENCE AND CURL OF SUMS

The gradient, divergence and curl are distributive with respect to the sum and difference of functions:

1. $\nabla(f \pm g) = \nabla f \pm \nabla g$

2. $\nabla \cdot (\bar{A} \pm \bar{B}) = (\nabla \cdot \bar{A}) \pm (\nabla \cdot \bar{B})$

3. $\nabla \times (\bar{A} \pm \bar{B}) = (\nabla \times \bar{A}) \pm (\nabla \times \bar{B})$.

The above results follow, since derivative of sum or difference of scalars or vectors is sum or difference of the derivatives of scalars or vectors. For example,

$$\begin{aligned} \nabla \cdot (\bar{A} \pm \bar{B}) &= \nabla \cdot ((A_1 \pm B_1)i + (A_2 \pm B_2)j + (A_3 \pm B_3)k) \\ &= \frac{\partial}{\partial x}(A_1 \pm B_1) + \frac{\partial}{\partial y}(A_2 \pm B_2) + \frac{\partial}{\partial z}(A_3 \pm B_3) \\ &= \left(\frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \right) \pm \left(\frac{\partial B_1}{\partial x} + \frac{\partial B_2}{\partial y} + \frac{\partial B_3}{\partial z} \right) \end{aligned}$$

$$\begin{aligned} &\pm \left(\frac{\partial B_1}{\partial x} + \frac{\partial B_2}{\partial y} + \frac{\partial B_3}{\partial z} \right) \\ &= \nabla \cdot \bar{A} \pm \nabla \cdot \bar{B}. \end{aligned}$$

Gradient, Divergence and Curl of Products

1. $\nabla(fg) = f\nabla g + g\nabla f$

2. $\nabla \cdot (f\bar{A}) = f\nabla \cdot \bar{A} + (\nabla f) \cdot \bar{A}$

3. $\nabla \times (f\bar{A}) = f\nabla \times \bar{A} + (\nabla f) \times \bar{A}$

4. $\nabla(\bar{A} \cdot \bar{B}) = (\bar{B} \cdot \nabla)\bar{A} + (\bar{A} \cdot \nabla)\bar{B} + \bar{B} \times (\nabla \times \bar{A}) + \bar{A} \times (\nabla \times \bar{B})$

5. $\nabla \cdot (\bar{A} \times \bar{B}) = \bar{B} \cdot (\nabla \times \bar{A}) - \bar{A} \cdot (\nabla \times \bar{B})$

6. $\nabla \times (\bar{A} \times \bar{B}) = (\bar{B} \cdot \nabla)\bar{A} - \bar{B}(\nabla \cdot \bar{A}) - (\bar{A} \cdot \nabla)\bar{B} + \bar{A}(\nabla \cdot \bar{B})$.

The results 1, 2, 3 follow from the fact that the derivative of a product of scalar functions is the product of the derivatives of the scalar functions.

For example,

$$\nabla \times (f\bar{A}) = \nabla \times (f(A_1i + A_2j + A_3k))$$

$$= \nabla \times (fA_1i + fA_2j + fA_3k)$$

$$= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ fA_1 & fA_2 & fA_3 \end{vmatrix}$$

$$= i \left[\frac{\partial(fA_3)}{\partial y} - \frac{\partial(fA_2)}{\partial z} \right]$$

$$- j \left[\frac{\partial(fA_3)}{\partial x} - \frac{\partial(fA_1)}{\partial z} \right]$$

$$+ k \left[\frac{\partial(fA_2)}{\partial x} - \frac{\partial(fA_1)}{\partial y} \right]$$

Expanding the product of the derivatives and rearranging the terms, we get

$$\begin{aligned} &= f \left[i \left(\frac{\partial A_3}{\partial y} - \frac{\partial A_2}{\partial z} \right) - j \left(\frac{\partial A_3}{\partial x} - \frac{\partial A_1}{\partial z} \right) \right. \\ &\quad \left. + k \left(\frac{\partial A_2}{\partial x} - \frac{\partial A_1}{\partial y} \right) \right] + i \left(A_3 \frac{\partial f}{\partial y} - A_2 \frac{\partial f}{\partial z} \right) \\ &\quad - j \left(A_3 \frac{\partial f}{\partial x} - A_1 \frac{\partial f}{\partial z} \right) + k \left(A_2 \frac{\partial f}{\partial x} - A_1 \frac{\partial f}{\partial y} \right) \end{aligned}$$

$$\nabla \times (f\bar{A}) = f\nabla \times \bar{A} + (\nabla f) \times \bar{A}.$$

Example 1: Prove that $\nabla \cdot (\bar{A} \times \bar{B}) = \bar{B} \cdot (\nabla \times \bar{A}) - \bar{A} \cdot (\nabla \times \bar{B})$.

Solution:

$$\bar{A} \times \bar{B} = \begin{vmatrix} i & j & k \\ A_1 & A_2 & A_3 \\ B_1 & B_2 & B_3 \end{vmatrix}$$

$$\bar{A} \times \bar{B} = i(A_2B_3 - A_3B_2) - j(A_1B_3 - A_3B_1) + k(A_1B_2 - A_2B_1)$$

$$\begin{aligned} \nabla \cdot (\bar{A} \times \bar{B}) &= \frac{\partial}{\partial x}(A_2B_3 - A_3B_2) - \frac{\partial}{\partial y}(A_1B_3 - A_3B_1) \\ &\quad + \frac{\partial}{\partial z}(A_1B_2 - A_2B_1). \end{aligned}$$

Expanding the derivatives of the products and rearranging the 12 terms in to 2 groups of 6 terms each, we get

$$\begin{aligned} \nabla \cdot (\bar{A} \times \bar{B}) &= \left[B_1 \left(\frac{\partial A_3}{\partial y} - \frac{\partial A_2}{\partial z} \right) + B_2 \left(\frac{\partial A_1}{\partial z} - \frac{\partial A_3}{\partial x} \right) \right. \\ &\quad \left. + B_3 \left(\frac{\partial A_2}{\partial x} - \frac{\partial A_1}{\partial y} \right) \right] - \left[A_1 \left(\frac{\partial B_3}{\partial y} - \frac{\partial B_2}{\partial z} \right) \right. \\ &\quad \left. + A_2 \left(\frac{\partial B_1}{\partial z} - \frac{\partial B_3}{\partial x} \right) + A_3 \left(\frac{\partial B_2}{\partial x} - \frac{\partial B_1}{\partial y} \right) \right] \end{aligned}$$

$$\nabla \cdot (\bar{A} \times \bar{B}) = \bar{B} \cdot (\nabla \times \bar{A}) - \bar{A} \cdot (\nabla \times \bar{B}).$$

Example 2: Prove that

$$\begin{aligned} \nabla \times (\bar{A} \times \bar{B}) &= (\bar{B} \cdot \nabla) \bar{A} - \bar{B} (\nabla \cdot \bar{A}) \\ &\quad - (\bar{A} \cdot \nabla) \bar{B} + \bar{A} (\nabla \cdot \bar{B}). \end{aligned}$$

Solution:

$$\begin{aligned} \nabla \times (\bar{A} \times \bar{B}) &= \left(\bar{i} \frac{\partial}{\partial x} + \bar{j} \frac{\partial}{\partial y} + \bar{k} \frac{\partial}{\partial z} \right) \times (\bar{A} \times \bar{B}) \\ &= i \times \frac{\partial}{\partial x} (\bar{A} \times \bar{B}) + j \times \frac{\partial}{\partial y} (\bar{A} \times \bar{B}) \\ &\quad + k \times \frac{\partial}{\partial z} (\bar{A} \times \bar{B}) \end{aligned}$$

Expanding the derivative of the products, we get 6 terms,

$$\begin{aligned} &= \left[i \times \left(\frac{\partial \bar{A}}{\partial x} \times \bar{B} \right) + i \times \left(\bar{A} \times \frac{\partial \bar{B}}{\partial x} \right) \right] \\ &\quad + \left[j \times \left(\frac{\partial \bar{A}}{\partial y} \times \bar{B} \right) + j \times \left(\bar{A} \times \frac{\partial \bar{B}}{\partial y} \right) \right] \end{aligned}$$

$$+ \left[\bar{k} \times \left(\frac{\partial \bar{A}}{\partial z} \times \bar{B} \right) + \bar{k} \times \left(\bar{A} \times \frac{\partial \bar{B}}{\partial z} \right) \right] \quad (1)$$

$$\text{Since } \bar{a} \times (\bar{b} \times \bar{c}) = (\bar{a} \cdot \bar{c})\bar{b} - (\bar{a} \cdot \bar{b})\bar{c},$$

$$\begin{aligned} \bar{i} \times \left(\frac{\partial \bar{A}}{\partial x} \times \bar{B} \right) &= (\bar{i} \cdot \bar{B}) \frac{\partial \bar{A}}{\partial x} - \left(\bar{i} \cdot \frac{\partial \bar{A}}{\partial x} \right) \bar{B} \\ &= (\bar{B} \cdot \bar{i}) \frac{\partial \bar{A}}{\partial x} - \left(\bar{i} \cdot \frac{\partial \bar{A}}{\partial x} \right) \bar{B} \quad (2) \end{aligned}$$

We get similar results for the 3rd and 5th terms in the R.H.S. of (1). Collecting these 3 terms from the R.H.S. of (1), namely 1st, 3rd and 5th terms and using the summation notation with respect to i (and x), we get

$$\begin{aligned} &i \times \left(\frac{\partial \bar{A}}{\partial x} \times \bar{B} \right) + j \times \left(\frac{\partial \bar{A}}{\partial y} \times \bar{B} \right) \\ &\quad + \bar{k} \times \left(\frac{\partial \bar{A}}{\partial z} \times \bar{B} \right) \\ &= \sum \bar{i} \times \left(\frac{\partial \bar{A}}{\partial x} \times \bar{B} \right) \\ &= \sum \left(\bar{B} \cdot \bar{i} \frac{\partial}{\partial x} \right) \bar{A} - \sum \left(\bar{i} \cdot \frac{\partial}{\partial x} \cdot \bar{A} \right) \bar{B} \end{aligned}$$

Since the summation is with respect to i , we get

$$\begin{aligned} &= \left(\bar{B} \cdot \sum \bar{i} \frac{\partial}{\partial x} \right) \bar{A} \\ &\quad - \left\{ \left(\sum \bar{i} \frac{\partial}{\partial x} \right) \cdot \bar{A} \right\} \bar{B} \\ \sum \bar{i} \times \left(\frac{\partial \bar{A}}{\partial x} \times \bar{B} \right) &= (\bar{B} \cdot \nabla) \bar{A} - (\nabla \cdot \bar{A}) \bar{B} \quad (3) \end{aligned}$$

In a similar manner, interchanging the roles of $\bar{A}$ and $\bar{B}$, for the remaining 3 terms namely 2nd, 4th and 6th terms of (1), we get

$$\sum i \times \left(\bar{A} \times \frac{\partial \bar{B}}{\partial x} \right) = (\nabla \cdot \bar{B}) \bar{A} - (\bar{A} \cdot \nabla) \bar{B} \quad (4)$$

Adding (3) and (4) the required result is obtained.

Example 3: Prove that

$$\begin{aligned} \nabla (\bar{A} \cdot \bar{B}) &= \bar{A} \times (\nabla \times \bar{B}) + \bar{B} \times (\nabla \times \bar{A}) \\ &\quad + (\bar{A} \cdot \nabla) \bar{B} + (\bar{B} \cdot \nabla) \bar{A}. \end{aligned}$$

15.16 — HIGHER ENGINEERING MATHEMATICS—IV

Solution: $\nabla(\bar{A} \cdot \bar{B}) = i \frac{\partial}{\partial x}(\bar{A} \cdot \bar{B}) + j \frac{\partial}{\partial y}(\bar{A} \cdot \bar{B}) + k \frac{\partial}{\partial z}(\bar{A} \cdot \bar{B})$.

Expanding the derivative of the product terms and rearranging the 6 terms, we get

$$\begin{aligned}\nabla(\bar{A} \cdot \bar{B}) &= \sum i \frac{\partial}{\partial x}(\bar{A} \cdot \bar{B}) \\ &= \left(\sum i \frac{\partial}{\partial x} \bar{A} \right) \cdot \bar{B} + \bar{A} \cdot \sum i \frac{\partial \bar{B}}{\partial x} \quad (1)\end{aligned}$$

Consider

$$\begin{aligned}\bar{A} \times (\nabla \times \bar{B}) &= \bar{A} \times \left(\left(\sum i \frac{\partial}{\partial x} \right) \times \bar{B} \right) \\ &= \bar{A} \times \left(\sum i \times \frac{\partial \bar{B}}{\partial x} \right)\end{aligned}$$

Using triple cross product result

$$\begin{aligned}&= \sum \left(\bar{A} \cdot \frac{\partial \bar{B}}{\partial x} \right) i - \left(\bar{A} \cdot \sum i \right) \frac{\partial \bar{B}}{\partial x} \\ &= \sum i \left(\bar{A} \cdot \frac{\partial \bar{B}}{\partial x} \right) - \left(\bar{A} \cdot \sum i \frac{\partial}{\partial x} \right) \bar{B}\end{aligned}$$

$$\bar{A} \times (\nabla \times \bar{B}) = \sum i \left(\frac{\partial \bar{B}}{\partial x} \cdot \bar{A} \right) - (\bar{A} \cdot \nabla) \bar{B}$$

Rewriting, we have

$$\begin{aligned}\bar{A} \times (\nabla \times \bar{B}) + (\bar{A} \cdot \nabla) \bar{B} &= \left(\sum i \frac{\partial \bar{B}}{\partial x} \right) \cdot \bar{A} \\ &= \bar{A} \cdot \left(\sum i \frac{\partial \bar{B}}{\partial x} \right) \quad (2)\end{aligned}$$

Similarly (interchanging the roles of $\bar{A}$ and $\bar{B}$), we get

$$\bar{B} \times (\nabla \times \bar{A}) + (\bar{B} \cdot \nabla) \bar{A} = \bar{B} \cdot \left(\sum i \frac{\partial \bar{A}}{\partial x} \right) \quad (3)$$

Addition of (2) and (3) gives the desired result.

15.6 SECOND-ORDER DIFFERENTIAL OPERATOR

It is a two-fold application of the operator ∇ to function.

Laplacian Operator ∇^2

$$\text{div grad } f = \nabla \cdot (\nabla f)$$

$$\begin{aligned}&= \nabla \cdot \left(i \frac{\partial f}{\partial x} + j \frac{\partial f}{\partial y} + k \frac{\partial f}{\partial z} \right) \\ &= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) + \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right) + \frac{\partial}{\partial z} \left(\frac{\partial f}{\partial z} \right) \\ &= \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2} \\ &= \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) f \\ &= \nabla^2 f = \Delta f\end{aligned}$$

Thus the scalar differential operator (read as “nabla squared” or “delta”)

$$\nabla^2 = \Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$$

is known as the Laplacian operator.

Thus we have following second order differential operators:

1. $\nabla \cdot \nabla f = \text{div grad } f = \nabla^2 f = \Delta f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}$
2. $\nabla \times \nabla f = \text{curl grad } f = 0$
3. $\nabla \cdot \nabla \times \bar{A} = \text{div cur } \bar{A} = 0$
4. $\nabla \times (\nabla \times \bar{A}) = \text{curl curl } \bar{A} = \nabla(\nabla \cdot \bar{A}) - \nabla^2 \bar{A}$
(4) may be rewritten as
5. $\nabla(\nabla \cdot \bar{A}) = \text{grad div } \bar{A} = \nabla \times (\nabla \times \bar{A}) + \nabla^2 \bar{A}$

The possible combinations of second order differential operators are tabulated below:

	Scalar field f	Vector field $\bar{A}$	
	grad	div	curl
grad	—	grad div $\bar{A}$	—
div	div grad f $= \Delta f$	—	div curl $\bar{A} = 0$
curl	curl grad $f = 0$	—	curl curl $\bar{A} =$ grad div $\bar{A}$ $-\Delta \bar{A}$

Example 1: Prove that $\nabla \times \nabla f = 0$ for any scalar function f .

Solution: $\nabla f = \frac{\partial f}{\partial x}i + \frac{\partial f}{\partial y}j + \frac{\partial f}{\partial z}k$ so

$$\begin{aligned}\nabla \times \nabla f &= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{\partial f}{\partial x} & \frac{\partial f}{\partial y} & \frac{\partial f}{\partial z} \end{vmatrix} \\ &= i \left(\frac{\partial^2 f}{\partial y \partial z} - \frac{\partial^2 f}{\partial z \partial y} \right) - j \left(\frac{\partial^2 f}{\partial x \partial z} - \frac{\partial^2 f}{\partial z \partial x} \right) \\ &\quad + k \left(\frac{\partial^2 f}{\partial x \partial y} - \frac{\partial^2 f}{\partial y \partial x} \right) \\ &= 0 + 0 + 0 = \bar{0}\end{aligned}$$

Since $f_{yz} = f_{zy}$, $f_{xz} = f_{zx}$, $f_{xy} = f_{yx}$.

Note: Gradient field describing a motion, in this case, is known as “irrotational”.

If gradient field is not a velocity field, then it is known as “conservative”.

Example 2: Prove that $\nabla \cdot (\nabla \times \bar{A}) = 0$ for any vector function $\bar{A}$.

Solution:

$$\begin{aligned}\nabla \times \bar{A} &= i \left(\frac{\partial A_3}{\partial y} - \frac{\partial A_2}{\partial z} \right) - j \left(\frac{\partial A_3}{\partial x} - \frac{\partial A_1}{\partial z} \right) \\ &\quad + k \left(\frac{\partial A_2}{\partial x} - \frac{\partial A_1}{\partial y} \right)\end{aligned}$$

So that

$$\begin{aligned}\nabla \cdot (\nabla \times \bar{A}) &= \frac{\partial}{\partial x} \left[\left(\frac{\partial A_3}{\partial y} - \frac{\partial A_2}{\partial z} \right) \right] + \frac{\partial}{\partial y} \left[\frac{\partial A_1}{\partial z} - \frac{\partial A_3}{\partial x} \right] \\ &\quad + \frac{\partial}{\partial z} \left(\frac{\partial A_2}{\partial x} - \frac{\partial A_1}{\partial y} \right) \\ &= \frac{\partial^2 A_3}{\partial x \partial y} - \frac{\partial^2 A_2}{\partial x \partial z} + \frac{\partial^2 A_1}{\partial y \partial z} - \frac{\partial^2 A_3}{\partial y \partial x} \\ &\quad + \frac{\partial^2 A_2}{\partial z \partial x} - \frac{\partial^2 A_1}{\partial z \partial y} = 0.\end{aligned}$$

Example 3: Show that $\nabla \times (\nabla \times \bar{A}) = \nabla(\nabla \cdot \bar{A}) - \nabla^2 \bar{A}$.

Solution:

$$\nabla \times (\nabla \times \bar{A})$$

$$= \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{\partial A_3}{\partial y} - \frac{\partial A_2}{\partial z} & \frac{\partial A_1}{\partial z} - \frac{\partial A_3}{\partial x} & \frac{\partial A_2}{\partial x} - \frac{\partial A_1}{\partial y} \end{vmatrix}$$

Expanding the determinant, we have

$$\begin{aligned}\nabla \times (\nabla \times \bar{A}) &= \left(\frac{\partial^2 A_2}{\partial y \partial x} - \frac{\partial^2 A_1}{\partial y^2} - \frac{\partial^2 A_1}{\partial z^2} + \frac{\partial^2 A_3}{\partial z \partial x} \right) \bar{i} \\ &\quad + \left(\frac{\partial^2 A_3}{\partial z \partial y} - \frac{\partial^2 A_2}{\partial z^2} - \frac{\partial^2 A_2}{\partial x^2} + \frac{\partial^2 A_1}{\partial x \partial y} \right) \bar{j} \\ &\quad + \left(\frac{\partial^2 A_1}{\partial x \partial z} - \frac{\partial^2 A_3}{\partial x^2} - \frac{\partial^2 A_3}{\partial y^2} + \frac{\partial^2 A_2}{\partial y \partial z} \right) \bar{k}\end{aligned}$$

Rearranging the 12 terms into 2 groups of 6 terms each, we get

$$\begin{aligned}\nabla \times (\nabla \times \bar{A}) &= \left[i \frac{\partial}{\partial x} \left\{ \frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \right\} \right. \\ &\quad \left. - i \left(\frac{\partial^2 A_1}{\partial x^2} + \frac{\partial^2 A_1}{\partial y^2} + \frac{\partial^2 A_1}{\partial z^2} \right) \right] \\ &\quad + \left[j \frac{\partial}{\partial y} \left\{ \frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \right\} \right. \\ &\quad \left. - j \left(\frac{\partial^2 A_2}{\partial x^2} + \frac{\partial^2 A_2}{\partial y^2} + \frac{\partial^2 A_2}{\partial z^2} \right) \right] \\ &\quad + \left[k \frac{\partial}{\partial z} \left\{ \frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \right\} \right. \\ &\quad \left. - k \left(\frac{\partial^2 A_3}{\partial x^2} + \frac{\partial^2 A_3}{\partial y^2} + \frac{\partial^2 A_3}{\partial z^2} \right) \right] \\ &= \left(\bar{i} \frac{\partial}{\partial x} + \bar{j} \frac{\partial}{\partial y} + \bar{k} \frac{\partial}{\partial z} \right) \times \left(\frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \right) \\ &\quad - \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) (A_1 \bar{i} + A_2 \bar{j} + A_3 \bar{k})\end{aligned}$$

$$\nabla \times (\nabla \times \bar{A}) = \nabla(\nabla \cdot \bar{A}) - \nabla^2 \bar{A}.$$

Example 4: Prove that

$\nabla \times (f \nabla g) = \nabla f \times \nabla g = -\nabla \times (g \nabla f)$ and deduce that $\nabla \times (f \nabla f) = 0$

Solution: $\nabla \times (f \nabla g) = \nabla f \times \nabla g + f \nabla \times \nabla g = \nabla f \times \nabla g$, also

$$-\nabla \times (g \nabla f) = -\nabla g \times \nabla f - g \nabla \times \nabla f$$

15.18 — HIGHER ENGINEERING MATHEMATICS—IV

$$= \nabla f \times \nabla g - 0$$

since $\nabla \times \nabla g = 0$.

Taking $f = g$, $\nabla \times (f \nabla f) = \nabla f \times \nabla f = 0$.

Example 5: Prove that $\nabla \cdot (f \nabla g \times g \nabla f) = 0$.

Solution: Since $\nabla \cdot (\bar{A} \times \bar{B}) = \bar{B} \cdot (\nabla \times \bar{A}) - \bar{A} \cdot (\nabla \times \bar{B})$

$$\begin{aligned} \nabla \cdot (f \nabla g \times g \nabla f) &= g \nabla f \cdot (\nabla \times (f \nabla g)) \\ &\quad - f \nabla g \cdot (\nabla \times (g \nabla f)) \\ &= 0 \end{aligned}$$

Since $\nabla \times (f \nabla g) = \nabla f \times \nabla g$ and $\nabla \times (g \nabla f) = -\nabla f \times \nabla g$, from just above example.

Example 6: Prove that

$$\nabla \cdot (f \nabla \times \bar{A}) = \nabla f \cdot (\nabla \times \bar{A}).$$

Solution:

$$\begin{aligned} \nabla \cdot (f \nabla \times \bar{A}) &= \nabla f \cdot (\nabla \times \bar{A}) + f \nabla \cdot (\nabla \times \bar{A}) \\ &= \nabla f \cdot (\nabla \times \bar{A}) \end{aligned}$$

Since $\nabla \cdot (\nabla \times \bar{A}) = 0$.

WORKED OUT EXAMPLES

Laplacian ∇^2

Example 1: Calculate $\nabla^2 f$ when $f = 3x^2z - y^2z^3 + 4x^3y + 2x - 3y - 5$ at the point $(1, 1, 0)$.

Solution:

$$\begin{aligned} \nabla^2 f &= \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) \\ &\quad \times (3x^2z - y^2z^3 + 4x^3y + 2x - 3y - 5) \end{aligned}$$

Consider

$$\begin{aligned} \frac{\partial}{\partial x} (3x^2z - y^2z^3 + 4x^3y + 2x - 3y - 5) \\ = 6xz + 12x^2y + 2 \end{aligned}$$

$$\begin{aligned} \frac{\partial^2}{\partial x^2} (3x^2z - y^2z^3 + 4x^3y + 2x - 3y - 5) \\ = 6z + 24xy. \end{aligned}$$

Similarly,

$$\frac{\partial^2}{\partial y^2} f = -2z^3$$

and

$$\frac{\partial^2}{\partial z^2} f = -6y^2z$$

Thus substituting these values, we have

$$\nabla^2 f = 6z + 24xy - 2z^3 - 6y^2z$$

$\nabla^2 f$ at the point $(1, 1, 0)$ is $0 + 24 \cdot 1 \cdot 1 + 0 + 0 = 24$.

Example 2: Prove that

a. $\nabla^2 f(r) = \frac{d^2 f}{dr^2} + \frac{2}{r} \frac{df}{dr}$

b. Find $f(r)$ such that $\nabla^2 f(r) = 0$.

Solution:

a. $\nabla^2 f(r) = \nabla \cdot \nabla f(r)$

Since $\frac{\partial f}{\partial x} = \frac{\partial f}{\partial r} \frac{\partial r}{\partial x} = \frac{\partial f}{\partial r} \frac{x}{r}$

$$\nabla f(r) = \frac{\partial f}{\partial r} (xi + yj + zk) \frac{1}{r}$$

i.e., $\nabla f(r) = \frac{\bar{r}}{r} \frac{df}{dr} = \bar{r} \left(\frac{f'(r)}{r} \right)$ (1)

Using (1), we have

$$\nabla^2 f(r) = \nabla \cdot (\nabla f(r)) = \nabla \cdot \left(\bar{r} \frac{f'(r)}{r} \right) = \nabla \cdot \left(\bar{r} \left(\frac{f'(r)}{r} \right) \right)$$

Applying the result

$$\nabla \cdot (\bar{A} f) = f(\nabla \cdot \bar{A}) + (\nabla f) \cdot \bar{A}$$

$$\nabla^2 f = \nabla \cdot \left(\bar{r} \left(\frac{f'(r)}{r} \right) \right) = \frac{f'}{r} \nabla \cdot \bar{r} + \left(\nabla \frac{f'}{r} \right) \cdot \bar{r} \quad (2)$$

Consider

$$\nabla \left(\frac{f'}{r} \right) = \nabla(f' r^{-1}) = r^{-1} \nabla f' + f' \nabla r^{-1}$$

Using (1) for f' , we get

$$\nabla f' = \bar{r} \frac{f''}{r}$$

and $\nabla r^{-1} = -1 \cdot r^{-1-2} \cdot \bar{r} = -\frac{\bar{r}}{r^3}$

We have

$$\begin{aligned} \nabla \left(\frac{f'}{r} \right) &= r^{-1} \frac{f''}{r} \bar{r} + f' \left(-\frac{\bar{r}}{r^3} \right) \\ &= \left(\frac{f''}{r^2} - \frac{f'}{r^3} \right) \bar{r} \end{aligned} \quad (3)$$

Also $\nabla \cdot \bar{r} = 3$ (4)

Substituting (3) and (4) in (2), we get

$$\begin{aligned}\nabla^2 f &= 3 \frac{f'}{r} + \left(\frac{f''}{r^2} - \frac{f'}{r^3} \right) \bar{r} \cdot \bar{r} \\ &= 3 \frac{f'}{r} + \left(\frac{f''}{r^2} - \frac{f'}{r^3} \right) r^2 \\ \nabla^2 f(r) &= f'' + \frac{2}{r} f' = \frac{d^2 f}{dr^2} + \frac{2}{r} \frac{df}{dr}\end{aligned}$$

b. Since $\nabla^2 f(r) = \frac{d^2 f}{dr^2} + \frac{2}{r} \frac{df}{dr} = 0$

This is a 2nd order homogeneous equation which is separable in f'

$$\frac{df'}{dr} + \frac{2}{r} f' = 0$$

with solution $f' = \frac{c}{r^2}$.

Integrating w.r.t. r

$$f(r) = B + \frac{A}{r}$$

where A and B are arbitrary constants.

Example 3: Prove that

- i. $\nabla^2 r^n = n(n+1)r^{n-2}$ where n is a constant
- ii. $\nabla^2 r^2 = 6$
- iii. $\nabla^2 \left(\frac{1}{r} \right) = 0$
- iv. $\nabla^2 \ln r = \frac{1}{r^2}$
- vi. $\nabla^2(gh) = g\nabla^2 h + h\nabla^2 g$.

Solution:

- i. With $f(r) = r^n$, from the result from above Example 3 (i), we get

$$\begin{aligned}\nabla^2 f &= \nabla^2 r^n = \frac{d^2}{dr^2}(r^n) + \frac{2}{r} \frac{d}{dr}(r^n) \\ &= \frac{d}{dr}(n \cdot r^{n-1}) + \frac{2}{r} \cdot n r^{n-1} \\ &= n \cdot (n-1)r^{n-2} + 2nr^{n-2} \\ &= nr^{n-2}[n-1+2] = n(n+1)r^{n-2}\end{aligned}$$

- ii. Put $n = 2$ in (i) $\nabla^2 r^2 = 2(2+1)r^{2-2} = 6$
- iii. Put $n = -1$ in (i)

$$\nabla^2 \left(\frac{1}{r} \right) = (-1)(-1+1)r^{-1-2} = 0$$

- iv. With $f(r) = \ln r$

$$\begin{aligned}\nabla^2 f &= \nabla^2 \ln r = \frac{d^2}{dr^2} \ln r + \frac{2}{r} \frac{d}{dr} \ln r \\ &= -\frac{1}{r^2} + \frac{2}{r} \cdot \frac{1}{r} = \frac{1}{r^2}\end{aligned}$$

- v. With $f = gh$

$$\begin{aligned}\nabla^2 f &= \nabla^2(gh) = \frac{d^2}{dr^2}(gh) + \frac{2}{r} \frac{d}{dr}(gh) \\ &= 2 \frac{dg}{dr} \frac{dh}{dr} + g \frac{d^2 h}{dr^2} + h \frac{d^2 g}{dr^2} + \frac{2}{r} \left\{ g \frac{dh}{dr} + h \frac{dg}{dr} \right\} \\ &= 2 \frac{dg}{dr} \frac{dh}{dr} + g \left[\frac{d^2 h}{dr^2} + \frac{2}{r} \frac{dh}{dr} \right] + h \left[\frac{d^2 g}{dr^2} + \frac{2}{r} \frac{dg}{dr} \right] \\ &= 2 \nabla g \cdot \nabla h + g \nabla^2 h + h \nabla^2 g\end{aligned}$$

where we have used result of above Example 2(a).

Aliter: The above examples can also be solved directly. For example consider

$$\begin{aligned}\nabla^2 \ln r &= \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) \ln r \\ &= \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) \ln \sqrt{x^2 + y^2 + z^2} \quad (1)\end{aligned}$$

Consider

$$\begin{aligned}&\frac{\partial}{\partial x} \ln \sqrt{x^2 + y^2 + z^2} \\ &= \frac{1}{\sqrt{x^2 + y^2 + z^2}} \cdot \frac{1}{2} \cdot \frac{2x}{\sqrt{x^2 + y^2 + z^2}} \cdot 2x \\ &= \frac{x}{r^2} \\ &\frac{\partial^2}{\partial x^2} \ln \sqrt{x^2 + y^2 + z^2} \\ &= \frac{\partial}{\partial x} \left[\frac{x}{r^2} \right] = \frac{r^2 \cdot 1 - x \cdot 2r \frac{\partial r}{\partial x}}{r^4} \\ &= \frac{r^2 - 2xr \frac{x}{r}}{r^4} = \frac{r^2 - 2x^2}{r^4} \quad (2)\end{aligned}$$

Similarly,

$$\frac{\partial^2}{\partial y^2} \ln \sqrt{x^2 + y^2 + z^2} = \frac{r^2 - 2y^2}{r^4} \quad (3)$$

$$\text{and } \frac{\partial^2}{\partial z^2} \ln \sqrt{x^2 + y^2 + z^2} = \frac{r^2 - 2z^2}{r^4} \quad (4)$$

15.20 — HIGHER ENGINEERING MATHEMATICS—IV

Substituting (2), (3), (4) in (1), we get

$$\begin{aligned}\nabla^2 \ln r &= \frac{r^2 - 2x^2}{r^4} + \frac{r^2 - 2y^2}{r^4} + \frac{r^2 - 2z^2}{r^4} \\ &= \frac{3r^2 - 2(x^2 + y^2 + z^2)}{r^4} = \frac{3r^2 - 2r^2}{r^4} = \frac{r^2}{r^4} = \frac{1}{r^2}.\end{aligned}$$

Example 4: Prove that

$$\nabla^2(fg) = f\nabla^2g + 2\nabla g \cdot \nabla f + g\nabla^2f.$$

Solution:

$$\begin{aligned}\nabla^2(fg) &= \nabla \cdot \nabla(fg) \\ &= \nabla \cdot [f\nabla g + g\nabla f] \\ &= \nabla \cdot (f\nabla g) + \nabla \cdot (g\nabla f) \\ &= [f\nabla \cdot \nabla g + \nabla f \cdot \nabla g] + [g\nabla \cdot \nabla f + \nabla g \cdot \nabla f] \\ \nabla^2 fg &= f\nabla^2g + 2\nabla f \cdot \nabla g + g\nabla^2f.\end{aligned}$$

Example 5: Find the directional derivative of $\nabla \cdot (\nabla f)$ at the point $(1, -2, 1)$ in the direction of the normal to the surface $xy^2z = 3x + z^2$ where $f = 2x^3y^2z^4$.

Solution: Let

$$\begin{aligned}U(x, y, z) &= \nabla \cdot \nabla f = \nabla^2 f = \nabla^2(2x^3y^2z^4) \\ &= \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) (2x^3y^2z^4) \\ &= 2 \cdot [6xy^2z^4 + 2x^3z^4 + 12x^3y^2z^2]\end{aligned}$$

Normal to the surface $g = xy^2z - 3x - z^2 = 0$ is

$$\nabla g = (y^2z - 3)\bar{i} + (2xyz)\bar{j} + (xy^2 - 2z)\bar{k}$$

$$\nabla g \Big|_{\text{at}(1, -2, 1)} = \bar{i} - 4\bar{j} + 2\bar{k}$$

Unit vector $\hat{a}$ in the direction of normal at the point $P(1, -2, 1)$ is

$$\hat{a} = \frac{\nabla g}{|\nabla g|} = \frac{i - 4j + 2k}{\sqrt{1 + 16 + 4}} = \frac{i - 4j + 2k}{\sqrt{21}}$$

Consider

$$\begin{aligned}\nabla U &= \nabla(12xy^2z^4 + 4x^3z^4 + 24x^3y^2z^2) \\ &= (12y^2z^4 + 12x^2z^4 + 72x^2y^2z^2)\bar{i} \\ &\quad + (24xyz^4 + 48x^3yz^2)\bar{j} \\ &\quad + (48xy^2z^3 + 16x^3z^3 + 48x^3y^2z)\bar{k}\end{aligned}$$

$$\nabla U \Big|_{\text{at}(1, -2, 1)} = 348\bar{i} - 144\bar{j} + 400\bar{k}$$

Thus the required directional derivative is

$$\nabla U \cdot \hat{a} = (348\bar{i} - 144\bar{j} + 400\bar{k}) \cdot \frac{(i - 4j + 2k)}{\sqrt{21}} = \frac{1724}{\sqrt{21}}.$$

Example 6: Evaluate $\nabla^2 \left[\nabla \cdot \left(\frac{\bar{r}}{r^2} \right) \right]$.

Solution: Consider

$$\begin{aligned}\nabla \cdot \left(\frac{\bar{r}}{r^2} \right) &= \nabla \cdot (r^{-2}\bar{r}) \\ &= r^{-2}\nabla \cdot \bar{r} + \bar{r} \cdot \nabla r^{-2} \\ &= 3r^{-2} + \bar{r} \cdot (-2r^{-4}\bar{r}) \\ &= 3r^{-2} - 2r^{-4}\bar{r} \cdot \bar{r} \\ \nabla \cdot \left(\frac{\bar{r}}{r^2} \right) &= 3r^{-2} - 2r^{-4}r^2 = r^{-2}\end{aligned}$$

Now

$$\nabla^2 \left[\nabla \cdot \left(\frac{\bar{r}}{r^2} \right) \right] = \nabla^2(r^{-2})$$

Applying result (i) of Example 3 above with $n = -2$

$$= -2(-2 + 1)r^{-2-2} = 2r^{-4}.$$

EXERCISE

Laplacian ∇^2

1. Show that $\nabla \cdot (\nabla f) = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}$

2. Calculate $\nabla^2 f$ when $f = 4x^2 + 9y^2 + z^2$

Ans. 28

3. Find $\nabla^2 f$ at the point $(2, 3, 1)$ when $f = xy/z$

Ans. $2xy/z^3$; 12

4. If $\bar{F} = r^a \bar{r}$ prove that

$$\nabla^2 \bar{F} = a(a + 3)r^{n-2}\bar{r}$$

5. Show that ∇f is both solenoidal and irrotational if $\nabla^2 f = 0$.

15.7 CURVILINEAR COORDINATES: CYLINDRICAL AND SPHERICAL COORDINATES

It is more convenient in many problems to define the position of a point P in space by three

numbers (q_1, q_2, q_3) instead of the three cartesian coordinates (x, y, z) . Then q_1, q_2, q_3 are known as “curvilinear coordinates” of the point P. The three surfaces $q_1 = c_1, q_2 = c_2$ and $q_3 = c_3$, (refer Fig. 15.2) where c_1, c_2, c_3 are constants, are known as “coordinate surfaces” of the system of curvilinear coordinates. On these coordinates surfaces, say $q_1 = c_1$, one of the coordinates, here q_1 , remains constant.

The “coordinate curves (lines) (axis)” are the curves (or lines) of intersection of any two coordinate surfaces. Thus on the coordinate curve say which is the intersection of $q_2 = c_2$ and $q_3 = c_3$, only q_1 varies, while q_2 and q_3 remain constant. Suppose the rectangular coordinates (x, y, z) of any point P in space be expressed as functions of (q_1, q_2, q_3) so that

$$\begin{aligned} x &= x(q_1, q_2, q_3), y = y(q_1, q_2, q_3), \\ z &= z(q_1, q_2, q_3) \end{aligned} \quad (1)$$

Solving (1) for q_1, q_2, q_3 in terms of x, y, z , we get

$$\begin{aligned} q_1 &= q_1(x, y, z), q_2 = q_2(x, y, z), \\ q_3 &= q_3(x, y, z) \end{aligned} \quad (2)$$

The set of Equations (1) and (2) are known as “transformation of coordinates”.

Fig. 15.2

If the coordinate surfaces intersect at right angles (and therefore the coordinate lines are at right angles), then the curvilinear coordinate system is known as “orthogonal curvilinear system of coordinates”.

Let $\bar{e}_1, \bar{e}_2, \bar{e}_3$ be unit vectors directed along the tangents to the coordinates axes q_1, q_2, q_3 at the point P in the direction of increasing q_1, q_2, q_3 respectively, such that $\bar{e}_1, \bar{e}_2, \bar{e}_3$ form a right-handed trihedral (triad).

Example: Rectangular cartesian coordinate system x, y, z , where the three coordinate surfaces are planes $x = c_1, y = c_2, z = c_3$ which are mutually at right angles.

Note: The basic difference between curvilinear coordinates and cartesian coordinates is that the unit vectors $\bar{i}, \bar{j}, \bar{k}$ in the cartesian coordinate system remain constant and are same for all points of space, while in any other system the unit vectors $\bar{e}_1, \bar{e}_2, \bar{e}_3$, generally speaking, are not constant i.e., change their directions when passing from one point P to the other.

Example: Cylindrical coordinates (refer Fig. 15.3)

Fig. 15.3

$$\left. \begin{aligned} q_1 &= r, & 0 \leq r < \infty \\ q_2 &= \theta, & 0 \leq \theta < 2\pi \\ q_3 &= z, & -\infty < z < +\infty \end{aligned} \right\} \quad (3)$$

coordinate surfaces are

$r = \text{constant}$: circular cylinders coaxial with z -axis

$\theta = \text{constant}$: half plane, adjoining z -axis, through z -axis

$z = \text{constant}$: plane perpendicular to z -axis

15.22 — HIGHER ENGINEERING MATHEMATICS—IV

coordinate lines (or axes) are

- r : rays with origin on z -axis and perpendicular to z -axis
- θ : circles with centre on z -axis and lying in planes perpendicular to z -axis
- z : straight lines parallel to the z -axis

The transformation that relate cartesian coordinates to cylindrical coordinates are

$$\left. \begin{aligned} x &= r \cos \theta \\ y &= r \sin \theta \\ z &= z \end{aligned} \right\} \quad (4)$$

$$r = \sqrt{x^2 + y^2}, \theta = \arctan \frac{y}{x}, z = z$$

Example: Spherical coordinates (see Fig. 15.4)

Fig. 15.4

$$\begin{aligned} q_1 &= r, & 0 \leq r < +\infty \\ q_2 &= \theta, & 0 \leq \theta \leq \pi \\ q_3 &= \phi, & 0 \leq \phi < 2\pi \end{aligned} \quad (5)$$

The coordinate surfaces are

- $r = c_1$, spheres centred at origin 0
- $\theta = c_2$, circular half-angle cones with z -axis with vertex at origin.
- $\phi = c_3$, (half) planes adjoining the z -axis through z -axis.

coordinate lines are:

- r : rays emanating from origin 0
- θ : meridians on a sphere
- ϕ : parallel on a sphere

cartesian coordinates are related to spherical coordinates as follows:

$$\left. \begin{aligned} x &= r \cos \phi \sin \theta \\ y &= r \sin \phi \sin \theta \\ z &= r \cos \theta. \end{aligned} \right\} \quad (6)$$

Unit Vectors in Curvilinear System

Suppose $\bar{r} = \bar{r}(q_1, q_2, q_3)$ be the position vector of a point P . A tangent vector of the q_1 curve at P (for which q_2 and q_3 are constants) is $\frac{\partial \bar{r}}{\partial q_1}$. Then a unit tangent vector $\bar{e}_1$ in this direction is

$$\bar{e}_1 = \frac{\partial \bar{r}}{\partial q_1} / \left| \frac{\partial \bar{r}}{\partial q_1} \right|$$

$$\text{so that} \quad \frac{\partial \bar{r}}{\partial q_1} = h_1 \bar{e}_1 \quad (7)$$

$$\text{where} \quad h_1 = \left| \frac{\partial \bar{r}}{\partial u_1} \right|.$$

Similarly if $\bar{e}_2$ and $\bar{e}_3$ are unit tangent vectors to the u_2 and u_3 curves at P respectively then

$$\frac{\partial \bar{r}}{\partial q_2} = h_2 \bar{e}_2 \quad (8)$$

$$\text{and} \quad \frac{\partial \bar{r}}{\partial q_3} = h_3 \bar{e}_3 \quad (9)$$

$$\text{where} \quad h_2 = \left| \frac{\partial \bar{r}}{\partial q_2} \right|, \quad h_3 = \left| \frac{\partial \bar{r}}{\partial q_3} \right|.$$

The quantities h_1, h_2, h_3 are called *scale factors* or *Lame coefficients* of the given curvilinear system of coordinates, and are given by

$$h_i = \sqrt{\left(\frac{\partial x}{\partial q_i} \right)^2 + \left(\frac{\partial y}{\partial q_i} \right)^2 + \left(\frac{\partial z}{\partial q_i} \right)^2}; \quad i = 1, 2, 3 \quad (10)$$

Thus

$$d\bar{r} = \frac{\partial \bar{r}}{\partial q_1} dq_1 + \frac{\partial \bar{r}}{\partial q_2} dq_2 + \frac{\partial \bar{r}}{\partial q_3} dq_3$$

or

$$d\vec{r} = h_1 dq_1 \vec{e}_1 + h_2 dq_2 \vec{e}_2 + h_3 dq_3 \vec{e}_3 \quad (11)$$

Example: In rectangular coordinate system (q_1, q_2, q_3) is replaced by (x, y, z) . Here

$$h_1 = h_2 = h_3 = 1, \quad \vec{e}_1 = \vec{i}, \quad \vec{e}_2 = \vec{j}, \quad \vec{e}_3 = \vec{k}$$

Example: Cylindrical coordinates

$$q_1 = r, \quad q_2 = \theta, \quad q_3 = z$$

By virtue of (10)

$$h_1 = H_r = \sqrt{\left(\frac{\partial x}{\partial r}\right)^2 + \left(\frac{\partial y}{\partial r}\right)^2 + \left(\frac{\partial z}{\partial r}\right)^2} = 1$$

$$h_2 = H_\theta = \sqrt{\left(\frac{\partial x}{\partial \theta}\right)^2 + \left(\frac{\partial y}{\partial \theta}\right)^2 + \left(\frac{\partial z}{\partial \theta}\right)^2} = r$$

$$h_3 = H_z = \sqrt{\left(\frac{\partial x}{\partial z}\right)^2 + \left(\frac{\partial y}{\partial z}\right)^2 + \left(\frac{\partial z}{\partial z}\right)^2} = 1$$

Example: Spherical coordinates

$$q_1 = r, \quad q_2 = \theta, \quad q_3 = \phi$$

Using (10), we get

$$h_1 = H_r = 1, \quad h_2 = H_\theta = r, \quad h_3 = H_\phi = r \sin \theta.$$

Expressions of Gradient, Divergence, Curl and Laplacian in Orthogonal Curvilinear, Spherical and Cylindrical Coordinates

WORKED OUT EXAMPLES

Example 1: Derive an expression for ∇f in orthogonal curvilinear coordinates. Hence deduce ∇ in rectangular cartesian coordinates.

Solution: Let

$$\nabla f = f_1 \vec{e}_1 + f_2 \vec{e}_2 + f_3 \vec{e}_3 \quad (1)$$

where f_1, f_2, f_3 are unknowns to be determined. Since

$$\begin{aligned} d\vec{r} &= \frac{\partial \vec{r}}{\partial q_1} dq_1 + \frac{\partial \vec{r}}{\partial q_2} dq_2 + \frac{\partial \vec{r}}{\partial q_3} dq_3 \\ d\vec{r} &= h_1 \vec{e}_1 dq_1 + h_2 \vec{e}_2 dq_2 + h_3 \vec{e}_3 dq_3 \end{aligned} \quad (2)$$

By taking dot product of (1) and (2), we have

$$df = \nabla f \cdot d\vec{r} = h_1 f_1 dq_1 + h_2 f_2 dq_2 + h_3 f_3 dq_3 \quad (3)$$

But by definition of differential,

$$df = \frac{\partial f}{\partial q_1} dq_1 + \frac{\partial f}{\partial q_2} dq_2 + \frac{\partial f}{\partial q_3} dq_3 \quad (4)$$

Equating (3) and (4), we get

$$f_1 = \frac{1}{h_1} \frac{\partial f}{\partial q_1}, \quad f_2 = \frac{1}{h_2} \frac{\partial f}{\partial q_2}, \quad f_3 = \frac{1}{h_3} \frac{\partial f}{\partial q_3} \quad (5)$$

Substituting (5) in (1), we get

$$\nabla f = \frac{\vec{e}_1}{h_1} \frac{\partial f}{\partial q_1} + \frac{\vec{e}_2}{h_2} \frac{\partial f}{\partial q_2} + \frac{\vec{e}_3}{h_3} \frac{\partial f}{\partial q_3}$$

Thus the nabla operator ∇ in orthogonal curvilinear coordinates is

$$\nabla = \frac{\vec{e}_1}{h_1} \frac{\partial}{\partial q_1} + \frac{\vec{e}_2}{h_2} \frac{\partial}{\partial q_2} + \frac{\vec{e}_3}{h_3} \frac{\partial}{\partial q_3} \quad (6)$$

Putting

$$\begin{aligned} h_1 = h_2 = h_3 &= 1, \quad \vec{e}_1 = \vec{i}, \\ \vec{e}_2 &= \vec{j}, \quad \vec{e}_3 = \vec{k} \end{aligned}$$

and

$$q_1 = x, \quad q_2 = y, \quad q_3 = z$$

(6) reduces to

$$\nabla = \vec{i} \frac{\partial}{\partial x} + \vec{j} \frac{\partial}{\partial y} + \vec{k} \frac{\partial}{\partial z}.$$

Example 2: Show that $\vec{e}_1 = h_2 h_3 \nabla q_2 \times \nabla q_3$.

Solution: From Example 1 with $f = q_1$, we have

$$\nabla f = \nabla q_1 = \frac{\vec{e}_1}{h_1} \frac{\partial q_1}{\partial q_1} + 0 + 0 = \frac{\vec{e}_1}{h_1}$$

$$\text{Similarly,} \quad \nabla q_2 = \frac{\vec{e}_2}{h_2}$$

$$\text{and} \quad \nabla q_3 = \frac{\vec{e}_3}{h_3}$$

Now

$$\nabla q_2 \times \nabla q_3 = \frac{\vec{e}_2}{h_2} \times \frac{\vec{e}_3}{h_3} = \frac{1}{h_2 h_3} \vec{e}_2 \times \vec{e}_3 = \frac{\vec{e}_1}{h_2 h_3}$$

$$\text{So} \quad \vec{e}_1 = h_2 h_3 \nabla q_2 \times \nabla q_3.$$

In a similar way, we get

$$\vec{e}_2 = h_3 h_1 \nabla q_3 \times \nabla q_1$$

$$\vec{e}_3 = h_1 h_2 \nabla q_1 \times \nabla q_2.$$

Example 3: Derive an expression for $\nabla \cdot \vec{A}$ in orthogonal curvilinear coordinates. Deduce $\nabla \cdot \vec{A}$ in

15.24 — HIGHER ENGINEERING MATHEMATICS—IV

rectangular coordinates

Solution: Let

$$\bar{A} = A_1 \bar{e}_1 + A_2 \bar{e}_2 + A_3 \bar{e}_3$$

So that

$$\begin{aligned} \nabla \cdot \bar{A} &= \nabla \cdot (A_1 \bar{e}_1 + A_2 \bar{e}_2 + A_3 \bar{e}_3) \\ &= \nabla \cdot (A_1 \bar{e}_1) + \nabla \cdot (A_2 \bar{e}_2) + \nabla \cdot (A_3 \bar{e}_3) \quad (1) \end{aligned}$$

Consider,

$$\nabla \cdot (A_1 \bar{e}_1) = \nabla \cdot (A_1 h_2 h_3 \nabla q_2 \times \nabla q_3)$$

Using result of above Example 2

$$\begin{aligned} &= \nabla(A_1 h_2 h_3) \cdot \nabla q_2 \times \nabla q_3 \\ &\quad + A_1 h_2 h_3 \nabla \cdot (\nabla q_2 \times \nabla q_3) \\ &= \nabla(A_1 h_2 h_3) \cdot \frac{\bar{e}_2}{h_2} \times \frac{\bar{e}_3}{h_3} + 0 \\ &= \nabla(A_1 h_2 h_3) \cdot \frac{\bar{e}_1}{h_2 h_3}. \end{aligned}$$

Using ∇f result from above Example 1.

$$\begin{aligned} \nabla \cdot (A_1 \bar{e}_1) &= \left[\frac{\bar{e}_1}{h_1} \frac{\partial}{\partial q_1} (A_1 h_2 h_3) + \frac{\bar{e}_2}{h_2} \frac{\partial}{\partial q_2} (A_1 h_2 h_3) \right. \\ &\quad \left. + \frac{\bar{e}_3}{h_3} \frac{\partial}{\partial q_3} (A_1 h_2 h_3) \right] \cdot \frac{\bar{e}_1}{h_2 h_3} \\ \nabla \cdot (A_1 \bar{e}_1) &= \frac{1}{h_1 h_2 h_3} \frac{\partial}{\partial q_1} (A_1 h_2 h_3) + 0 + 0 \quad (2) \end{aligned}$$

Similarly, we get

$$\nabla \cdot (A_2 \bar{e}_2) = \frac{1}{h_1 h_2 h_3} \frac{\partial}{\partial q_2} (A_2 h_3 h_1) \quad (3)$$

$$\nabla \cdot (A_3 \bar{e}_3) = \frac{1}{h_1 h_2 h_3} \frac{\partial}{\partial q_3} (A_3 h_1 h_2) \quad (4)$$

Adding (2), (3), (4) and using (1), we get the required result as

$$\begin{aligned} \nabla \cdot \bar{A} &= \frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} (A_1 h_2 h_3) + \frac{\partial}{\partial q_2} (A_2 h_3 h_1) \right. \\ &\quad \left. + \frac{\partial}{\partial q_3} (A_3 h_1 h_2) \right]. \end{aligned}$$

Putting $h_1 = h_2 = h_3 = 1$

$$q_1 = x, \quad q_2 = y, \quad q_3 = z$$

$$\nabla \cdot \bar{A} = \frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z}$$

Example 4: Derive an expression for $\nabla \times \bar{A}$ in orthogonal curvilinear coordinates. Deduce $\nabla \times \bar{A}$ for cartesian coordinates.

Solution: If

$$\bar{A} = A_1 \bar{e}_1 + A_2 \bar{e}_2 + A_3 \bar{e}_3$$

then

$$\begin{aligned} \nabla \times \bar{A} &= \nabla \times (A_1 \bar{e}_1 + A_2 \bar{e}_2 + A_3 \bar{e}_3) \\ \nabla \times \bar{A} &= \nabla \times (A_1 \bar{e}_1) + \nabla \times (A_2 \bar{e}_2) + \nabla \times (A_3 \bar{e}_3) \quad (1) \end{aligned}$$

Consider

$$\nabla \times (A_1 \bar{e}_1) = \nabla \times (A_1 h_1 \nabla q_1)$$

Since

$$\bar{e}_1 = h_1 \nabla q_1$$

$$\begin{aligned} \nabla \times (A_1 \bar{e}_1) &= \nabla(A_1 h_1) \times \nabla q_1 + A_1 h_1 \nabla \times \nabla q_1 \\ &= \nabla(A_1 h_1) \times \frac{\bar{e}_1}{h_1} + 0 \end{aligned}$$

Substituting gradient value from above Example 1

$$\begin{aligned} \nabla \times (A_1 \bar{e}_1) &= \left[\frac{\bar{e}_1}{h_1} \frac{\partial}{\partial q_1} (A_1 h_1) + \frac{\bar{e}_2}{h_2} \frac{\partial}{\partial q_2} (A_1 h_1) \right. \\ &\quad \left. + \frac{\bar{e}_3}{h_3} \frac{\partial}{\partial q_3} (A_1 h_1) \right] \times \frac{\bar{e}_1}{h_1} \\ &= 0 - \frac{\bar{e}_3}{h_2 h_1} \frac{\partial}{\partial q_2} (A_1 h_1) \\ &\quad + \frac{\bar{e}_2}{h_3 h_1} \frac{\partial}{\partial q_3} (A_1 h_1) \quad (2) \end{aligned}$$

In a similar way, we get

$$\begin{aligned} \nabla \times (A_2 \bar{e}_2) &= \frac{\bar{e}_3}{h_1 h_2} \frac{\partial}{\partial q_1} (A_2 h_2) \\ &\quad - \frac{\bar{e}_1}{h_2 h_3} \frac{\partial}{\partial q_3} (A_2 h_2) \quad (3) \end{aligned}$$

and

$$\begin{aligned} \nabla \times (A_3 \bar{e}_3) &= \frac{\bar{e}_1}{h_2 h_3} \frac{\partial}{\partial q_2} (A_3 h_3) \\ &\quad - \frac{\bar{e}_2}{h_3 h_1} \frac{\partial}{\partial q_1} (A_3 h_3) \quad (4) \end{aligned}$$

Adding (2), (3), (4), we get the required expression for which can be written as

$$\nabla \times \bar{A} = \frac{1}{h_1 h_2 h_3} \begin{vmatrix} h_1 \bar{e}_1 & h_2 \bar{e}_2 & h_3 \bar{e}_3 \\ \frac{\partial}{\partial q_1} & \frac{\partial}{\partial q_2} & \frac{\partial}{\partial q_3} \\ A_1 h_1 & A_2 h_2 & A_3 h_3 \end{vmatrix}.$$

For cartesian system,

$$\nabla \times A = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ A_1 & A_2 & A_3 \end{vmatrix}$$

Example 5: Express $\nabla^2 f$ in orthogonal curvilinear coordinates. Deduce for cartesian system

Solution: From Example 1,

$$\nabla f = \frac{\bar{e}_1}{h_1} \frac{\partial f}{\partial q_1} + \frac{\bar{e}_2}{h_2} \frac{\partial f}{\partial q_2} + \frac{\bar{e}_3}{h_3} \frac{\partial f}{\partial q_3}$$

$$\text{If } \bar{A} = A_1 \bar{e}_1 + A_2 \bar{e}_2 + A_3 \bar{e}_3 = \nabla f$$

Then equating coefficients of $\bar{e}_1, \bar{e}_2, \bar{e}_3$, we get

$$A_1 = \frac{1}{h_1} \frac{\partial f}{\partial q_1}, A_2 = \frac{1}{h_2} \frac{\partial f}{\partial q_2}, A_3 = \frac{1}{h_3} \frac{\partial f}{\partial q_3}$$

Thus

$$\begin{aligned} \nabla^2 f &= \nabla \cdot \nabla f = \nabla \cdot \bar{A} \\ &= \frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} (A_1 h_2 h_3) \right. \\ &\quad \left. + \frac{\partial}{\partial q_2} (A_2 h_3 h_1) + \frac{\partial}{\partial q_3} (A_3 h_1 h_2) \right] \\ &= \frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} \left(\frac{h_2 h_3}{h_1} \frac{\partial f}{\partial q_1} \right) + \frac{\partial}{\partial q_2} \left(\frac{h_3 h_1}{h_2} \frac{\partial f}{\partial q_2} \right) \right. \\ &\quad \left. + \frac{\partial}{\partial q_3} \left(\frac{h_1 h_2}{h_3} \frac{\partial f}{\partial q_3} \right) \right] \end{aligned}$$

For cartesian system,

$$\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}.$$

Example 6: Express (a) ∇f , (b) $\nabla \cdot \bar{A}$, (c) $\nabla \times \bar{A}$, (d) $\nabla^2 f$ in cylindrical coordinates (r, θ, z) .

Solution: For cylindrical coordinates (r, θ, z) , we know that

$$q_1 = r, \quad q_2 = \theta, \quad q_3 = z, \quad \bar{e}_1 = \bar{e}_r, \quad \bar{e}_2 = \bar{e}_\theta, \quad \bar{e}_3 = \bar{e}_z$$

and

$$h_1 = h_r = 1, \quad h_2 = h_\theta = r, \quad h_3 = h_z = 1$$

a. From Example 1

$$\nabla f = \frac{\bar{e}_1}{h_1} \frac{\partial f}{\partial q_1} + \frac{\bar{e}_2}{h_2} \frac{\partial f}{\partial q_2} + \frac{\bar{e}_3}{h_3} \frac{\partial f}{\partial q_3}$$

$$\nabla f = \frac{1}{r} \frac{\partial f}{\partial r} \bar{e}_r + \frac{1}{r} \frac{\partial f}{\partial \theta} \bar{e}_\theta + \frac{1}{1} \frac{\partial f}{\partial z} \bar{e}_z$$

b. From Example 3

$$\begin{aligned} \nabla \cdot \bar{A} &= \frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} (h_2 h_3 A_1) + \frac{\partial}{\partial q_2} (h_3 h_1 A_2) \right. \\ &\quad \left. + \frac{\partial}{\partial q_3} (h_1 h_2 A_3) \right] \end{aligned}$$

$$\begin{aligned} &= \frac{1}{1 \cdot r \cdot 1} \left[\frac{\partial}{\partial r} (r \cdot 1 \cdot A_r) + \frac{\partial}{\partial \theta} (1 \cdot 1 \cdot A_\theta) \right. \\ &\quad \left. + \frac{\partial}{\partial z} (1 \cdot r \cdot A_z) \right] \end{aligned}$$

$$\nabla \cdot \bar{A} = \frac{1}{r} \left[\frac{\partial}{\partial r} (r A_r) + \frac{\partial}{\partial \theta} A_\theta + \frac{\partial}{\partial z} (r A_z) \right]$$

$$\begin{aligned} \text{c. } \nabla \times \bar{A} &= \frac{1}{h_1 h_2 h_3} \begin{vmatrix} h_1 \bar{e}_1 & h_2 \bar{e}_2 & h_3 \bar{e}_3 \\ \frac{\partial}{\partial q_1} & \frac{\partial}{\partial q_2} & \frac{\partial}{\partial q_3} \\ h_1 A_1 & h_2 A_2 & h_3 A_3 \end{vmatrix} \\ &= \frac{1}{1 \cdot r \cdot 1} \begin{vmatrix} \bar{e}_r & r \bar{e}_\theta & \bar{e}_z \\ \frac{\partial}{\partial r} & \frac{\partial}{\partial \theta} & \frac{\partial}{\partial z} \\ A_r & r A_\theta & A_z \end{vmatrix}. \end{aligned}$$

d. From Example 5,

$$\begin{aligned} \nabla^2 f &= \frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} \left(\frac{h_2 h_3}{h_1} \frac{\partial f}{\partial q_1} \right) \right. \\ &\quad \left. + \frac{\partial}{\partial q_2} \left(\frac{h_3 h_1}{h_2} \frac{\partial f}{\partial q_2} \right) + \frac{\partial}{\partial q_3} \left(\frac{h_1 h_2}{h_3} \frac{\partial f}{\partial q_3} \right) \right] \\ &= \frac{1}{1 \cdot r \cdot 1} \left[\frac{\partial}{\partial r} \left(\frac{r \cdot 1}{1} \frac{\partial f}{\partial r} \right) \right. \\ &\quad \left. + \frac{\partial}{\partial \theta} \left(\frac{1 \cdot 1}{r} \frac{\partial f}{\partial \theta} \right) + \frac{\partial}{\partial z} \left(\frac{1 \cdot r}{1} \frac{\partial f}{\partial z} \right) \right] \end{aligned}$$

$$\nabla^2 f = \frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial f}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2 f}{\partial \theta^2} + \frac{\partial^2 f}{\partial z^2}.$$

15.26 — HIGHER ENGINEERING MATHEMATICS—IV

Example 7: Express (a) ∇f , (b) $\nabla \cdot \bar{A}$, (c) $\nabla \times \bar{A}$, (d) $\nabla^2 f$ in spherical curvilinear coordinates.

Solution: Here

$$q_1 = r, \quad q_2 = \theta, \quad q_3 = \phi,$$

$$\bar{e}_1 = \bar{e}_r, \quad \bar{e}_2 = \bar{e}_\theta, \quad \bar{e}_3 = \bar{e}_\phi$$

$$h_1 = h_r = 1, \quad h_2 = h_\theta = r, \quad h_3 = h_\phi = r \sin \theta.$$

$$\text{a.} \quad \nabla f = \frac{\bar{e}_1}{h_1} \frac{\partial f}{\partial q_1} + \frac{\bar{e}_2}{h_2} \frac{\partial f}{\partial q_2} + \frac{\bar{e}_3}{h_3} \frac{\partial f}{\partial q_3}$$

$$\nabla f = \frac{\bar{e}_r}{1} \frac{\partial f}{\partial r} + \frac{\bar{e}_\theta}{r} \frac{\partial f}{\partial \theta} + \frac{\bar{e}_\phi}{r \sin \theta} \frac{\partial f}{\partial \phi}$$

$$\text{b.} \quad \nabla \cdot \bar{A} = \frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} (h_2 h_3 A_1) + \frac{\partial}{\partial q_2} (h_3 h_1 A_2) + \frac{\partial}{\partial q_3} (h_1 h_2 A_3) \right]$$

$$= \frac{1}{1 \cdot r \cdot r \cdot \sin \theta} \left[\frac{\partial}{\partial r} (r \cdot r \sin \theta A_r) + \frac{\partial}{\partial \theta} (r \sin \theta \cdot 1 \cdot A_\theta) + \frac{\partial}{\partial \phi} (1 \cdot r \cdot A_\phi) \right]$$

$$\nabla \cdot \bar{A} = \frac{1}{r^2 \sin \theta} \left[\frac{\partial}{\partial r} (r^2 \sin \theta A_r) + \frac{\partial}{\partial \theta} (r \sin \theta A_\theta) + \frac{\partial}{\partial \phi} (r A_\phi) \right]$$

$$\nabla \cdot \bar{A} = \frac{1}{r^2} \frac{\partial}{\partial r} (r^2 A_r) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} (\sin \theta A_\theta) + \frac{1}{r \sin \theta} \cdot \frac{\partial}{\partial \phi} (A_\phi).$$

$$\text{c.} \quad \nabla \times \bar{A} = \frac{1}{h_1 h_2 h_3} \begin{vmatrix} h_1 \bar{e}_1 & h_2 \bar{e}_2 & h_3 \bar{e}_3 \\ \frac{\partial}{\partial q_1} & \frac{\partial}{\partial q_2} & \frac{\partial}{\partial q_3} \\ h_1 A_1 & h_2 A_2 & h_3 A_3 \end{vmatrix}$$

$$\begin{aligned} \nabla \times \bar{A} &= \frac{1}{1 \cdot r \cdot r \sin \theta} \begin{vmatrix} \bar{e}_r & r \bar{e}_\theta & r \sin \theta \bar{e}_\phi \\ \frac{\partial}{\partial r} & \frac{\partial}{\partial \theta} & \frac{\partial}{\partial \phi} \\ A_r & r A_\theta & r \sin \theta A_\phi \end{vmatrix} \\ &= \frac{1}{r^2 \sin \theta} \left[\left\{ \frac{\partial}{\partial \theta} (r \sin \theta A_\phi) - \frac{\partial}{\partial \phi} (r A_\theta) \right\} \bar{e}_r \right. \\ &\quad \left. - \left\{ \frac{\partial}{\partial r} (r \sin \theta A_\phi) - \frac{\partial}{\partial \phi} (A_r) \right\} r \bar{e}_\theta \right. \\ &\quad \left. + \left\{ \frac{\partial}{\partial r} (r A_\theta) - \frac{\partial}{\partial \theta} (A_r) \right\} r \sin \theta \bar{e}_\phi \right]. \end{aligned}$$

$$\begin{aligned} \text{d.} \quad \nabla^2 f &= \frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} \left(\frac{h_2 h_3}{h_1} \frac{\partial f}{\partial q_1} \right) + \frac{\partial}{\partial q_2} \left(\frac{h_3 h_1}{h_2} \frac{\partial f}{\partial q_2} \right) + \frac{\partial}{\partial q_3} \left(\frac{h_1 h_2}{h_3} \frac{\partial f}{\partial q_3} \right) \right] \\ \nabla^2 f &= \frac{1}{1 \cdot r \cdot r \sin \theta} \left[\frac{\partial}{\partial r} \left(\frac{r \cdot r \sin \theta}{1} \frac{\partial f}{\partial r} \right) + \frac{\partial}{\partial \theta} \left(\frac{r \sin \theta \cdot 1}{r} \frac{\partial f}{\partial \theta} \right) + \frac{\partial}{\partial \phi} \left(\frac{1 \cdot r}{r \cdot \sin \theta} \frac{\partial f}{\partial \phi} \right) \right] \\ \nabla^2 f &= \frac{1}{r^2 \sin \theta} \left[\sin \theta \frac{\partial}{\partial r} \left(r^2 \frac{\partial f}{\partial r} \right) + \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial f}{\partial \theta} \right) + \frac{1}{\sin \theta} \frac{\partial^2 f}{\partial \phi^2} \right]. \end{aligned}$$

Example 8: Prove that a spherical coordinate system is orthogonal.

Solution: The position vector of any point in spherical coordinates is

$$\begin{aligned} \bar{r} &= x\bar{i} + y\bar{j} + z\bar{k} = \rho \sin \theta \cos \phi \bar{i} \\ &\quad + \rho \sin \theta \sin \phi \bar{j} + \rho \cos \theta \bar{k} \end{aligned}$$

The tangent vectors to the ρ , θ , ϕ curves are given respectively by $\frac{\partial \bar{r}}{\partial \rho}$, $\frac{\partial \bar{r}}{\partial \theta}$, $\frac{\partial \bar{r}}{\partial \phi}$ where

$$\frac{\partial \bar{r}}{\partial \rho} = \sin \theta \cos \phi \bar{i} + \sin \theta \sin \phi \bar{j} + \cos \theta \bar{k}$$

$$\frac{\partial \bar{r}}{\partial \theta} = \rho \cos \theta \cos \phi \bar{i} + \rho \cos \theta \sin \phi \bar{j} - \rho \sin \theta \bar{k}$$

$$\frac{\partial \bar{r}}{\partial \phi} = -\rho \sin \theta \sin \phi \bar{i} + \rho \sin \theta \cos \phi \bar{j} + 0$$

The unit vectors in these directions are

$$\begin{aligned} \bar{e}_1 = \bar{e}_\rho &= \frac{\partial \bar{r} / \partial \rho}{|\partial \bar{r} / \partial \rho|} \\ &= \frac{\sin \theta \cos \phi \bar{i} + \sin \theta \sin \phi \bar{j} + \cos \theta \bar{k}}{\sin^2 \theta \cos^2 \phi + \sin^2 \theta \sin^2 \phi + \cos^2 \theta} \\ &= \frac{\sin \theta \cos \phi \bar{i} + \sin \theta \sin \phi \bar{j} + \cos \theta \bar{k}}{1} \end{aligned}$$

$$\begin{aligned} \bar{e}_2 = \bar{e}_\theta &= \frac{\partial \bar{r} / \partial \theta}{|\partial \bar{r} / \partial \theta|} \\ &= \frac{\rho \cos \theta \cos \phi \bar{i} + \rho \cos \theta \sin \phi \bar{j} - \rho \sin \theta \bar{k}}{\rho} \end{aligned}$$

$$\bar{e}_3 = \bar{e}_\phi = \frac{\partial \bar{r} / \partial \phi}{|\partial \bar{r} / \partial \phi|} = \frac{-\rho \sin \theta \sin \phi \bar{i} + \rho \sin \theta \cos \phi \bar{j}}{\rho \sin \theta}$$

Then

$$\begin{aligned}\bar{e}_1 \cdot \bar{e}_2 &= \sin \theta \cdot \cos \theta \cdot \cos^2 \phi + \sin \theta \cdot \cos \theta \cdot \sin^2 \phi \\ &\quad - \cos \theta \sin \theta = 0\end{aligned}$$

$$\bar{e}_1 \cdot \bar{e}_3 = -\sin \theta \cdot \cos \phi \sin \phi + \sin \theta \cdot \sin \phi \cdot \cos \phi = 0$$

$$\bar{e}_2 \cdot \bar{e}_3 = -\cos \theta \cdot \cos \phi \sin \phi + \cos \theta \sin \phi \cos \phi = 0.$$

So $\bar{e}_1, \bar{e}_2, \bar{e}_3$ are mutually perpendicular and the spherical coordinate system is orthogonal.

Example 9: Find the Jacobian of x, y, z with respect to the orthogonal curvilinear coordinates q_1, q_2, q_3 .

Solution:

$$\begin{aligned}J\left(\frac{x, y, z}{q_1, q_2, q_3}\right) &= \frac{\partial(x, y, z)}{\partial(q_1, q_2, q_3)} \\ &= \begin{vmatrix} \frac{\partial x}{\partial q_1} & \frac{\partial y}{\partial q_1} & \frac{\partial z}{\partial q_1} \\ \frac{\partial x}{\partial q_2} & \frac{\partial y}{\partial q_2} & \frac{\partial z}{\partial q_2} \\ \frac{\partial x}{\partial q_3} & \frac{\partial y}{\partial q_3} & \frac{\partial z}{\partial q_3} \end{vmatrix}\end{aligned}$$

This determinant is triple scalar product given by

$$\begin{aligned}J &= \left(\frac{\partial x}{\partial q_1} \bar{i} + \frac{\partial y}{\partial q_1} \bar{j} + \frac{\partial z}{\partial q_1} \bar{k} \right) \\ &\quad \cdot \left(\frac{\partial x}{\partial q_2} \bar{i} + \frac{\partial y}{\partial q_2} \bar{j} + \frac{\partial z}{\partial q_2} \bar{k} \right) \\ &\quad \times \left(\frac{\partial x}{\partial q_3} \bar{i} + \frac{\partial y}{\partial q_3} \bar{j} + \frac{\partial z}{\partial q_3} \bar{k} \right) \\ &= \frac{\partial \bar{r}}{\partial q_1} \cdot \frac{\partial \bar{r}}{\partial q_2} \times \frac{\partial \bar{r}}{\partial q_3} = h_1 \bar{e}_1 \cdot h_2 \bar{e}_2 \times h_3 \bar{e}_3\end{aligned}$$

$$\text{Jacobian } J = h_1 h_2 h_3 \bar{e}_1 \cdot \bar{e}_2 \times \bar{e}_3 = h_1 h_2 h_3.$$

Note: If $J = 0$, $\bar{e}_1, \bar{e}_2, \bar{e}_3$ are coplanar and coordinate transformation breaks.

Example 10: Find the Jacobian $J\left(\frac{x, y, z}{q_1, q_2, q_3}\right)$ for

- cylindrical,
- spherical coordinates.

Solution:

$$\text{a. } J = h_1 h_2 h_3 = 1 \cdot r \cdot 1 = r$$

$$\text{b. } J = h_1 h_2 h_3 = 1 \cdot r \cdot r \cdot \sin \theta = r^2 \sin \theta.$$

Example 11: Find

$$\frac{\partial \bar{r}}{\partial q_1}, \frac{\partial \bar{r}}{\partial q_2}, \frac{\partial \bar{r}}{\partial q_3}, \nabla q_1, \nabla q_2, \nabla q_3$$

in cylindrical coordinates.

Solution:

$$\bar{r} = xi + yj + zk = \rho \cos \theta i + \rho \sin \theta j + zk$$

Then

$$\frac{\partial \bar{r}}{\partial q_1} = \frac{\partial \bar{r}}{\partial \rho} = \cos \theta \bar{i} + \sin \theta \bar{j}$$

$$\frac{\partial \bar{r}}{\partial q_2} = \frac{\partial \bar{r}}{\partial \theta} = -\rho \sin \theta \bar{i} + \rho \cos \theta \bar{j}$$

$$\frac{\partial \bar{r}}{\partial q_3} = \frac{\partial \bar{r}}{\partial z} = \bar{k}$$

$$\begin{aligned}\nabla q_1 = \nabla \rho &= \frac{1}{h_1} \frac{\partial \rho}{\partial \rho} \bar{e}_\rho + \frac{1}{h_2} \frac{\partial \rho}{\partial \theta} \bar{e}_\theta + \frac{1}{h_3} \frac{\partial \rho}{\partial z} \bar{e}_z \\ &= \frac{1}{1} \cdot 1 \cdot \bar{e}_\rho = \cos \theta \bar{i} + \sin \theta \bar{j}\end{aligned}$$

Similarly,

$$\nabla q_2 = \nabla \theta = \frac{1}{h_2} \frac{\partial \theta}{\partial \theta} \bar{e}_\theta = \frac{1}{\rho} \bar{e}_\theta = \frac{-\sin \theta \bar{i} + \cos \theta \bar{j}}{\rho}$$

$$\nabla q_3 = \nabla z = \frac{1}{h_3} \frac{\partial z}{\partial z} \bar{e}_z = \bar{e}_z = \bar{k}.$$

Example 12: Prove that the surface area of a given region R of the surface $\bar{r} = \bar{r}(u, v)$ is $\int \int_R \sqrt{EG - F^2} du dv$. Use this to determine the surface area of a sphere.

Fig. 15.5

Solution: Element of area is given by

$$\begin{aligned}dS &= \left| \left(\frac{\partial \bar{r}}{\partial u} du \right) \times \frac{\partial \bar{r}}{\partial v} dv \right| = \left| \frac{\partial \bar{r}}{\partial u} \times \frac{\partial \bar{r}}{\partial v} \right| du dv \\ &= \sqrt{\left(\frac{\partial \bar{r}}{\partial u} \times \frac{\partial \bar{r}}{\partial v} \right) \cdot \left(\frac{\partial \bar{r}}{\partial u} \times \frac{\partial \bar{r}}{\partial v} \right)} du dv\end{aligned}$$

15.28 — HIGHER ENGINEERING MATHEMATICS—IV

Using

$$(\bar{A} \times \bar{B}) \cdot (\bar{C} \times \bar{D}) = (\bar{A} \cdot \bar{C})(\bar{B} \cdot \bar{D}) - (\bar{A} \cdot \bar{D})(\bar{B} \cdot \bar{C}),$$

we have

$$\begin{aligned} dS &= \sqrt{\left(\frac{\partial \bar{r}}{\partial u} \cdot \frac{\partial \bar{r}}{\partial u}\right)\left(\frac{\partial \bar{r}}{\partial v} \cdot \frac{\partial \bar{r}}{\partial v}\right) - \left(\frac{\partial \bar{r}}{\partial u} \cdot \frac{\partial \bar{r}}{\partial v}\right)\left(\frac{\partial \bar{r}}{\partial v} \cdot \frac{\partial \bar{r}}{\partial u}\right)} \\ &\quad \times du dv \\ dS &= \sqrt{EG - F^2} du dv \end{aligned}$$

where

$$E = \frac{\partial \bar{r}}{\partial u} \cdot \frac{\partial \bar{r}}{\partial u}, \quad G = \frac{\partial \bar{r}}{\partial v} \cdot \frac{\partial \bar{r}}{\partial v}, \quad F = \frac{\partial \bar{r}}{\partial u} \cdot \frac{\partial \bar{r}}{\partial v},$$

Integrating over the region R , the surface area of the given region R is given by

$$S = \iint_R \sqrt{EG - F^2} du dv$$

To find the surface area of a sphere of radius b the position vector $\bar{r}$ of any point on the surface is

$$\bar{r} = xi + yj + zk$$

In spherical coordinates

$$\bar{r} = b \sin \theta \cos \phi \bar{i} + b \sin \theta \sin \phi \bar{j} + b \cos \theta \bar{k}$$

$$\bar{r} = \bar{r}(\theta, \phi)$$

Differentiating partially w.r.t. θ and ϕ , we get

$$\frac{\partial \bar{r}}{\partial \theta} = b \cos \theta \cos \phi \bar{i} + b \cos \theta \sin \phi \bar{j} - b \sin \theta \bar{k}$$

$$\frac{\partial \bar{r}}{\partial \phi} = -b \sin \theta \sin \phi \bar{i} + b \sin \theta \cos \phi \bar{j}$$

$$E = \frac{\partial \bar{r}}{\partial \theta} \cdot \frac{\partial \bar{r}}{\partial \theta} = b^2, \quad G = \frac{\partial \bar{r}}{\partial \phi} \cdot \frac{\partial \bar{r}}{\partial \phi} = b^2 \sin^2 \theta,$$

$$F = \frac{\partial \bar{r}}{\partial \phi} \cdot \frac{\partial \bar{r}}{\partial \theta} = 0$$

$$\begin{aligned} S &= \iint_R \sqrt{EG - F^2} d\theta d\phi \\ &= \int_0^{2\pi} \int_0^\pi \sqrt{b^2 \cdot b^2 \sin^2 \theta - 0} d\theta d\phi \\ &= 2\pi b^2(-1 - 1) = 4\pi b^2. \end{aligned}$$

Example 13: Prove that curl of gradient $f = 0$ in any orthogonal curvilinear coordinate system.

Solution: In any orthogonal curvilinear coordinate system

$$\nabla f = \frac{1}{h_1} \frac{\partial f}{\partial q_1} \bar{e}_1 + \frac{1}{h_2} \frac{\partial f}{\partial q_2} \bar{e}_2 + \frac{1}{h_3} \frac{\partial f}{\partial q_3} \bar{e}_3$$

Then

$$\begin{aligned} \nabla \times \nabla f &= \frac{1}{h_1 h_2 h_3} \begin{vmatrix} h_1 \bar{e}_1 & h_2 \bar{e}_2 & h_3 \bar{e}_3 \\ \frac{\partial}{\partial q_1} & \frac{\partial}{\partial q_2} & \frac{\partial}{\partial q_3} \\ h_1 \frac{1}{h_1} \frac{\partial f}{\partial q_1} & h_2 \frac{1}{h_2} \frac{\partial f}{\partial q_2} & h_3 \frac{1}{h_3} \frac{\partial f}{\partial q_3} \end{vmatrix} \\ &= \frac{1}{h_1 h_2 h_3} \left[h_1 \bar{e}_1 \left\{ \frac{\partial^2 f}{\partial q_2 \partial q_3} - \frac{\partial^2 f}{\partial q_3 \partial q_2} \right\} \right. \\ &\quad \left. - h_2 \bar{e}_2 \left\{ \frac{\partial^2 f}{\partial q_1 \partial q_3} - \frac{\partial^2 f}{\partial q_3 \partial q_1} \right\} \right. \\ &\quad \left. + h_3 \bar{e}_3 \left\{ \frac{\partial^2 f}{\partial q_1 \partial q_2} - \frac{\partial^2 f}{\partial q_2 \partial q_1} \right\} \right] = 0. \end{aligned}$$

Example 14: Find the square of the element of arc length in cylindrical coordinates and determine the corresponding scale factors.

Solution: The position vector is

$$\bar{r} = \rho \cos \theta \bar{i} + \rho \sin \theta \bar{j} + z \bar{k}$$

Then

$$\begin{aligned} d\bar{r} &= \frac{\partial \bar{r}}{\partial \rho} d\rho + \frac{\partial \bar{r}}{\partial \theta} d\theta + \frac{\partial \bar{r}}{\partial z} dz \\ &= (\cos \theta \bar{i} + \sin \theta \bar{j}) d\rho \\ &\quad + (-\rho \sin \theta \bar{i} + \rho \cos \theta \bar{j}) d\theta + \bar{k} dz \\ d\bar{r} &= (\cos \theta d\rho - \rho \sin \theta d\theta) \bar{i} \\ &\quad + (\sin \theta d\rho + \rho \cos \theta d\theta) \bar{j} + \bar{k} dz \end{aligned}$$

Thus

$$\begin{aligned} ds^2 &= d\bar{r} \cdot d\bar{r} = (\cos \theta d\rho - \rho \sin \theta d\theta)^2 \\ &\quad + (\sin \theta d\rho + \rho \cos \theta d\theta)^2 + (dz)^2 \\ &= (d\rho)^2 + \rho^2 (d\theta)^2 + (dz)^2 \end{aligned}$$

Here

$$h_1 = h_\rho = 1, \quad h_2 = h_\theta = \rho, \quad h_3 = h_z = 1$$

are the scale factors.

Example 15: A vector field is given in cylindrical coordinates as

$$\bar{A}(P) = \rho \bar{e}_\rho + \theta \bar{e}_\theta$$

Find the vector lines of the field.

Solution: It is given that $a_1 = 1$, $a_2 = \theta$, $a_3 = 0$. So that

$$\frac{d\rho}{1} = \frac{P d\theta}{\theta} = \frac{dz}{0}$$

whence

$$z = c_1$$

$$\rho = c_2 \theta$$

which are Archimedean spirals lying in planes parallel to the xy -plane (i.e., $z = \text{constant}$).

Example 16: Compute the gradient of the scalar field $f = \rho + z \cos \theta$ specified in cylindrical coordinates (ρ, θ, z) .

Solution:

$$\begin{aligned} \nabla f &= \frac{\partial f}{\partial \rho} \bar{e}_\rho + \frac{1}{\rho} \frac{\partial f}{\partial \theta} \bar{e}_\theta + \frac{\partial f}{\partial z} \bar{e}_z \\ &= 1 \cdot \bar{e}_\rho + \frac{1}{\rho} (-z \sin \theta) \bar{e}_\theta + \cos \theta \bar{e}_z. \end{aligned}$$

Example 17: Compute the curl of $\bar{A}$ specified in cylindrical coordinates where

$$\bar{A} = \sin \theta \bar{e}_\rho + \frac{\cos \theta}{\rho} \bar{e}_\theta - \rho z \bar{e}_z$$

Solution: Since

$$\begin{aligned} \nabla \times \bar{A} &= \begin{vmatrix} \frac{1}{\rho} \bar{e}_\rho & \bar{e}_\theta & \frac{1}{\rho} \bar{e}_z \\ \frac{\partial}{\partial \rho} & \frac{\partial}{\partial \theta} & \frac{\partial}{\partial z} \\ a_1 & a_2 & a_3 \end{vmatrix} = \begin{vmatrix} \frac{1}{\rho} \bar{e}_\rho & \bar{e}_\theta & \frac{1}{\rho} \bar{e}_z \\ \frac{\partial}{\partial \rho} & \frac{\partial}{\partial \theta} & \frac{\partial}{\partial z} \\ \sin \theta & \cos \theta & -\rho z \end{vmatrix} \\ &= \frac{1}{\rho} \bar{e}_\rho (0 - 0) - \bar{e}_\theta (-z - 0) + \frac{1}{\rho} \bar{e}_z (0 - \cos \theta) \\ \nabla \times \bar{A} &= z \bar{e}_\theta - \frac{\cos \theta}{\rho} \bar{e}_z \end{aligned}$$

Example 18: Show that the vector field $\bar{A}$ in spherical coordinates

$$\bar{A} = \frac{2 \cos \theta}{r^3} \bar{e}_r + \frac{\sin \theta}{r^3} \bar{e}_\theta$$

is solenoidal.

Solution: We know that divergence in spherical co-

ordinates

$$\begin{aligned} \nabla \cdot \bar{A} &= \frac{1}{\rho^2} \frac{\partial(\rho^2 a_1)}{\partial \rho} + \frac{1}{\rho \sin \theta} \frac{\partial}{\partial \theta} (\sin \theta a_2) + \frac{1}{\rho \sin \theta} \frac{\partial a_3}{\partial \phi} \\ \nabla \cdot \bar{A} &= \frac{1}{\rho^2} \frac{\partial}{\partial r} \left(\rho^2 \cdot \frac{2 \cos \theta}{\rho^3} \right) \\ &\quad + \frac{1}{\rho \sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \cdot \frac{\sin \theta}{\rho^3} \right) + 0 \\ &= \frac{1}{\rho^2} \left(-\frac{2 \cos \theta}{\rho^2} \right) + \frac{1}{\rho^4 \sin \theta} \cdot 2 \cdot \sin \theta \cos \theta = 0 \end{aligned}$$

wherever $r \neq 0$, which means that the vector field $\bar{A}$ is solenoidal at all points except at $r = 0$.

Example 19: Find the potential of

$$\bar{A} = \frac{1}{\rho} e^{\theta \phi} \bar{e}_r + \frac{\theta \ln \rho}{r \sin \theta} e^{\theta \phi} \bar{e}_\theta + \frac{\ln \rho}{\rho} \phi e^{\theta \phi} \bar{e}_\phi$$

given in spherical coordinates.

Solution: In spherical coordinates

$$\nabla \times \bar{A} = \frac{1}{\rho^2 \sin \theta} \begin{vmatrix} \bar{e}_r & \rho \bar{e}_\theta & r \sin \theta \bar{e}_\phi \\ \frac{\partial}{\partial \rho} & \frac{\partial}{\partial \theta} & \frac{\partial}{\partial \phi} \\ \frac{1}{\rho} e^{\theta \phi} & \phi \ln r e^{\theta \phi} & \theta \ln r e^{\theta \phi} \end{vmatrix} = 0.$$

Thus $\bar{A}$ is a potential field in the region where $r > 0$, $\theta \neq n\pi$ ($n = 0, \neq 1, \dots$).

$$\text{Let } \bar{A} = \nabla f = \frac{\partial f}{\partial \rho} \bar{e}_\rho + \frac{\partial f}{\partial \theta} \bar{e}_\theta + \frac{\partial f}{\partial \phi} \bar{e}_\phi$$

where $f = f(\rho, \theta, \phi)$ is the desired potential function, which is the solution of the following system of differential equations.

$$\frac{\partial f}{\partial \rho} = \frac{1}{\rho} e^{\theta \phi} \quad (1)$$

$$\frac{\partial f}{\partial \theta} = \phi e^{\theta \phi} \ln \rho \quad (2)$$

$$\frac{\partial f}{\partial \phi} = \theta e^{\theta \phi} \ln r \quad (3)$$

Integrating (1) w.r.t. ρ we get

$$f = e^{\theta \phi} \ln \rho + c_1(\phi, \theta) \quad (4)$$

Differentiating (4) w.r.t. ' θ ' and equating it with (2)

$$\phi e^{\theta \phi} \ln r = \frac{\partial f}{\partial \theta} = \phi e^{\theta \phi} \ln \rho + \frac{\partial c_1}{\partial \theta}$$

15.30 — HIGHER ENGINEERING MATHEMATICS—IV

i.e., $\frac{\partial c_1}{\partial \theta} = 0$ whence

$$c_1(\phi, \theta) = c_2(\phi) \quad (5)$$

Substituting (5) in (4)

$$f = e^{\theta\phi} \ln \rho + c_2(\phi) \quad (6)$$

Differentiating (6) w.r.t. ϕ and equating it with (3) we obtain

$$\theta e^{\theta\phi} \ln r = \frac{\partial f}{\partial \phi} = \theta e^{\theta\phi} \ln r + \frac{dc_2}{d\phi}$$

so $\frac{dc_2}{d\phi} = 0$ i.e., $c_2 = c = \text{constant}$. The desired potential is

$$f(r, \theta, \phi) = e^{\theta\rho} \ln r + c$$

Example 20: Find all the solutions of the Laplace's equation $\nabla^2 f = 0$ that depend solely on the distance ρ .

Solution: Laplace's equation in spherical coordinates with spherical symmetry (f must not depend on θ or ϕ , i.e., $f = f(r)$). We have

$$\nabla^2 f = \frac{1}{\rho^2} \frac{\partial}{\partial \rho} \left(\rho^2 \frac{\partial f}{\partial \rho} \right) = 0$$

so that

$$\rho^2 \frac{\partial f}{\partial \rho} = c_1 = \text{const.}$$

whence

$$f = \frac{c_1}{\rho} + c_2$$

where c_1 and c_2 are constants.

Example 21: Find the Laplacian of

$$f(\rho, \theta, z) = \rho^2 \theta + z^2 \theta^3 - \rho \theta z$$

Solution:

$$\nabla^2 f = \frac{1}{\rho} \left[\frac{\partial}{\partial \rho} \left(\rho \frac{\partial f}{\partial \rho} \right) + \frac{\partial}{\partial \theta} \left(\frac{1}{\rho} \frac{\partial f}{\partial \theta} \right) + \frac{\partial}{\partial z} \left(\rho \frac{\partial f}{\partial z} \right) \right]$$

Here

$$\frac{\partial f}{\partial \rho} = 2\theta + 0 - \theta z, \quad \frac{\partial^2 f}{\partial \rho^2} = 2\theta$$

$$\frac{\partial f}{\partial \theta} = \rho^2 + 3z^2 \theta^2 - \rho z, \quad \frac{\partial^2 f}{\partial \theta^2} = 6z^2 \theta$$

$$\frac{\partial f}{\partial z} = 2z\theta^3 - \rho\theta, \quad \frac{\partial^2 f}{\partial z^2} = 2\theta^3$$

$$\nabla^2 f = \frac{1}{\rho} \left[\frac{\partial f}{\partial \rho} + \rho \frac{\partial^2 f}{\partial \rho^2} + \frac{1}{\rho} \frac{\partial^2 f}{\partial \theta^2} + \rho \frac{\partial^2 f}{\partial z^2} \right]$$

Substituting the above partial derivatives

$$\nabla^2 f = \frac{1}{\rho} [2\rho\theta - \theta z + \rho 2\theta + \frac{1}{\rho} 6z^2 \theta + \rho 2\theta^3]$$

$$\nabla^2 f = 4\theta - \frac{\theta z}{\rho} + \frac{6\theta z^2}{\rho^2} + 2\theta^3$$

Example 22: (a) Find the unit vectors $\bar{e}_\rho, \bar{e}_\theta, \bar{e}_\phi$ in spherical coordinate system in terms of i, j, k . (b) Solve for i, j, k in terms of e_r, e_θ, e_ϕ .

Solution: From Example 8

$$\bar{e}_\rho = \sin \theta \cos \phi \bar{i} + \sin \theta \sin \phi \bar{j} + \cos \theta \bar{k} \quad (1)$$

$$\bar{e}_\theta = \cos \theta \cos \phi \bar{i} + \cos \theta \sin \phi \bar{j} - \sin \theta \bar{k} \quad (2)$$

$$\bar{e}_\phi = -\sin \phi \bar{i} + \cos \phi \bar{j} \quad (3)$$

Solving (1), (2), (3) simultaneously

$$(1) \times \sin \theta: \quad \sin \theta \bar{e}_\rho$$

$$= \sin^2 \theta (\cos \phi \bar{i} + \sin \phi \bar{j}) + \sin \theta \cos \theta \bar{k}$$

$$(2) \times \cos \theta: \quad \cos \theta \bar{e}_\theta$$

$$= \cos^2 \theta (\cos \phi \bar{i} + \sin \phi \bar{j}) - \sin \theta \cos \theta \bar{k}$$

Adding

$$\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta = \cos \phi \bar{i} + \sin \phi \bar{j} \quad (4) \times \sin \phi$$

$$\bar{e}_\phi = -\sin \phi \bar{i} + \cos \phi \bar{j} \quad (5) \times \cos \phi$$

Adding

$$\bar{j} = (\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta) \sin \phi + \cos \phi \bar{e}_\phi \quad (6)$$

Substituting (6) in (3)

$$\bar{i} = \frac{1}{\sin \phi} (\cos \phi \bar{j} - \bar{e}_\phi)$$

$$\bar{i} = \frac{1}{\sin \phi} \left[\{(\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta) \sin \phi + \cos \phi \bar{e}_\phi\} \times \cos \phi - \bar{e}_\phi \right]$$

$$\begin{aligned} \bar{i} &= \{\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta + \cot \phi \bar{e}_\phi\} \\ &\times \cos \phi - \operatorname{cosec} \phi \bar{e}_\phi \end{aligned} \quad (7)$$

Substituting (6) and (7) in (2)

$$\begin{aligned} \bar{e}_\theta &= \cos \theta \cdot \cos \phi [\{\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta + \cot \phi \bar{e}_\phi\} \\ &\times \cos \phi - \operatorname{cosec} \phi \bar{e}_\phi] + \cos \theta \sin \phi \\ &\times [(\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta) \sin \phi + \cos \phi \bar{e}_\phi] - \sin \theta \bar{k} \end{aligned}$$

Solving for $\bar{k}$,

$$\begin{aligned} \bar{k} &= \cot \theta \cdot \cos \phi [\{\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta + \cot \phi \bar{e}_\phi\} \\ &\times \cos \phi - \operatorname{cosec} \phi \bar{e}_\phi] + \cot \theta \sin \phi [(\sin \theta \bar{e}_\rho \\ &+ \cos \theta \bar{e}_\theta) \sin \phi + \cos \phi \bar{e}_\phi] - \operatorname{cosec} \theta \cdot \bar{e}_\theta \end{aligned} \quad (8)$$

Example 23: Represent the vector $\bar{A} = 2yi - zj + 3xk$ in spherical coordinates and determine A_r, A_θ, A_ϕ .

Solution: Substituting (7), (6), (8) in $\bar{A} = 2yi - zj + 3xk$ from the above Example 22, we get $\bar{A}$ in spherical coordinates as

$$\begin{aligned} \bar{A} &= [\{\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta + \cot \phi \bar{e}_\phi\} \cos \phi - \operatorname{cosec} \phi \bar{e}_\phi] \\ &\times 2r \sin \theta \sin \phi - [(\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta) \sin \phi + \cos \phi \bar{e}_\phi] \\ &\times r \cos \theta + 3r \sin \theta \cot \theta \cos \phi [\{\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta \\ &+ \cot \phi \bar{e}_\phi\} \cos \phi - \operatorname{cosec} \phi \bar{e}_\phi] + 3r \sin \theta \cdot \cos \phi \\ &\times \cot \theta \cdot \sin \phi [(\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta) \sin \phi + \cos \phi \bar{e}_\phi] \\ &- 3r \sin \theta \cdot \cos \phi \operatorname{cosec} \theta \bar{e}_\theta. \end{aligned}$$

Collecting the coefficients of $\bar{e}_\rho, \bar{e}_\theta$ and $\bar{e}_\phi$, we rewrite

$$\begin{aligned} \bar{A} &= [2r \sin^2 \theta \cdot \sin \phi \cos \phi - r \sin \theta \cos \theta \sin \phi \\ &+ 3r \sin^2 \theta \cot \theta \cos^2 \phi \cos \phi \\ &+ 3r \sin^2 \theta \cot \theta \cdot \cos \phi \sin \phi \cdot \sin \phi] \bar{e}_\rho \\ &+ [\cos \theta \cdot \cos \phi \cdot 2r \cdot \sin \theta \cdot \sin \phi - \cos \theta \cdot \sin \phi r \cos \theta \\ &+ 3r \sin \theta \cdot \cos \phi \cdot \cot \theta \cdot \cos \phi \cos \theta \cdot \cos \phi \\ &+ 3r \sin \theta \cdot \cos \phi \cdot \cot \theta \cdot \sin \phi \cos \theta \sin \phi \\ &- 3r \sin \theta \cdot \cos \phi \cdot \operatorname{cosec} \theta] \bar{e}_\theta + [(\cot \phi \cos \phi \\ &- \operatorname{cosec} \phi) 2r \sin \theta \sin \phi - \cos \phi r \cos \theta \\ &+ \{\cot \phi \cdot \cos \phi - \operatorname{cosec} \phi\} 3r \sin \theta \cdot \cot \theta \cdot \cos^2 \phi \\ &+ \cos \phi \cdot 3r \sin \theta \cdot \cot \theta \cdot \cos \phi \cdot \sin \phi] \bar{e}_\phi \end{aligned}$$

Simplifying the result, we get

$$\begin{aligned} A_r &= 2r \sin^2 \theta \sin \phi \cdot \cos \phi - r \sin \theta \cdot \cos \theta \cdot \sin \phi \\ &+ 3r \sin \theta \cos \theta \cdot \cos \phi \\ A_\theta &= 2r \sin \theta \cos \theta \cdot \sin \phi \cos \phi - r \cos^2 \theta \cdot \sin \phi \\ &- 3r \sin^2 \theta \cdot \cos \phi \\ A_\phi &= -2r \sin \theta \sin^2 \phi - r \cos \theta \cos \phi \end{aligned}$$

Example 24: Express the velocity $\bar{v}$ and acceleration $\bar{a}$ of a particle in spherical coordinates.

Solution: In rectangular coordinates the position vector, velocity and acceleration vectors are

$$\begin{aligned} \bar{r} &= x\bar{i} + y\bar{j} + z\bar{k} \\ \bar{V} &= \frac{d\bar{r}}{dt} = \dot{x}\bar{i} + \dot{y}\bar{j} + \dot{z}\bar{k} \\ \bar{a} &= \frac{d^2\bar{r}}{dt^2} = \ddot{x}\bar{i} + \ddot{y}\bar{j} + \ddot{z}\bar{k} \end{aligned}$$

In spherical coordinates

$$\begin{aligned} \bar{r} &= x\bar{i} + y\bar{j} + z\bar{k} \\ &= r \sin \theta \cos \phi \bar{i} + r \sin \theta \sin \phi \bar{j} + r \cos \theta \bar{k} \end{aligned}$$

Substituting $\bar{i}, \bar{j}, \bar{k}$ from (7), (6), (8) of the previous Example 22, we get

$$\begin{aligned} \bar{r} &= r \sin \theta \cos \phi [\{\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta\} \cos \phi - \sin \phi \bar{e}_\phi] \\ &+ r \sin \theta \sin \phi [\{\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta\} \sin \phi + \cos \phi \bar{e}_\phi] \\ &+ r \cos \theta [\cot \theta \cdot \cos \phi \{(\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta) \cos \phi \\ &- \sin \phi \bar{e}_\phi\}] + r \cos \theta [\cot \theta \sin \phi \{(\sin \theta \bar{e}_\rho \\ &+ \cos \theta \bar{e}_\theta) \sin \phi + \cos \phi \bar{e}_\phi\}] - r \cos \theta \cdot \operatorname{cosec} \theta \bar{e}_\theta \end{aligned}$$

Collecting the coefficients of $\bar{e}_\rho, \bar{e}_\theta, \bar{e}_\phi$

$$\begin{aligned} \bar{r} &= [r \sin^2 \theta \cdot \cos^2 \phi + r \sin^2 \theta \cdot \sin^2 \phi \\ &+ r \cos \theta \cdot \cot \theta \cdot \sin \theta \cdot \cos^2 \phi \\ &+ r \cos \theta \cdot \cot \theta \cdot \sin^2 \phi \cdot \sin \theta] \bar{e}_\rho \\ &+ \bar{e}_\theta [r \sin \theta \cdot \cos^2 \phi \cdot \cos \theta + r \sin \theta \sin^2 \phi \cdot \cos \theta \\ &+ r \cos \theta \cdot \cot \theta \cdot \cos^2 \phi \cos \theta \\ &+ r \cos \theta \cdot \cot \theta \cdot \sin^2 \phi \cos \theta - r \cos \theta \cos \theta] \\ &+ [-r \sin \theta \cdot \cos \phi \sin \phi + r \sin \theta \cdot \sin \phi \cos \phi \\ &- r \cos \theta \cot \theta \cdot \cos \phi \cdot \sin \phi \\ &+ r \cos \theta \cdot \cot \theta \cdot \sin \phi \cos \phi] \bar{e}_\phi \end{aligned}$$

15.32 — HIGHER ENGINEERING MATHEMATICS—IV

Simplifying, we get

$$\bar{r} = r\bar{e}_\rho + 0 \cdot \bar{e}_\theta + 0\bar{e}_\phi \quad (1)$$

Differentiating (1) w.r.t. 't'

$$\text{Velocity} = \bar{V} = \frac{d\bar{r}}{dt} = \frac{dr}{dt}\bar{e}_\rho + r \frac{d}{dt}\bar{e}_\rho \quad (2)$$

Here

$$\begin{aligned} \frac{d}{dt}\bar{e}_\rho &= \frac{d}{dt}(\sin \theta \cos \phi \bar{i} + \sin \theta \sin \phi \bar{j} + \cos \theta \bar{k}) \\ &= \cos \theta \cdot \dot{\theta} \cos \phi \bar{i} - \sin \theta \sin \phi \cdot \dot{\phi} \bar{i} \\ &\quad + \cos \theta \cdot \dot{\theta} \cdot \sin \phi \bar{j} + \sin \theta \cdot \cos \phi \dot{\phi} \bar{j} - \sin \theta \dot{\theta} \bar{k} \\ &= \dot{\theta}(\cos \theta \cdot \cos \phi \bar{i} + \cos \theta \sin \phi \bar{j} - \sin \theta \bar{k}) \\ &\quad + \dot{\phi} \sin \theta (-\sin \phi \bar{i} + \cos \phi \bar{j}) \end{aligned}$$

$$\frac{d}{dt}(\bar{e}_\rho) = \dot{\theta}\bar{e}_\theta + \dot{\phi} \sin \theta \bar{e}_\phi \quad (3)$$

Substituting (3) in (1)

$$\begin{aligned} \bar{V} &= \dot{r}\bar{e}_\rho + r[\dot{\theta}\bar{e}_\theta + \dot{\phi} \sin \theta \bar{e}_\phi] \\ \bar{V} &= v_\rho \bar{e}_\rho + v_\theta \bar{e}_\theta + v_\phi \bar{e}_\phi \quad (4) \end{aligned}$$

where

$$v_\rho = \dot{r}, v_\theta = \dot{r}\dot{\theta}, v_\phi = \dot{r}\dot{\phi} \sin \theta$$

Differentiating (4) w.r.t. 't'

$$\begin{aligned} \text{Acceleration} = \bar{a} &= \frac{d\bar{V}}{dt} \\ &= \frac{dv_\rho}{dt}\bar{e}_\rho + v_\rho \frac{d}{dt}\bar{e}_\rho + \frac{dv_\theta}{dt} \cdot \bar{e}_\theta \\ &\quad + v_\theta \cdot \frac{d\bar{e}_\theta}{dt} + \frac{dv_\phi}{dt}\bar{e}_\phi + v_\phi \cdot \frac{d}{dt}\bar{e}_\phi \quad (5) \end{aligned}$$

Here

$$\begin{aligned} \frac{dv_\rho}{dt} &= \frac{d}{dt}\dot{r} = \ddot{r}, \\ \frac{dv_\theta}{dt} &= \frac{d}{dt}(\dot{r}\dot{\theta}) = \dot{r}\ddot{\theta} + \ddot{r}\dot{\theta} \\ \frac{dv_\phi}{dt} &= \frac{d}{dt}(r\dot{\phi} \sin \theta) = \dot{r}\dot{\phi} \sin \theta + r\ddot{\phi} \sin \theta + r\dot{\phi}\dot{\theta} \cos \theta \\ \frac{d\bar{e}_\theta}{dt} &= -\sin \theta \cdot \dot{\theta} \cos \phi \bar{i} - \cos \theta \cdot \sin \phi \dot{\phi} \bar{i} \\ &\quad - \sin \theta \dot{\theta} \sin \phi \bar{j} + \cos \theta \cdot \cos \phi \dot{\phi} \bar{j} - \cos \theta \dot{\theta} \bar{k} \\ &= -\dot{\theta}(\sin \theta \cdot \cos \phi \bar{i} + \sin \theta \sin \phi \bar{j} + \cos \theta \bar{k}) \\ &\quad + \dot{\phi} \cos \theta (-\sin \phi \bar{i} + \cos \phi \bar{j}) \end{aligned}$$

$$\frac{d\bar{e}_\theta}{dt} = -\dot{\theta}\bar{e}_\rho + \dot{\phi} \cos \theta \bar{e}_\phi$$

$$\begin{aligned} \frac{d\bar{e}_\phi}{dt} &= \frac{d}{dt}(-\sin \phi \bar{i} + \cos \phi \bar{j}) = -\cos \phi \dot{\phi} \bar{i} - \sin \phi \dot{\phi} \bar{j} \\ &= -\dot{\phi}(\cos \phi \bar{i} + \sin \phi \bar{j}) \end{aligned}$$

Substituting these values in (5), we get and replacing $\bar{i}$ and $\bar{j}$ by (7) and (6) of previous Example 22

$$\begin{aligned} \bar{a} &= \ddot{r}\bar{e}_\rho + \dot{r}(\dot{\theta}\bar{e}_\theta + \dot{\phi} \sin \theta \bar{e}_\phi) + (\dot{r}\ddot{\theta} + r\ddot{\theta})\bar{e}_\theta \\ &\quad + r\dot{\theta}(-\dot{\theta}\bar{e}_\rho + \dot{\phi} \cos \theta \bar{e}_\phi) + (\dot{r}\dot{\phi} \sin \theta + r\ddot{\phi} \sin \theta \\ &\quad + r\dot{\phi}\dot{\theta} \cos \theta)\bar{e}_\phi - r\dot{\phi}^2 \sin \theta \cdot \cos \phi [(\sin \theta \bar{e}_\rho \\ &\quad + \cos \theta \bar{e}_\theta) \cos \phi - \sin \phi \bar{e}_\phi] - r\dot{\phi}^2 \sin \theta \sin \phi \\ &\quad \times [(\sin \theta \bar{e}_\rho + \cos \theta \bar{e}_\theta) \sin \phi + \cos \theta \bar{e}_\phi] \end{aligned}$$

Rearranging the terms

$$\begin{aligned} \bar{a} &= [\ddot{r} - r\dot{\theta}^2 - r\dot{\phi}^2 \sin^2 \theta (\cos^2 \phi + \sin^2 \phi)]\bar{e}_\rho \\ &\quad + [2\dot{r}\dot{\theta} + r\ddot{\theta} - r\dot{\phi}^2 \sin \theta \cdot \cos \theta \cdot (\cos^2 \phi \\ &\quad + \sin^2 \phi)]\bar{e}_\theta + [\dot{r}\dot{\phi} \sin \theta + 2r\dot{\theta}\dot{\phi} \cos \theta + \dot{r}\dot{\phi} \sin \theta \\ &\quad + r\ddot{\phi} \sin \theta + r\dot{\phi}^2 \sin \theta \cdot \cos \phi \sin \phi \\ &\quad - r\dot{\phi}^2 \sin \theta \cdot \sin \phi \cos \phi]\bar{e}_\phi \end{aligned}$$

Thus

$$\bar{a} = a_r \bar{e}_r + a_\theta \bar{e}_\theta + a_\phi \bar{e}_\phi$$

where $a_r = \ddot{r} - r\dot{\theta}^2 - r \sin^2 \theta \dot{\phi}^2$

$$a_\theta = \frac{1}{r} \frac{d}{dt}(r^2 \dot{\theta}) - r \sin \theta \cos \theta \dot{\phi}^2$$

$$a_\phi = \frac{1}{r \sin \theta} \cdot \frac{d}{dt}(r^2 \sin^2 \theta \dot{\phi}).$$

EXERCISE

Find the equations of the vector fields $\bar{A}$ where:

$$1. \bar{A} = \bar{e}_\rho + \frac{1}{\rho} \bar{e}_\theta + \bar{e}_z \text{ (cylindrical)}$$

$$\text{Ans. } \rho = \theta + c_1, \rho = z + c_2$$

$$2. \bar{A} = 2\alpha \frac{\cos \theta}{\rho^3} \bar{e}_r + \frac{\alpha \sin \theta}{\rho^3} \bar{e}_\theta, \alpha = \text{constant} \text{ (spherical)}$$

$$\text{Ans. } \phi = c_1, \rho = c_2 \sin^2 \theta$$

Find the gradient of the scalar fields f :

3. $f = \rho z \cos \theta$ (cylindrical)

Ans. $(z \cos \theta) \bar{e}_\rho - (z \sin \theta) \bar{e}_\theta + (\rho \cos \theta) \bar{e}_z$

4. $f = \rho^2 \sin 2\theta \sin \phi$ (spherical)

Ans. $(2\rho \sin 2\theta \sin \phi) \bar{e}_\rho + (2\rho \cos 2\theta \sin \phi) \bar{e}_\theta + (2\rho \cos \theta \cos \phi) \bar{e}_\phi$

5. $f = xyz$ in (a) cylindrical (b) spherical coordinates

Ans. a. $(\rho z \sin 2\theta) \bar{e}_\rho + (\rho z \cos 2\theta) \bar{e}_\theta + \left(\frac{\rho^2}{2} \sin 2\theta\right) \bar{e}_z$

b. $(3\rho^2 \sin^2 \theta \cos \theta \cdot \sin \phi \cos \phi) \bar{e}_\rho + \frac{\rho^2}{2} \sin 2\phi \{-\sin^3 \theta + 2 \sin \theta \cos^2 \theta\} \bar{e}_\theta + (\rho^2 \sin \theta \cos \theta \cos 2\theta) \bar{e}_\phi$

6. $f = \rho^2 + 2\rho \cos \theta - e^z \sin \theta$ (in cylindrical)

Ans. $2(\rho + \cos \theta) \bar{e}_\rho - (2 \sin \theta + \frac{1}{\rho} e^z \cos \theta) \bar{e}_\theta - e^z \sin \theta \bar{e}_z$

7. $f = 3\rho^2 \sin \theta + e^\rho \cos \phi - r$ (in spherical)

Ans. $(6\rho \cdot \sin \theta + e^\rho \cos \phi - 1) \bar{e}_\rho + 3\rho \cos \theta \bar{e}_\theta - \frac{e^\rho \sin \phi}{\rho \sin \theta} \bar{e}_\phi$

Compute the divergence of $\bar{A}$:

8. $\bar{A} = \theta \arctan \rho \bar{e}_\rho + 2\bar{e}_\theta - z^2 e^z \bar{e}_z$ (in cylindrical)

Ans. $\frac{\theta}{\rho} \arctan \rho + \frac{\theta}{1+\rho^2} - (z^2 + 2z) e^z$

9. $\bar{A} = \rho^2 \bar{e}_\rho - 2 \cos^2 \phi \bar{e}_\theta + \frac{\phi}{\rho^2+1} \bar{e}_\phi$ (in spherical)

Ans. $4\rho - \frac{2}{\rho} \cos^2 \phi \cot \theta + \frac{1}{\rho(\rho^2+1) \sin \theta}$

Compute the curl of $\bar{A}$:

10. $\bar{A} = (2\rho + \alpha \cos \phi) \bar{e}_\rho - \alpha \sin \theta \bar{e}_\theta + \rho \cos \theta \bar{e}_\phi$, $\alpha = \text{constant}$ (in spherical)

Ans. $\frac{\cos 2\theta}{\sin \theta} \bar{e}_r - (2 \cos \theta + \frac{\alpha \sin \phi}{\rho \sin \theta}) \bar{e}_\theta - \frac{\alpha \sin \theta}{\rho} \bar{e}_\phi$

11. $\bar{A} = \cos \theta \bar{e}_\rho - \frac{\sin \theta}{\rho} \bar{e}_\theta + \rho^2 \bar{e}_z$ (in cylindrical)

Ans. $-2\rho \bar{e}_\theta + \frac{\sin \theta}{\rho} \bar{e}_z$

12. a. Show that $\bar{A} = z \{(\sin \theta) \bar{e}_\rho + \cos \theta \bar{e}_\theta\} - \rho \cos \theta \bar{e}_z$ (in cylindrical) is solenoidal.

Hint: $\nabla \cdot \bar{A} = 0$

b. Show that $\bar{A} = (\rho z \sin 2\theta) \bar{e}_\rho + (\rho z \cos 2\theta) \bar{e}_\theta + \frac{\rho^2 \sin^2 \theta}{2} \bar{e}_z$ is irrotational.

Hint: $\nabla \times \bar{A} = 0$.

13. Show that $\bar{A}$ is a potential field where

$\bar{A} = \frac{2 \cos \theta}{\rho^3} \bar{e}_r + \frac{\sin \theta}{\rho^3} \bar{e}_\theta$ (in spherical)

14. Show that $\bar{A} = f(\rho) \bar{e}_\rho$ is a potential field where f is any differentiable function.

Hint: $\bar{e}_1 = \cos \theta \bar{i} + \sin \theta \bar{j}$, $\bar{e}_2 = -\sin \theta \bar{i} + \cos \theta \bar{j}$, $\bar{e}_3 = \bar{k}$ prove that $\bar{e}_1 \cdot \bar{e}_2 = \bar{e}_2 \cdot \bar{e}_3 = \bar{e}_1 \cdot \bar{e}_3 = 0$.

15. In cylindrical coordinate ρ, θ, z , show that $\nabla(\log \rho)$ and $\nabla \theta$ are solenoidal vectors (if $\rho \neq 0, \theta \neq 0$).

16. Show that $\nabla^2 f = 2\rho^2 \cos 2\theta$ when $f = \rho^2 z^2 \cos 2\theta$ (in cylindrical)

17. Prove that $\nabla^2 f = 2 \sin 2\theta + 2 \cot \theta \cos 2\theta - \frac{2}{\rho^2} \operatorname{cosec}^2 \theta \cos 2\phi$ if $f = \rho^2 \sin 2\theta + \cos^2 \phi$ (in spherical)

18. Represent the vector $\bar{A} = zi - 2xj + yk$ in cylindrical coordinates. Determine A_ρ, A_θ, A_z .

Ans. $A_\rho = z \cos \theta - 2\rho \cos \theta \cdot \sin \theta$

$A_\theta = -z \sin \theta - 2\rho \cos^2 \theta$

$A_z = \rho \sin \theta$

19. Represent the vector $\bar{A} = xy\bar{i} - z\bar{j} + xz\bar{k}$ in spherical coordinate system.

Ans. $A_\rho = \rho^2 \sin^3 \theta \sin \phi \cos^2 \phi - \rho \sin \theta \cos \theta \sin \phi + \rho^2 \sin \theta \cos^2 \theta \cos \phi$

$A_\theta = \rho^2 \sin^2 \theta \cos \theta \sin \phi \cos^2 \phi$

$-\rho \cos^2 \theta \cdot \sin \phi - \rho^2 \sin^2 \theta \cdot \cos \theta \cos \phi$

$A_\phi = -\rho^2 \sin^2 \theta \sin^2 \phi \cos \phi - \rho \cos \theta \cos \phi$

20. Express $\bar{A} = 2y\bar{i} - z\bar{j} + 3x\bar{k}$ in spherical polar coordinate system.

Ans. $A_\rho = 2\rho \sin^2 \theta \cdot \sin \phi \cos \phi - \rho \sin \theta \cos \theta \cdot \sin \phi + 3\rho \sin \theta \cos \theta \cos \rho$

$A_\theta = 2\rho \sin \theta \cdot \cos \theta \sin \phi \cos \phi$

9. Div A	$\frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z}$	$\frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} (h_2 h_3 A_1) + \frac{\partial}{\partial q_2} (h_1 h_3 A_2) + \frac{\partial}{\partial q_3} (h_1 h_2 A_3) \right]$	$\text{Div A} = \frac{1}{r^2 \sin \theta} \left[\frac{\partial}{\partial r} (r^2 \sin \theta A_1) + \frac{\partial}{\partial \theta} (r \sin \theta A_2) + \frac{\partial}{\partial \phi} (r A_3) \right]$	$\frac{1}{\rho} \left[\frac{\partial}{\partial \rho} (\rho A_1) + \frac{\partial}{\partial \theta} (\rho A_2) + \frac{\partial}{\partial z} (\rho A_3) \right]$
10. Curl A	$\begin{vmatrix} \bar{i} & \bar{j} & \bar{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ A_1 & A_2 & A_3 \end{vmatrix}$	$\begin{vmatrix} h_1 \bar{e}_1 & h_2 \bar{e}_2 & h_3 \bar{e}_3 \\ \frac{\partial}{\partial q_1} & \frac{\partial}{\partial q_2} & \frac{\partial}{\partial q_3} \\ \frac{A_1}{h_1} & \frac{A_2}{h_2} & \frac{A_3}{h_3} \end{vmatrix}$	$\begin{vmatrix} \bar{e}_r & r \bar{e}_\theta & r \sin \theta \bar{e}_\phi \\ \frac{\partial}{\partial r} & \frac{\partial}{\partial \theta} & \frac{\partial}{\partial \phi} \\ A_1 & r A_2 & (r \sin \theta) A_3 \end{vmatrix}$	$\begin{vmatrix} \bar{e}_\rho & \rho \bar{e}_\theta & \bar{e}_z \\ \frac{\partial}{\partial \rho} & \frac{\partial}{\partial \theta} & \frac{\partial}{\partial z} \\ A_1 & \rho A_2 & A_3 \end{vmatrix}$
11. Laplacian ($\nabla^2 f$)	$\frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}$	$\frac{1}{h_1 h_2 h_3} \left[\frac{\partial}{\partial q_1} \left(\frac{h_2 h_3}{h_1} \frac{\partial f}{\partial q_1} \right) + \frac{\partial}{\partial q_2} \left(\frac{h_1 h_3}{h_2} \frac{\partial f}{\partial q_2} \right) + \frac{\partial}{\partial q_3} \left(\frac{h_1 h_2}{h_3} \frac{\partial f}{\partial q_3} \right) \right]$	$\frac{\partial^2 f}{\partial r^2} + \frac{2}{r} \frac{\partial f}{\partial r} + \frac{1}{r^2} \frac{\partial^2 f}{\partial \theta^2} + \frac{\cos \theta}{r^2} \frac{\partial f}{\partial \theta} + \frac{1}{r^2 \sin^2 \theta} \frac{\partial^2 f}{\partial \phi^2}$	$\frac{\partial^2 f}{\partial \rho^2} + \frac{1}{\rho} \frac{\partial f}{\partial \rho} + \frac{1}{\rho^2} \frac{\partial^2 f}{\partial \theta^2} + \frac{\partial^2 f}{\partial z^2}$

$$- \rho \cos^2 \theta \sin \phi - 3\rho \sin^2 \theta \cos \phi$$

$$A_\phi = -2\rho \sin \theta \sin^2 \phi - \rho \cos \theta \cos \rho$$

21. Prove that a cylindrical coordinate system is orthogonal.

22. Find the square of the element of arc length in spherical coordinates and determine the corresponding scale factors.

Ans. $(ds)^2 = (dr)^2 + \rho^2(d\theta)^2 + \rho^2 \sin^2 \theta (d\phi)^2$

$$h_1 = h_\rho = 1, h_2 = h_\theta = \rho, h_3 = h_\phi = \rho \sin \theta$$

23. Prove that in any orthogonal curvilinear coordinate system, $\nabla \cdot \nabla \times \vec{A} = 0$

24. If q_1, q_2, q_3 are general coordinates, show that $\frac{\partial \vec{r}}{\partial q_1}, \frac{\partial \vec{r}}{\partial q_2}, \frac{\partial \vec{r}}{\partial q_3}$ and $\nabla q_1, \nabla q_2, \nabla q_3$ are reciprocal system of vectors.

Hint: Use $\nabla q_1 \cdot d\vec{r} = dq_1 = (\nabla q_1 \cdot \frac{\partial \vec{r}}{\partial q_1}) dq_1 + (\nabla q_1 \cdot \frac{\partial \vec{r}}{\partial q_2}) dq_2 + (\nabla q_1 \cdot \frac{\partial \vec{r}}{\partial q_3}) dq_3$

25. Prove that

$$\left\{ \frac{\partial \vec{r}}{\partial q_1} \cdot \frac{\partial \vec{r}}{\partial q_2} \times \frac{\partial \vec{r}}{\partial q_3} \right\} \{ \nabla q_1 \cdot \nabla q_2 \times \nabla q_3 \} = 1.$$

Hint: $V\left(\frac{1}{V}\right) = 1$ or $J\left(\frac{x, y, z}{q_1, q_2, q_3}\right) \cdot J\left(\frac{q_1, q_2, q_3}{x, y, z}\right) = 1$

26. In cylindrical coordinate system ρ, θ, z prove that

$$\nabla \rho^n = n\rho^{n-1} \vec{e}_\rho$$

$$\nabla^2(\rho^n \cos n\theta) = 0.$$

27. In spherical coordinate system ρ, θ, ϕ , prove that

$$28. \nabla \cdot [\vec{e}_\rho \cdot \cot \phi - 2\vec{e}_\phi] = 0$$

$$29. \nabla^2 \left[\left(\rho + \frac{1}{\rho^2} \right) \cos \phi \right] = 0$$

30. Find $\frac{\partial \vec{r}}{\partial q_1}, \frac{\partial \vec{r}}{\partial q_2}, \frac{\partial \vec{r}}{\partial q_3}, \nabla q_1, \nabla q_2, \nabla q_3$ in spherical coordinate system

Ans. $\frac{\partial \vec{r}}{\partial \rho} = \sin \theta \cos \phi \vec{i} + \sin \theta \sin \phi \vec{j} + \cos \theta \vec{k}$

$$\frac{\partial \vec{r}}{\partial \theta} = \rho \cos \theta \cos \phi \vec{i} + \rho \cos \theta \sin \phi \vec{j} - \rho \sin \theta \vec{k}$$

$$\frac{\partial \vec{r}}{\partial \phi} = -\rho \sin \theta \sin \phi \vec{i} + \rho \sin \theta \cos \phi \vec{j}$$

$$\nabla \rho = \sin \theta \cos \phi \vec{i} + \sin \theta \sin \phi \vec{j} + \cos \theta \vec{k}$$

$$\nabla \theta = \frac{\cos \theta \cdot \cos \phi \vec{i} + \cos \theta \cdot \sin \phi \vec{j} - \sin \theta \vec{k}}{\rho}$$

$$\nabla \phi = \frac{-\sin \phi \vec{i} + \cos \phi \vec{j}}{\rho \sin \theta}$$

31. Express the velocity $\vec{V}$ and acceleration $\vec{a}$ of a particle in cylindrical coordinates.

Ans. $\vec{r} = \rho \vec{e}_\rho + z \vec{e}_z$

$$\vec{V} = \dot{\rho} \vec{e}_\rho + \rho \dot{\theta} \vec{e}_\theta + \dot{z} \vec{e}_z$$

$$\vec{a} = (\ddot{\rho} - \rho \dot{\theta}^2) \vec{e}_\rho + (\rho \ddot{\theta} + 2\dot{\rho} \dot{\theta}) \vec{e}_\theta + \ddot{z} \vec{e}_z$$

Chapter 16

Vector Integral Calculus

INTRODUCTION

Vector integral calculus extends the concepts of (ordinary) integral calculus to vector functions. It has applications in fluid flow, design of underwater transmission cables, heat flow in stars, study of satellites. Line integrals are useful in the calculation of work done by variable forces along paths in space and the rates at which fluids flow along curves (circulation) and across boundaries (flux). In this chapter we consider three important integral theorems. Green's theorem, a great theorem of calculus, which converts line integrals to double integrals, evaluates flow and flux integrals across closed plane curves in non-conservative vector fields. Stokes theorem states that the circulation of a vector field around the boundary of a surface in space equals the integral of the normal component of the curl of the field over the surface. Gauss divergence theorem, which is important in electricity, magnetism and fluid flow, says that the outward flux of a vector field across a closed surface equals the triple integral of the divergence of the field over the region enclosed by the surface.

16.1 VECTOR INTEGRATION: INTEGRATION OF A VECTOR FUNCTION OF A SCALAR ARGUMENT

Definitions

Primitive

A vector function $\bar{F}(u)$ is the primitive of the vector function $\bar{f}(u)$ if

$$\frac{d\bar{F}(u)}{du} = \bar{f}(u)$$

Indefinite integral

Indefinite integral of the vector function $\bar{f} = \bar{f}(u)$ of a scalar argument u is the collection of all primitive functions of $\bar{f}(u)$ and is denoted by

$$\int \bar{f}(u) du = \int \frac{d\bar{F}(u)}{du} du = \bar{F}(u) + \bar{c}$$

where $\bar{c}$ is an arbitrary constant vector.

Properties

1. $\int \alpha \bar{f}(u) du = \alpha \int \bar{f}(u) du$,
(α = numerical constant)
2. $\int [\bar{f}(u) \pm \bar{g}(u)] du = \int \bar{f}(u) du \pm \int \bar{g}(u) du$
3. If $\bar{f}(u) = f_1(u)i + f_2(u)j + f_3(u)k$ then
$$\int \bar{f}(u) du = i \int f_1(u) du + j \int f_2(u) du + k \int f_3(u) du$$

Note: The integration of a vector function reduces to the evaluation of three ordinary real (scalar) integrals.

Definite integral between limits $u = a$ and $u = b$ is

$$\int_a^b \bar{f}(u) du = \bar{F}(u) + \bar{c} \Big|_a^b = \bar{F}(b) - \bar{F}(a)$$

WORKED OUT EXAMPLES

Example 1: Evaluate

- a. $\int \bar{A}(u) du$ and

16.2 — HIGHER ENGINEERING MATHEMATICS—V

b. $\int_2^4 \bar{A}(u) du$

if $\bar{A}(u) = (3u^2 - u)i + (2 - 6u)j - 4uk$.

Solution:

$$\begin{aligned} \text{a. } \int \bar{A}(u) du &= \int [(3u^2 - u)i + (2 - 6u)j - 4uk] du \\ &= i \int (3u^2 - u) du + j \int (2 - 6u) du \\ &\quad + k \int -4u du \end{aligned}$$

$$= \left(u^3 - \frac{u^2}{2} \right) i + (2u - 3u^2) j - 2u^2 k + \bar{c}$$

$$\begin{aligned} \text{b. } \int_2^4 \bar{A}(u) du &= \left(u^3 - \frac{u^2}{2} \right) i \\ &\quad + (2u - 3u^2) j - 2u^2 k \Big|_2^4 \\ &= 50i - 32j - 24k. \end{aligned}$$

Example 2: If $\bar{A}(u) = ui - u^2 j + (u - 1)k$ and $\bar{B}(u) = 2u^2 i + 6uk$ then evaluate $\int_0^2 \bar{A} \times \bar{B} du$.

Solution:

$$\bar{A} \times \bar{B} = \begin{vmatrix} i & j & k \\ u & -u^2 & (u-1) \\ 2u^2 & 0 & 6u \end{vmatrix}$$

$$\bar{A} \times \bar{B} = -6u^3 i + (2u^3 - 8u^2) j + 2u^4 k$$

$$\begin{aligned} \int_0^2 \bar{A} \times \bar{B} du &= \int_0^2 [-6u^3 i + (2u^3 - 8u^2) j + 2u^4 k] du \\ &= -\frac{6u^4}{4} i + \left(\frac{2u^4}{4} - \frac{8u^3}{3} \right) j + \frac{2u^5}{5} k \Big|_0^2 \\ &= -24i - \frac{40}{3} j + \frac{64}{5} k. \end{aligned}$$

Example 3: Let $\bar{A} = ti - 3j + 2tk$, $\bar{B} = i - 2j + 2k$, $\bar{D} = 3i + tj - k$. Evaluate $\int_1^2 \bar{A} \cdot \bar{B} \times \bar{D} dt$.

Solution:

$$\begin{aligned} \bar{A} \cdot \bar{B} \times \bar{D} &= \begin{vmatrix} t & -3 & 2t \\ 1 & -2 & 2 \\ 3 & t & -1 \end{vmatrix} \\ &= t(2 - 2t) + 3(-1 - 6) + 2t(t + 6) \\ &= 14t - 21 \end{aligned}$$

$$\begin{aligned} \int_1^2 (\bar{A} \cdot \bar{B} \times \bar{D}) dt &= \int_1^2 (14t - 21) dt = (7t^2 - 21t) \Big|_1^2 \\ &= 0. \end{aligned}$$

Example 4: The acceleration $\bar{a}$ of a particle at any time $t \geq 0$ is given by

$$\bar{a}(t) = e^{-t} i - 6(t + 1)j + 3 \sin t k$$

If the velocity $\bar{v}$ and displacement $\bar{r}$ are zero at $t = 0$, find $\bar{v}$ and $\bar{r}$ at any time t .

Solution: $\bar{a} = \frac{d\bar{v}}{dt} = e^{-t} i - 6(t + 1)j + 3 \sin t k$.
Integrating with respect to t

$$\begin{aligned} \bar{v}(t) &= i \int e^{-t} dt - j \int 6(t + 1) dt + 3k \int \sin t dt \\ &= -e^{-t} i - j(3t^2 + 6t) - 3k \cos t + \bar{c} \end{aligned}$$

Given that $\bar{v} = 0$ when $t = 0$

$$\text{so } 0 = -i - 3k + \bar{c}$$

$$\text{or } \bar{c} = i + 3k$$

Thus

$$\bar{v}(t) = (1 - e^{-t})i - j(3t^2 + 6t) + 3k(1 - \cos t)$$

Integrating $\bar{v} = \frac{d\bar{r}}{dt}$ with respect to t

$$\begin{aligned} \bar{r}(t) &= \int \bar{v}(t) dt = i \int (1 - e^{-t}) dt - j \int (3t^2 + 6t) dt \\ &\quad + 3k \int (1 - \cos t) dt \end{aligned}$$

$$\bar{r} = i(t + e^{-t}) - j(t^3 + 3t^2) + 3k(t - \sin t) + \bar{c}_1$$

since $\bar{r} = 0$ at $t = 0$, we have

$$0 = i + \bar{c}_1 \quad \text{so } \bar{c}_1 = -i$$

Thus

$$\bar{r}(t) = i(-1 + t + e^{-t}) - j(t^3 + 3t^2) + (3t - 3 \sin t)k.$$

Example 5: If $\bar{A}(u) = ui + u^2 j + u^3 k$, $\bar{B}(u) = u^3 i + u^2 j + uk$

$$\text{find } \int_1^2 \left[\bar{A}(u) \times \frac{d\bar{B}}{du} + \frac{d\bar{A}}{du} \times \bar{B}(u) \right] du$$

Solution:

$$I = \int_1^2 \left[A \times \frac{dB}{du} + \frac{dA}{du} \times B \right] du$$

$$= \int_1^2 \frac{d}{du} (\bar{A} \times \bar{B}) du = \bar{A} \times \bar{B} + \bar{c} \Big|_1^2$$

since $\frac{d}{du} (\bar{A} \times \bar{B}) = \bar{A} \times \frac{d\bar{B}}{du} + \frac{d\bar{A}}{du} \times \bar{B}$.

Here $\bar{A} \times \bar{B} = \begin{vmatrix} i & j & k \\ u & u^2 & u^3 \\ u^3 & u^2 & u \end{vmatrix}$

$$= (u^3 - u^5)i + (u^6 - u^2)j + (u^3 - u^5)k$$

$$I = -24i + 60j - 24k.$$

Example 6: Evaluate $\int_2^3 \bar{A} \cdot \frac{d\bar{A}}{dt}$ if

$$\bar{A}(2) = 2i - j + 2k \text{ and } \bar{A}(3) = 4i - 2j + 3k.$$

Solution: Since $\bar{A} \cdot \frac{d\bar{A}}{dt} = \frac{A dA}{dt}$ where $A = |\bar{A}|$

$$\begin{aligned} \int_2^3 \bar{A} \cdot \frac{d\bar{A}}{dt} dt &= \int_2^3 A \frac{dA}{dt} dt = \int_2^3 A dA \\ &= \frac{A^2}{2} \Big|_2^3 = \frac{1}{2} [A^2(3) - A^2(2)] \\ &= \frac{1}{2} [29 - 9] = 10 \end{aligned}$$

since

$$A(3) = |A(3)| = \sqrt{16 + 4 + 9} = \sqrt{29},$$

$$A(2) = |A(2)| = \sqrt{4 + 1 + 4} = \sqrt{9}.$$

EXERCISE

1. Find (a) $\int \bar{A}(u) du$ and (b) $\int_1^2 \bar{A}(u) du$ if $\bar{A}(u) = (u - u^2)i + 2u^3j - 3k$.

Ans. a. $\left(\frac{u^2}{2} - \frac{u^3}{3}\right)i + \frac{u^4}{2}j - 3uk + \bar{c}$
 b. $\frac{-5}{6}i + \frac{15}{2}j - 3k$

2. Evaluate $\int_0^{\pi/2} (3 \sin ui + 2 \cos uj) du$.

Ans. $3i + 2j$

3. Find $\int \bar{A}(u) du$ where $\bar{A}(u) = (3u^2 - \sin u)i + (e^u + \cos u)j + 4u^3k$.

Ans. $(u^3 + \cos u)i + (e^u + \sin u)j + u^4k + c$

4. Find $\int_0^1 t \bar{F}(t) dt$ when $\bar{F}(t) = 2ti - t^2j + t^3k$.

Ans. $\frac{2}{3}u^3i - \frac{u^4}{4}j + \frac{u^5}{5}k \Big|_0^1 = \frac{2}{3}i - \frac{1}{4}j + \frac{1}{5}k$

5. Evaluate $\int_0^2 \bar{A} \cdot \bar{B} dt$ where $\bar{A} = ti - t^2j + (t - 1)k$ and $\bar{B} = 2t^2i + 6tk$.

Ans. 12

6. Let $\bar{A} = ti - 3j + 2tk$, $\bar{B} = i - 2j + 2k$, $\bar{D} = 3i + tj - k$ then evaluate

$$\int_1^2 \bar{A} \times (\bar{B} \times \bar{D}) dt.$$

Ans. $\frac{-87}{2}i - \frac{44}{3}j + \frac{15}{2}k$

7. Evaluate

$$\int \bar{A} \times \frac{d^2\bar{A}}{dt^2} dt$$

Hint:

$$\begin{aligned} \frac{d}{dt} \left(\bar{A} \times \frac{d\bar{A}}{dt} \right) &= A \times \frac{d^2\bar{A}}{dt^2} + \frac{dA}{dt} \times \frac{d\bar{A}}{dt} \\ &= A \times \frac{d^2\bar{A}}{dt^2}. \end{aligned}$$

Ans. $\bar{A} \times \frac{d\bar{A}}{dt} + \bar{c}$

8. Let $\bar{A}(t) = e^{-t} \sin t i + e^{-t} \cos t j + t^2k$. Evaluate

$$\int_1^2 \bar{A} \cdot \frac{d\bar{A}}{dt} dt.$$

Hint: see Worked Out Example 6, on page 16.3, above.

Ans. $\frac{1}{2} [15 + e^{-4} - e^{-2}]$

9. The acceleration of a particle at any time $t \geq 0$ is given by $\bar{a} = 12 \cos 2ti - 8 \sin 2tj + 16tk$.

If the velocity $\bar{V}$ and displacement $\bar{r}$ are zero at $t = 0$, find $\bar{V}$ and $\bar{r}$ at any time t .

Ans. $\bar{V} = 6 \sin 2ti + (4 \cos 2t - 4)j + 8t^2k$

$$\bar{r} = (3 - 3 \cos 2t)i + (2 \sin 2t - 4t)j + 8 \frac{t^3}{3}k$$

10. Find the velocity and displacement of a particle having acceleration $4t^3i - 5t^4j + 3t^2k$ at any time t , given that acceleration and velocity are initially $i - j$ and $i + j + k$ respectively.

Ans. Velocity: $(t^4 + 1)i - (t^4 + 1)j + t^3k$

displacement:

$$\left(\frac{t^5}{5} + t + 1\right)i - \left(\frac{t^6}{6} + t - 1\right)j + \left(\frac{t^4}{4} + 1\right)k$$

16.4 — HIGHER ENGINEERING MATHEMATICS—V

11. Find $\bar{A}$ if $\frac{d^2\bar{A}}{du^2} = 6ui - 12u^2j + 4\cos uk$ and given that $\frac{d\bar{A}}{du} = -1 - 3k$ and $\bar{A} = 2i + j$ when $u = 0$.

Ans. $(u^3 - u + 2)i + (1 - u^4)j + (4 - 4\cos u - 3u)k$

12. Find the areal velocity of a particle which moves along the path $\bar{r} = a \cos wt i + b \sin wt j$ where a, b, w are constants and t is time.

Hint: Areal velocity $= \frac{1}{2} \bar{r} \times \bar{V}$, where $\bar{V}$ = velocity.

Ans. $\frac{1}{2} a b w k$

16.2 LINE INTEGRALS: WORK DONE, POTENTIAL, CONSERVATIVE FIELD AND AREA

For the ordinary definite integral $\int_a^b f(x)dx$ the region of integration is an interval $a \leq x \leq b$ on the x -axis. i.e., we integrate along the x -axis from a to b .

This concept can be generalized to define a definite integral evaluated along a curve.

Line Integrals

Let c be curve defined from A to B with corresponding arc lengths $s = a$ and $s = b$ respectively. Divide c into n arbitrary portions (see Fig. 16.1).

Fig. 16.1

Evaluate the given function f at a point in each of these portions and form the sum

$$J_n = \sum_{m=1}^n f(Q_m) \Delta s_m$$

where $\Delta s_m = s_m - s_{m-1}$. The limit of this sum as $n \rightarrow \infty$ is known as the line integral of f along c from A to B and is denoted by

$$\int_c f(p)ds = \int_a^b f(s)ds = \int_c f(x, y, z)ds \quad (1)$$

when P has coordinates $x(s), y(s), z(s)$. The line integral (1) is also known as curve integral or curvilinear integral.

Thus in a line integral, the integrand f is integrated (evaluated) along a curve (line). The curve c is known as path of integration. Its end points a and b are called the initial and terminal points.

The direction along the curve c from a to b is called the sense of integration.

Curve is said to be a closed curve (path) when the end points coincide. In such case the line integral is denoted as $\oint_c$.

Let the parametric equation of the curve c be

$$\bar{r}(t) = x(t)\bar{i} + y(t)\bar{j} + z(t)\bar{k}, \quad a \leq t \leq b \quad (2)$$

Properties of line integrals

Let $\bar{F} = F_1\bar{i} + F_2\bar{j} + F_3\bar{k}$ be a vector function. Then a line integral of $\bar{F}(\bar{r})$ along (taken over) the curve c is defined as

$$\begin{aligned} \int_c \bar{F}(\bar{r}) \cdot d\bar{r} &= \int_c F_1 dx + F_2 dy + F_3 dz \\ &= \int_c F_1 \frac{dx}{dt} + F_2 \frac{dy}{dt} + F_3 \frac{dz}{dt} \\ &= \int_a^b \bar{F}_1(\bar{r}(t)) \cdot \frac{d\bar{r}}{dt} dt \end{aligned} \quad (3)$$

Observation

Evaluation of a line integral reduces to evaluation of an ordinary integral along a coordinate axis (say x -axis).

For the line integral (3) the following properties follow from integral calculus:

1. $\int_c k \bar{F} \cdot d\bar{r} = k \int_c \bar{F} \cdot d\bar{r}$, $k = \text{constant}$
2. $\int_c (\bar{F} \pm \bar{G}) \cdot d\bar{r} = \int_c \bar{F} \cdot d\bar{r} \pm \int_c \bar{G} \cdot d\bar{r}$
3. $\int_c \bar{F} \cdot d\bar{r} = \int_{c_1} \bar{F} \cdot d\bar{r} + \int_{c_2} \bar{F} \cdot d\bar{r}$

Fig. 16.2

where c is the sum of two curves c_1 and c_2 (see Fig. 16.2)

4. $\int_a^b \bar{F} \cdot d\bar{r} = - \int_b^a \bar{F} \cdot d\bar{r}$.

Applications of Line Integral

A. Work done by a force (work integral)

A natural application of the line integral is to define the work done by a force $\vec{F}$ in moving (displacing) a particle along a curve c from point P_1 to point P_2 as

$$\text{Work done} = \int_{P_1}^{P_2} \vec{F} \cdot d\vec{r} \quad (4)$$

When $\vec{F}$ denotes velocity of a fluid, then the *circulation* of $\vec{F}$ around a closed curve c is defined by

$$\text{Circulation} = \oint_c \vec{F} \cdot d\vec{r}$$

B. Independence of path; conservative field and scalar potential

If $\vec{F} = \nabla\phi$ then the line integral from P_1 and P_2 is independent of path joining P_1 to P_2 (Fig. 16.3)

$$\begin{aligned} \int_{P_1}^{P_2} \vec{F} \cdot d\vec{r} &= \int_{P_1}^{P_2} \nabla\phi \cdot d\vec{r} \\ &= \int_{P_1}^{P_2} \left(\frac{\partial\phi}{\partial x} dx + \frac{\partial\phi}{\partial y} dy + \frac{\partial\phi}{\partial z} dz \right) \\ &= \int_{P_1}^{P_2} d\phi = \phi(P_2) - \phi(P_1) \end{aligned}$$

Thus the line integral depends only on the end points P_1 and P_2 and not on the path joining them. Recall that when $\vec{F} = \nabla\phi$, then $\nabla \times \vec{F} = \nabla \times \nabla\phi = 0$. In such a case, $\vec{F}$ is called a conservative vector field and ϕ is called its scalar potential.

Note: That a conservative force field is also irrotational (since $\nabla \times \vec{F} = 0$).

Result 1: The work done in a conservative force field in moving a particle from P_1 to P_2 is independent of the path joining P_1 and P_2 , but depends only on the end points P_1 and P_2 . In such cases a scalar potential ϕ exists such that force field $\vec{F} = \nabla\phi$ and thus the work done from P_1 to $P_2 = \phi(P_2) - \phi(P_1)$ (without the need to evaluate the work integral).

Result 2: In a conservative field $\vec{F}$

$$\oint_c \vec{F} \cdot d\vec{r} = 0$$

Fig. 16.3

along any closed curve c because

$$\begin{aligned} \oint_c \vec{F} \cdot d\vec{r} &= \int_{P_1 P_3 P_2 P_4} \vec{F} \cdot d\vec{r} = \int_{P_1 P_3 P_2} + \int_{P_2 P_4 P_1} \\ &= \int_{P_1 P_3 P_2} \vec{F} \cdot d\vec{r} - \int_{P_1 P_4 P_2} \vec{F} \cdot d\vec{r} = 0. \end{aligned}$$

which follows from the independence of path.

C. Test for exact differential

For $\vec{F} = F_1\vec{i} + F_2\vec{j} + F_3\vec{k}$, the necessary and sufficient condition that

$$F_1 dx + F_2 dy + F_3 dz$$

be an exact differential is that $\vec{F}$ must be conservative i.e., $\nabla \times \vec{F} = 0$. When $\nabla \times \vec{F} = 0$, there exists a scalar ϕ such that $\vec{F} = \nabla\phi$. Then

$$\begin{aligned} F_1 dx + F_2 dy + F_3 dz &= \vec{F} \cdot d\vec{r} = \nabla\phi \cdot d\vec{r} = d\phi \\ &= \text{Exact differential} \end{aligned}$$

D. Area A of a regular region D

Bounded by a curve c (Fig. 16.4):

Fig. 16.4

$$\begin{aligned} A &= \int_a^b y_2(x) dx - \int_a^b y_1(x) dx \\ &= - \int_{NPM} y dx - \int_{MQN} y dx = - \int_c y dx \end{aligned}$$

16.6 — HIGHER ENGINEERING MATHEMATICS—V

Similarly, $A = \int_c x \, dy$

Thus $A = \frac{1}{2} \int_c (x \, dy - y \, dx)$

WORKED OUT EXAMPLES

Example 1: Evaluate $\int_c y^2 dx - 2x^2 dy$ along the parabola $y = x^2$ from $(0, 0)$ to $(2, 4)$.

Solution:

$$\begin{aligned} \int_c (y^2 dx - 2x^2 dy) &= \int_0^2 (x^2)^2 dx - 2x^2 d(x^2) \\ &= \int_0^2 x^4 dx - 4x^3 dx \\ &= \left[\frac{x^5}{5} - 4 \frac{x^4}{4} \right]_0^2 = -\frac{48}{5}. \end{aligned}$$

Example 2: Evaluate the line integral

$$\int_c x^{-1}(y+z)ds$$

where c the arc of circle $x^2 + y^2 = 4$, $z = 0$ from $(2, 0, 0)$ to $(\sqrt{2}, \sqrt{2}, 0)$ in the counterclockwise direction.

Solution: Equation of circle in parametric form is

$$x = 2 \cos t, \quad y = 2 \sin t$$

when $x = 2$, then $t = 0$ and when $x = \sqrt{2}$, then $t = \frac{\pi}{4}$

$$\vec{r} = xi + yj + zk = 2 \cos ti + 2 \sin tj + 0$$

$$\frac{d\vec{r}}{dt} = -2 \sin ti + 2 \cos tj$$

$$\vec{r} \cdot \frac{d\vec{r}}{dt} = \frac{d\vec{r}}{dt} \cdot \frac{d\vec{r}}{dt} = 4 \sin^2 t + 4 \cos^2 t = 4$$

$$\frac{ds}{dt} = \sqrt{\vec{r} \cdot \frac{d\vec{r}}{dt}} = \sqrt{4} = 2$$

Along c : $z = 0$ and $ds = 2dt$ so that

$$\begin{aligned} \int_c x^{-1}(y+z)ds &= \int \frac{y+0}{x} ds = \int_e \frac{2 \sin t}{2 \cos t} \cdot 2dt \\ &= 2 \int_0^{\pi/4} \tan t \cdot dt = 2 \ln \sec t \Big|_0^{\pi/4} \\ &= 2 \ln \sqrt{2} = \ln 2. \end{aligned}$$

Example 3: If $\vec{F} = (2x + y^2)i + (3y - 4x)\vec{j}$ evaluate $\oint_c \vec{F} \cdot d\vec{r}$ around a triangle ABC in the xy -plane with $A(0, 0)$, $B(2, 0)$, $C(2, 1)$ (refer Fig. 16.5). (a) in the counterclockwise direction (b) what is the value in the opposite direction?

Solution: **a.** In the counterclockwise direction:

$$\begin{aligned} I &= \oint_c \vec{F} \cdot d\vec{r} = \int_{c_1} \vec{F} \cdot d\vec{r} + \int_{c_2} \vec{F} \cdot d\vec{r} + \int_{c_3} \vec{F} \cdot d\vec{r} \\ &= I_1 + I_2 + I_3 \end{aligned}$$

Along c_1 : The straight line from $A(0, 0)$ to $B(2, 0)$, $y = 0$, $z = 0$ and x varies from 0 to 2

Thus $\vec{r} = xi$, $d\vec{r} = i dx$, $dy = 0$,

So with $y = 0$

$$I_1 = \int_{c_1} \vec{F} \cdot d\vec{r} = \int_0^2 (2xi) \cdot i dx = \int_0^2 2x dx = x^2 \Big|_0^2 = 4$$

Fig. 16.5

Along c_2 : The straight line from $B(2, 0)$ to $C(2, 1)$, $x = 2$, $z = 0$, y varies from 0 to 1

Thus $\vec{r} = 2i + yj$, $d\vec{r} = j dy$

So with $x = 2$

$$\begin{aligned} I_2 &= \int_{c_2} \vec{F} \cdot d\vec{r} = \int_0^1 [(4 + y^2)i + (3y - 8)j] \cdot [j dy] \\ &= \int_0^1 (3y - 8) dy \\ &= \left[\frac{3y^2}{2} - 8y \right]_0^1 = \frac{3}{2} - 8 = -\frac{13}{2} \end{aligned}$$

Along c_3 : Straight line from $C(2, 1)$ to $A(0, 0)$ is $y = \frac{1}{2}x$, $dy = \frac{1}{2}dx$, x varies from 2 to 0

Thus $\vec{r} = xi + \frac{1}{2}xj$, $d\vec{r} = \left(i + \frac{1}{2}j\right) dx$

So with $y = \frac{x}{2}$

$$\begin{aligned} I_3 &= \int_{c_3} \bar{F} \cdot d\bar{r} = \\ &= \int_2^0 \left[\left(2x + \frac{x^2}{4} \right) i + \left(\frac{3x}{2} - 4x \right) j \right] \cdot \left[i + \frac{j}{2} \right] dx \\ &= \int_2^0 \left(2x + \frac{x^2}{4} + \frac{3x}{4} - \frac{4x}{2} \right) dx = \frac{x^3}{12} + \frac{3x^2}{8} \Big|_2^0 \\ &= - \left(\frac{8}{12} + \frac{12}{8} \right) = -\frac{13}{6} \end{aligned}$$

The required line integral in the counterclockwise direction

$$I = \oint_c \bar{F} \cdot d\bar{r} = I_1 + I_2 + I_3 = 4 - \frac{13}{2} - \frac{13}{6} = -\frac{14}{3}$$

b. Line integral value in the opposite direction is $\frac{14}{3}$.

Example 4: Evaluate $\int_c f d\bar{r}$ where $f = 2xy^2z + x^2y$ and c is the curve $x = t, y = t^2, z = t^3$ from $t = 0$ to 1 .

Solution:

$$\begin{aligned} \bar{r} &= xi + yj + zk = ti + t^2j + t^3k \\ d\bar{r} &= (i + 2tj + 3t^2k)dt \end{aligned}$$

Along c :

$$\begin{aligned} f &= 2t \cdot (t^2)^2(t^3) + (t^2) \cdot t^2 = 2t^8 + t^4 \\ \int_c f d\bar{r} &= \int_0^1 (2t^8 + t^4) (\bar{i} + 2t\bar{j} + 3t^2\bar{k}) dt \\ &= \bar{i} \int_0^1 (2t^8 + t^4) dt + \bar{j} \int_0^1 (4t^9 + 2t^5) dt \\ &\quad + \bar{k} \int_0^1 (6t^{10} + 3t^6) dt \\ &= i \left(\frac{2t^9}{9} + \frac{t^5}{5} \right) \Big|_0^1 + \bar{j} \left(\frac{4t^{10}}{10} + \frac{2t^6}{6} \right) \Big|_0^1 \\ &\quad + \bar{k} \left(\frac{6t^{11}}{11} + \frac{3t^7}{7} \right) \Big|_0^1 \\ &= \frac{19}{45} \bar{i} + \frac{11}{15} \bar{j} + \frac{75}{77} \bar{k}. \end{aligned}$$

Example 5: Find the work done in moving a particle in the force field $\bar{F} = 3x^2\bar{i} + (2xz - y)\bar{j} + z\bar{k}$ along

- straight line from $A(0, 0, 0)$ to $B(2, 1, 3)$
- space curve $c: x = 2t^2, y = t, z = 4t^2 - t$ from $t = 0$ to $t = 1$
- curve c : defined by $x^2 = 4y, 3x^3 = 8z$ from $x = 0$ to $x = 2$.

Solution: **Work done along a curve c is $\int_c \bar{F} \cdot d\bar{r}$:**

$$\begin{aligned} \text{a. } \bar{r} &= 2ti + tj + 3tk \\ d\bar{r} &= (2i + j + 3k)dt \\ \bar{F} &= 3x^2\bar{i} + (2xz - y)\bar{j} + z\bar{k} \\ &= 12t^2\bar{i} + (12t^2 - t)\bar{j} + 3t\bar{k} \end{aligned}$$

work done by $\bar{F}$ in moving along the straight line from $A(0, 0, 0)$ to $B(2, 1, 3)$

$$\begin{aligned} &= \int_A^B \bar{F} \cdot d\bar{r} \\ &= \int_0^1 [12t^2i + (12t^2 - t)j + 3tk] \cdot [2i + j + 3k] dt \\ &= \int_0^1 (24t^2 + 12t^2 - t + 9t) dt \\ &= 12t^3 + 4t^2 \Big|_0^1 = 16 \end{aligned}$$

$$\begin{aligned} \text{b. } \bar{r} &= xi + yj + zk \\ \bar{r} &= 2t^2i + t\bar{j} + (4t^2 - t)\bar{k} \\ d\bar{r} &= 4ti + j + (8t - 1)\bar{k} \\ \bar{F} &= 3(2t^2)^2i + [2 \cdot (2t^2)(4t^2 - t) - t]\bar{j} + (4t^2 - t)k \end{aligned}$$

Work done

$$\begin{aligned} &= \int_c \bar{F} \cdot d\bar{r} = \int_0^1 [12t^4i + [4t^2(4t^2 - t) - t]j \\ &\quad + (4t^2 - t)k] \cdot [4ti + j + (8t - 1)k] \\ &= \int_0^1 [48t^5 + (16t^4 - 4t^3 - t) + (8t - 1)(4t^2 - t)] dt \\ &= 8t^6 + 16\frac{t^5}{5} + 7t^4 - 4t^3 \Big|_0^1 = 8 + \frac{16}{5} + 7 - 4 \\ &= 14.2 \end{aligned}$$

16.8 — HIGHER ENGINEERING MATHEMATICS—V

$$\begin{aligned} \text{c. } \vec{r} &= xi + y\vec{j} + z\vec{k} = xi + \frac{x^2}{4}\vec{j} + \frac{3}{8}x^3\vec{k} \\ &= ti + \frac{t^2}{4}\vec{j} + \frac{3}{8}t^3\vec{k} \\ d\vec{r} &= \left(i + \frac{t}{2}\vec{j} + \frac{9}{8}t^2\vec{k} \right) \\ \vec{F} &= 3x^2\vec{i} + \left(2 \cdot x \cdot \frac{3}{8}x^3 - \frac{x^2}{4} \right) \vec{j} + \frac{3}{8}x^3\vec{k} \end{aligned}$$

Work done

$$\begin{aligned} &= \int \vec{F} \cdot d\vec{r} = \int_0^2 \left[3t^2 + \frac{t}{2} \left(\frac{3}{4}t^4 - \frac{t^2}{4} \right) + \frac{27}{64}t^5 \right] dt \\ &= t^3 + \frac{t^6}{16} - \frac{t^4}{32} + \frac{27t^6}{384} \Big|_0^2 = 16 \end{aligned}$$

Example 6: If $\vec{A} = (y - 2x)\vec{i} + (3x + 2y)\vec{j}$, compute the circulation of $\vec{A}$ about a circle c in the xy plane with centre at the origin and radius 2, if c is traversed in the positive direction.

Solution: c : circle: $x^2 + y^2 = 4$

In parametric form $x = 2 \cos t$, $y = 2 \sin t$ with t varying 0 to 2π

$$\vec{A} = (2 \sin t - 2(2 \cos t))\vec{i} + (3(2 \cos t) + 2(2 \sin t))\vec{j}$$

$$d\vec{r} = d(xi + yj) = dx\vec{i} + dy\vec{j}$$

$$d\vec{r} = (-2 \sin t \vec{i} + 2 \cos t \vec{j}) dt$$

By definition

$$\text{circulation along curve } c = \int_c \vec{F} \cdot d\vec{r}$$

$$\begin{aligned} &= \int_0^{2\pi} [(2 \sin t - 4 \cos t)i + (6 \cos t + 4 \sin t)j] \cdot [-2 \sin t \vec{i} + 2 \cos t \vec{j}] dt \\ &= 4 \int_0^{2\pi} [-\sin^2 t + 2 \sin t \cos t + 3 \cos^2 t + 2 \sin t \cos t] dt \\ &= 16 \int_0^{2\pi} \sin t d(\sin t) - 4 \int_0^{2\pi} \frac{1 - \cos 2t}{2} dt \\ &\quad + 12 \int_0^{2\pi} \frac{1 + \cos 2t}{2} dt \\ &= 8\pi. \end{aligned}$$

Example 7: Prove that $\vec{F} = (y^2 \cos x + z^3)\vec{i} + (2y \sin x - 4)\vec{j} + (3xz^2 + 2)\vec{k}$ is (a) conservative

field (b) find scalar potential of $\vec{F}$ (c) find work done in moving an object in this field from $P_1(0, 1, -1)$ to $P_2(\frac{\pi}{2}, -1, 2)$.

Solution:

a. $\vec{F}$ is conservative if $\nabla \times \vec{F} = 0$

$$\begin{aligned} \nabla \times \vec{F} &= \begin{vmatrix} \vec{i} & \vec{j} & \vec{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y^2 \cos x + z^3 & 2y \sin x - 4 & 3xz^2 + 2 \end{vmatrix} \\ &= i(0 - 0) - j(3z^2 - 3z^2) \\ &\quad + k(2y \cos x - 2y \cos x) \\ &= 0 \end{aligned}$$

Hence $\vec{F}$ is conservative.

b. Let f be the scalar potential such that $\vec{F} = \nabla f$ then comparing the components of $\vec{i}, \vec{j}, \vec{k}$, we get

$$\frac{\partial f}{\partial x} = y^2 \cos x + z^3 \quad (1)$$

$$\frac{\partial f}{\partial y} = 2y \sin x - 4 \quad (2)$$

$$\frac{\partial f}{\partial z} = 3xz^2 + 2 \quad (3)$$

Integrating (1) partially w.r.t. x ,

$$f = y^2 \sin x + xz^3 + g(y, z) \quad (4)$$

Differentiating (4) partially w.r.t. y and using (2)

$$2y \sin x + 0 + \frac{\partial g}{\partial y} = \frac{\partial f}{\partial y} = 2y \sin x - 4$$

Integrating w.r.t. y

$$g(y, z) = -4y + c_1(z) \quad (5)$$

Substituting (5) in (4)

$$f = y^2 \sin x + xz^3 - 4y + c_1(z) \quad (6)$$

Differentiating (6) partially w.r.t. z and using (3)

$$0 + 3xz^2 - 0 + \frac{dc_1}{dz} = \frac{\partial f}{\partial z} = xz^2 + 2$$

Integrating w.r.t. z

$$c_1(z) = z^2 + c \quad (7)$$

Substituting (7) in (6)

$$f(x, y, z) = y^2 \sin x + xz^3 - 4y + z^2 + c$$

c. Work done

$$\begin{aligned} &= f(P_2) - f(P_1) = f\left(\frac{\pi}{2}, -1, 2\right) - f(0, 1, -1) \\ &= 12 + 4\pi. \end{aligned}$$

Example 8: Show that $(z - e^{-x} \sin y)dx + (1 + e^{-x} \cos y)dy + (x - 8z)dz$ is an exact differential of a function f and find f .

Solution: Let

$$\begin{aligned} \bar{A} &= A_i + A_2 \bar{j} + A_3 \bar{k} = (z - e^{-x} \sin y) \bar{i} \\ &\quad + (1 + e^{-x} \cos y) \bar{j} + (x - 8z) \bar{k} \end{aligned}$$

Then

$$\begin{aligned} \nabla \times \bar{A} &= \begin{vmatrix} \bar{i} & \bar{j} & \bar{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ z - e^{-x} \sin y & 1 + e^{-x} \cos y & x - 8z \end{vmatrix} \\ &= i(0 - 0) - j(1 - 1) + k(-e^{-x} \cos y \\ &\quad - (-e^{-x} \cos y)) = 0 \end{aligned}$$

Since $\nabla \times \bar{A} = 0$ (see Section 16.2 C)

$A_1 dx + A_2 dy + A_3 dz$ will be an exact differential

$$\begin{aligned} &(z - e^{-x} \sin y)dx + (1 + e^{-x} \cos y)dy \\ &\quad + (x - 8z)dz = df \end{aligned}$$

Regrouping

$$\begin{aligned} &(zdx + xdz) - 8zdz + dy + (e^{-x} \cos y dy \\ &\quad - e^{-x} \sin y dx) = df \end{aligned}$$

$$\therefore df = d(xz) - d(4z^2) + dy + d(e^{-x} \sin y)$$

$$\therefore f = xz - 4z^2 + y + e^{-x} \sin y.$$

Example 9: If $\bar{A} = (x - y)\bar{i} + (x + y)\bar{j}$ evaluate $\oint_c \bar{A} \cdot d\bar{r}$ around the curve c consisting of $y = x^2$ and $y^2 = x$

Solution:

$$\therefore I = \oint_c \bar{F} \cdot d\bar{r} = \int_{c_1} \bar{F} \cdot d\bar{r} + \int_{c_2} \bar{F} \cdot d\bar{r} = I_1 + I_2$$

Fig. 16.6

where $c_1: y = x^2$ and $c_2: y^2 = x$ as shown in Fig. 16.6 meet at points $A(0, 0)$ and $B(1, 1)$.

Along the curve $c_1: y = x^2$, so that,

$$\bar{r} = xi + yj = xi + x^2 j = ti + t^2 j$$

$d\bar{r} = (i + 2tj)dt$ with t varying from 0 to 1

$$\begin{aligned} I_1 &= \int_{c_1} (\bar{A} \cdot d\bar{r}) \\ &= \int_0^1 [(t - t^2)\bar{i} + (t + t^2)\bar{j}] \cdot [i + 2tj] dt \\ &= \int_0^1 [(t - t^2) + 2t(t + t^2)] dt = \int_0^1 (2t^3 + t^2 + t) dt \\ I_1 &= \frac{2t^4}{4} + \frac{t^3}{3} + \frac{t^2}{2} \Big|_0^1 = \frac{1}{2} + \frac{1}{3} + \frac{1}{2} = 1 + \frac{1}{3} = \frac{4}{3} \end{aligned}$$

Along the curve $c_2: y^2 = x$, $y = \sqrt{x}$

$$\bar{r} = xi + yj = xi + \sqrt{x}j = ti + \sqrt{t}j$$

$$d\bar{r} = (i + \frac{1}{2\sqrt{t}}j)dt$$

with t varying from 1 to 0

$$\begin{aligned} I_2 &= \int_{c_2} \bar{A} \cdot d\bar{r} \\ &= \int_1^0 [(t - \sqrt{t})\bar{i} + (t + \sqrt{t})\bar{j}] \cdot \left[i + \frac{1}{2\sqrt{t}}j\right] dt \\ &= \int_1^0 \left[(t - \sqrt{t}) + \frac{1}{2}(\sqrt{t} + 1)\right] dt \\ &= \int_1^0 \left(t - \frac{\sqrt{t}}{2} + \frac{1}{2}\right) dt \\ &= \frac{t^2}{2} - \frac{t^{\frac{3}{2}}}{\frac{3}{2}} + \frac{1}{2}t \Big|_1^0 = -\frac{1}{2} + \frac{1}{3} - \frac{1}{2} = -\frac{2}{3} \end{aligned}$$

$$\text{Line integral } I = I_1 + I_2 = \frac{4}{3} - \frac{2}{3} = \frac{2}{3}.$$

Example 10: Compute the area of the region bounded by one arch of a cycloid $x = a(t - \sin t)$,

16.10 — HIGHER ENGINEERING MATHEMATICS—V

$y = a(1 - \cos t)$ and the x -axis.

Solution: Area $A = \frac{1}{2} \int_c x dy - y dx$

$$\begin{aligned} A &= \frac{1}{2} \int_0^{2\pi} a(t - \sin t) \cdot [a \sin t dt] \\ &\quad - a(1 - \cos t)[a(1 - \cos t)dt] \\ &= \frac{a^2}{2} \int_0^{2\pi} (t \sin t - \sin^2 t - 1 - \cos^2 t + 2 \cos t) dt \\ &= \frac{a^2}{2} \int_0^{2\pi} (-2 + t \sin t + 2 \cos t) dt \\ &= \frac{a^2}{2} [-4\pi - 2\pi + 0] = -\frac{6\pi a^2}{2}. \end{aligned}$$

EXERCISE

Evaluate the following line integrals:

- $\int_c xy^3 ds$ where c is the segment of the line $y = 2x$ in the xy plane from $A(-1, -2, 0)$ to $B(1, 2, 0)$.

Ans. $16/\sqrt{5}$.

- $\int_c (x^2 + xy) dx + (x^2 + y^2) dy$; c : square: $x \pm 1, y = \pm 1$

Ans. 0

- $\int_c x^2 y dx + (x - z) dy + xyz dz$ where c is the arc of parabola $y = x^2$ in plane $z = 2$ from $A(0, 0, 2)$ to $B(1, 1, 2)$.

Ans. $-17/15$

- $\int_c (x^2 + y^2 + z^2)^2 ds$ where c is the arc of circular helix $r(t) = \cos t i + \sin t j + 3t k$ from $A(1, 0, 0)$ to $B(1, 0, 6\pi)$.

Ans. $\sqrt{10}(2\pi + 6(2\pi)^3 + \frac{81}{5}(2\pi)^5)$

- If $\bar{A}(t) = t\bar{i} - t^2\bar{j} + (t - 1)\bar{k}$, $\bar{B}(t) = 2t^2\bar{i} + 6t\bar{k}$ evaluate $\int_0^2 \bar{A} \cdot \bar{B} dt$.

Ans. 12

- If $\bar{A}(t) = t\bar{i} - 3\bar{j} + 2t\bar{k}$, $\bar{B}(t) = \bar{i} - 2\bar{j} + 2\bar{k}$, $\bar{C}(t) = 3\bar{i} + t\bar{j} - \bar{k}$ then evaluate

a. $\int_1^2 \bar{A} \cdot (\bar{B} \times \bar{C}) dt$

b. $\int_1^2 (\bar{A} \times (\bar{B} \times \bar{C})) dt$

Ans. **a.** 0 **b.** $-\frac{87}{2}\bar{i} - \frac{44}{3}\bar{j} + \frac{15}{2}\bar{k}$

- If $\bar{A}(2) = 2\bar{i} - \bar{j} + 2\bar{k}$, $\bar{A}(3) = 4\bar{i} - 2\bar{j} + 3\bar{k}$ then evaluate $\int_2^3 \bar{A} \cdot \frac{d\bar{A}}{dt} dt$.

Ans. 10

- Evaluate $\int_c \bar{A} \times d\bar{r}$ where $\bar{A} = 2y\bar{i} - z\bar{j} + x\bar{k}$ and c is the curve

$x = \cos t, y = \sin t, z = 2 \cos t$ from $t = 0$ to $\pi/2$.

Ans. $i(2 - \frac{\pi}{4}) + j(\pi - \frac{1}{2})$

- Evaluate $\int_c \bar{A} \cdot d\bar{r}$ where

a. $\bar{A} = 2xi + 4yj - 3zk$,

c : curve: $\bar{r}(t) = \cos t \bar{i} + \sin t \bar{j} + t \bar{k}$ from $t = 0$ to π

b. $\bar{A} = yi + zj + xk$

c : circle $y^2 + z^2 = 1, x = 0$

c. $\bar{A} = yzi + zxj + xyk$

c : curve from $(0, 0, 0)$ to $(1, 1, 0)$ along the curve $x = y^2, z = 0$ in xy -plane, followed by the straight line path from $(1, 1, 0)$ to $(1, 1, 1)$.

Ans. **a.** $-3\pi^2/2$ **b.** $-\pi$ **c.** $3/4$

- Determine whether the force field

$\bar{F} = 2xz\bar{i} + (x^2 - y)\bar{j} + (2z - x^2)\bar{k}$ is conservative or not.

Ans. $\nabla \times \bar{F} \neq 0$ so non-conservative

- a.** Prove that $\bar{F} = (4xy - 3x^2z^2)\bar{i} + 2x^2\bar{j} - 2x^3z\bar{k}$ is a conservative field.

b. Find its scalar potential f .

c. Also find the work done in moving an object in this field from $(1, 1, 1)$ to $(0, 0, 0)$.

Ans. **a.** $\nabla \times \bar{F} = 0$, so conservative

b. scalar potential $f = 2x^2y - x^3z^2 + c$.

c. work done $= f(1, 1, 1) - f(0, 0, 0) = 1$.

- If $\bar{A} = (2xy + z^3)\bar{i} + x^2\bar{j} + 3xz^2\bar{k}$

a. Prove that the line integral $\int_c \bar{A} \cdot d\bar{r}$ is independent of the curve c joining two given points $P_1(1, -2, 1)$ and $P_2(3, 1, 4)$.

b. Show that there exists a scalar function f such that $\bar{A} = \nabla f$ and find f .

c. Also find the work done in moving an object from P_1 to P_2 .

Ans. **a.** $\nabla \times \bar{A} = 0, \bar{A}$ is conservative, so line integral is independent of path

b. $x^2y + xz^3 + \text{constant}$

c. work done: 202

13. Find b such that the force field

$\vec{A} = (e^x z - bxy)\vec{i} + (1 - bx^2)\vec{j} + (e^x + bz)\vec{k}$ is conservative. Find the scalar potential f of $\vec{A}$ when $\vec{A}$ is conservative.

Ans. $b = 0$, $f = y + ze^x + c$

14. Find the scalar potential f of

$\vec{F} = (z + \sin y)\vec{i} + (-z + x \cos y)\vec{j} + (x - y)\vec{k}$.

Ans. $f = xz + x \sin y - yz + c$

15. Find the total work done in moving a particle in a force field $\vec{A} = 3xy\vec{i} - 5z\vec{j} + 10x\vec{k}$ along the curve $x = t^2 + 1$, $y = 2t^2$, $z = t^3$ from $t = 1$ to $t = 2$.

Ans. 303

16. Calculate the work done in a force field given by $\vec{A} = (2y + 3)\vec{i} + xz\vec{j} + (yz - x)\vec{k}$ when an object is moved from the point $P_1(0, 0, 0)$ to $P_2(2, 1, 1)$ along the curve $x = 2t^2$, $y = t$, $z = t^3$.

Ans. $\frac{288}{35}$

17. If $\vec{A} = (2x - y + 2z)\vec{i} + (x + y - z)\vec{j} + (3x - 2y - 5z)\vec{k}$ calculate the circulation of $\vec{A}$ along the circle in the xy -plane of radius 2 and centre at origin.

Ans. Circulation $= \int \vec{A} \cdot d\vec{r} = 8\pi$.

18. Determine the circulation of $\vec{A} = yi + zj + xk$ around the curve $x^2 + y^2 = 1$, $z = 0$.

Ans. $-\pi$

19. If $\int_{P_1}^{P_2} \vec{A} \cdot d\vec{r}$ is independent of the path joining any two given points P_1 and P_2 in a given region then $\oint_c \vec{A} \cdot d\vec{r} = 0$ for all closed paths in the region passing through P_1 and P_2 .

Hint: $P_1 B P_2 D P_1$ be any closed curve c

$$\begin{aligned} \oint_c &= \int_{P_1 B P_2 D P_1} = \int_{P_1 B P_2} + \int_{P_2 D P_1} \\ &= \int_{P_1 B P_2} - \int_{P_1 D P_2} = 0. \end{aligned}$$

20. Prove that the work done in moving an object from P_1 to P_2 in a conservative force field $\vec{F}$ is independent of the path joining the two points P_1 and P_2 .

Hint: Since $\vec{F}$ is conservative, $\vec{F} = \nabla f$

$$\int_{P_1}^{P_2} \vec{F} \cdot d\vec{r} = \int_{P_1}^{P_2} \nabla f \cdot d\vec{r}$$

$$\begin{aligned} &= \int_{P_1}^{P_2} \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy + \frac{\partial f}{\partial z} dz \\ &= \int_{P_1}^{P_2} df = f(P_2) - f(P_1) \end{aligned}$$

Hint: Use $\frac{1}{2} \int_c x dy - y dx$ to compute area enclosed by c .

21. Compute the area of the ellipse $x = a \cos t$, $y = b \sin t$.

Ans. πab

22. Find the area under of one arch of the astroid $x = a \cos^3 t$, $y = a \sin^3 t$.

Ans. $3\pi a^2/8$

23. Find the area of the loop of the folium of descartes

$$x = \frac{3at}{1+t^3}, y = \frac{3at^2}{1+t^3}$$

Ans. $3a^2/2$.

16.3 SURFACE INTEGRALS: SURFACE AREA AND FLUX

The concept of surface integral is a simple and natural generalization of a double integral

$$\iint_R f(x, y) dx dy$$

taken over a plane region R . In a surface integral $f(x, y)$ is integrated over a curved surface.

Let S be a two-sided surface with one side of S taken arbitrarily as the positive side (the outer side if S is closed) (refer Fig. 16.7). A unit normal $\vec{n}$ at any point of the positive side of S is known as positive outward drawn unit normal.

In the xyz -space, the equation of a surface S is

$$g(x, y, z) = 0$$

with unit normal $\vec{n} = \frac{\nabla g}{|\nabla g|}$

When S is represented in parametric form as

$$\vec{r}(u, v) = x(u, v)\vec{i} + y(u, v)\vec{j} + z(u, v)\vec{k}$$

with the two parameters u and v varying in a region R of uv -plane, then the unit normal $\vec{n}$ to S at P is given by

$$\vec{n} = \frac{\vec{N}}{|\vec{N}|}$$

Fig. 16.7

where

$$\bar{N} = \bar{r}_u \times \bar{r}_v$$

The surface integral of a given vector function $\bar{F}$ taken over a surface S is defined as

$$\begin{aligned} \iint_S \bar{F} \cdot \bar{n} dS &= \iint_S \bar{F} \cdot d\bar{S} \\ &= \iint_R \bar{F}(\bar{r}(u, v)) \cdot \bar{N}(u, v) du dv \end{aligned}$$

In the component form, where

$$\begin{aligned} \bar{F} &= F_1 \bar{i} + F_2 \bar{j} + F_3 \bar{k} \\ \bar{n} &= \cos \alpha \bar{i} + \cos \beta \bar{j} + \cos \gamma \bar{k} \\ \bar{N} &= N_1 \bar{i} + N_2 \bar{j} + N_3 \bar{k} \end{aligned}$$

the surface integral takes the form

$$\begin{aligned} \iint_S \bar{F} \cdot \bar{n} dS &= \iint_S (F_1 \cos \alpha + F_2 \cos \beta + F_3 \cos \gamma) dS \\ &= \iint_R (F_1 N_1 + F_2 N_2 + F_3 N_3) du dv \end{aligned}$$

Here α, β, γ are the angles between $\bar{n}$ and the positive directions of the coordinate axes (i.e., $\bar{n} \cdot \bar{i} = |\bar{n}| |\bar{i}| \cos \alpha = \cos \alpha$, etc.)

Apart from the normal surface integral

$$\iint_S \bar{F}(\bar{r}) \cdot \bar{n} dS$$

the other types of surface integrals are

$$\iint_S \phi dS, \iint_S \phi \bar{n} dS, \iint_S \bar{A} \times \bar{n} dS$$

where ϕ is a scalar function.

Evaluation of a Surface Integral

A surface integral is evaluated by reducing it to a double integral by projecting the given surface S onto one of the coordinate planes. Let D be the projection of S onto the xy -plane (see Fig. 16.7). Then,

$$dS = \frac{dx dy}{|\bar{n} \cdot \bar{k}|}$$

Then,

$$\iint_S \bar{F} \cdot \bar{n} dS = \iint_D \bar{F} \cdot \bar{n} \frac{dx dy}{|\bar{n} \cdot \bar{k}|}$$

where $\bar{n}$ is unit outward drawn normal to S . The R.H.S. double integral in x, y over the plane region D is evaluated as an two-fold iterated integral. In a similar way the surface integral can be evaluated by projecting S onto the Yz -plane as D_1 and Xz -plane as D_2 as follows

$$\begin{aligned} \iint_S \bar{F} \cdot \bar{n} dS &= \iint_{D_1} \bar{F} \cdot \bar{n} \frac{dy dz}{|\bar{n} \cdot \bar{i}|} \\ \iint_S \bar{F} \cdot \bar{n} dS &= \iint_{D_2} \bar{F} \cdot \bar{n} \frac{dx dz}{|\bar{n} \cdot \bar{j}|} \end{aligned}$$

Surface Area of a Curved Surface

Let S be a surface represented by the equation

$$F(x, y, z) = 0 \quad (1)$$

Then the unit normal to the surface S is given by

$$\hat{n} = \frac{\nabla F}{|\nabla F|} = \frac{F_x \bar{i} + F_y \bar{j} + F_z \bar{k}}{\sqrt{F_x^2 + F_y^2 + F_z^2}}$$

where F_x, F_y, F_z are partial derivatives of F w.r.t. x, y, z respectively. Let D be the projection of S onto the xy -plane. Then

$$\begin{aligned} \text{Surface area of } S &= \iint_S dS = \iint_D \frac{dx dy}{|\bar{n} \cdot \bar{k}|} \\ &= \iint_D \frac{\sqrt{F_x^2 + F_y^2 + F_z^2}}{|F_z|} dx dy \end{aligned}$$

since

$$\bar{n} \cdot \bar{k} = \frac{F_z}{\sqrt{F_x^2 + F_y^2 + F_z^2}}$$

Corollary 1: If the equation of the surface S is $z = f(x, y)$ then

$$\text{Surface area} = \iint_D \sqrt{1 + z_x^2 + z_y^2} dx dy.$$

Flux

The normal component $\vec{F} \cdot \vec{n}$ is a scalar. Let ρ be the density, $\vec{V}$ be the velocity of a fluid and $\vec{F} = \rho \vec{V}$. Then flux of $\vec{F}$ represents the total quantity of fluid flowing in unit time through (across) the surface S in the positive direction. The flux of $\vec{F}$ across S is given by the flux integral

$$\text{Flux of } \vec{F} \text{ across } S = \iint_S \vec{F} \cdot \vec{n} dS.$$

WORKED OUT EXAMPLES

Example 1: Evaluate $\iint_S \vec{A} \cdot \vec{n} dS$ over the entire surface S of the region bounded by the cylinder $x^2 + z^2 = 9$, $x = 0$, $y = 0$, $z = 0$ and $y = 8$ where $\vec{A} = 6z\vec{i} + (2x + y)\vec{j} - x\vec{k}$ (see Fig. 16.8).

Solution: Here the entire surface S consists of 5 surfaces namely S_1 the curved (lateral) surface of the cylinder, $ABDCA$, $S_2 : AOEC$, $S_3 : OBDE$, $S_4 : OAB$, $S_5 : CDE$. Thus

$$\begin{aligned} \iint_S \vec{A} \cdot \vec{n} dS &= \iint_{S_1 + S_2 + \dots + S_5} \vec{A} \cdot \vec{n} dS \\ &= \iint_{S_1} + \iint_{S_2} + \dots + \iint_{S_5} \\ &= SI_1 + SI_2 + SI_3 + SI_4 + SI_5 \end{aligned}$$

For the curved (lateral) surface S_1 of the cylinder

$$\begin{aligned} \text{unit normal } \vec{n} &= \frac{\nabla(x^2 + z^2)}{|\nabla(x^2 + z^2)|} = \frac{2x\vec{i} + 2z\vec{k}}{\sqrt{4x^2 + 4z^2}} \\ &= \frac{x\vec{i} + z\vec{k}}{2} \end{aligned}$$

so

$$\begin{aligned} \vec{A} \cdot \vec{n} &= (6z\vec{i} + (2x + y)\vec{j} - x\vec{k}) \cdot \left(\frac{x\vec{i} + z\vec{k}}{2} \right) = \frac{5}{2}xz \\ \vec{n} \cdot \vec{k} &= \frac{z}{2} \\ SI_1 &= \iint_{S_1} \vec{A} \cdot \vec{n} dS = \iint \frac{\vec{A} \cdot \vec{n}}{|\vec{n} \cdot \vec{k}|} dx dy \\ &= \iint \frac{5}{2} \frac{xz}{(z/2)} dx dy \\ &= 5 \int_0^8 \int_0^3 x dx dy = 180 \end{aligned}$$

Fig. 16.8

On the plane $S_2 : AOEC : z = 0, \vec{n} = -\vec{k}$,
 $\vec{A} \cdot \vec{n} = x$

$$SI_2 = \iint_{S_2} \vec{A} \cdot \vec{n} dS = \int_0^8 \int_0^3 x dx dy = 36$$

On the plane $S_3 : OBDE : x = 0, \vec{n} = -\vec{i}$,
 $\vec{A} \cdot \vec{n} = -6z$

$$SI_3 = \iint_{S_3} \vec{A} \cdot \vec{n} dS = \int_0^8 \int_0^3 -6z dz dy = -216$$

On the sector $S_4 : OAB : y = 0, \vec{n} = -\vec{j}$,
 $\vec{A} \cdot \vec{n} = -(2x + y) = -2x$

$$SI_4 = \iint_{S_4} \vec{A} \cdot \vec{n} dS = \iint_{OAB} -2x dx dz$$

In polar coordinates

$$SI_4 = \int_0^{\pi/2} \int_0^3 -2 \cdot r \cos t \cdot r dr dt = -18$$

On the sector $S_5 : CDE : y = 8, \vec{n} = \vec{j}$, $\vec{A} \cdot \vec{n} = 2x + y = 2x + 8$

$$SI_5 = \iint_{S_5} \vec{A} \cdot \vec{n} dS = \iint_{CDE} (2x + 8) dx dz$$

In polar coordinates

$$SI_5 = \int_0^{\pi/2} \int_0^3 (2r \cos t + 8)r dr dt = 18 + 18\pi$$

Thus the required surface integral is

$$\begin{aligned} SI &= (180) + (36) + (-216) + (-18) + (18 + 18\pi) \\ &= 18\pi. \end{aligned}$$

Example 2: Evaluate

a. $\iint_S (\nabla \times \vec{F}) \cdot \vec{n} dS$ and

16.14 — HIGHER ENGINEERING MATHEMATICS—V

- b. $\iint \phi \bar{n} dS$ if $\bar{F} = (x + 2y)\bar{i} - 3z\bar{j} + x\bar{k}$,
 $\phi = 4x + 3y - 2z$ and S is the surface of the
 plane $2x + y + 2z = 6$ bounded by the coordi-
 nate planes $x = 0$, $y = 0$ and $z = 0$ (Fig. 16.9).

Solution: The unit normal $\hat{n}$ to the surface S is

$$\hat{n} = \frac{\nabla(2x + y + 2z)}{|\nabla(2x + y + 2z)|} = \frac{2\bar{i} + \bar{j} + 2\bar{k}}{\sqrt{4 + 1 + 4}}$$

$$\hat{n} = \frac{2\bar{i} + \bar{j} + 2\bar{k}}{3}$$

Fig. 16.9

a. $\nabla \times \bar{F} = \begin{vmatrix} \bar{i} & \bar{j} & \bar{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x+2y & -3z & x \end{vmatrix} = 3\bar{i} - \bar{j} - 2\bar{k}$

so $(\nabla \times \bar{F}) \cdot \hat{n} = (3\bar{i} - \bar{j} - 2\bar{k}) \cdot \left(\frac{2\bar{i} + \bar{j} + 2\bar{k}}{3}\right) = \frac{1}{3}$

$$SI = \iint_S (\nabla \times \bar{F}) \cdot \hat{n} dS = \frac{1}{3} \iint_S dS = \frac{1}{3} \iint \frac{dxdy}{|n \cdot k|}$$

$$= \frac{1}{3} \cdot \int_{x=0}^3 \int_{y=0}^{6-2x} \frac{dydx}{2/3} = \frac{1}{2} \int_0^3 (6 - 2x) dx = \frac{9}{2}$$

b. $SI = \iint \phi \hat{n} dS = \iint (4x + 3y - 2z) \frac{(2\bar{i} + \bar{j} + 2\bar{k})}{3} dS$

Eliminate z using, $z = \frac{6-2x-y}{2}$

$$SI = \frac{2\bar{i} + \bar{j} + 2\bar{k}}{3} \cdot \int_{x=0}^3 \int_{y=0}^{6-2x} (6x + 4y - 6) \frac{dydx}{2/3}$$

$$= (2\bar{i} + \bar{j} + 2\bar{k}) \int_0^3 [3(x-1)(6-2x) + (6-2x)^2] dx$$

$$SI = 72\bar{i} + 36\bar{j} + 72\bar{k}.$$

Example 3: Find the surface area of the plane $x + 2y + 2z = 12$ cut off by $x = 0$, $y = 0$, and $x^2 + y^2 = 16$ (refer Fig. 16.10).

Solution: Rewriting equation of plane

$$z = \frac{12 - x - 2y}{2}$$

we have $z_x = -\frac{1}{2}$, $z_y = -1$

$$\text{Surface area} = \iint_R \sqrt{1 + z_x^2 + z_y^2} dxdy$$

$$= \iint \sqrt{1 + 1 + 1} dxdy$$

$$= \frac{3}{2} \iint dxdy$$

In polar coordinates $= \frac{3}{2} \int_0^{\frac{\pi}{2}} \int_0^4 r dr d\theta = 6\pi$.

Fig. 16.10

Aliter: $F(x, y, z) = x + 2y + 2z - 12 = 0$, so
 $F_x = 1$, $F_y = 2$, $F_z = 2$

$$\sqrt{F_x^2 + F_y^2 + F_z^2} = \sqrt{1 + 4 + 4} = 3$$

$$\text{Surface area} = \iint \frac{\sqrt{F_x^2 + F_y^2 + F_z^2}}{|F_z|} dxdy$$

$$= \iint \frac{3}{2} dxdy = 6\pi.$$

Flux

Example 4: Find the flux of the vector field $\bar{A} = (x - 2z)\bar{i} + (x + 3y + z)\bar{j} + (5x + y)\bar{k}$ through the upper side of the triangle ABC with vertices at the points $A(1, 0, 0)$, $B(0, 1, 0)$, $C(0, 0, 1)$ (see Fig. 16.11).

Solution: Equation of the plane in which the triangle ABC lies is

$$x + y + z = 1$$

Unit normal $\hat{n}$ to ABC is

$$\frac{\nabla(x + y + z - 1)}{|\nabla(x + y + z - 1)|} = \frac{\bar{i} + \bar{j} + \bar{k}}{\sqrt{3}}$$

Fig. 16.11

$$\begin{aligned}\bar{A} \cdot \bar{n} &= \frac{1}{\sqrt{3}} [(x - 2z) + (x + 3y + z) + (5x + y)] \\ &= \frac{7x + 4y - z}{\sqrt{3}}\end{aligned}$$

Let AOB be the projection of ABC onto the xy -plane. Then

$$dS = \frac{dx \, dy}{|\bar{n} \cdot \bar{k}|} = \sqrt{3} \, dx \, dy$$

$$\begin{aligned}\text{Flux across the triangle } ABC &= \iint_S \bar{A} \cdot \bar{n} \, dS \\ &= \iint_{AOB} \frac{7x + 4y - z}{\sqrt{3}} \sqrt{3} \, dx \, dy\end{aligned}$$

Replace z by $1 - x - y$

$$\begin{aligned}&= \iint_{AOB} [7x + 4y - (1 - x - y)] \, dx \, dy \\ &= \int_{x=0}^1 \int_{y=0}^{1-x} (8x + 5y - 1) \, dy \, dx = \frac{5}{3}.\end{aligned}$$

EXERCISE

1. If S is the surface $2x + y + 2z = 6$ bounded by $x = 0, x = 1, y = 0, y = 2$, evaluate (a) $\iint_S (\nabla \times \bar{F}) \cdot \bar{n} \, dS$ and (b) $\iint_S \phi \bar{n} \, dS$.

Ans. a. 1 b. $2i + j + 2k$

2. Evaluate $\iint_S \bar{A} \cdot \bar{n} \, dS$ where $\bar{A} = 18zi - 12j + 3yk$ and S is that part of the plane $2x + 3y + 6z = 12$ which is located in the first octant.

Ans. 24

3. Evaluate $\iint_S (\nabla \times \bar{F}) \cdot \bar{n} \, dS$ where $\bar{F} = yi + (x - 2xz)j - x\bar{y}k$ and S is the surface of the sphere $x^2 + y^2 + z^2 = a^2$ above the xy -plane.

Ans. 0

4. If S is the entire surface of the cube bounded by $x = 0, x = b, y = 0, y = b, z = 0$, and $z = b$ and $\bar{A} = 4xz\bar{i} - y^2\bar{j} + yz\bar{k}$ then evaluate $\iint_S \bar{F} \cdot \bar{n} \, dS$.

Ans. $3b^4/2$

5. Let S be the surface of the cylinder $x^2 + y^2 = 16$ included in the first octant between $z = 0$ and $z = 5$. Evaluate $\iint_S \bar{A} \cdot \bar{n} \, dS$ where $\bar{A} = zi + xj - 3y^2zk$.

Ans. 90

6. For the surface S defined in the previous problem 5, evaluate $\iint_S \phi \bar{n} \, dS$ where $\phi = \frac{3}{8}xyz$.

Ans. $100(i + j)$.

7. Find the surface integral over the parallelepiped $x = 0, y = 0, z = 0, x = 1, y = 2, z = 3$ when $\bar{A} = 2xyi + yz^2j + xzk$.

Ans. 33

8. If S is the surface of the sphere $x^2 + y^2 + z^2 = d^2$ and $\bar{A} = axi + byj + czk$, evaluate $\iint_S \bar{F} \cdot \bar{n} \, dS$.

Hint: Project S onto xoy -plane and use symmetry.

Ans. $2 \cdot \frac{2\pi d^3}{3}(a + b + c)$

9. Let S be the surface of the cylinder $x^2 + y^2 = a^2$ in the first octant between the planes $z = 0$ and $z = h$. Evaluate $\iint_S \bar{A} \cdot \bar{n} \, dS$ where $\bar{A} = zi + xj - 3zy^2k$.

Ans. $ah(a + h)/2$

Flux

10. Calculate the flux of water through the parabolic cylinder $y = x^2$, between the planes $x = 0, z = 0, x = 3, z = 2$ if the velocity vector is $\bar{A} = yi + 2j + xzk$ m/sec.

Hint: Flux of $\bar{F}$ across S is $\iint_S \bar{F} \cdot \bar{n} \, dS$.

Ans. $69 \, \text{m}^3/\text{sec}$

11. Find the flux across the surface of the parabolic cylinder $y^2 = 8x$ in the first octant bounded by the planes $y = 4$ and $z = 6$ when the velocity vector $\bar{V} = 2yi - zj + x^2k$.

Ans. 132

16.16 — HIGHER ENGINEERING MATHEMATICS—V

12. Find the flux of $\vec{A} = i - j + xyz\vec{k}$ through the circular region S obtained by cutting the sphere $x^2 + y^2 + z^2 = a^2$ with a plane $y = x$ (take the side of S facing the positive side of the x -axis).

Hint: S is bounded by the ellipse $2x^2 + z^2 = a^2$, $\hat{n} = (i - j)/\sqrt{2}$, $dS = \sqrt{2}dx dz$, area of the ellipse with semi axis $a/\sqrt{2}$ and a is $\pi a^2/\sqrt{2}$.

Ans. $\sqrt{2}\pi a^2$

13. Compute the flux of the vector field $\vec{A} = xi + yj + \sqrt{x^2 + y^2 - 1} k$ through the outer side of the hyperboloid of one sheet $z = \sqrt{x^2 + y^2 - 1}$ bounded by the planes $z = 0$ and $z = \sqrt{3}$.

Hint: $\hat{n} = \frac{xi+yj}{\sqrt{x^2+y^2-1}} - k$, $\vec{A} \cdot \vec{n} = \frac{1}{\sqrt{x^2+y^2-1}}$ with polar coordinates, flux = $\int_0^{2\pi} \int_1^2 \frac{r dr d\theta}{\sqrt{r^2-1}} = 2\sqrt{3}\pi$.

Ans. $2\sqrt{3}\pi$

14. Evaluate $\iint_S \vec{F} \cdot \vec{n} dS$ where $\vec{F} = \vec{r}/r^3$ and S is the sphere $x^2 + y^2 + z^2 = b^2$.

Ans. 4π

15. Calculate the surface integral of the vector function $\vec{A} = xi + yj$ over the portion of the surface of the unit sphere $S: x^2 + y^2 + z^2 = 1$ above the xy -plane $z \geq 0$.

Ans. $\frac{4\pi}{3}$

16. If S is the triangular surface with vertices $(2, 0, 0)$, $(0, 2, 0)$ and $(0, 0, 4)$ and $\vec{A} = xi + (z^2 - zx)j - xy\vec{k}$ then evaluate $\iint_S \vec{F} \cdot \vec{n} dS$.

Ans. $-\frac{22}{3}$

Surface area

17. What is the surface area of the surface S whose equation is $F(x, y, z) = 0$?

Ans. $\iint_R \frac{\sqrt{F_x^2 + F_y^2 + F_z^2}}{|F_z|} dx dy$

where R is the projection of S on xy -plane.

18. Find the surface area of the plane $x + 2y + 2z = 12$ cut off by $x = 0, y = 0, x = 1, y = 1$.

Ans. $\frac{3}{2}$

19. Find the surface area of $z = x^2 + y^2$ included between $z = 0$ and $z = 1$.

Ans. $\frac{\pi}{6} (\sqrt{125} - 1)$

20. Find the surface area of the region common to the intersecting cylinders $x^2 + y^2 = a^2$ and $x^2 + z^2 = a^2$.

Ans. $16a^2$.

16.4 VOLUME INTEGRALS

Let V be a region in space enclosed by a closed surface $\vec{r} = \vec{r}(u, v)$. Let $\vec{F}(\vec{r})$ be a vector point function. Then the triple integral

$$\iiint_V \vec{F}(\vec{r}) dV \quad \text{or briefly} \quad \iiint_V \vec{F} dV$$

is known as volume integral or space integral.

In the component form

$$\begin{aligned} \iiint_V \vec{F} dV &= \vec{i} \iiint_V F_1 dx dy dz \\ &+ \vec{j} \iiint_V F_2 dx dy dz \\ &+ \vec{k} \iiint_V F_3 dx dy dz \end{aligned}$$

$\iiint_V \phi dV$ is another form of a volume integral. These integrals are evaluated as three-fold iterated integrals.

WORKED OUT EXAMPLES

Example 1: Evaluate $\iiint_V f dV$ where $f = 2x + y$, V is the closed region bounded by the cylinder $z = 4 - x^2$ and the planes $x = 0, y = 0, y = 2$ and $z = 0$ (see Fig. 16.12).

Solution: This closed region is covered if x and z

Fig. 16.12

varies covering the area OAB and y varies from 0 to 2. Thus

$$\begin{aligned} \iiint_V (2x + y) dV &= \int_{y=0}^2 \int_{z=0}^4 \int_{x=0}^{\sqrt{4-z}} (2x + y) dx dz dy \\ &= \int_0^2 \int_0^4 (x^2 + xy) \Big|_0^{\sqrt{4-z}} dz dy \\ &= \int_0^2 \int_0^4 \left[(4-z) + y\sqrt{4-z} \right] dz dy \\ &= \int_0^2 \left[4z - \frac{z^2}{2} - \frac{2}{3}y(4-z)^{\frac{3}{2}} \right]_0^4 dy \\ &= \int_0^2 \left(8 + \frac{16}{3}y \right) dy \\ &= 8y + \frac{16}{6}y^2 \Big|_0^2 \\ &= \frac{80}{3}. \end{aligned}$$

Example 2: If V is the region in the first octant bounded by $y^2 + z^2 = 9$ and the plane $x = 2$ and $\vec{F} = 2x^2y\mathbf{i} - y^2z\mathbf{j} + 4xz^2\mathbf{k}$. Then evaluate

$$\iiint_V (\nabla \cdot \vec{F}) dV.$$

Solution: $\nabla \cdot \vec{F} = 4xy - 2y + 8xz$

The volume V of the solid region is covered by covering the plane region OAB while x varies

Fig. 16.13

from 0 to 2 (Fig. 16.13). Thus

$$\begin{aligned} \iiint_V (\nabla \cdot \vec{F}) dV &= \int_{x=0}^2 \int_{y=0}^3 \int_{z=0}^{\sqrt{9-y^2}} (4xy - 2y + 8xz) dz dy dx \\ &= \int_0^2 \int_0^3 \left[4xyz - 2yz + 4xz^2 \right]_0^{\sqrt{9-y^2}} dy dx \\ &= \int_0^2 \int_0^3 \left[(4xy - 2y)\sqrt{9-y^2} + 4x(9-y^2) \right] dy dx \\ &= \int_0^2 \left[(4x-2) \left(-\frac{1}{3}(9-y^2)^{\frac{3}{2}} \right) + 4x \left(9y - \frac{y^3}{3} \right) \right]_0^3 dx \\ &= \int_0^2 [9(4x-2) + 72x] dx \\ &= 18x^2 - 18x + 36x^2 \Big|_0^2 = 180. \end{aligned}$$

Example 3: Evaluate $\iiint_V \nabla \times \vec{A} dV$ where $\vec{A} = (x+2y)\mathbf{i} - 3z\mathbf{j} + x\mathbf{k}$ and V is the closed region in the first octant bounded by the plane $2x + 2y + z = 4$

Solution: The solid region is covered by covering the plane region OAB in the xy -plane while z is varying from 0 to the plane $2x + 2y + z = 4$ (Fig. 16.14).

Thus

z varies from 0 to $4 - 2x - 2y$,

y varies from 0 to $2 - x$

and

x varies from 0 to 2.
