$$\nabla \times \bar{A} = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x+2y & -3z & x \end{vmatrix} = 3i - j - 2k$$

$$\begin{aligned} \iiint_V \nabla \times \bar{A} dV &= \int_{x=0}^2 \int_{y=0}^{2-x} \int_{z=0}^{4-2x-2y} (3i - j + 2k) dz dy dx \\ &= (3i - j + 2k) \int_0^2 \int_0^{2-x} (4 - 2x - 2y) dy dx \\ &= 2(3i - j + 2k) \int_0^2 \left((2-x)^2 - \frac{(2-x)^2}{2} \right) dx \\ &= (3i - j + 2k) \left[4x + \frac{x^3}{3} - 2x^2 \right]_0^2 \\ &= \frac{8}{3}(3i - j + 2k). \end{aligned}$$

Example 4: Find the volume enclosed between the two surfaces $S_1 : z = 8 - x^2 - y^2$ and $S_2 : z = x^2 + 3y^2$ (see Fig. 16.15).

Solution: Eliminating z from the given two surfaces S_1 and S_2 , we get $8 - x^2 - y^2 = z = x^2 + 3y^2$ i.e., $x^2 + 2y^2 = 4$. Thus the given two surfaces S_1 and S_2 intersect on the elliptic cylinder $x^2 + 2y^2 = 4$.

So the solid region between S_1 and S_2 is covered when

z varies from $x^2 + 3y^2$ to $8 - x^2 - y^2$,

y varies from $-\sqrt{\frac{4-x^2}{2}}$ to $\sqrt{\frac{4-x^2}{2}}$ and

x varies from -2 to 2 .

Fig. 16.15

So the required volume V enclosed between the two surfaces S_1 and S_2 is

$$\begin{aligned} V &= \int_{-2}^2 \int_{-\sqrt{\frac{4-x^2}{2}}}^{\sqrt{\frac{4-x^2}{2}}} \int_{x^2+3y^2}^{8-x^2-y^2} dz dy dx \\ &= \int_{-2}^2 \int_{-\sqrt{\frac{4-x^2}{2}}}^{\sqrt{\frac{4-x^2}{2}}} (8 - 2x^2 - 4y^2) dy dx \\ &= \int_{-2}^2 \left[2(8 - 2x^2) \sqrt{\frac{4-x^2}{2}} - \frac{8}{3} \left(\frac{4-x^2}{2} \right)^{\frac{3}{2}} \right] dx \\ V &= \frac{4\sqrt{2}}{3} \int_{-2}^2 (4 - x^2)^{\frac{3}{2}} dx = 8\pi\sqrt{2}. \end{aligned}$$

EXERCISE

1. Evaluate $\iiint_V f dV$ where $f = 45x^2y$ and V denotes the closed region bounded by the planes $4x + 2y + z = 8$, $x=0$, $y=0$, $z=0$.

Ans. 128

2. If $\bar{A} = (2x^2 - 3z)\bar{i} - 2xy\bar{j} - 4x\bar{k}$ and V is the closed region bounded by the planes $x=0$, $y=0$, $z=0$ and $2x + 2y + z = 4$, evaluate $\iiint_V (\nabla \times \bar{A}) dV$.

Ans. $\frac{8}{3}(j - k)$

3. Evaluate $\iiint_V \bar{A} dV$ where $\bar{A} = x\bar{i} + y\bar{j} + 2z\bar{k}$ and V is the volume enclosed by the planes $x=0$, $y=0$, $y=a$, $z=b^2$ and the surface $z=x^2$.

Ans. $\frac{ab^4}{4}\bar{i} + \frac{a^2b^3}{3}\bar{j} + \frac{4ab^5}{5}\bar{k}$

4. Evaluate $\iiint_V \bar{B} dV$ where V is the region bounded by the surfaces $x=0$, $y=0$, $y=6$, $z=x^2$, $z=4$ and $\bar{B} = 2xz\bar{i} - x\bar{j} + y^2\bar{k}$.

Ans. $128i - 24j + 384k$

5. If $\vec{A} = (x^3 - yz)\vec{i} - 2x^3yj + 2k$, evaluate $\iiint_V (\nabla \cdot \vec{A}) dV$ over the volume of a cube of side b .

Ans. $\frac{1}{3}b^3$

6. Evaluate $\iiint_V (\nabla \cdot \vec{B}) dV$ over the solid region of the sphere $x^2 + y^2 + z^2 = a^2$ when $\vec{B} = px\vec{i} + qy\vec{j} + rz\vec{k}$ where p, q, r are constants.

Ans. $\frac{4}{3}\pi a^2(p + q + r)$

Volume

7. Find the volume of the region common to the intersecting cylinders $x^2 + y^2 = a^2$ and $x^2 + z^2 = a^2$.

Ans. $16a^3/3$

8. Find the volume of the region bounded below by the paraboloid $z = x^2 + y^2$ and above by the plane $z = 2y$.

Ans. $\frac{\pi}{2}$

9. Find the volume cut from the sphere $x^2 + y^2 + z^2 = 4a^2$ by the cylinder $x^2 + y^2 = a^2$.

Ans. $4\pi a^3(8 - 3\sqrt{3})/3$

10. Find the volume bounded above by the sphere $x^2 + y^2 + z^2 = 2a^2$ and below by the paraboloid $az = x^2 + y^2$.

Ans. $(8\sqrt{2} - 7)\pi a^3/6$.

16.5 GREEN'S* THEOREM IN PLANE: TRANSFORMATION BETWEEN LINE INTEGRAL AND DOUBLE INTEGRAL AREA IN CARTESIAN AND POLAR COORDINATES

If R is a closed region in the xy -plane bounded by a simple closed curve c and if $M(x, y)$ and $N(x, y)$ are continuous functions of x and y having continuous derivatives in R , then

$$\oint_c M dx + N dy = \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx dy$$

*George Green (1793–1841) English mathematician.

where c is traversed in the positive direction (refer Fig. 16.16).

Proof: Let the equations of the curves AEB and AFB be $y = Y_1(x)$ and $y = Y_2(x)$ respectively, consider

$$\begin{aligned} \iint_R \frac{\partial M}{\partial y} dx dy &= \int_{x=a}^b \int_{y=Y_1(x)}^{Y_2(x)} \frac{\partial M}{\partial y} dy dx \\ &= \int_a^b [M(x, Y_2) - M(x, Y_1)] dx \\ &= - \int_b^a M(x, Y_2) dx - \int_a^b M(x, Y_1) dx \\ &= - \int_{BFA} M(x, y) dx - \int_{AEB} M(x, y) dx \\ &= - \int_{BFAEB} M(x, y) dx \\ &= - \oint_c M(x, y) dx \end{aligned} \quad (1)$$

Fig. 16.16

Similarly let the equations of the curves EAF and EBF be $x = X_1(y)$ and $x = X_2(y)$ respectively. Then

$$\begin{aligned} \iint_R \frac{\partial N}{\partial x} dx dy &= \int_{y=e}^f \int_{x=X_1(y)}^{X_2(y)} \frac{\partial N}{\partial x} dx dy \\ &= \int_e^f [N(X_2, y) - N(X_1, y)] dy \\ &= \int_e^f N(X_2, y) dy + \int_f^e N(X_1, y) dy \\ &= \oint_c N(x, y) dy \end{aligned} \quad (2)$$

Adding (1) and (2), we get

$$\oint_c M dx + N dy = \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx dy$$

Corollary 1: Vector notation of Green's theorem

Let $\vec{A} = Mi + Nj$ and $\vec{r} = xi + yj$ so that

$$\vec{A} \cdot d\vec{r} = M dx + N dy$$

$$\nabla \times \vec{A} = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ M & N & O \end{vmatrix} = \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) \vec{k}$$

Thus

$$\oint_c \vec{A} \cdot d\vec{r} = \iint_R (\nabla \times \vec{A}) \cdot \vec{k} dR$$

where $dR = dxdy$.

Corollary 2: Area A of the plane region R

bounded by the simple closed curve c

Let $N = x$, $M = -y$ so that

$$\begin{aligned} \oint_c x dy - y dx &= \iint_R (1 + 1) dxdy \\ &= 2 \iint_R dxdy = 2A \end{aligned}$$

Thus

$$A = \frac{1}{2} \oint_c x dy - y dx.$$

Corollary 3: Area A in polar coordinates

Let $x = r \cos t$, $y = r \sin t$, so that

$$dx = \cos t dr - r \sin t dt$$

$$dy = \sin t dr + r \cos t dt$$

Thus

$$A = \frac{1}{2} \int_c r^2 dt$$

Corollary 4: Green's theorem is valid for a doubly (multiply) connected domain R where c is the boundary of the region R consisting of c_1 and c_2 (several) curves all traversed in the positive direction.

Corollary 5: If $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ then by Green's theorem

$$\oint_c M dx + N dy = 0.$$

WORKED OUT EXAMPLES

Green's theorem in plane

Example: Verify Green's theorem in plane for

$$\oint_c (x^2 - 2xy)dx + (x^2y + 3)dy$$

where c is the boundary of the region defined by $y^2 = 8x$ and $x = 2$ (refer Fig. 16.17).

Solution: Green's theorem states that

Line integral = Double integral.

a. The L.H.S. of the Green's theorem result is the line integral

$$= LI = \oint_c (x^2 - 2xy)dx + (x^2y + 3)dy.$$

Here c consists of the curves OA , ADB , BO , so

$$\begin{aligned} LI &= \oint_c = \int_{OA+ADB+BO} \\ &= \int_{OA} + \int_{ADB} + \int_{BO} = LI_1 + LI_2 + LI_3 \end{aligned}$$

Fig. 16.17

Along OA : $y = -2\sqrt{2}\sqrt{x}$, so $dy = -\sqrt{\frac{2}{x}}dx$

$$\begin{aligned} LI_1 &= \int_{OA} (x^2 - 2xy)dx + (x^2y + 3)dy \\ &= \int_0^2 [x^2 - 2x(-2\sqrt{2}\sqrt{x})]dx \\ &\quad + [x^2(-2\sqrt{2}\sqrt{x}) + 3] \left(-\sqrt{\frac{2}{x}} \right) dx \\ &= \int_0^2 (5x^2 + 4\sqrt{2}x^{\frac{3}{2}} - 3\sqrt{2}x^{-\frac{1}{2}})dx \\ &= \left[\frac{5x^3}{3} + 4\sqrt{2} \cdot \frac{2}{5} \cdot x^{\frac{5}{2}} - 3\sqrt{2} \cdot 2\sqrt{x} \right]_0^2 \\ &= \frac{40}{3} + \frac{64}{5} - 12 \end{aligned}$$

Along ADB : $x = 2$, $dx = 0$

$$\begin{aligned} LI_2 &= \int_{ADB} (x^2 - 2xy)dx + (x^2y + 3)dy \\ &= \int_{-4}^4 (4y + 3)dy = 24 \end{aligned}$$

Along BO: $y = 2\sqrt{2}\sqrt{x}$ with $x : 2$ to 0 ,
 $dy = \sqrt{\frac{2}{x}}dx$

$$\begin{aligned} LI_3 &= \int_{BO} (x^2 - 2xy)dx + (x^2y + 3)dy \\ &= \int_2^0 (5x^2 - 4\sqrt{2}x^{\frac{3}{2}} + 3\sqrt{2}x^{-\frac{1}{2}})dx \\ &= -\frac{40}{3} + \frac{64}{5} - 12 \end{aligned}$$

$$\begin{aligned} LI &= LI_1 + LI_2 + LI_3 = \left(\frac{40}{3} + \frac{64}{5} - 12\right) + (24) \\ &+ \left(-\frac{40}{3} + \frac{64}{5} - 12\right) = \frac{128}{5} \end{aligned}$$

b. Here

$$M = x^2 - 2xy, N = x^2y + 3,$$

$$\frac{\partial M}{\partial y} = -2x, \frac{\partial N}{\partial x} = 2xy.$$

So the R.H.S. of the Green's theorem is the double integral given by

$$\begin{aligned} DI &= \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx dy \\ &= \iint_R [(2xy - (-2x))] dx dy \end{aligned}$$

The region R is covered with y varying from $-2\sqrt{2}\sqrt{x}$ of the lower branch of the parabola to its upper branch $2\sqrt{2}\sqrt{x}$ while x varies from 0 to 2 . Thus

$$\begin{aligned} DI &= \int_{x=0}^2 \int_{y=-\sqrt{8x}}^{\sqrt{8x}} (2xy + 2x) dy dx \\ &= \int_0^2 xy^2 + 2xy \Big|_{-\sqrt{8x}}^{\sqrt{8x}} dx \\ &= 8\sqrt{2} \int_0^2 x^{\frac{3}{2}} dx = \frac{128}{5} \end{aligned}$$

Since L.I. = D.I. the Green's theorem is thus verified.

Area of a plane region

Example 2: Using Green's theorem, find the area of the region in the first quadrant bounded by the curves $y = x$, $y = \frac{1}{x}$, $y = \frac{x}{4}$. (see Fig. 16.18)

Solution: By Green's theorem area A of the region bounded by a closed curve c is given by

$$A = \frac{1}{2} \oint_c x dy - y dx$$

Fig. 16.18

Here c consists of the curves $c_1: y = \frac{x}{4}$, $c_2: y = \frac{1}{x}$ and $c_3: y = x$. So

$$A = \frac{1}{2} \oint_c = \frac{1}{2} \left[\int_{c_1} + \int_{c_2} + \int_{c_3} \right] = \frac{1}{2} [I_1 + I_2 + I_3]$$

Along c_1 : $y = \frac{x}{4}$, $dy = \frac{1}{4}dx$, $x: 0$ to 2

$$I_1 = \int_{c_1} x dy - y dx = \int_{c_1} x \frac{1}{4} dx - \frac{x}{4} dx = 0$$

Along c_2 : $y = \frac{1}{x}$, $dy = -\frac{1}{x^2}dx$, $x: 2$ to 1

$$\begin{aligned} I_2 &= \int_{c_2} x dy - y dx = \int_2^1 x \cdot \left(-\frac{1}{x^2}\right) dx - \frac{1}{x} dx \\ &= -2 \ln x \Big|_2^1 = 2 \ln 2 \end{aligned}$$

Along c_3 : $y = x$, $dy = dx$; $x: 1$ to 0

$$I_3 = \int_{c_3} x dy - y dx = \int x dx - x dx = 0$$

$$A = \frac{1}{2} (I_1 + I_2 + I_3) = \frac{1}{2} (0 + 2 \ln 2 + 0) = \ln 2.$$

Example 3: Find the area bounded by the hypocycloid $x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}}$ with $a > 0$ (see Fig. 16.19).

Solution: Parametric equations of the hypocycloid are

$$x = a \cos^3 t, y = a \sin^3 t$$

$$dx = -3a \cos^2 t \sin t dt,$$

$$dy = 3a \sin^2 t \cos t dt$$

Fig. 16.19

Area bounded by the hypocycloid

$$= 4 \cdot \text{area under one leaf } AB$$

$$= 4 \text{ area of the region } AOB$$

$$\text{Area of region } AOB = \frac{1}{2} \int_{ABOA} x dy - y dx$$

$$= \frac{1}{2} \int_{AB} + \int_{BO} + \int_{OA}$$

$$= \frac{1}{2} \int_{AB} + 0 + 0$$

since $x = 0$ along BO and $y = 0$ along OA

$$= \frac{1}{2} \int_0^{\pi/2} \left[a \cos^3 t \cdot (3a \sin^2 t \cos t dt) - a \sin^3 t (-3a) \cos^2 t \sin t dt \right]$$

$$= \frac{3a^2}{2} \int_0^{\pi/2} \sin^2 t \cos^4 t dt + \cos^2 t \sin^4 t dt$$

$$= \frac{3a^2}{2} \left[\frac{1 \cdot 3 \cdot 1}{6 \cdot 4 \cdot 2} \cdot \frac{\pi}{2} \right] + \frac{3a^2}{2} \left[\frac{3 \cdot 1 \cdot 1}{6 \cdot 4 \cdot 2} \cdot \frac{\pi}{2} \right] = 3 \frac{\pi a^2}{32}$$

$$\text{Area bounded by hypocycloid} = 4 \cdot \frac{3\pi a^2}{32} = \frac{3\pi a^2}{8}$$

Doubly connected region

Example 4: Verify Green's theorem in the plane for

$$\oint_c (2x - y^3) dx - xy dy$$

where c is the boundary of the annulus (doubly connected) region enclosed by the circles $x^2 + y^2 = 1$ and $x^2 + y^2 = 9$ (refer Fig. 16.20).

Solution: Here $M = 2x - y^3$, $N = -xy$ so that $\frac{\partial M}{\partial y} = -3y^2$, $\frac{\partial N}{\partial x} = -y$

Thus R.H.S. of Green's theorem is

$$= \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx dy$$

$$= \iint_R (y + 3y^2) dx dy$$

where R is the annulus region.

Fig. 16.20

Put $x = r \cos t$, $y = r \sin t$, so that t varies from 0 to 2π and r from 1 to 3

$$\text{R.H.S.} = \int_0^{2\pi} \int_1^3 (r \sin t + 3r^2 \sin^2 t) r dr dt$$

$$= \frac{26}{3} \int_0^{2\pi} \sin t dt + 60 \int_0^{2\pi} \frac{1 - \sin 2t}{2} dt = 60\pi$$

$$\text{L.H.S.} = \int_c M dx + N dy = \int_{c_1+c_2} (2x - y^3) dx - xy dy$$

Changing to polar coordinate r, t

$$= \int (2r \cos t - r^3 \sin^3 t) (-r \sin t dt) - \int r^3 \cos^2 t \sin t dt$$

$$= r^4 \frac{3\pi}{4} \Big|_1^3 = 60\pi.$$

EXERCISE

Use Green's theorem to evaluate the line integral $\oint_c M dx + N dy$ when $M dx + N dy$ equals to:

1. $-y^3 dx + x^3 dy$ where c : circle $x^2 + y^2 = 1$

Ans. $\frac{3\pi}{2}$

2. $x^{-1} e^y dx + (e^y \ln x + 2x) dy$ where c : the boundary of the region bounded by $y = 2$, $y = x^4 + 1$,

Ans. $\frac{16}{5}$

3. $(\cos x \sin y - xy)dx + \sin x \cos y \cdot dy$ where c : circle $x^2 + y^2 = 1$

Ans. 0

4. $(x^2 - \cosh y)dx + (y + \sin x)dy$ where c : the boundary of the rectangle $0 \leq x \leq \pi$, $0 \leq y \leq 1$

Ans. $\pi(\cosh 1 - 1)$

5. $(3x^2 - 8y^2)dx + (4y - 6xy)dy$ where c : boundary of the region defined by $x = 0$, $y = 0$, $x + y = 1$.

Ans. $\frac{5}{3}$

6. $e^{-x}(\sin y dx + \cos y dy)$ where c : rectangle with vertices at $(0, 0)$, $(\pi, 0)$, $(\pi, \pi/2)$, $(0, \pi/2)$

Ans. $2(e^{-\pi} - 1)$

Verify Green's theorem or evaluate the line integral $\oint_c Mdx + Ndy$ (a) directly (b) using Green's theorem, where $Mdx + Ndy$ is:

7. $(xy + y^2)dx + x^2dy$ with c : closed curve of the region bounded by $y = x$ and $y = x^2$

Ans. common value: $-\frac{1}{20}$

8. $(3x^2 - 8y^2)dx + (4y - 6xy)dy$ with c : boundary of the region defined by $y = \sqrt{x}$ and $y = x^2$

Ans. common value: $\frac{3}{2}$

9. $(2x - y^3)dx - xydy$ with c : boundary of the region enclosed by the circles $x^2 + y^2 = 1$ and $x^2 + y^2 = 9$

Ans. common value: 60π

10. $(3x + 4y)dx + (2x - 3y)dy$ with c : $x^2 + y^2 = 4$

Ans. common value: -8π

Area using Green's theorem

11. Find the area of the region bounded by $y = x^2$ and $y = x + 2$.

Ans. $\frac{9}{2}$

12. Calculate the area bounded by the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

Deduce the area bounded by the circle $x^2 + y^2 = a^2$.

Hint: Put $x = a \cos t$, $y = b \sin t$.

Ans. Area of ellipse πab

put $a = b$, area of circle: πa^2

13. Find the area of the loop of the folium of descartes $x^3 + y^3 = 3axy$, $a > 0$.

Hint: Put $y = tx$, $t : 0$ to ∞ .

Ans. $A = \frac{1}{2} \int x^2 dt = \frac{9}{2} \int_0^\infty \frac{a^2 t^2}{(1+t^3)^2} dt = \frac{3a^2}{2}$

14. Find the area of a loop of the four-leaved rose $\rho = 3 \sin 2\phi$.

Hint: $A = \frac{1}{2} \int_0^{\pi/2} \rho^2 d\phi = \frac{9\pi}{8}$.

15. Find the area of the cardioid $\rho = a(1 - \cos \theta)$, with $0 \leq \theta \leq 2\pi$.

Ans. $\frac{3\pi a^2}{2}$

16. Find the area bounded by one arch of the cycloid $x = a(\theta - \sin \theta)$, $y = a(1 - \cos \theta)$, $a > 0$ and the x -axis.

Ans. $3\pi a^2$

17. Evaluate $\int_c \bar{A} \cdot d\bar{r}$ where

$$\bar{A} = \alpha[-3a \sin^2 t \cos t i + a(2 \sin t - 3 \sin^3 t)j + b \sin 2tk]$$

and the curve c is given by

$$\bar{r} = a \cos t i + a \sin t j + btk$$

and t varying from $\pi/4$ to $\pi/2$.

Ans. $\frac{\alpha}{2}(a^2 + b^2)$

18. Show that $\int_c f dg = \iint_R \left(\frac{\partial f}{\partial x} \frac{\partial g}{\partial y} - \frac{\partial f}{\partial y} \frac{\partial g}{\partial x} \right) dx dy$ where R is the region bounded by the simple closed curve c .

Hint: Use Green's theorem with $M = f \frac{\partial g}{\partial x}$ and $N = f \frac{\partial g}{\partial y}$.

19. Prove that $\int_c \frac{dF}{dn} dS = \iint_R \left(\frac{\partial^2 F}{\partial x^2} + \frac{\partial^2 F}{\partial y^2} \right) dx dy$ where $\frac{dF}{dn}$ is the directional derivative of F in the direction of the outer normal $\bar{n}$ to the curve c bounding the region R .

Hint: Choose $M = -\frac{\partial F}{\partial y}$, $N = \frac{\partial F}{\partial x}$ and note that $\bar{n} = \frac{dy}{ds} i - \frac{dx}{ds} j$.

20. If $\nabla^2 f = 0$ in R , show that

$$\iint_R \left[\left(\frac{\partial f}{\partial x} \right)^2 + \left(\frac{\partial f}{\partial y} \right)^2 \right] dx dy = \int_c f \frac{\partial f}{\partial n} dS.$$

Hint: Take $M = -f \frac{\partial f}{\partial y}$, $N = f \frac{\partial f}{\partial x}$ and note that $\bar{n} = \frac{dy}{ds}i - \frac{dx}{ds}j$.

21. Show that Green's theorem can be written in the form $\int_c \bar{F} \cdot \bar{n} ds = \iint_R \nabla \cdot \bar{F} dx dy$ where $\bar{F} = Mi - Nj$ and $\bar{n}$ is the outer unit normal to the curve c .

16.6 STOKES'* THEOREM

Transformation between line integral and surface integral. Let $\bar{A}$ be a vector function, having continuous first partial derivatives in a domain in space containing an open two sided surface S bounded by a simple closed curve c then

$$\iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS = \oint_c \bar{A} \cdot d\bar{r} \quad (1)$$

where $\bar{n}$ is a unit normal of S and c is traversed in the positive direction.

Proof: See Fig. 16.21. Assume that S can be represented as $z = f(x, y)$ or $x = g(y, z)$, or $y = h(x, z)$ where f, g, h are continuous, differentiable functions. Also assume that projections of S on the xy, yz, zx planes are regions bounded by simple closed curves. If $\bar{A} = A_1i + A_2j + A_3k$ then the result of Stokes' theorem (1) can be written as

$$\begin{aligned} \iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS &= \oint_c \bar{A} \cdot d\bar{r} \\ &= \iint_S (\nabla \times (A_1i + A_2j + A_3k)) \cdot \bar{n} dS = \oint_c \bar{A} \cdot d\bar{r} \\ &= \oint_c (A_1i + A_2j + A_3k) \cdot (dx\bar{i} + dy\bar{j} + dz\bar{k}) \\ &= \oint_c A_1 dx + A_2 dy + A_3 dz \end{aligned} \quad (2)$$

Fig. 16.21

To show that

$$\iint_S (\nabla \times A_1i) \cdot \bar{n} dS = \oint_c A_1 dx \quad (3)$$

Consider

$$\nabla \times A_1i = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ A_1 & 0 & 0 \end{vmatrix} = \frac{\partial A_1}{\partial z} \bar{j} - \frac{\partial A_1}{\partial y} \bar{k}$$

so that

$$(\nabla \times A_1i) \cdot \bar{n} dS = \left(\frac{\partial A_1}{\partial z} \bar{n} \cdot \bar{j} - \frac{\partial A_1}{\partial y} \bar{n} \cdot \bar{k} \right) dS \quad (4)$$

Take the equation of S as $z = f(x, y)$. Then the position vector $\bar{r}$ to any point of S is

$$\bar{r} = x\bar{i} + y\bar{j} + z\bar{k} = x\bar{i} + y\bar{j} + f(x, y)\bar{k}$$

$$\text{so } \frac{\partial \bar{r}}{\partial y} = 0 + \bar{j} + \frac{\partial f}{\partial y} \bar{k} \quad (5)$$

$$\text{Now } \bar{n} \cdot \frac{\partial \bar{r}}{\partial y} = 0$$

since normal $\bar{n}$ to S is perpendicular to the tangent $\frac{\partial \bar{r}}{\partial y}$ to S .

Thus taking dot product of (5) with $\bar{n}$, we have

$$\begin{aligned} 0 &= \bar{n} \cdot \frac{\partial \bar{r}}{\partial y} = \bar{n} \cdot \bar{j} + \frac{\partial f}{\partial y} \bar{n} \cdot \bar{k} \\ \text{or } \bar{n} \cdot \bar{j} &= -\frac{\partial f}{\partial y} \bar{n} \cdot \bar{k} = -\frac{\partial z}{\partial y} \bar{n} \cdot \bar{k} \end{aligned} \quad (6)$$

Substituting (6) in (4), we get

$$(\nabla \times A_1i) \cdot \bar{n} dS = - \left(\frac{\partial A_1}{\partial z} \frac{\partial z}{\partial y} + \frac{\partial A_1}{\partial y} \right) \bar{n} \cdot \bar{k} dS \quad (7)$$

Now on S ,

$$A_1(x, y, z) = A_1(x, y, f(x, y)) = F(x, y)$$

$$\text{so that } \frac{\partial A_1}{\partial y} + \frac{\partial A_1}{\partial z} \frac{\partial z}{\partial y} = \frac{\partial F}{\partial y} \quad (8)$$

Using (8) in (7), we get

$$\begin{aligned} \iint_S (\nabla \times A_1i) \cdot \bar{n} dS &= \iint_S -\frac{\partial F}{\partial y} \bar{n} \cdot \bar{k} dS \\ &= - \iint_R \frac{\partial F}{\partial y} dx dy \end{aligned} \quad (9)$$

where R is the projection of S on xy -plane and

$$\bar{n} \cdot \bar{k} dS = dx dy$$

*Sir George Gabriel Stokes (1819–1903) Irish mathematician.

Applying Green's theorem in plane

$$-\iint_R \frac{\partial F}{\partial y} dx dy = \oint_{c_1} F dx = \oint_c A_1 dx \quad (10)$$

since at each point (x, y) of c_1 the value of F is the same as the value of A_1 at each point (x, y, z) of c and since dx is same for both the curves c and c_1 . Thus from (9) of (10), we arrive at

$$\iint_S (\nabla \times A_1 i) \cdot \bar{n} dS = \oint_c A_1 dx \quad (3)$$

Similarly by projecting S on to other coordinate planes, we get

$$\iint_S (\nabla \times A_2 j) \cdot \bar{n} dS = \oint_c A_2 dy \quad (11)$$

and

$$\iint_S (\nabla \times A_3 k) \cdot \bar{n} dS = \oint_c A_3 dz \quad (12)$$

Adding (3), (11) and (12), we get (1) the result of Stokes' theorem.

Note 1: Stokes' theorem in rectangular form is

$$\begin{aligned} \iint_S \left[\left(\frac{\partial A_3}{\partial y} - \frac{\partial A_2}{\partial z} \right) \cos \alpha + \left(\frac{\partial A_1}{\partial z} - \frac{\partial A_3}{\partial x} \right) \cos \beta \right. \\ \left. + \left(\frac{\partial A_2}{\partial x} - \frac{\partial A_1}{\partial y} \right) \cos \gamma \right] dS \\ = \oint_c A_1 dx + A_2 dy + A_3 dz \end{aligned}$$

where $\bar{n} = \cos \alpha i + \cos \beta j + \cos \gamma k$, and α, β, γ are angles made by normal $\bar{n}$ with $\bar{i}, \bar{j}, \bar{k}$.

Note 2: Green's theorem in plane is a special case of Stoke's theorem.

Note 3: The circulation of $\bar{A}$ around a closed curve c is given by the line integral

$$\oint_c \bar{A} \cdot d\bar{r}$$

where $\bar{A}$ represents the velocity of a fluid circulation has applications in fluid mechanics and aerodynamics.

WORKED OUT EXAMPLES

Example 1: Prove that $\oint_c f d\bar{r} = \iint_S d\bar{S} \times \nabla f$.

Solution: Choose $\bar{A} = f\bar{c}$, where $\bar{c}$ is a constant vector, in the Stoke's theorem. Then

$$\begin{aligned} \text{L.H.S.} &= \oint_c \bar{A} \cdot d\bar{r} = \oint_c f\bar{c} \cdot d\bar{r} \\ &= \oint_c \bar{c} \cdot (f d\bar{r}) = \bar{c} \cdot \oint_c f d\bar{r} \end{aligned}$$

Now $\nabla \times \bar{A} = \nabla \times (f\bar{c}) = (\nabla f) \times \bar{c} + f(\nabla \times \bar{c}) = \nabla f \times \bar{c}$ since $\nabla \times \bar{c} = 0$

So $(\nabla \times \bar{A}) \cdot \bar{n} = (\nabla f \times \bar{c}) \cdot \bar{n} = \bar{c} \cdot (\bar{n} \times \nabla f)$

$$\begin{aligned} \text{R.H.S.} &= \iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS = \iint_S \bar{c} \cdot (\bar{n} \times \nabla f) dS \\ &= \bar{c} \cdot \iint_S (\bar{n} \times \nabla f) dS \end{aligned}$$

Thus

$$\bar{c} \cdot \oint_c f d\bar{r} = \bar{c} \cdot \iint_S (\bar{n} \times \nabla f) dS$$

Since this is true for any arbitrary constant $\bar{c}$, hence, we get the result.

$$\begin{aligned} \oint_c f d\bar{r} &= \iint_S (\bar{n} \times \nabla f) dS = \iint_S \bar{n} dS \times \nabla f \\ &= \iint_S d\bar{S} \times \nabla f. \end{aligned}$$

Example 2: Evaluate $\iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS$ over the surface of intersection of the cylinders $x^2 + y^2 = a^2$, $x^2 + z^2 = a^2$ which is included in the first octant, given that $\bar{A} = 2yzi - (x + 3y - 2)j + (x^2 + z)k$ (refer Fig. 16.22).

Fig. 16.22

16.26 — HIGHER ENGINEERING MATHEMATICS—V

Solution: By Stokes' theorem the given surface integral can be converted to a line integral i.e.,

$$SI = \iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS = \oint_c \bar{A} \cdot d\bar{r} = LI$$

Here c is the curve consisting of the four curves $c_1 : x^2 + z^2 = a^2, y = 0$; $c_2 : x^2 + y^2 = a^2, z = 0$; $c_3 : x = 0, y = a, 0 \leq z \leq a$; $c_4 : x = 0, z = a, 0 \leq y \leq a$

$$LI = \oint_c \bar{A} \cdot d\bar{r} = \int_{c_1+c_2+c_3+c_4} \bar{A} \cdot d\bar{r} = \int_{c_1} + \int_{c_2} + \int_{c_3} + \int_{c_4}$$

$$= LI_1 + LI_2 + LI_3 + LI_4$$

On the curve c_1 : $y = 0; x^2 + z^2 = a^2$

$$LI_1 = \int_{c_1} \bar{A} \cdot d\bar{r} = \int_{c_1} (x^2 + z) dz$$

$$= \int_a^0 [(a^2 - z^2) + z] dz = -\frac{2}{3}a^3 - \frac{a^2}{2}$$

On the curve c_2 : $z = 0, x^2 + y^2 = a^2$

$$LI_2 = \int_{c_2} \bar{A} \cdot d\bar{r} = \int_{c_2} -(x + 3y - 2) dy$$

$$= - \int_0^a (\sqrt{a^2 - y^2} + 3y - 2) dy$$

$$= -\frac{\pi a^2}{4} - \frac{3}{2}a^2 + 2a$$

On the curve c_3 : $x = 0, y = a, 0 \leq z \leq a$

$$LI_3 = \int_{c_3} \bar{A} \cdot d\bar{r} = \int_0^a z dz = \frac{a^2}{2}$$

On c_4 : $x = 0, z = a, 0 \leq y \leq a$

$$LI_4 = \int_{c_4} \bar{A} \cdot d\bar{r} = \int_a^0 (2 - 3y) dy = -2a + \frac{3a^2}{2}$$

$$SI = \iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS = LI = \left(-\frac{2a^3}{3} - \frac{a^2}{2} \right)$$

$$+ \left(-\frac{\pi a^2}{4} - \frac{3a^2}{2} + 2a \right) + \frac{a^2}{2} + \left(-2a + \frac{3a^2}{2} \right)$$

$$SI = \frac{-a^2}{12} (3\pi + 8a).$$

Example 3: Verify Stokes' theorem for $\bar{A} = xzi - yj + x^2yk$ where S is the surface of the region

bounded by $x = 0, y = 0, z = 0, 2x + y + 2z = 8$ which is not included in the xz -plane (Fig. 16.23).

Solution: Stokes' theorem states that

$$\oint_c \bar{A} \cdot d\bar{r} = \iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS$$

Fig. 16.23

Here c is curve consisting of the straight lines AO, OD and DA .

$$\text{L.H.S.} = \oint_c \bar{A} \cdot d\bar{r} = \int_{AO+OD+DA} \bar{A} \cdot d\bar{r}$$

$$= \int_{AO} + \int_{OD} + \int_{DA} = LI_1 + LI_2 + LI_3$$

On the straight line AO : $y = 0, z = 0, \bar{A} = 0$ so

$$LI_1 = \int_{AO} \bar{A} \cdot d\bar{r} = 0$$

On the straight line OD : $x = 0, y = 0, \bar{A} = 0$ so

$$LI_2 = \int_{OD} \bar{A} \cdot d\bar{r} = 0$$

On the straight line DA : $x + z = 4$ and $y = 0$ so

$$\bar{A} = xzi = x(4-x)i$$

$$LI_3 = \int_{DA} \bar{A} \cdot d\bar{r} = \int_0^4 x(4-x)i \cdot dx i = \int_0^4 x(4-x) dx = \frac{32}{3}$$

$$LI = 0 + 0 + \frac{32}{3} = \frac{32}{3}$$

Here the surface S consists of 3 surfaces (planes) $S_1 : OAB, S_2 : OBD, S_3 : ABD$, so that

$$\text{R.H.S.} = \iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS = \iint_{S_1+S_2+S_3} (\nabla \times \bar{A}) \cdot \bar{n} dS$$

$$= \iint_{S_1} + \iint_{S_2} + \iint_{S_3} = SI_1 + SI_2 + SI_3$$

$$\nabla \times \bar{A} = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ xz & -y & x^2y \end{vmatrix} = x^2i + x(1-2y)j$$

On the surface S_1 : plane OAB : $z = 0, \bar{n} = -\bar{k}$, so

$$(\nabla \times \bar{A}) \cdot \bar{n} = [x^2i + x(1-2y)j] \cdot (-k) = 0$$

$$SI_1 = \int \int_{S_1} (\nabla \times \bar{A}) \cdot \bar{n} dS = 0$$

On surface S_2 : plane OBD : plane $x = 0, \bar{n} = -i$ so

$$\nabla \times \bar{A} = 0$$

$$SI_2 = \int \int_{S_2} (\nabla \times \bar{A}) \cdot \bar{n} dS = 0$$

On surface S_3 : plane ABD : $2x + y + 2z = 8$.

Unit normal $\hat{n}$ to the surface $S_3 = \frac{\nabla(2x+y+2z)}{|\nabla(2x+y+2z)|}$

$$\hat{n} = \frac{2i + j + 2k}{\sqrt{4+1+4}} = \frac{2i + j + 2k}{3}$$

$$(\nabla \times \bar{A}) \cdot \bar{n} = \frac{2}{3}x^2 + \frac{1}{3}x(1-2y)$$

To evaluate the surface integral on the surface S_3 , project S_3 on to say xz -plane i.e., projection of ABD on xz -plane is AOD

$$dS = \frac{dx dz}{n \cdot j} = \frac{dx dz}{\frac{1}{3}} = 3dx dz$$

Thus

$$\begin{aligned} SI_3 &= \int \int_{S_3} (\nabla \times \bar{A}) \cdot \bar{n} dS \\ &= \int \int_{AOD} \left[\frac{2}{3}x^2 + \frac{x}{3}(1-2y) \right] 3dx dz \\ &= \int_{x=0}^4 \int_{z=0}^{4-x} [2x^2 + x(1-2y)] dz dx \end{aligned}$$

since the region AOD is covered by varying z from 0 to $4-x$, while x varies from 0 to 4. Using the equation of the surface S_3 , $2x + y + 2z = 8$, eliminate y , then

$$\begin{aligned} SI_3 &= \int_0^4 \int_0^{4-x} \{2x^2 + x[1-2(8-2x-2z)]\} dz dx \\ &= \int_0^4 \int_0^{4-x} (6x^2 - 15x + 4xz) dz dx \\ &= \int_0^4 6x^2z - 15xz + \frac{4xz^2}{2} \Big|_0^{4-x} dx \\ &= \int_0^4 (23x^2 - 4x^3 - 28x) dx = \frac{32}{3} \end{aligned}$$

Thus L.H.S = L.I. = R.H.S. = S.I.

Hence Stokes' theorem is verified.

Example 4: Verify Stokes' theorem for $\bar{A} = y^2i + xyj - xzk$ where S is the hemisphere

$$x^2 + y^2 + z^2 = a^2, z \geq 0.$$

Solution: The curve c which is the boundary of the given hemisphere is the base circle (see Fig. 16.24)

Fig. 16.24

On curve c : $z = 0, x^2 + y^2 = a^2$

$$\begin{aligned} \text{L.H.S.} = LI &= \oint_c \bar{A} \cdot d\bar{r} = \int y^2 dx + xy dy - xz dz \\ &= \int y^2 dx + xy dy \end{aligned}$$

Introducing polar coordinates $x = a \cos t$, $y = a \sin t$, with t varying from 0 to 2π

$$\begin{aligned} LI &= \int_0^{2\pi} a^2 \sin^2 t d(a \cos t) + a \cos t \cdot a \sin t \cdot d(a \sin t) \\ &= a^3 \int_0^{2\pi} (-\sin^3 t + \cos^2 t \sin t) dt = 0 \end{aligned}$$

Now

$$\nabla \times \bar{A} = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y^2 & xy & -xz \end{vmatrix} = zj - yk$$

Unit normal $\hat{n}$ to the sphere is

$$\begin{aligned} \hat{n} &= \frac{\nabla(x^2 + y^2 + z^2)}{|\nabla(x^2 + y^2 + z^2)|} = \frac{2xi + 2yj + 2zk}{\sqrt{4x^2 + 4y^2 + 4z^2}} \\ &= \frac{xi + yj + zk}{a} \end{aligned}$$

$$\begin{aligned} (\nabla \times \bar{A}) \cdot \bar{n} &= (zj - yk) \cdot \left(\frac{xi + yj + zk}{a} \right) \\ &= \frac{1}{a} (zy - zy) = 0 \end{aligned}$$

so

$$\text{R.H.S.} = SI = \iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS = 0$$

Thus

$$\text{L.H.S.} = \text{L.I.} = 0 = \text{S.I.} = \text{R.H.S.}$$

Hence the Stokes' theorem is verified.

EXERCISE

Stokes' theorem

1. If $\nabla \times \bar{A} = 0$, then prove that $\oint_c \bar{A} \cdot d\bar{r} = 0$ for every closed curve c .
2. Prove that $\iint_S \nabla \times \bar{A} \cdot \bar{n} dS = 0$ for any closed surface S .
3. Prove that $\oint_c d\bar{r} \times \bar{B} = \iint_S (\bar{n} \times \nabla) \times \bar{B} ds$.

Hint: Choose $\bar{A} = \bar{B} \times \bar{c}$, where $\bar{c}$ is a constant vector, and apply Stokes' theorem. Note that

$$(\bar{n} \times \nabla) \times \bar{B} = \nabla(\bar{B} \cdot \bar{n}) - \bar{n}(\nabla \cdot \bar{B}).$$

4. Prove that $\oint_c f \nabla g \cdot d\bar{r} = \iint_S (\nabla f \times \nabla g) \cdot \bar{n} dS$ and deduce that $\oint_c f \nabla f \cdot d\bar{r} = 0$.

Hint: Take $\bar{A} = f \nabla g$ in Stokes' theorem. Note that $\nabla \times \nabla g = 0$.

For deduction, take $f = g$ and note that $\nabla f \times \nabla f = 0$.

5. Evaluate $\iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS$ where S is the surface of the hemisphere $x^2 + y^2 + z^2 = 16$ above the xy -plane and $\bar{A} = (x^2 + y - 4)i + 3xyj + (2xz + z^2)k$.

Ans. -16π

6. If $\bar{A} = (y^2 + z^2 + x^2)i + (z^2 + x^2 - y^2)j + (x^2 + y^2 - z^2)k$ evaluate $\iint_S (\nabla \times \bar{A}) \cdot \bar{n} dS$ taken over the surface $S = x^2 + y^2 - 2ax + az = 0, z \geq 0$.

Ans. $2\pi a^3$

7. Evaluate $\iint_S \nabla \times (yi + zj + xk) \cdot \bar{n} dS$ over the surface of the paraboloid $z = 1 - x^2 - y^2, z \geq 0$.

Ans. π

8. Evaluate $\iint_S \nabla \times (yi + 2xj + zk) \cdot \bar{n} dS$ where S is the paraboloid $z = 1 - x^2 - y^2, z \geq 0$.

Ans. π

9. What is the surface integral of the normal component of the curl of the vector function $(x + y)i + (y - x)j + z^3k$ over the upper half of the sphere $x^2 + y^2 + z^2 = 1$.

Ans. -2π

10. Evaluate $\int_c y dx + z dy + x dz$ where c is the curve given by $x^2 + y^2 + z^2 - 2ax - 2ay = 0, x + y = 2a$, beginning at the point $(2a, 0, 0)$ and going at first below the z -plane.

Ans. $-2\sqrt{2}\pi a^2$

11. Evaluate $\oint_c \sin z dx - \cos x dy + \sin y dz$ where c : rectangle $0 \leq x \leq \pi, 0 \leq y \leq 1, z = 3$.

Ans. 2

12. Evaluate $\oint_c y dx + z dy + x dz$ where c is the curve of intersection of the sphere $x^2 + y^2 + z^2 = a^2$ and the plane $x + z = a$.

Ans. $-\pi a^2/\sqrt{2}$.

Verification of Stokes' theorem

13. Evaluate $\oint_c y dx + xz^3 dy - zy^2 dz$ (a) directly (b) using Stokes' theorem, given that c is the circle: $x^2 + y^2 = 4, z = -3$.

Ans. -28.4π

14. Evaluate (a) directly (b) using Stokes' theorem $\oint_c 4z dx - 2x dy + 2x dz$ where c is the ellipse $x^2 + y^2 = 1, z = y + 1$.

Ans. -4π

Verify Stokes' theorem in the following examples for:

15. $\bar{A} = (2x - y)i - yz^2 j - y^2 zk$ where S : upper half surface of the sphere $x^2 + y^2 + z^2 = 1$

Hint: Here $c: x^2 + y^2 = 1, z = 0$.

Ans. π

16. $\bar{A} = x^2 \bar{i} + xy \bar{j}$ where S is square $0 \leq x \leq a, 0 \leq y \leq a$ in the xy -plane

Hint: c : square $0 \leq x \leq a, 0 \leq y \leq a, z = 0$

Ans. $a^3/2$

17. $\vec{A} = (x^2 + y^2)\vec{i} - 2xy\vec{j}$ taken around the rectangle bounded by $x = a$, $x = -a$, $y = 0$, $y = b$

Ans. $-4ab^2$

18. $\vec{A} = e^z(\vec{i} + \sin y\vec{j} + \cos y\vec{k})$ where $S: z = y^2$, $0 \leq x \leq 4$, $0 \leq y \leq 2$

Ans. $\pm 4(1 - e^4)$ from $(0, 0, 0)$ to $(4, 0, 0)$

$\mp 4e^4$ from $(4, 2, 4)$ to $(0, 2, 4)$

The integrals over the parabolas cancel each other.

19. $\vec{A} = y^2\vec{i} + z^2\vec{j} + x^2\vec{k}$ where S : portion of paraboloid $x^2 + y^2 = z$, $y \geq 0$, $z \leq 1$

Ans. $\pm \frac{4}{3}$.

Work done around closed curve by Stokes' theorem

Find the work done by the force F in the displacement around the closed curve c where:

20. $\vec{F} = 2xy^3 \sin z\vec{i} + 3x^2y^2 \sin z\vec{j} + x^2y^3 \cos z\vec{k}$
 c : intersection of paraboloid $z = x^2 + y^2$ and cylinder $(x - 1)^2 + y^2 = 1$

Hint: $\nabla \times \vec{F} = 0$.

Ans. 0

21. $\vec{F} = x^3\vec{i} + e^{3y}\vec{j} + e^{-3z}\vec{k}$, c : $x^2 + 9y^2 = 9$, $z = x^2$

Hint: $\nabla \times \vec{F} = 0$.

Ans. 0.

16.7 GAUSS* DIVERGENCE THEOREM

Transformation between surface integral and volume integral. Let $\vec{A}$ be a vector function of position, having continuous derivatives, in a volume V bounded by a closed surface S then

$$\oint_S \vec{A} \cdot \vec{n} dS = \iiint_V \nabla \cdot \vec{A} dV \quad (1)$$

where $\vec{n}$ is the outward drawn (positive) normal to S .

Proof: Assume that S is such that any line parallel to coordinate axes meets S in at most two points. Let

S_1 and S_2 be the lower (below) and upper (top), portions of S having equations $z = f_1(x, y)$ and $z = f_2(x, y)$ and having $\vec{n}_1$ and $\vec{n}_2$ as normals respectively (See Fig. 16.25). Let R be the projection of the surface S on the xy -plane. If $\vec{A} = A_1\vec{i} + A_2\vec{j} + A_3\vec{k}$, then the result of Gauss divergence theorem (1) in component form is

Fig. 16.25

$$\begin{aligned} \iint_S (A_1\vec{i} + A_2\vec{j} + A_3\vec{k}) \cdot \vec{n} dS \\ = \iiint_V \left(\frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \right) dV \quad (2) \end{aligned}$$

Consider

$$\begin{aligned} \iiint_V \frac{\partial A_3}{\partial z} dV &= \iiint_V \frac{\partial A_3}{\partial z} dz dy dx \\ &= \iint_R \left[\int_{z=f_1}^{z=f_2} \frac{\partial A_3}{\partial z} dz \right] dy dx \\ &= \iint_R [A_3(x, y, f_2) - A_3(x, y, f_1)] dy dx \\ &= \iint_R A_3\vec{k} \cdot \vec{n}_2 dS_2 - \iint_R A_3\vec{k} \cdot (-\vec{n}_1) dS_1 \end{aligned}$$

since for upper surface S_2 , $\vec{k} \cdot \vec{n}_2 dS_2 = dy dx$ while for lower surface S_1 , $\vec{k} \cdot (-\vec{n}_1) dS_1 = dy dx$. Thus

$$\iiint_V \frac{\partial A_3}{\partial z} dV = \iint_S A_3\vec{k} \cdot \vec{n} dS \quad (3)$$

Similarly, projecting S on to yz -plane and xz -planes we have

$$\iiint_V \frac{\partial A_1}{\partial x} dV = \iint_S A_1\vec{i} \cdot \vec{n} dS \quad (4)$$

$$\iiint_V \frac{\partial A_2}{\partial y} dV = \iint_S A_2\vec{j} \cdot \vec{n} dS \quad (5)$$

*Karl Frierich Gauss (1777–1855), German mathematician.

16.30 — HIGHER ENGINEERING MATHEMATICS—V

Adding (3), (4), (5), we get the required result (2).

Note 1: Gauss divergence theorem (G.D.T.) transforms volume integrals to surface integrals and vice versa.

Note 2: G.D.T in rectangular form

$$\begin{aligned} \iiint_V \left(\frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \right) dx dy dz \\ = \iint_S (A_1 \bar{i} + A_2 \bar{j} + A_3 \bar{k}) \cdot (n_1 \bar{i} + n_2 \bar{j} + n_3 \bar{k}) ds \\ = \iint_S (A_1 n_1 + A_2 n_2 + A_3 n_3) dS \\ = \iint_S (A_1 \cos \alpha + A_2 \cos \beta + A_3 \cos \gamma) dS \end{aligned}$$

where $n_1 = n \cdot i = \cos \alpha$, $n_2 = n \cdot j = \cos \beta$, $n_3 = n \cdot k = \cos \gamma$. Here α, β, γ are the angles which $\bar{n}$ makes with the positive x, y, z axes.

Note 3: Apart from (1), G.D.T. can also be written in the following forms:

$$\begin{aligned} \iint_S \bar{n} \times \bar{A} dS &= \iiint_V \nabla \times \bar{A} dV \quad (\text{see Example 14 on Page 16.33}) \\ \iint_S \bar{n} \phi dS &= \iiint_V \nabla \phi dV \quad (\text{see W.O.E. 7 on Page 16.31}) \end{aligned}$$

Note 4: G.D.T. is also known as “Green’s theorem in space” because G.D.T. generalizes the “Green’s theorem in plane” by replacing the (plane) region R and its closed boundary (curve) c by a (space) region V and its closed boundary (surface) S .

Note 5: When $\bar{A} = \bar{V}$ = velocity of a fluid then G.D.T. has the following physical interpretation:

$$\left. \begin{array}{l} \text{Volume of fluid emerging} \\ \text{(diverging) from a closed} \\ \text{surfaces in unit time} \end{array} \right\} = \left\{ \begin{array}{l} \text{Volume of fluid} \\ \text{supplied from within} \\ \text{volume } V \text{ in unit time} \end{array} \right.$$

WORKED OUT EXAMPLES

Surface to volume integral using divergence theorem

Example 1: Find the volume V of a region bounded by a surface S .

Solution: By Gauss’ divergence theorem

$$\iiint_V \nabla \cdot \bar{A} dV = \iint_S \bar{A} \cdot \bar{n} dS \quad (1)$$

Choose $\bar{A} = xi$, so that $\nabla \cdot \bar{A} = 1$, with this (1) reduces to

$$\begin{aligned} V = \text{Volume} &= \iiint_V 1 \cdot dV \\ &= \iint_S x(\bar{i} \cdot \bar{n}) dS = \iint_S x dy dz \end{aligned}$$

Similarly by taking $\bar{A} = yj$ and $\bar{A} = zk$, we get

$$V = \iint_S y dz dx \quad \text{and} \quad V = \iint_S z dx dy$$

$$\text{or} \quad V = \frac{1}{3} \iint_S (x dy dz + y dz dx + z dx dy).$$

Example 2: Evaluate $\iint_S e^x dy dz - ye^x dz dx + 3z dx dy$ where S is the surface of the cylinder $x^2 + y^2 = c^2$, $0 \leq z \leq h$ (Fig. 16.26).

Solution: Here $A_1 = e^x$, $A_2 = -ye^x$, $A_3 = 3z$, so that $\nabla \cdot \bar{A} = \frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} = e^x - e^x + 3 = 3$ using divergence theorem, given surface integral

Fig. 16.26

$$\begin{aligned} &= \iiint_V \nabla \cdot \bar{A} dV = 3 \iiint_V dx dy dz \\ &= 3 \int_{z=0}^h \int_{-c}^c \int_{-\sqrt{c^2-x^2}}^{+\sqrt{c^2-x^2}} dy dx dz \\ &= 3 \cdot 2 \cdot 2 \cdot \int_0^h \int_0^c \int_0^{\sqrt{c^2-x^2}} dy dx dz \\ &= 12h \int_0^c \sqrt{c^2 - x^2} dx \quad a = 3\pi hc^2. \end{aligned}$$

Example 3: Evaluate $\iint_S \bar{A} \cdot \bar{n} dS$ where $\bar{A} = 2xyi + yz^2j + xzk$, and S is the surface of the

region bounded by $x = 0$, $y = 0$, $z = 0$, $y = 3$ and $x + 2z = 6$ (refer Fig. 16.27).

Solution: $\nabla \cdot \bar{A} = 2y + z^2 + x$.

By Gauss' divergence theorem

Fig. 16.27

$$\begin{aligned}
 SI &= \iint_S \bar{A} \cdot \bar{n} dS = \iiint_V \nabla \cdot \bar{A} dV \\
 &= \iiint_V (2y + z^2 + x) dV \\
 &= \int_{y=0}^3 \int_{x=0}^6 \int_{z=0}^{\frac{6-x}{2}} (2y + z^2 + x) dz dx dy \\
 &= \int_0^3 \int_0^6 (2y + x)z + \frac{z^3}{3} \Big|_0^{\frac{6-x}{2}} dx \\
 &= \int_0^3 \int_0^6 \left[y(6-x) + \frac{6x-x^2}{2} + \frac{1}{24}(6-x)^3 \right] dx \\
 &= \int_0^3 y \left(6x - \frac{x^2}{2} \right) + \frac{1}{2} \left(\frac{6x^2}{2} - \frac{x^3}{3} \right) \\
 &\quad - \frac{1}{24} \left(\frac{6-x}{4} \right)^4 \Big|_0^6 dy \\
 &= \int_0^3 \left[18y + 216 \left(\frac{1}{12} + \frac{1}{16} \right) \right] dy = \frac{351}{2}.
 \end{aligned}$$

Example 4: Evaluate $\iint_S \frac{\bar{r}}{r^2} \cdot \bar{n} dS$.

Solution: Take $\bar{A} = \frac{\bar{r}}{r^2} = \frac{xi+yj+zk}{x^2+y^2+z^2}$ so that

$$\begin{aligned}
 \nabla \cdot \bar{A} &= \nabla \cdot \left(\frac{\bar{r}}{r^2} \right) \\
 &= \frac{(r^2 - 2x^2)}{r^4} + \frac{(r^2 - 2y^2)}{r^4} + \frac{(r^2 - 2z^2)}{r^4} \\
 &= \frac{3r^2 - 2r^2}{r^4} = \frac{1}{r^2}
 \end{aligned}$$

Applying Gauss divergence theorem, we get

$$\begin{aligned}
 \iint \frac{\bar{r}}{r^2} \cdot \bar{n} dS &= \iint_S \bar{A} \cdot \bar{n} dS = \iiint_V \nabla \cdot \bar{A} dV \\
 &= \iiint_V \frac{1}{r^2} dV
 \end{aligned}$$

Example 5: Evaluate $\iint_S r^5 \bar{n} dS$

Solution: Put $f = r^5$ so that $\nabla f = \nabla r^5 = 5r^3 \bar{r}$

Applying Gauss divergence theorem

$$\begin{aligned}
 \iint_S r^5 \bar{n} dS &= \iint f \bar{n} dS = \iiint_V \nabla f dV \\
 &= \iiint_V 5r^3 \bar{r} dV
 \end{aligned}$$

Example 6: Evaluate $\iint_S \bar{B} \cdot \bar{n} dS$ when $\bar{B} = \nabla \times \bar{A}$ and S is any closed surface.

Solution: By Gauss divergence theorem

$$\begin{aligned}
 \iint_S \bar{B} \cdot \bar{n} dS &= \iiint_V \nabla \cdot \bar{B} dV \\
 &= \iiint_V \nabla \cdot (\nabla \times \bar{A}) dV = 0
 \end{aligned}$$

since $\nabla \cdot (\nabla \times \bar{A}) = 0$ for any $\bar{A}$.

Example 7: Prove that $\iiint_V \nabla f dV = \iint_S f \bar{n} dS$.

Solution: Choose $\bar{A} = f\bar{c}$ where $\bar{c}$ is a constant vector

so that $\nabla \cdot \bar{A} = \nabla \cdot (f\bar{c}) = \bar{c} \cdot \nabla f + f \nabla \cdot \bar{c} = \bar{c} \cdot \nabla f$

since $\nabla \cdot \bar{c} = 0$

Also $\bar{A} \cdot \bar{n} = (f\bar{c}) \cdot \bar{n} = (f\bar{n}) \cdot \bar{c} = \bar{c} \cdot (f\bar{n})$

Applying Gauss divergence theorem

$$\begin{aligned}
 \iiint_V \nabla \cdot \bar{A} dV &= \iiint_V \bar{c} \cdot \nabla f dV \\
 &= \iint_S \bar{A} \cdot \bar{n} dS \\
 &= \iint_S \bar{c} \cdot (f\bar{n}) dS
 \end{aligned}$$

or $\bar{c} \cdot \iiint_V \nabla f dV = \bar{c} \cdot \iint_S f \bar{n} dS$

Since $\bar{c}$ is arbitrary constant vector, the result follows.

Example 8: Prove that

$$\iint_S \vec{r} \times d\vec{S} = \vec{0} \text{ for any closed surface } S.$$

Solution: We know that

$$\iint_S \vec{n} \times \vec{B} dS = \iiint_V \nabla \times \vec{B} dV \quad (1)$$

Consider

$$\iint_S \vec{r} \times d\vec{S} = \iint_S \vec{r} \times \vec{n} dS = - \iint_S \vec{n} \times \vec{r} dS$$

Choose $\vec{B} = -\vec{r}$ in the above result (1). Note that

$$\nabla \times \vec{B} = \nabla \times (-\vec{r}) = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ -x & -y & -z \end{vmatrix} = 0$$

Thus

$$\begin{aligned} \iint_S \vec{r} \times d\vec{S} &= - \iint_S \vec{n} \times \vec{r} dS \\ &= - \iiint_V \nabla \times \vec{r} dV = 0 \end{aligned}$$

Green's formulas:

Green's first formula (identity)

Example 9: Prove that

$$\iint_S f \frac{\partial g}{\partial n} dS = \iiint_V (f \nabla^2 g + \nabla f \cdot \nabla g) dV$$

Solution: Choose $\vec{A} = f \nabla g$ in the divergence theorem then

$$\begin{aligned} \nabla \cdot \vec{A} &= \nabla \cdot (f \nabla g) = f \nabla \cdot \nabla g + \nabla f \cdot \nabla g \\ &= f \nabla^2 g + \nabla f \cdot \nabla g \\ \vec{A} \cdot \vec{n} &= \vec{n} \cdot f \nabla g = f \vec{n} \cdot \nabla g = f \nabla g \cdot \vec{n} = f \frac{\partial g}{\partial n} \end{aligned}$$

From divergence theorem

$$\begin{aligned} \iint_S \vec{A} \cdot \vec{n} dS &= \iint_S f \frac{\partial g}{\partial n} dS = \iiint_V \nabla \cdot \vec{A} dV \\ &= \iiint_V (f \nabla^2 g + \nabla f \cdot \nabla g) dV \end{aligned}$$

since $\frac{\partial g}{\partial n} dS = \nabla g \cdot \vec{n} dS = \nabla g \cdot d\vec{S}$

Green's first identity can also be written as

$$\iint_S f \nabla g \cdot d\vec{S} = \iiint_V (f \nabla^2 g + \nabla f \cdot \nabla g) dV$$

Green's second formula (identity) or symmetrical theorem

Example 10: Show that

$$\iiint_V (f \nabla^2 g - g \nabla^2 f) dV = \iint_S \left(f \frac{\partial g}{\partial n} - g \frac{\partial f}{\partial n} \right) dS$$

Solution: From Green's first formula (above Example 9) we have

$$\iint_S f \frac{\partial g}{\partial n} dS = \iiint_V (f \nabla^2 g + \nabla f \cdot \nabla g) dV \quad (1)$$

Interchanging f and g , we obtain

$$\iint_S g \frac{\partial f}{\partial n} dS = \iiint_V (g \nabla^2 f + \nabla g \cdot \nabla f) dV \quad (2)$$

Subtracting (2) from (1), we get

$$\iint_S \left(f \frac{\partial g}{\partial n} - g \frac{\partial f}{\partial n} \right) dS = \iiint_V (f \nabla^2 g - g \nabla^2 f) dV$$

Note: Since

$$\begin{aligned} \iint_S [f(\nabla g \cdot \vec{n}) - g(\nabla f \cdot \vec{n})] dS \\ = \iint_S (f \nabla g - g \nabla f) \cdot \vec{n} dS = \iint_S (f \nabla g - g \nabla f) \cdot d\vec{S} \end{aligned}$$

Green's second identity can also be written as

$$\iint_S (f \nabla g - g \nabla f) \cdot d\vec{S} = \iiint_V (f \nabla^2 g - g \nabla^2 f) dV.$$

EXERCISE

Surface to volume integral, using divergence theorem

Using divergence theorem, evaluate the surface integral:

$$1. \iint_S yz dy dz + zx dz dx + xy dx dy \text{ where } S: x^2 + y^2 + z^2 = 4$$

Ans. 0

$$2. \iint_S x^3 dy dz + x^2 y dz dx + x^2 z dx dy \text{ where } S: \text{closed surface consisting of the circular cylinder } x^2 + y^2 = a^2, (0 \leq z \leq b) \text{ and the circular disks } z = 0 \text{ and } z = b, (x^2 + y^2 \leq a^2).$$

Ans. $5\pi a^4 b/4$

3. $\iint_S \sin x dy dz + (2 - \cos x) y dz dx$ where S : parallelepiped $0 \leq x \leq 3, 0 \leq y \leq 2, 0 \leq z \leq 1$

Ans. 12

4. $\iint_S (ax^2 + by^2 + cz^2) dS$ where S : sphere of unit radius centered at origin.

Ans. $4\pi(a + b + c)/3$

5. $\iint_S (x^2 - yz) dz dy - 2x^2 y dz dx + z dx dy$ where S : cube of side b and three of whose edges are along the axes.

Ans. $b^3(b^2 + 3)/3$

6. $\iint_S 9x dy dz + y \cosh^2 x dz dx - z \sinh^2 x dx dy$ where S : ellipsoid $4x^2 + y^2 + 9z^2 = 36$

Ans. 480π

7. $\iint_S \sin x dy dz + y dz dx + z dx dy$ where S : surface of $0 \leq x \leq \pi/2, x \leq y \leq z, 0 \leq z \leq 1$

Ans. $\frac{3}{2} - \frac{\pi^2}{4}$

8. $\iint_S \vec{r} \cdot \vec{n} dS$ where S : sphere of radius 2 with centre at origin

Ans. 32π

9. $\iint_S \vec{r} \cdot \vec{n} dS$ where S : surface of cube bounded by the planes $x = -1, y = -1, z = -1, x = 1, y = 1, z = 1$

Hint: For examples 6 and 7 use result of worked example 4

Ans. 24

10. $\iint_S \vec{F} \cdot \vec{n} dS$ where $\vec{F} = 2xyi + yz^2j + xzk$ and S : surface of parallelepiped $0 \leq x \leq 2, 0 \leq y \leq 1, 0 \leq z \leq 3$

Ans. 30

11. If S is any closed surface enclosing a volume V and $\vec{A} = axi + byj + czk$, then evaluate $\iint_S \vec{A} \cdot \vec{n} dS$.

Ans. $(a + b + c)V$

12. If $\vec{n}$ is the unit outward drawn normal to any closed surface of area S , then evaluate $\iiint_V \nabla \cdot \vec{n} dV$.

Ans. S

13. Prove that $\iint_S \vec{n} dS = \vec{0}$ for any closed surface S .

Hint: Choose $f = 1$.

14. Prove that $\iint_S \vec{n} \times \vec{B} dS = \iiint_V \nabla \times \vec{B} dV$.

Hint: Take $\vec{A} = \vec{B} \times \vec{C}$ in divergence theorem, with $\vec{C}$ any arbitrary constant vector.

15. Evaluate $\iiint_V \nabla \times \vec{B} dV$ where V is the region bounded by a closed surface S and $\vec{B}$ is always normal to S .

Hint: Normal $\vec{n}$ to S and $\vec{B}$ are parallel, so $\vec{n} \times \vec{B} = 0$. Use result of Exercise Example 14

Ans. 0

16. Prove that $\iint_S \frac{\partial f}{\partial n} dS = \iiint_V \nabla^2 f dV$. Further if f is harmonic (solution of Laplace's equation) in a domain D , then evaluate $\iint_D \frac{\partial f}{\partial n} dS$.

Hint: Take $\vec{A} = \nabla f$ in divergence theorem and note that $\vec{A} \cdot \vec{n} = \nabla f \cdot \vec{n} = \frac{\partial f}{\partial n}$.

Ans. 0

17. If f and g are harmonic in V then evaluate $\iint_S \left(f \frac{\partial g}{\partial n} - g \frac{\partial f}{\partial n} \right) dS$.

Hint: Use Green's second identity (formula) and note that $\nabla^2 f = 0$ and $\nabla^2 g = 0$

Ans. 0

Gauss' theorem

18. Let S be a closed surface and let $\vec{r}$ be the position vector of any point (x, y, z) measured from an origin O . Then prove that

$$\iint_S \frac{\vec{n} \cdot \vec{r}}{r^3} dS = \begin{cases} 0 & \text{if } O \text{ lies outside } S \\ 4\pi & \text{if } O \text{ lies inside } S \end{cases}$$

Hint: If O lies outside S , note that $r \neq 0$ and $\nabla \cdot \frac{\vec{r}}{r^3} = 0$. Now use divergence theorem

If O lies inside S , enclose O by a small sphere S^* of radius a then from the above result

$$\iint_{S+S^*} \frac{\vec{n} \cdot \vec{r}}{r^3} dS = 0$$

Note that $\iint_{S^*} \frac{\vec{n} \cdot \vec{r}}{r^3} dS = -4\pi$

19. Prove that $\iint_S \nabla(x^2 + y^2 + z^2) \cdot \vec{n} dS = 6V$ where S is any closed surface enclosing a volume V .

20. If $\vec{A} = (x^2 + y - 4)i + 3xyj + (2xz + z^2)k$ and S is the surface of the paraboloid $x^2 + y^2 + z = 4$ above the xy -plane, evaluate $\iint_S (\nabla \times \vec{A}) \cdot \vec{n} dS$

Ans. -4π .

Verification of Gauss Divergence Theorem

WORKED OUT EXAMPLES

Example 1: Verify the divergence theorem for $\vec{A} = 2x^2y\vec{i} - y^2\vec{j} + 4xz^2\vec{k}$ taken over the region in the first octant bounded by the cylinder $y^2 + z^2 = 9$ and the plane $x = 2$ (refer Fig. 16.28).

Solution: Here $\nabla \cdot \vec{A} = 4xy - 2y + 8xz$

Fig. 16.28

The solid region is covered when z varies from 0 to $\sqrt{9 - y^2}$, y varies from 0 to 3 and x varies from 0 to 2 (height of the cylinder) so

$$\begin{aligned} \text{R.H.S.} &= \int_0^2 \int_0^3 \int_0^{\sqrt{9-y^2}} (4xy - 2y + 8xz) dz dy dx \\ &= \int_0^2 \int_0^3 \left[(4xy - 2y) \left(\sqrt{9-y^2} \right) + 4x(9-y^2) \right] dy dx \\ &= \int_0^2 \left[\frac{(2-4x)(9-y^2)^{3/2}}{3/2} \right]_0^3 dx \\ &\quad + \int_0^2 \left[36yx - 4x \frac{y^3}{3} \right]_0^3 dx \\ &= \int_0^2 -18(1-2x) dx + \int_0^2 (108x - 36x) dx \end{aligned}$$

$$\text{R.H.S.} = 180$$

The entire surface S consists of five surfaces S_1, S_2, S_3, S_4, S_5 . So

$$\begin{aligned} \text{L.H.S.} &= \iint_S \vec{A} \cdot \vec{n} dS = \iint_{S_1} + \iint_{S_2} + \dots \\ &\quad + \iint_{S_5} = SI_1 + SI_2 + \dots + SI_5 \end{aligned}$$

On S_1 : OAB : $x = 0, \hat{n} = -\vec{i}, \vec{A} \cdot \vec{n} = 0$ so

$$SI_1 = \iint_{S_1} \vec{A} \cdot \vec{n} dS = 0$$

On S_2 : CED : $x = 2, \hat{n} = \vec{i}, \vec{A} \cdot \vec{n} = 8y$ so

$$\begin{aligned} SI_2 &= \iint_{S_2} \vec{A} \cdot \vec{n} dS = \iint_{S_2} 8y dy dz \\ &= \int_0^3 \int_0^{\sqrt{9-z^2}} 8y dy dz = \int_0^3 4(9-z^2) dz = 72 \end{aligned}$$

On S_3 : plane $OBDE$: $y = 0, \vec{n} = -\vec{j}, \vec{A} \cdot \vec{n} = 0$ so

$$SI_3 = \iint_{S_3} \vec{A} \cdot \vec{n} dS = 0$$

On S_4 : plane $OACE$: $z = 0, \vec{n} = -\vec{k}, \vec{A} \cdot \vec{n} = 0$, so

$$SI_4 = \iint_{S_4} \vec{A} \cdot \vec{n} dS = 0$$

On S_5 : the curved surface $ABDC$ of the cylinder:

$$y^2 + z^2 = 9$$

$$\text{unit normal } \hat{n} \text{ to } S_5: \frac{\nabla(y^2+z^2)}{|\nabla(y^2+z^2)|} = \frac{2y\vec{j}+2z\vec{k}}{\sqrt{4y^2+4z^2}}$$

$$\hat{n} = \frac{y\vec{j} + z\vec{k}}{3}$$

$$\text{so that } \vec{A} \cdot \hat{n} = \frac{-y^3 + 4xz^3}{3}$$

$$\text{and } \vec{n} \cdot \vec{k} = \frac{y\vec{j} + z\vec{k}}{3} \cdot \vec{k} = \frac{z}{3} = \frac{\sqrt{9-y^2}}{3}$$

Projecting the surface S_5 on the yx -plane

$$\begin{aligned} SI_5 &= \iint_{S_5} \vec{A} \cdot \vec{n} dS = \iint \frac{(4xz^3 - y^3)}{3} \cdot \frac{dx dy}{n \cdot k} \\ &= \iint_R \frac{(4xz^3 - y^3)}{3 \sqrt{9-y^2}} dx dy \\ &= \int_{x=0}^2 \int_{y=0}^3 \left[4x(9-y^2) - y^3(9-y^2)^{-1/2} \right] dy dx \\ &= \int_0^2 72x dx + 18 \int_0^2 dx = 144 - 36 = 108 \end{aligned}$$

so

$$\text{L.H.S.} = 0 + 72 + 0 + 0 + 108 = 180$$

Hence the divergence theorem is verified.

Example 2: Compute the flux of the vector field

$$\begin{aligned} \bar{A} = & \left(\frac{x^2 y}{1 + y^2} + 6yz^2 \right) \bar{i} + \\ & + 2x \arctan y \bar{j} - \frac{2xz(1 + y) + 1 + y^2}{1 + y^2} \bar{k} \end{aligned}$$

through the outer side of that part of the surface of the paraboloid of revolution $z = 1 - x^2 - y^2$ located above the xy -plane.

Solution: The flux of $\bar{A}$ through a surface S is given by the surface integral,

flux = $\iint_S \bar{A} \cdot \bar{n} dS$ (1)
Since the given surface S_1 is the surface of the paraboloid of revolution $z = 1 - x^2 - y^2$, which is not a closed surface, so we close this surface from below with the circular portion S_2 of the xy -plane that is bounded by the circle $x^2 + y^2 = 1, z = 0$ (see Fig. 16.29).

Fig. 16.29

Let V be the volume of the resulting solid bounded above by S_1 and below by S_2 .

Now the flux (1) is calculated, using divergence theorem for the closed region V . Thus

$$\text{Flux} = \iint_S \bar{A} \cdot \bar{n} dS = \iiint_V (\nabla \cdot \bar{A}) dV = 0$$

Since

$$\nabla \cdot \bar{A} = \frac{2xy}{1 + y^2} + \frac{2x}{1 + y^2} - \frac{2x(1 + y)}{1 + y^2} = 0$$

Flux across $S = S_1 + S_2$ is additive. So

$$\text{Flux} = \iint_S = \iint_{S_1 + S_2} = \iint_{S_1} + \iint_{S_2} = 0$$

Thus

$$\iint_{S_1} \bar{A} \cdot \bar{n} dS = - \iint_{S_2} \bar{A} \cdot \bar{n} dS$$

i.e., flux across the required surface $S_1 = -\text{flux across the circular region } S_2$

On S_2 : $z = 0, x^2 + y^2 \leq 1, \bar{n} = -\bar{k}$ so that

$$\bar{A} \cdot \bar{n} = \left(\frac{x^2 y}{1 + y^2} \bar{i} + 2x \arctan y \bar{j} - k \right) \cdot k = 1$$

$$\begin{aligned} \iint_{S_2} \bar{A} \cdot \bar{n} dS &= \iint_{S_2} dS = S_2 = \text{area of the circular region} \\ &= \pi r^2 = \pi \cdot 1^2 = \pi \end{aligned}$$

Thus the required flux of $\bar{A}$ across the outer side of that part of the surface S_1 of the paraboloid of revolution $z = 1 - x^2 - y^2$ is $-\pi$

EXERCISE

Verify Gauss divergence theorem for:

1. $\bar{A} = 4xi - 2y^2j + z^2k$ taken over the region bounded by $x^2 + y^2 = 4, z = 0$ and $z = 3$.

Ans. common value: 84π

2. $\bar{A} = (x^3 - yz)i - 2x^2yj + zk$ taken over the entire surface of the cube $0 \leq x \leq a, 0 \leq y \leq a, 0 \leq z \leq a$.

Ans. common value: $\frac{a^5}{3} + a^3$

3. $\bar{A} = axi + byj + czk$, theorem taken over the entire surface of the sphere of radius d and centered at origin.

Ans. common value: $\frac{4\pi}{3} d^3 (a + b + c)$

4. $\bar{A} = 2xyi + yz^2j + xzk$ and S is the total surface of the rectangular parallelepiped bounded by the coordinate planes and $x = 1, y = 2, z = 3$.

Ans. common value: 33

5. $\bar{A} = 2xzi + yzj + z^2k$ over the upper half of the sphere $x^2 + y^2 + z^2 = a^2$

Ans. common value: $5\pi a^4/4$

16.36 — HIGHER ENGINEERING MATHEMATICS—V

6. $\vec{A} = (x^2 - yz)\vec{i} + (y^2 - zx)\vec{j} + (z^2 - xy)\vec{k}$ taken over the rectangular parallelepiped bounded by the coordinate planes and $x = a$, $y = b$ and $z = c$

Ans. common value: $abc(a + b + c)$

7. $\vec{A} = x^2\vec{i} + y^2\vec{j} + z^2\vec{k}$ taken over the surface of the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

Ans. common value: 0

8. $\vec{A} = xi + yj$ taken over the upper half of the unit sphere $x^2 + y^2 + z^2 = 1$

Ans. common value: $4\pi/3$

9. $\vec{A} = x^3\vec{i} + x^2y\vec{j} + x^2z\vec{k}$ taken over the closed region of the cylinder $x^2 + y^2 = a^2$, bounded by the planes $z = 0$ and $z = b$

Ans. common value; $5\pi ba^4/4$

10. Compute the flux of the vector $\vec{A} = 4xi - yj + zk$ through the surface of a torus.

Hint: Volume of a torus with R_1 and R_2 as the inner and outer radii of the torus is $\frac{\pi^2}{4}(R_2 - R_1)^2(R_2 + R_1)$.

Ans. flux = $\pi^2(R_2 - R_1)^2(R_2 + R_1)$.

Fourier Series

INTRODUCTION

Fourier series introduced in 1807 by Fourier (after work by Euler and Daniel Bernoulli) was one of the most important developments in applied mathematics. It is very useful in the study of heat conduction, mechanics, concentrations of chemicals and pollutants, electrostatics, acoustics and in areas unheard of in Fourier's day such as computing and CAT scan (computer assisted tomography).

Fourier* series is an infinite series representation of periodic function in terms of the trigonometric sine and cosine functions. Fourier series is very powerful method to solve ordinary and partial differential equations particularly with periodic functions appearing as non-homogeneous terms. While Taylor's series expansion is valid only for functions which are continuous and differentiable, Fourier series is possible not only for continuous functions but for periodic functions, functions discontinuous in their values and derivatives. Further, because of the periodic nature, Fourier series constructed for one period is valid for all values. Harmonic analysis is the theory of expanding functions in Fourier series.

Periodic Function

A function $f(x)$ is said to be periodic if $f(x + T) = f(x)$ for all real x and for some positive number T .

T is known as the period of $f(x)$.

Fundamental period

or primitive period or simply period of $f(x)$ is the smallest positive period of f .

Example: $\cos x$, $\sin x$, $\sec x$, $\operatorname{cosec} x$, are periodic functions with period 2π .

$\tan x$, $\cot x$ are periodic with period π .

Result 1: If T is the period of $f(x)$ then nT is also period of f for any integer n .

i.e. $f(x + nT) = f(x) \quad (n \neq 0)$

Example: $\cos(x + 4\pi) = \cos(x + 2 \cdot 2\pi) = \cos((x + 2\pi) + 2\pi) = \cos(x + 2\pi) = \cos 2\pi$.

Result 2: The function $h(x) = af(x) + bg(x)$ has period T if $f(x)$ and $g(x)$ have period T . Here a , b are constants.

Example: If $h(x) = a \cos x + b \sin x$, then

$$\begin{aligned} h(x + 2\pi) &= a \cos(x + 2\pi) + b \sin(x + 2\pi) \\ &= a \cos x + b \sin x = h(x). \end{aligned}$$

Result 3: If $f(x)$ is a periodic function of period T , then $f(ax)$ with $a \neq 0$, is a periodic function of period $\frac{T}{a}$.

Example: $\sin 2x$ has period $\frac{2\pi}{2} = \pi$
 $\cos 3x$ has period $\frac{2\pi}{3}$ and so on.

Result 4: The period of a sum of a number of periodic functions is the least common multiple of the periods.

Example: $f(x) = \sin x + \frac{1}{2} \sin 2x + \frac{1}{3} \sin 3x + \frac{1}{4} \sin 4x$. Note that $\sin x$, $\sin 2x$, $\sin 3x$, $\sin 4x$ have

* Jean-Baptiste Joseph Fourier (1768–1830), French physicist and mathematician.

17.2 — HIGHER ENGINEERING MATHEMATICS—V

periods 2π , π , $\frac{2\pi}{3}$ and $\frac{\pi}{2}$ respectively. Then the period of $f(x)$ is 2π which is the L.C.M. of these periods.

Result 5: A constant function is periodic for any positive T .

Trigonometric Series is a functional series of the form

$$\frac{a_0}{2} + a_1 \cos x + b_1 \sin x + a_2 \cos 2x + b_2 \sin 2x + \dots$$

$$\text{or} \quad \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$$

where the constants $a_0, a_n, b_n (n = 1, 2, 3, \dots)$ are called the coefficients.

Result 1: Let n and m be integers, $n \neq 0, m \neq 0$. For $m \neq n$

- $\int_{\alpha}^{\alpha+2\pi} \cos mx \cdot \cos nx \, dx = 0$
- $\int_{\alpha}^{\alpha+2\pi} \sin mx \cdot \sin nx \, dx = 0$
- $\int_{\alpha}^{\alpha+2\pi} \sin mx \cdot \cos nx \, dx = 0$
- $\int_{\alpha}^{\alpha+2\pi} \cos mx \, dx = 0$
- $\int_{\alpha}^{\alpha+2\pi} \sin mx \, dx = 0$

For $m = n$

- $\int_{\alpha}^{\alpha+2\pi} \cos mx \cdot \cos nx \, dx = \int_{\alpha}^{\alpha+2\pi} \cos^2 mx \, dx = \pi$
- $\int_{\alpha}^{\alpha+2\pi} \sin^2 mx \, dx = \pi$
- $\int_{\alpha}^{\alpha+2\pi} \cos mx \cdot \sin mx \, dx = 0.$

17.1 EULER'S (FOURIER-EULER) FORMULAE

Let $f(x)$, a periodic function with period 2π defined in the interval $(\alpha, \alpha + 2\pi)$, be the sum of a trigonometric series i.e.,

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx) \quad (1)$$

To determine the coefficient a_0

Integrate both sides of (1) with respect to x in the interval α to $\alpha + 2\pi$. Then

$$\int_{\alpha}^{\alpha+2\pi} f(x) \, dx$$

$$\begin{aligned} &= \int_{\alpha}^{\alpha+2\pi} \frac{a_0}{2} \, dx + \int_{\alpha}^{\alpha+2\pi} \left(\sum_{n=1}^{\infty} a_n \cos nx + b_n \sin nx \right) \, dx \\ &= \frac{a_0}{2} \cdot x \Big|_{\alpha}^{\alpha+2\pi} + \sum_{n=1}^{\infty} \left[a_n \int_{\alpha}^{\alpha+2\pi} \cos nx \, dx + b_n \int_{\alpha}^{\alpha+2\pi} \sin nx \, dx \right] \end{aligned}$$

From result 6, the last two integrals for all n will be zero. Thus

$$\int_{\alpha}^{\alpha+2\pi} f(x) \, dx = \frac{a_0}{2} \cdot 2\pi = \pi a_0$$

Hence

$$a_0 = \frac{1}{\pi} \int_{\alpha}^{\alpha+2\pi} f(x) \, dx \quad (2)$$

To determine coefficient a_n for $n = 1, 2, 3, \dots$: Multiplying both sides of (1) by $\cos mx$ and integrating w.r.t. x in $(\alpha, \alpha + 2\pi)$, we get

$$\begin{aligned} &\int_{\alpha}^{\alpha+2\pi} f(x) \cos mx \, dx \\ &= \int_{\alpha}^{\alpha+2\pi} \frac{a_0}{2} \cdot \cos mx \, dx \\ &\quad + \int_{\alpha}^{\alpha+2\pi} \left(\sum_{n=1}^{\infty} a_n \cdot \cos nx \cdot \cos mx \right) \, dx \\ &\quad + \int_{\alpha}^{\alpha+2\pi} \left(\sum b_n \sin nx \cdot \cos mx \right) \, dx \end{aligned}$$

In R.H.S., except the integral of a_n (with $m = n$) all other integrals vanish (Result 6). For $m = n$, the integral of a_n is π . Thus

$$a_n = \frac{1}{\pi} \int_{\alpha}^{\alpha+2\pi} f(x) \cos nx \, dx \quad \text{for } n = 1, 2, 3 \dots \quad (3)$$

Similarly,

$$b_n = \frac{1}{\pi} \int_{\alpha}^{\alpha+2\pi} f(x) \sin nx \, dx \quad \text{for } n = 1, 2, 3 \dots \quad (4)$$

The formulae (2), (3), (4) are known as Euler (or Fourier-Euler) formulae which gives the coefficients a_0, a_n and b_n , which are known as **Fourier coefficients** of $f(x)$.

Fourier series

Fourier Series of a periodic function $f(x)$ with period 2π is the trigonometric series (1) with the Fourier coefficients a_0, a_n, b_n given by the Euler formulae (2), (3), (4). The individual terms in Fourier series are known as harmonics.

Dirichlet conditions

Dirichlet conditions for the expansion of $f(x)$ in Fourier series:

Let $f(x)$ be a periodic function with period 2π . Let $f(x)$ be piecewise continuous, and bounded in the interval $(\alpha, \alpha + 2\pi)$ with finite number of extrema. Then at the points of continuity, the Fourier series of $f(x)$ (R.H.S. of (1)) converges to $f(x)$ (L.H.S. of (1)). At a point of discontinuity x_0 , the Fourier series of $f(x)$ converges to the arithmetic mean of the left and right hand limits of $f(x)$ at x_0 i.e., $f(x_0) = \frac{1}{2} [f(x_0 - 0) + f(x_0 + 0)]$.

Method of obtaining Fourier series of $f(x)$

- I. $f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos nx + \sum_{n=1}^{\infty} b_n \sin nx$
- II. $a_0 = \frac{1}{\pi} \int_{\alpha}^{\alpha+2\pi} f(x) dx$
- III. $a_n = \frac{1}{\pi} \int_{\alpha}^{\alpha+2\pi} f(x) \cos nx dx, \quad n = 1, 2, 3, \dots$
- IV. $b_n = \frac{1}{\pi} \int_{\alpha}^{\alpha+2\pi} f(x) \sin nx dx, \quad n = 1, 2, 3, \dots$

Result 1: *Leibnitz's Rule:* $\int u v dx = uv_1 - u'v_2 + u''v_3 - u'''v_4 + \dots$ where $'$ denotes differentiation and suffix integration w.r.t. x .

Result 2: $\cos n\pi = (-1)^n$; $\sin n\pi = 0$; $\cos(2n + 1)\frac{\pi}{2} = 0$; $\sin(2n + 1)\frac{\pi}{2} = (-1)^n$.

WORKED OUT EXAMPLES

Example 1: Find the Fourier series of

$$f(x) = \begin{cases} 0, & \text{when } -\pi \leq x \leq 0 \\ x^2, & \text{when } 0 \leq x \leq \pi \end{cases}$$

which is assumed to be periodic with period 2π .

Solution: The Fourier series is given by

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$$

Here

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx = \frac{1}{\pi} \int_{-\pi}^0 0 dx + \frac{1}{\pi} \int_0^{\pi} x^2 dx$$

$$a_0 = \frac{1}{\pi} \left[\frac{x^3}{3} \right]_0^{\pi} = \frac{\pi^3}{3\pi} = \frac{\pi^2}{3}$$

$$\begin{aligned} a_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx dx \\ &= \frac{1}{\pi} \int_{-\pi}^0 0 \cdot \cos nx dx + \frac{1}{\pi} \int_0^{\pi} x^2 \cos nx dx \end{aligned}$$

Integrating by parts,

$$\begin{aligned} &= \frac{1}{\pi} \left[x^2 \cdot \frac{\sin nx}{n} - (2x) \cdot \left(\frac{-\cos nx}{n^2} \right) \right. \\ &\quad \left. + 2 \cdot \left(\frac{-\sin nx}{n^3} \right) \right]_0^{\pi} \end{aligned}$$

$$a_n = \frac{1}{\pi} \frac{2\pi}{n^2} \cos n\pi = \frac{2}{n^2} (-1)^n, \quad \text{for } n = 1, 2, 3, \dots$$

$$\begin{aligned} b_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx dx = \frac{1}{\pi} \int_0^{\pi} x^2 \sin nx dx \\ &= \frac{1}{\pi} \left[x^2 \left(\frac{-\cos nx}{n} \right) - 2x \cdot \left(\frac{-\sin nx}{n^2} \right) \right. \\ &\quad \left. + 2 \left(\frac{+\cos nx}{n^3} \right) \right]_0^{\pi} \end{aligned}$$

$$\begin{aligned} b_n &= \frac{1}{\pi} \left[\frac{-\pi^2}{n} \cos n\pi + \frac{2}{n^3} (\cos n\pi - 1) \right] \\ &= \frac{-\pi}{n} (-1)^n + \frac{2}{\pi n^3} [(-1)^n - 1] \end{aligned}$$

Substituting a_0, a_n and b_n we get the required Fourier series of $f(x)$ in the interval $(-\pi, \pi)$ as

$$\begin{aligned} f(x) &= \frac{\pi^2}{6} + 2 \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2} \cos nx \\ &\quad + \sum_{n=1}^{\infty} \left\{ \frac{\pi}{n} (-1)^{n+1} + \frac{2}{\pi n^3} [(-1)^n - 1] \right\} \sin nx. \end{aligned}$$

17.4 — HIGHER ENGINEERING MATHEMATICS—V

Example 2: Obtain the Fourier series expansion of $f(x) = e^{ax}$ in $(0, 2\pi)$.

Solution:

$$a_0 = \frac{1}{\pi} \int_0^{2\pi} f(x) dx = \frac{1}{\pi} \int_0^{2\pi} e^{ax} dx = \frac{e^{ax}}{\pi} \Big|_0^{2\pi}$$

$$a_0 = \frac{e^{2a\pi} - 1}{\pi}$$

$$\begin{aligned} a_n &= \frac{1}{\pi} \int_0^{2\pi} f(x) \cos nx \, dx \\ &= \frac{1}{\pi} \int_0^{2\pi} e^{ax} \cos nx \, dx \end{aligned}$$

Using

$$\int e^{ax} \cos bx \, dx = e^{ax} [a \cos bx + b \sin bx] / (a^2 + b^2)$$

$$a_n = \frac{1}{\pi} \left[e^{ax} \frac{a \cos nx + n \cdot \sin nx}{(a^2 + n^2)} \right]_0^{2\pi}$$

$$\begin{aligned} a_n &= \frac{1}{\pi(a^2 + n^2)} [ae^{2a\pi} \cos 2n\pi - e^0 \cdot \cos 0] \\ &= \frac{1}{\pi(a^2 + n^2)} [ae^{2a\pi} - 1] \end{aligned}$$

$$\begin{aligned} b_n &= \frac{1}{\pi} \int_0^{2\pi} e^{ax} \sin nx \, dx \\ &= \frac{1}{\pi} \left[e^{ax} \frac{a \sin nx - n \cos nx}{a^2 + n^2} \right]_0^{2\pi} \end{aligned}$$

Since

$$\int e^{ax} \sin bx \, dx = e^{ax} [a \sin bx - b \cos bx] / (a^2 + b^2)$$

$$\begin{aligned} b_n &= \frac{n}{\pi(a^2 + n^2)} \cdot [-e^{2a\pi} \cos 2n\pi + 1] \\ &= \frac{n}{\pi(a^2 + n^2)} (1 - e^{2a\pi}) \end{aligned}$$

Substituting these values the required Fourier series is

$$\begin{aligned} f(x) &= \left(\frac{e^{2a\pi} - 1}{\pi} \right) \left[\frac{1}{2} + \sum_{n=1}^{\infty} \left(\frac{1}{a^2 + n^2} \right) (-n \sin nx) \right] \\ &\quad + \frac{ae^{2a\pi} - 1}{\pi} \sum_{n=1}^{\infty} \frac{\cos nx}{(a^2 + n^2)}. \end{aligned}$$

Example 3: If $f(x) = x$ in $(-\frac{\pi}{2}, \frac{\pi}{2})$ and $f(x) = 0$

in $(\frac{\pi}{2}, 3\pi/2)$ find the Fourier series of $f(x)$. Deduce that $\frac{\pi^2}{8} = \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2}$ (refer Fig. 17.1).

Solution:

$$a_0 = \frac{1}{\pi} \int_{-\frac{\pi}{2}}^{\frac{3\pi}{2}} f(x) dx = \frac{1}{\pi} \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} x \, dx + \frac{1}{\pi} \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} 0 \cdot dx$$

$$a_0 = \frac{1}{\pi} \left[\frac{x^2}{2} \right]_{-\frac{\pi}{2}}^{\frac{\pi}{2}} = \frac{1}{2\pi} \left[\frac{\pi^2}{4} - \frac{\pi^2}{4} \right] = 0$$

$$a_n = \frac{1}{\pi} \int_{-\frac{\pi}{2}}^{\frac{3\pi}{2}} f(x) \cos nx \, dx = \frac{1}{\pi} \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} x \cos nx \, dx$$

$$a_n = \frac{1}{\pi} \left[x \frac{\sin nx}{n} + \frac{1}{n} \cdot \frac{\cos nx}{n} \right]_{-\frac{\pi}{2}}^{\frac{\pi}{2}} = 0$$

$$b_n = \frac{1}{\pi} \int_{-\frac{\pi}{2}}^{\frac{3\pi}{2}} f(x) \sin nx \, dx = \frac{1}{\pi} \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} x \sin nx \, dx$$

$$= \frac{1}{\pi} \left[x \cdot \frac{(-\cos nx)}{n} + \frac{1}{n\pi} \frac{\sin nx}{n} \right]_{-\frac{\pi}{2}}^{\frac{\pi}{2}}$$

$$b_n = \frac{-1}{n} \left[\cos n \frac{\pi}{2} \right] + \frac{2}{n^2\pi} \sin \frac{n\pi}{2}$$

Fig. 17.1

For $n = 1, b_1 = \frac{2}{\pi}, b_2 = 0 + \frac{1}{2}, b_3 = -\frac{2}{9\pi}, b_4 = -\frac{1}{4}, b_5 = \frac{2}{25\pi}$ etc. Thus the Fourier series is

$$f(x) = 0 + 0 + \sum_{n=1}^{\infty} \left(\frac{-\cos n \frac{\pi}{2}}{n} + \frac{2}{n^2\pi} \sin n \frac{\pi}{2} \right) \sin nx$$

At $x = \frac{\pi}{2}$ which is a point of discontinuity,

$$f\left(\frac{\pi}{2}\right) = \frac{1}{2} \left[f\left(\frac{\pi}{2} - 0\right) + f\left(\frac{\pi}{2} + 0\right) \right]$$

$$= \frac{1}{2} \left[\frac{\pi}{2} + 0 \right] = \frac{\pi}{4}.$$

Putting $x = \frac{\pi}{2}$ in the Fourier series expansion

$$\begin{aligned} \frac{\pi}{4} &= f\left(\frac{\pi}{2}\right) = \sum_{n=1}^{\infty} \left(\frac{-\cos}{n} \left(\frac{n\pi}{2}\right) + \frac{2}{n^2\pi} \cdot \sin \frac{n\pi}{2} \right) \sin \frac{n\pi}{2} \\ &= \sum_{n=1}^{\infty} \left(0 + \frac{2}{(2n-1)^2\pi} \right) (-1)^{2n} \end{aligned}$$

or
$$\frac{\pi^2}{8} = \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2}.$$

Example 4: Obtain the Fourier series of $f(x) = (\pi - x)/2$ in the interval $(0, 2\pi)$. Deduce

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \dots$$

Solution:

$$a_0 = \frac{1}{\pi} \int_0^{2\pi} f(x) dx = \frac{1}{\pi} \int_0^{2\pi} \left(\frac{\pi - x}{2} \right) dx$$

$$= \frac{1}{2\pi} \left[\pi x - \frac{x^2}{2} \right]_0^{2\pi} = 0$$

$$a_n = \frac{1}{\pi} \int_0^{2\pi} f(x) \cos nx \, dx$$

$$= \frac{1}{\pi} \int_0^{2\pi} \left(\frac{\pi - x}{2} \right) \cos nx \, dx$$

$$a_n = \frac{1}{2\pi} \left[(\pi - x) \cdot \frac{\sin nx}{n} - (-1) \frac{(-\cos nx)}{n^2} \right]_0^{2\pi} = 0$$

$$b_n = \frac{1}{\pi} \int_0^{2\pi} \left(\frac{\pi - x}{2} \right) \sin nx \, dx$$

$$= \frac{1}{2\pi} \left[(\pi - x) \left(\frac{-\cos nx}{n} \right) - (-1) \left(\frac{-1}{n} \right) \right. \\ \left. \times \frac{\sin nx}{n} \right]_0^{2\pi}$$

$$b_n = \frac{1}{2\pi} \left[\frac{\pi}{n} + \frac{\pi}{n} \right] = \frac{1}{n}$$

$$f(x) = \frac{\pi - x}{2} = 0 + 0 + \sum_{n=1}^{\infty} \frac{1}{n} \sin nx$$

$$= \sin x + \frac{\sin 2x}{2} + \frac{\sin 3x}{3} + \dots$$

Put $x = \frac{\pi}{2}$ then $\frac{\pi - \frac{\pi}{2}}{2} = \frac{\pi}{4} = \sum_{n=1}^{\infty} \frac{1}{n} \sin n \frac{\pi}{2}$

$$= 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \dots$$

Example 5: Sum of functions: suppose the Fourier series of $f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos \frac{n\pi x}{L} + b_n \sin \frac{n\pi x}{L})$ and $g(x) = \frac{c_0}{2} + \sum_{n=1}^{\infty} (c_n \cos \frac{n\pi x}{L} + d_n \sin \frac{n\pi x}{L})$ in the interval e to $e + 2L$ then find the Fourier series of $h(x) = \alpha f(x) + \beta g(x)$.

Solution:

$$h(x) = \alpha \left[\frac{a_0}{2} + \sum a_n \cos \frac{n\pi x}{L} + b_n \sin \frac{n\pi x}{L} \right]$$

$$+ \beta \left[\frac{C_0}{2} + \sum c_n \cos \frac{n\pi x}{L} + d_n \sin \frac{n\pi x}{L} \right]$$

$$h(x) = \left(\alpha \frac{a_0}{2} + \beta \frac{c_0}{2} \right) + \sum (\alpha a_n + \beta c_n) \cos \frac{n\pi x}{L}$$

$$+ \sum (\alpha b_n + \beta d_n) \sin \frac{n\pi x}{L}$$

$$h(x) = \frac{A_0}{2} + \sum_{n=1}^{\infty} \left[A_n \cdot \cos \left(\frac{n\pi x}{L} \right) + B_n \sin \left(\frac{n\pi x}{L} \right) \right]$$

where $A_0 = \alpha a_0 + \beta c_0, A_n = \alpha a_n + \beta c_n, B_n = \alpha b_n + \beta d_n$.

EXERCISE

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$$

Find the Fourier series of the following functions $f(x)$ which are periodic with period 2π and defined in the indicated interval.

1. Modified saw-toothed wave form

$$f(x) = 0 \text{ for } -\pi < x \leq 0$$

$$= x \text{ for } 0 < x \leq \pi.$$

$$\text{Deduce } \frac{\pi^2}{8} = \sum_{n=1}^{\infty} 1/(2n-1)^2.$$

Hint: $a_n = \frac{1}{\pi n^2} \cos nx \Big|_0^{\pi} = \frac{-2}{\pi n^2}$ for n odd, 0 when n is even.

$$b_n = -\frac{\cos n\pi}{n} = \frac{1}{n} \text{ for } n \text{ odd, } \frac{-1}{n} \text{ for } n \text{ even}$$

Put $x = 0$ in the equation below

$$0 = \frac{\pi}{4} - \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2}.$$

17.6 — HIGHER ENGINEERING MATHEMATICS—V

Ans. $f(x) = \frac{\pi}{4} - \frac{2}{\pi} \left(\frac{\cos x}{1^2} + \frac{\cos 3x}{3^2} + \frac{\cos 5x}{5^2} + \dots \right) + \left(\frac{\sin x}{1} - \frac{\sin 2x}{2} + \dots \right).$

2. $f(x) = 0$ in $(-\pi, 0)$
 $= \sin x$ in $(0, \pi)$

Deduce $\frac{\pi-2}{4} = \frac{1}{1.3} - \frac{1}{1.5} + \frac{1}{5.7} + \dots$

Hint: $a_0 = \frac{2}{\pi}$, $a_1 = 0$, $a_n = \frac{1+\cos n\pi}{\pi(1-n^2)}$, $b_1 = \frac{1}{2}$, $b_n = 0$

Put $x = \frac{\pi}{2}$, $\sin \frac{\pi}{2} = 1 = \frac{1}{\pi} + \frac{1}{2} \sin \frac{\pi}{2} - \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1+\cos n\pi/2}{\pi(1-n^2)}.$

$\left(1 - \frac{1}{2} - \frac{1}{\pi}\right) \frac{\pi}{2} = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{(2n+1)(2n-1)}.$

Ans. $f(x) = \frac{1}{\pi} + \frac{\sin x}{2} - \frac{2}{\pi} \left(\frac{\cos 2x}{3} + \frac{\cos 4x}{15} + \frac{\cos 6x}{35} + \frac{\cos 8x}{63} + \dots \right).$

3. $f(x) = x$ in $(0, 2\pi)$.

Ans. $f(x) = x = \pi - 2 \left(\sin x + \frac{1}{2} \sin 2x + \frac{1}{3} \sin 3x + \dots \right)$

$a_0 = \pi$, $a_n = 0$, $b_n = \frac{1}{\pi} \left[-2\pi \frac{\cos 2n\pi}{n} \right] = -\frac{2}{n}$

4. $f(x) = x$ if $0 \leq x \leq \pi$
 $= 2\pi - x$ if $\pi \leq x \leq 2\pi$.

Hint: $a_n = \frac{1}{\pi} \left\{ \frac{\cos n\pi - 1}{n^2} - \frac{1 - \cos n\pi}{n^2} \right\}$, $b_n = 0$.

Ans. $f(x) = \frac{\pi}{2} - \frac{4}{\pi} \left(\cos x + \frac{\cos 3x}{3^2} + \frac{\cos 5x}{5^2} + \dots \right)$

5. $f(x) = e^{ax}$ in $(-\pi, \pi)$; Deduce when $x = 0$.

Ans. $a_0 = \frac{2 \sinh a\pi}{a\pi}$, $a_n = \frac{2a(-1)^n \sinh a\pi}{\pi(n^2 + a^2)}$

$b_n = -(2n)(-1)^n \sinh a\pi / [\pi(n^2 + a^2)]$

when $x = 0$, $\frac{\pi}{2 \sinh a\pi}$
 $= \left\{ \frac{1}{2a} - \frac{a}{a^2+1^2} + \frac{a}{a^2+2^2} - \frac{a}{a^2+3^2} + \dots \right\}$

6. $f(x) = a \sin t$, if $0 \leq t \leq \pi$ (Half-wave)
 $= 0$, if $\pi \leq t \leq 2\pi$ rectifier

Deduce $\frac{1}{2} = \frac{1}{1.3} + \frac{1}{3.5} + \frac{1}{5.7} + \dots$

Ans. $f(x) = \frac{a}{\pi} + \frac{1}{2}a \sin x - \frac{2a}{\pi} \sum_{n=1}^{\infty} \frac{\cos 2nx}{4n^2 - 1}$

Put $t = \pi$, then $0 = a \sin \pi = \frac{a}{\pi} + \frac{a}{2} \sin \pi -$

$\frac{2a}{\pi} \sum_{n=1}^{\infty} \frac{\cos 2n\pi}{4n^2 - 1}$

7. $f(x) = -\pi$, if $-\pi < x < 0$

$= x$, if $0 < x < \pi$

Deduce that $\frac{\pi^2}{8} = \frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \dots$

Ans. $a_0 = -\frac{\pi}{2}$, $a_n = \frac{1}{\pi n^2} (\cos n\pi - 1)$;

$b_n = -\frac{1}{n} (1 - 2 \cos n\pi)$

$f(x) = -\frac{\pi}{4} - \frac{2}{\pi} \left(\cos x + \frac{\cos 3x}{3^2} + \frac{\cos 5x}{5^2} + \dots \right)$
 $+ 3 \sin x - \frac{\sin 2x}{2} + \frac{3 \sin 3x}{3} - \frac{\sin 4x}{4} + \dots$

$x = 0$ is a point of discontinuity. At $x = 0$,

$-\frac{\pi}{2} = \frac{1}{2} [-\pi + 0] = \frac{1}{2} [f(0-0) + f(0+0)]$

$= -\frac{\pi}{4} - \frac{2}{\pi} \left[\frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \dots \right]$

8. $f(x) = x^2$ when $0 < x < 2\pi$

Deduce $\frac{\pi^2}{6} = \frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \dots$

Ans. $f(x) = x^2 = \frac{4\pi^2}{3} +$

$\sum_{n=1}^{\infty} \left(\frac{4}{n^2} \cos nx - \frac{4\pi}{n} \cdot \sin nx \right)$

$x = 0$ is a point of discontinuity. So

$f(0) = \frac{1}{2} [f(0-0) + f(0+0)]$

$= \frac{1}{2} [(2\pi)^2 + 0^2] = 2\pi^2$

Putting $x = 0$ in Fourier series expansion

$2\pi^2 = f(0) = \frac{4\pi^2}{3} + \sum_{n=1}^{\infty} \left(\frac{4}{n^2} \cos 0 - 0 \right)$

9. $f(x) = e^{-x}$ in $0 < x < 2\pi$.

Ans. $e^{-x} = \frac{1-e^{-2\pi}}{\pi} \left[\frac{1}{2} + \left(\frac{1}{2} \cos x + \frac{1}{5} \cos 2x + \frac{1}{10} \cos 3x + \dots \right) + \left(\frac{1}{2} \sin x + \frac{2}{5} \sin 2x + \frac{3}{10} \sin 3x + \dots \right) \right]$

10. $f(x) = x + x^2$ in $(-\pi, \pi)$.

Hint: Treating $f(x) = x + x^2 = g(x) + h(x)$ as the sum of two functions $g(x) = x$ and $h(x) = x^2$, the Fourier series of $f(x)$ can be obtained as the sum of the Fourier series of $g(x)$ and $h(x)$ i.e. FS of $f(x) = FS$ of $g(x) + FS$ of $h(x)$ or

$$f(x) = \left[2 \sum_{n=1}^{\infty} (-1)^{n+1} \frac{\sin nx}{n} \right] + \left[\frac{\pi^2}{3} + 4 \sum_{n=1}^{\infty} (-1)^n \frac{\cos nx}{n^2} \right].$$

Ans. $x + x^2 = \frac{\pi^2}{3} + 2 \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin nx +$

$$4 \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2} \cos nx$$

11. $f(x) = \left(\frac{\pi-x}{2}\right)^2$ in $(0, 2\pi)$.

Deduce $\frac{\pi^2}{6} = \sum_{n=1}^{\infty} \frac{1}{n^2}$.

Ans. $f(x) = \frac{\pi^2}{12} + \sum_{n=1}^{\infty} \frac{\cos nx}{n^2}$; put $x = 0$ for deduction.

12. $f(x) = x \sin x$ in $0 \leq x \leq 2\pi$.

Ans. $a_0 = -2, a_1 = -\frac{1}{2}, a_n = \frac{2}{n^2-1}, b_1 = \pi, b_n = 0$

$$f(x) = -1 - \frac{\cos x}{2} + \sum_{n=2}^{\infty} \left(\frac{2 \cos nx}{(n^2-1)} + \pi \sin x \right)$$

13. $f(x) = 2x$ when $0 \leq x \leq \pi$
 $= x$ when $-\pi < x \leq 0$.

Ans. $f(x) = \frac{\pi}{4} - \frac{2}{\pi} \left(\frac{\cos x}{1^2} + \frac{\cos 3x}{3^2} + \frac{\cos 5x}{5^2} + \dots \right) + 3 \left(\frac{\sin x}{1} - \frac{\sin 2x}{2} + \frac{\sin 3x}{3} - \dots \right)$

14. $f(x) = -x$ if $-\pi < x \leq 0$
 $= 0$ if $0 < x \leq \pi$.

Ans. $f(x) = \frac{\pi}{4} - \frac{2}{\pi} \sum_{n=0}^{\infty} \frac{\cos (2n+1)x}{(2n+1)^2} - \sum_{n=1}^{\infty} (-1)^{n-1} \frac{\sin nx}{n}$

15. $f(x) = 1$ if $-\pi < x \leq 0$
 $= -2$ if $0 < x \leq \pi$

Ans. $f(x) = -\frac{1}{2} - \frac{6}{\pi} \sum_{n=0}^{\infty} \frac{\sin (2n+1)x}{2n+1}$.

17.2 FOURIER SERIES FOR EVEN AND ODD FUNCTIONS

Definitions

Even function

A function $f(x)$ is said to be even if

$$f(-x) = f(x) \quad \text{for all } x.$$

Notes:

1. The graph of $f(x)$ is symmetric about y-axis.

2. $f(x)$ contains only even powers of x and may contain only $\cos x, \sec x$.

3. $\int_{-a}^a f(x) dx = 2 \int_0^a f(x) dx$ when $f(x)$ is even.

4. The sum of two even functions is even i.e., $h(x) = f(x) + g(x)$ is even when both $f(x)$ and $g(x)$ are even (or $e + e = e$).

5. Product of two even functions is even i.e., $h(x) = f(x) \cdot g(x)$ is even when both f and g are even (or $e \cdot e = e$).

Example: $x^2, \cos x, x^4 + \cos 2x + 2$

Odd function

A function $f(x)$ is said to be odd if

$$f(-x) = -f(x) \quad \text{for all } x.$$

Notes:

1. The graph of $f(x)$ is symmetric about the origin (lies in opposite quadrants Ist and IIIrd).

2. $f(x)$ contains only odd powers of x and may contain only $\sin x, \csc x$.

3. $\int_{-a}^a f(x) dx = 0$ when $f(x)$ is odd.

4. The sum of two odd functions is odd i.e., $h(x) = f(x) + g(x)$ is odd when both $f(x)$ and $g(x)$ are odd (or $0 + 0 = 0$).

5. Product of an odd function and even function is odd i.e., $h(x) = f(x)g(x)$ is odd when f is even and g is odd or vice versa (or $0 \cdot e = 0$).

6. Product of two odd functions is even even i.e., $0 \cdot 0 = e$.

Example: $x^3, \sin x$.

Result: Most functions are neither even nor odd. But any function $f(x)$ can be written as the arithmetic mean of an even and odd function as

$$f(x) = \frac{1}{2} [f(x) + f(-x)] + \frac{1}{2} [f(x) - f(-x)].$$

Fourier Series for Even and Odd Functions

Let the Fourier series of $f(x)$ in $(-\pi, \pi)$ be

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx) \quad (1)$$

where $a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx \quad (2)$

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx \, dx \quad (3)$$

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx \, dx \quad (4)$$

Case 1: Suppose $f(x)$ is even function in $(-\pi, \pi)$. Then all b_n 's will be zero since the integrand in (4) is an odd function ($e \cdot o = o$). Thus the Fourier series of an even function contains “only cosine terms” and is known as “**Fourier cosine series**” given by

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos nx \quad (5)$$

where

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \, dx = \frac{2}{\pi} \int_0^{\pi} f(x) \, dx \quad (6)$$

and

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx \, dx = \frac{2}{\pi} \int_0^{\pi} f(x) \cos nx \, dx \quad (7)$$

Case 2: Suppose $f(x)$ is odd function in $(-\pi, \pi)$. Then all a_n 's are zero because the integrand in (3) is an odd function ($o \cdot e = o$). Also a_0 is zero since f is odd. Thus the Fourier series of an odd function contains “only sine terms” and is known as “**Fourier sine series**” given by

$$f(x) = \sum_{n=1}^{\infty} b_n \sin nx \quad (8)$$

where

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx \, dx = \frac{2}{\pi} \int_0^{\pi} f(x) \sin nx \, dx \quad (9)$$

(Note that the integrand in the above integral is even i.e. $o \cdot o = e$).

Procedure

1. Identify whether the given function f is even or odd function in the given interval.
2. If f is even, calculate only a_0 and a_n 's from (6) and (7) (no need to calculate b_n 's). The Fourier cosine series is given by (5).
3. If f is odd, calculate only b_n 's from (9). The Fourier sine series is given by (8).

WORKED OUT EXAMPLES

Example 1: Expand the function $f(x) = \frac{\pi^2}{12} - \frac{x^2}{4}$ in Fourier series in the interval $(-\pi, \pi)$ (Fig. 17.2).

Solution: $f(x)$ is even since $f(-x) = f(x)$. The Fourier series reduces to Fourier cosine series given by

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos nx$$

Fig. 17.2

where

$$a_0 = \frac{2}{\pi} \int_0^{\pi} f(x) \, dx = \frac{2}{\pi} \int_0^{\pi} \left(\frac{\pi^2}{12} - \frac{x^2}{4} \right) \, dx$$

$$= \frac{2}{\pi} \left[\frac{\pi^2}{12} x - \frac{x^3}{12} \right]_0^{\pi} = 0$$

$$a_n = \frac{2}{\pi} \int_0^{\pi} \left(\frac{\pi^2}{12} - \frac{x^2}{4} \right) \cos nx \, dx$$

$$= \frac{2}{\pi} \left[\left(\frac{\pi^2}{12} - \frac{x^2}{4} \right) \frac{\sin nx}{n} - \left(\frac{-2x}{4} \right) \times \left(\frac{-\cos nx}{n^2} \right) + \left(-\frac{1}{2} \right) \left(\frac{-\sin nx}{n^3} \right) \right]_0^{\pi}$$

$$a_n = \frac{2}{\pi} \left(-\frac{1}{n^2} \right) \frac{\pi}{2} \cdot \cos n\pi = \frac{(-1)^{n+1}}{n^2}$$

$$f(x) = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2} \cdot \cos nx$$

$$= \cos x - \frac{\cos 2x}{2^2} + \frac{\cos 3x}{3^2} - \frac{\cos 4x}{4^2} + \dots$$

Example 2: Find Fourier series of $f(x) = x^3$ in $(-\pi, \pi)$.

Solution: Since $f(x)$ is odd (i.e., $f(-x) = -f(x)$) the series reduces to Fourier sine series given by

$$f(x) = \sum_{n=1}^{\infty} b_n \sin nx$$

where

$$\begin{aligned} b_n &= \frac{2}{\pi} \int_0^{\pi} f(x) \sin nx \, dx = \frac{2}{\pi} \int_0^{\pi} x^3 \sin nx \, dx \\ &= \frac{2}{\pi} \left[x^3 \left(\frac{-\cos nx}{n} \right) - 3x^2 \left(\frac{-\sin nx}{n^2} \right) \right. \\ &\quad \left. + 6x(-1)(-)\frac{\cos nx}{n^3} - \frac{6}{n^4} \sin nx \right]_0^{\pi} \\ b_n &= \frac{2}{\pi} \left[\frac{-\pi^3}{n} \cos n\pi + \frac{6\pi}{n^3} \cos n\pi \right] \\ &= 2(-1)^n \left[\frac{-\pi^2}{n} + \frac{6}{n^3} \right] \\ f(x) &= 2 \sum_{n=1}^{\infty} \left(\frac{6}{n^3} - \frac{\pi^2}{n} \right) (-1)^n \sin nx \\ &= 2 \left[\left(\frac{\pi^2}{1} - \frac{6}{1^3} \right) \sin x - \left(\frac{\pi^2}{2} - \frac{6}{2^3} \right) \sin 2x + \dots \right]. \end{aligned}$$

EXERCISE

Find the Fourier series expansion of the following functions $f(x)$ in the indicated interval. $f(x)$ is periodic with period 2π :

1. *Saw-toothed wave form:* $f(x) = x$ in $(-\pi, \pi)$.

Ans. Odd function, $f(x) = \sum_{n=1}^{\infty} -\frac{2}{n}(-1)^n \sin nx$.

2. $f(x) = x^2$ in $(-\pi, \pi)$

Deduce that

- a. $\frac{\pi^2}{12} = \frac{1}{1^2} - \frac{1}{2^2} + \frac{1}{3^2} - \frac{1}{4^2} + \dots$
 b. $\frac{\pi^2}{6} = \frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \dots$
 c. $\frac{\pi^2}{8} = \frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \dots$

Ans. Even function, $f(x) = \frac{\pi^2}{3} + 4 \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2} \cos nx$

(a) and (b) are obtained by putting $x = 0$ and $x = \pi$ in Fourier series respectively. (c) is the arithmetic mean of results (a) and (b).

3. *Triangular waveform*

$$\begin{aligned} f(x) &= 1 + \frac{2x}{\pi} \quad \text{if } -\pi \leq x \leq 0 \\ &= 1 - \frac{2x}{\pi} \quad \text{if } 0 \leq x \leq \pi \end{aligned}$$

Deduce that $\frac{\pi^2}{8} = \frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \dots$

Ans. $f(x) = 0 + \frac{4}{\pi^2} \sum_{n=1}^{\infty} \frac{[1-(-1)^n]}{n^2} \cos nx$

since f is even function.

Putting $x = 0$, $1 = f(0) = \frac{8}{\pi^2} \left(\frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \dots \right)$

4. $f(x) = |x|$ in $(-\pi, \pi)$ or
 $f(x) = -x$ in $(-\pi, 0)$ and
 $= x$ in $(0, \pi)$.

Ans. $f(x) = \frac{\pi}{2} + \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{[(-1)^n - 1]}{n^2} \cos nx$,
 even function.

5. *Square waveform:*

$$\begin{aligned} f(x) &= -k, \quad \text{if } -\pi < x < 0 \\ &= k, \quad \text{if } 0 < x < \pi. \end{aligned}$$

Ans. Odd function, $f(x) = \frac{2k}{\pi} \sum_{n=1}^{\infty} \frac{(1 - \cos n\pi)}{n} \sin nx$

6. $f(x) = -(\pi + x)/2$ for $-\pi \leq x < 0$
 $= (\pi - x)/2$ for $0 \leq x < \pi$.

Ans. Odd function, $f(x) = \sin x + \frac{1}{2} \sin 2x + \frac{1}{3} \sin 3x + \dots$

7. $f(x) = |\cos x|$ in $(-\pi, \pi)$.

Ans. Even function, $f(x) = \frac{2}{\pi} + \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos n\frac{\pi}{2}}{1-n^2} \cos nx$.

8. $f(x) = |\sin x|$ in $(-\pi, \pi)$.

Ans. Even function, $f(x) = \frac{2}{\pi} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos 2nx}{(4n^2-1)}$.

9. $f(x) = \sin ax$ in $(-\pi, \pi)$, where a is not an integer.

17.10 — HIGHER ENGINEERING MATHEMATICS—V

Ans. Odd function, $f(x) = \frac{2 \sin a\pi}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^n}{a^2 - n^2} \sin nx$.

10. $f(x) = \cos ax$ in $(-\pi, \pi)$, where a is not an integer.

Ans. $f(x) = \frac{\sin a\pi}{\pi} + \frac{2a \sin a\pi}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^n}{a^2 - n^2} \cos nx$,
even function.

11. $f(x) = x \sin x$ in $(-\pi, \pi)$.

Deduce that $\frac{\pi-2}{4} = \frac{1}{1.3} - \frac{1}{3.5} + \frac{1}{5.7} - \frac{1}{7.9} + \dots$

Ans. $f(x) = 1 - \frac{1}{2} \cos x + \sum_{n=2}^{\infty} \frac{2(-1)^{n+1}}{n^2 - 1} \cos nx$,
even function.

Put $x = \frac{\pi}{2}$,

$$\frac{\pi}{2} \sin \frac{\pi}{2} = 1 - 0 - \frac{2}{1.3}(-1) + \frac{2}{2.4} \cdot (0) - \frac{2}{3.5} + \dots$$

12. $f(x) = x \cos x$ in $(-\pi, \pi)$.

Ans. $f(x) = -\frac{1}{2} \sin x + \sum_{n=2}^{\infty} \frac{(-1)^n}{(n^2 - 1)} \sin nx$,
odd function.

13. $f(x) = \sqrt{1 - \cos x}$ in $(-\pi, \pi)$ or $-\sqrt{2} \sin \frac{x}{2}$
in $(-\pi, 0)$ and $\sqrt{2} \sin (x/2)$ in $(0, \pi)$.

Ans. Even, $f(x) = \frac{2\sqrt{2}}{\pi} - \frac{4\sqrt{2}}{\pi} \sum_{n=1}^{\infty} \cos nx / (4n^2 - 1)$

14. $f(x) = -x^2$ in $(-\pi, 0)$ and $= x^2$ in $(0, \pi)$.

Ans. $f(x) = \frac{2}{\pi} \sum_{n=1}^{\infty} \left\{ \frac{\pi^2}{n^3} (-1)^{n+1} + \frac{2[1 - (-1)^{n+1}]}{n^3} \right\} \sin nx$
odd function.

17.3 FOURIER SERIES FOR FUNCTIONS HAVING PERIOD $2L$

Fourier series of periodic function with period 2π was considered so far. Now consider the Fourier series expansion of a function in an interval of length $2L$.

Let $f(x)$ be a periodic function with arbitrary period $2L$ defined in the interval $c < x < c + 2L$. Introduce a new variable z as

$$\frac{x}{2L} = \frac{z}{2\pi} \quad \text{or } x = \frac{Lz}{\pi} \quad \text{or } z = \frac{\pi x}{L} \quad (1)$$

At $x = c$, $z = \frac{\pi c}{L} = d$ say

At $x = c + 2L$, $z = \frac{\pi}{L}(c + 2L) = \frac{\pi c}{L} + 2\pi = d + 2\pi$

Thus as $c < x < c + 2L$, the new variable z lies in the interval

$$d < z < d + 2\pi$$

So z varies in the interval $(d, d + 2\pi)$ of length 2π . Substituting for x from (1)

$$f(x) = f\left(\frac{Lz}{\pi}\right) = F(z) \quad (2)$$

Let the Fourier series of $F(z)$ defined in the interval $(d, d + 2\pi)$ and with period 2π be

$$F(z) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nz + b_n \sin nz) \quad (3)$$

where $a_0 = \frac{1}{\pi} \int_d^{d+2\pi} F(z) dz$.

Changing the variable to x

$$a_0 = \frac{1}{\pi} \int_c^{c+2L} f(x) \cdot \left(\frac{\pi}{L} dx\right)$$

Since

$$dz = \frac{\pi}{L} dx$$

Thus

$$a_0 = \frac{1}{L} \int_c^{c+2L} f(x) dx \quad (4)$$

Similarly,

$$\begin{aligned} a_n &= \frac{1}{\pi} \int_d^{d+2\pi} F(z) \cos(nz) dz \\ &= \frac{1}{\pi} \int_c^{c+2L} f(x) \cdot \cos\left(\frac{n\pi x}{L}\right) \frac{\pi}{L} dx \end{aligned}$$

$$\text{So } a_n = \frac{1}{L} \int_c^{c+2L} f(x) \cdot \cos\left(\frac{n\pi x}{L}\right) dx \quad (5)$$

In a similar way

$$b_n = \frac{1}{L} \int_c^{c+2L} f(x) \sin\left(\frac{n\pi x}{L}\right) dx \quad (6)$$

Hence the Fourier series expansion for a function $f(x)$ with period $2L$ is

$$\begin{aligned} f(x) &= F(z) \\ &= \frac{a_0}{2} + \sum_{n=1}^{\infty} \left[a_n \cdot \cos\left(\frac{n\pi x}{L}\right) + b_n \sin\left(\frac{n\pi x}{L}\right) \right] \end{aligned}$$

with the Fourier coefficients a_0, a_n, b_n given by (4), (5), (6).

Result:

$$\int_{-L}^L \cos\left(\frac{m\pi x}{L}\right) \cdot \cos\left(\frac{n\pi x}{L}\right) dx = \begin{cases} 2L & \text{if } m = n = 0 \\ L & \text{if } m = n \neq 0 \\ 0 & \text{if } m \neq n \end{cases}$$

Result:

$$\int_{-L}^L \sin\left(\frac{m\pi x}{L}\right) \cdot \sin\left(\frac{n\pi x}{L}\right) dx = \begin{cases} 0 & \text{if } m = n = 0 \\ L & \text{if } m = n \neq 0 \\ 0 & \text{if } m \neq n \end{cases}$$

Result:

$$\int_{-L}^L \sin\left(\frac{m\pi x}{L}\right) \cdot \cos\left(\frac{n\pi x}{L}\right) dx = 0 \quad \text{for all integers } m \text{ and } n.$$

Fourier Series for Even and Odd FunctionsDefined in the interval $(-L, L)$ of length $2L$.**Case 1:** $f(x)$ be even function in $(-L, L)$. Then the **Fourier cosine series** is

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi x}{L}$$

where

$$a_0 = \frac{2}{L} \int_0^L f(x) dx$$

and

$$a_n = \frac{2}{L} \int_0^L f(x) \cos \frac{n\pi x}{L} dx.$$

Case 2: $f(x)$ be odd function in $(-L, L)$. Then the **Fourier sine series** is

$$f(x) = \sum_{n=1}^{\infty} b_n \sin \frac{n\pi x}{L}$$

where

$$b_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx.$$

WORKED OUT EXAMPLES**Example 1:** Find the Fourier series of $f(x)$ defined

$$\begin{aligned} f(x) &= 0 & \text{when } -c < x < 0 \\ &= 1 & \text{when } 0 < x < c \end{aligned}$$

Find the value of Fourier series at the point of discontinuity $x = 0$.**Solution:** The given interval is of length $2c$. The fourier series is

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} \left(a_n \cos \frac{n\pi x}{c} + b_n \sin \frac{n\pi x}{c} \right)$$

Here

$$a_0 = \frac{1}{c} \int_{-c}^c f(x) dx = \frac{1}{c} \int_{-c}^0 0 \cdot dx + \frac{1}{c} \int_0^c 1 \cdot dx$$

$$= \frac{1}{c} \cdot x \Big|_0^c = 1$$

$$a_n = \frac{1}{c} \int_{-c}^c f(x) \cos \frac{n\pi x}{c} dx = \frac{1}{c} \int_0^c \cos \frac{n\pi x}{c} dx$$

$$a_n = \frac{1}{c} \cdot \left(\frac{c}{n\pi} \right) \sin \left(\frac{n\pi x}{c} \right) \Big|_0^c = \frac{1}{n\pi} [\sin n\pi - \sin 0] = 0$$

$$b_n = \frac{1}{c} \int_{-c}^c f(x) \sin \frac{n\pi x}{c} dx = \frac{1}{c} \int_0^c \sin \frac{n\pi x}{c} dx$$

$$= \frac{1}{c} \left(\frac{c}{n\pi} \right) \left(-\frac{\cos n\pi x}{c} \right) \Big|_0^c = -\frac{1}{n\pi} [\cos n\pi - 1]$$

$$b_n = \frac{1}{n\pi} [1 - (-1)^n]$$

Thus the required Fourier series is

$$f(x) = \frac{1}{2} + \frac{1}{\pi} \sum_{n=1}^{\infty} \left[\frac{1 - (-1)^n}{n} \right] \sin \left(\frac{n\pi x}{c} \right)$$

The sum of the series at $x_0 = 0$ is obtained by putting $x = 0$ in the above seriesi.e., $f(0) = \frac{1}{2} + \frac{1}{\pi} \cdot 0 = \frac{1}{2}$. At a point of discontinuity $x_0 = 0$, $f(0) = \frac{1}{2} [f(0+0) + f(0-0)] = \frac{1}{2} [1 + 0] = \frac{1}{2}$.**Example 2:** Obtain the Fourier series expansion of $f(x) = (\pi - x)/2$ in $0 < x < 2$.**Solution:** Here the length of interval is $2L = 2$ (i.e., $L = 1$)

$$a_0 = \frac{1}{1} \int_0^2 f(x) dx = \int_0^2 \frac{\pi - x}{2} dx$$

$$= \frac{1}{2} \left[\pi x - \frac{x^2}{2} \right]_0^2 = (\pi - 1)$$

$$a_n = \frac{1}{1} \int_0^2 f(x) \cos \frac{n\pi x}{1} dx$$

$$\begin{aligned}
 &= \int_0^2 \left(\frac{\pi - x}{2} \right) \cos n\pi x \, dx \\
 &= \frac{1}{2} \left[(\pi - x) \left(\frac{1}{n\pi} \right) \sin n\pi x \right. \\
 &\quad \left. - (-1) \times \frac{1}{n\pi} \cdot (-1) \frac{\cos n\pi x}{n\pi} \right]_0^2
 \end{aligned}$$

$$a_n = -\frac{1}{2n^2\pi^2} [\cos 2n\pi - \cos 0]$$

$$= -\frac{1}{2n^2\pi^2} [1 - 1] = 0$$

$$b_n = \frac{1}{1} \int_0^2 f(x) \sin \frac{n\pi x}{1} \, dx$$

$$= \int_0^2 \left(\frac{\pi - x}{2} \right) \sin n\pi x \, dx$$

$$= \frac{1}{2} \left[(\pi - x) \left(\frac{-\cos n\pi x}{n\pi} \right) - (-1) \cdot (-1) \frac{\sin n\pi x}{n^2\pi^2} \right]_0^2$$

$$b_n = \frac{-1}{2n\pi} [(\pi - 2) \cos 2n\pi - \pi \cdot \cos 0] = \frac{1}{n\pi}$$

$$f(x) = \frac{\pi - x}{2} = \frac{(\pi - 1)}{2} + 0 + \sum_{n=1}^{\infty} \frac{1}{n\pi} \cdot \sin n\pi x.$$

Example 3: Find the Fourier series of (Fig. 17.3)

$$f(t) = \begin{cases} 0 & \text{if } -2 \leq t \leq -1 \\ 1+t & \text{if } -1 \leq t \leq 0 \\ 1-t & \text{if } 0 \leq t \leq 1 \\ 0 & \text{if } 1 \leq t \leq 2. \end{cases}$$

Solution: $f(t)$ is defined in the interval $(-2, 2)$ of length $2L = 4$ (i.e., $L = 2$). Observe that $f(t)$ is an even function (symmetric about y-axis). Fourier series reduces to Fourier cosine series (with all $b_n = 0$).

$$f(t) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cdot \cos \frac{n\pi t}{2}$$

Fig. 17.3

Here

$$a_0 = \frac{2}{L} \int_0^L f(t) \, dt = \frac{2}{L} \int_0^2 f(t) \, dt$$

$$a_0 = \int_0^1 (1-t) \, dt + \int_1^2 0 \cdot dt = \left(\frac{t-t^2}{2} \right) \Big|_0^1 = \frac{1}{2}$$

Now

$$a_n = \frac{2}{L} \int_0^L f(t) \cos \left(\frac{n\pi t}{2} \right) \, dt$$

$$= \frac{2}{2} \int_0^2 f(t) \cos \left(\frac{n\pi t}{2} \right) \, dt$$

$$= \int_0^1 (1-t) \cos \left(\frac{n\pi t}{2} \right) \, dt + 0$$

$$= \left[(1-t) \cdot \frac{2}{n\pi} \cdot \sin \left(\frac{n\pi t}{2} \right) \right.$$

$$\left. - (-1) \frac{2}{n\pi} \cdot \frac{2}{n\pi} \cdot (-1) \cos \left(\frac{n\pi t}{2} \right) \right] \Big|_0^1$$

$$a_n = \frac{-4}{n^2\pi^2} \left[\cos \frac{n\pi}{2} - 1 \right]$$

$$= 0 \quad \text{when } n = 4, 8, 12, \dots$$

$$= \frac{8}{n^2\pi^2} \quad \text{when } n = 2, 6, 10, \dots$$

$$= \frac{4}{n^2\pi^2} \quad \text{when } n = 1, 3, 5, \dots$$

Thus the Fourier series is

$$f(t) = \frac{1}{4} + \frac{4}{\pi^2} \sum_{n=1}^{\infty} \frac{1 - \cos(n\pi/2)}{n^2} \cdot \cos \left(\frac{n\pi t}{2} \right)$$

Example 4: Obtain Fourier series expansion of $f(x) = x \cdot \cos \left(\frac{\pi x}{L} \right)$ in the interval $-L \leq x \leq L$.

Solution: $f(x)$ is an odd function (since $0 \cdot e = 0$) in the interval $(-L, L)$ of length $2L$. So a_0 and a_n 's are zero. The Fourier sine series is

$$f(x) = \sum_{n=1}^{\infty} b_n \cdot \sin \left(\frac{n\pi x}{L} \right)$$

$$\text{For } n = 1, b_1 = \frac{2}{L} \int_0^L f(x) \sin \left(\frac{\pi x}{L} \right) \, dx$$

$$b_1 = \frac{2}{L} \int_0^L x \cdot \cos \left(\frac{\pi x}{L} \right) \cdot \sin \left(\frac{\pi x}{L} \right) \, dx$$

$$= \frac{2}{L} \cdot \frac{L}{\pi} \cdot \int_0^L x \cdot \sin \left(\frac{\pi x}{L} \right) \, d \left(\frac{\sin \pi x}{L} \right)$$

$$\begin{aligned}
&= \frac{2}{\pi} \int_0^L \frac{x}{2} \cdot d \left(\frac{\sin^2 \pi x}{L} \right) \\
&= \frac{1}{\pi} \left[x \cdot \sin^2 \frac{\pi x}{2} \Big|_0^L - \int_0^L \sin^2 \frac{\pi x}{L} dx \right] \\
&= -\frac{1}{\pi} \int_0^L \sin^2 \frac{\pi x}{L} dx \\
&= -\frac{1}{\pi} \int_0^L \frac{1}{2} \left(1 - \cos \frac{2\pi x}{L} \right) dx \\
&= -\frac{1}{2\pi} \left[x - \frac{L}{2\pi} \cdot \sin \frac{2\pi x}{L} \right]_0^L
\end{aligned}$$

So $b_1 = -\frac{L}{2\pi}$
For $n \neq 1$

$$\begin{aligned}
b_n &= \frac{2}{L} \int_0^L \left(x \cdot \cos \frac{\pi x}{L} \right) \sin \left(\frac{n\pi x}{L} \right) dx \\
&= \frac{2}{L} \int_0^L x \frac{1}{2} \left[\sin \left(\frac{(n-1)\pi x}{L} \right) \right. \\
&\quad \left. + \sin \left(\frac{(n+1)\pi x}{L} \right) \right] dx \\
&= I_1 + I_2
\end{aligned}$$

where

$$\begin{aligned}
I_1 &= \frac{1}{L} \int_0^L x \cdot \sin \left(\frac{(n-1)\pi x}{L} \right) dx \\
&= \frac{1}{L} \left[x \cdot \frac{L}{(n-1)\pi} \left(-\cos \frac{(n-1)\pi x}{L} \right) \right. \\
&\quad \left. - 1 \cdot \frac{L^2}{(n-1)^2\pi^2} (-1) \cdot \sin \frac{(n-1)\pi x}{L} \right]_0^L \\
I_1 &= \frac{L}{\pi(n-1)} (-1)(-1)^{n-1}
\end{aligned}$$

similarly,

$$\begin{aligned}
I_2 &= \frac{1}{L} \int_0^L x \cdot \sin \left(\frac{(n+1)\pi x}{L} \right) dx \\
I_2 &= \frac{1}{L} \left[x \cdot \frac{L}{(n+1)\pi} \left(-\cos \frac{(n+1)\pi x}{L} \right) \right. \\
&\quad \left. - \frac{L^2(-1)}{(n+1)^2\pi^2} \cdot \sin \left(\frac{(n+1)\pi x}{L} \right) \right]_0^L \\
I_2 &= \frac{L}{\pi(n+1)} (-1)(-1)^{n+1}
\end{aligned}$$

Thus

$$\begin{aligned}
b_n &= I_1 + I_2 = \frac{L(-1)^n}{\pi} \left[\frac{1}{n-1} + \frac{1}{n+1} \right] \\
&= \frac{2Ln}{\pi} \frac{(-1)^n}{(n^2-1)}
\end{aligned}$$

Hence

$$f(x) = -\frac{L}{2\pi} \sin \left(\frac{\pi x}{L} \right) + \frac{2L}{\pi} \sum_{n=2}^{\infty} \frac{(-1)^n n}{n^2-1} \sin \left(\frac{n\pi x}{L} \right).$$

EXERCISE

Find the Fourier series of $f(x)$ in the indicated interval:

$$1. f(t) = \begin{cases} 0 & \text{if } -L < t < 0 \\ E \sin wt & \text{if } 0 < t < L \end{cases}$$

Ans. $a_0 = \frac{2E}{\pi}$, $a_n = \frac{-2E}{(n^2-1)\pi}$ for $n = 2, 4, 6, \dots$

$b_1 = E/2$, $b_n = 0$ for $n = 2, 3, 4, \dots$

$$f(t) = \frac{E}{\pi} + \frac{E}{2} \sin wt - \frac{2E}{\pi} \left(\frac{1}{1.3} \cos 2wt + \frac{1}{3.5} \cos 4wt + \dots \right)$$

2. $f(x) = e^x$ in $(-L, L)$

Ans. $f(x) = \sinh L \left[\frac{1}{L} + 2L \sum_{n=1}^{\infty} \frac{(-1)^n \cos(n\pi x/L)}{L^2 + n^2\pi^2} \right. \\ \left. + 2\pi \sum_{n=1}^{\infty} \frac{(-1)^{n-1} n \sin(n\pi x/L)}{L^2 + n^2\pi^2} \right]$

3. $f(x) = x$ for $0 < x < 1$
 $= 0$ for $1 < x < 2$

Ans. $f(x) = \frac{1}{4} + \frac{1}{\pi^2} \sum_{n=1}^{\infty} \left(\frac{\cos n\pi - 1}{n^2} \right) \cos n\pi x \\ + \frac{1}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} \sin n\pi x$

4. $f(x) = x$ for $-1 < x \leq 0$
 $= x + 2$ for $0 < x \leq 1$

Deduce that $\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \dots$

Ans. $f(x) = 1 + \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} [1 - 2(-1)^n] \sin n\pi x$

Put $x = \frac{1}{2}$ on both sides to deduce the result.

17.14 — HIGHER ENGINEERING MATHEMATICS—V

$$\begin{aligned} 5. \quad f(x) &= 0 \quad \text{when } -5 < x < 0 \\ &= 3 \quad \text{when } 0 < x < 5 \end{aligned}$$

$$\text{Ans. } f(x) = \frac{3}{2} + \sum_{n=1}^{\infty} \frac{3(1-\cos n\pi)}{n\pi} \sin\left(\frac{n\pi x}{5}\right)$$

$$\begin{aligned} 6. \quad f(x) &= \pi x \quad \text{when } 0 \leq x \leq 1 \\ &= \pi(2-x) \quad \text{when } 1 \leq x \leq 2 \end{aligned}$$

$$\text{Ans. } f(x) = \frac{\pi}{2} + \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{[(-1)^n - 1]}{n^2} \cos n\pi x$$

$$7. \quad f(x) = \begin{cases} 1 & \text{if } 0 < x < 1 \\ 2 & \text{if } 1 < x < 2 \end{cases}$$

$$\text{Ans. } f(x) = 3 - \sum_{n=1}^{\infty} \frac{2}{(2n-1)\pi} \cdot \sin(2n-1)\pi x$$

Even and odd functions

$$8. \quad f(x) = \begin{cases} 0 & \text{if } -2 < x < -1 \\ k & \text{if } -1 < x < 1 \\ 0 & \text{if } 1 < x < 2 \end{cases}$$

$$\text{Ans. even, } f(x) = \frac{k}{2} + \frac{2k}{\pi} \sum_{n=1}^{\infty} \frac{\sin(n\pi/2)}{n} \cdot \cos\left(\frac{n\pi x}{2}\right)$$

$$9. \quad f(t) = 4 - t^2 \text{ in } (-2, 2)$$

$$\text{Ans. even, } f(t) = \frac{8}{3} + \frac{16}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2} \cos \frac{n\pi t}{2}$$

$$\begin{aligned} 10. \quad f(x) &= \frac{1}{2} + x \quad \text{when } -1 \leq x \leq 0 \\ &= \frac{1}{2} - x \quad \text{when } 0 \leq x \leq 1 \end{aligned}$$

$$\text{Ans. even, } f(x) = -\frac{4}{\pi^2} \sum_{n=1}^{\infty} \frac{\cos[(2n-1)\pi x]}{(2n-1)^2}$$

$$11. \quad f(x) = |x| \text{ in } (-L, L)$$

$$\text{Ans. even, } f(x) = \frac{L}{2} - \frac{4L}{\pi^2} \sum_{n=\text{odd}} \frac{\cos(n\pi x/L)}{n^2}$$

$$12. \quad f(x) = x^2 \text{ in } (-L, L)$$

$$\text{Ans. even, } f(x) = \frac{L^3}{3} + \sum_{n=1}^{\infty} \frac{(-1)^n 4L^2}{n^2 \pi^2} \cos\left(\frac{n\pi x}{L}\right)$$

$$13. \quad f(x) = \pi x \text{ from } x = -c \text{ to } x = c$$

$$\text{Ans. } 2c \sin \frac{\pi x}{c} - \frac{1}{2} \sin \frac{2\pi x}{c} + \frac{1}{3} \sin \frac{3\pi x}{c} - \frac{1}{4} \sin \frac{4\pi x}{c} + \dots$$

$$\begin{aligned} 14. \quad f(x) &= -a \quad \text{when } -c < x < 0 \\ &= a \quad \text{when } 0 < x < c \end{aligned}$$

$$\text{Ans. odd, } f(x) = \frac{2a}{\pi} \sum_{n=1}^{\infty} \left(\frac{1-\cos n\pi}{n} \right) \cdot \sin\left(\frac{n\pi x}{c}\right)$$

$$15. \quad f(x) = \sin ax \text{ in } (-L, L)$$

$$\text{Ans. odd, } f(x) = \sin a L \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2 \pi^2 - a^2 L^2} \sin\left(\frac{n\pi x}{L}\right)$$

$$16. \quad f(x) = x + x^2 \text{ in } (-1, 1)$$

Hint: $f(x)$ may be treated as the sum of an odd function $g(x) = x$ and an even function $h(x) = x^2$. Fourier series of $f(x)$ is obtained by adding the Fourier series of $g(x)$ and $h(x)$.

$$\begin{aligned} \text{Ans. } f(x) &= \frac{1}{3} + \frac{4}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2} \cos n\pi x + \\ &+ \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin n\pi x. \end{aligned}$$

17.4 HALF RANGE EXPANSIONS: FOURIER COSINE AND SINE SERIES

So far we have considered the Fourier series expansion of a function which is periodic, defined in an interval c to $c + 2L$ of length $2L$. Now we consider the procedure to expand a **non-periodic** function $f(x)$ defined in half of the above interval say $(0, L)$ of length L . Such expansions are known as **half range expansions or half range Fourier series**. In particular, a half range expansion containing only cosine terms is known as **half range Fourier cosine series** of $f(x)$ in the interval $(0, L)$. In a similar way **half range Fourier sine series** contains only sine terms.

Note that the given function $f(x)$ is neither periodic nor even nor odd. In order to obtain a Fourier cosine series for $f(x)$ in the interval $(0, L)$, we construct (define) a new function $g(x)$ such that

- i. $g(x) \equiv f(x)$ in the interval $(0, L)$ (Fig. 17.4)
- ii. $g(x)$ is even function in $(-L, L)$ and is periodic with period $2L$. (Fig. 17.5)

Such a function $g(x)$ is known as the “even periodic continuation (or extension) of $f(x)$ ”. The Fourier cosine series for $g(x)$ valid in $(-L, L)$ (or in fact for all x) is readily obtained as

$$g(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x}{L}\right) \quad (1)$$

where

$$a_0 = \frac{2}{L} \int_0^L g(x) dx = \frac{2}{L} \int_0^L f(x) dx \quad (2)$$

$$a_n = \frac{2}{L} \int_0^L g(x) \cos \frac{n\pi x}{L} dx$$

or

$$a_n = \frac{2}{L} \int_0^L f(x) \cos \left(\frac{n\pi x}{L} \right) dx \quad (3)$$

Since by construction $f(x)$ and $g(x)$ are equal in $(0, L)$, the required half-range Fourier cosine series (or half-range expansion in cosines) of $f(x)$ is given by (1) with a_0, a_n given by (2) and (3).

Fig. 17.4

Fig. 17.5

Here
$$\begin{aligned} g(x) &= f(x) && \text{in } (0, L) \\ &= f(-x) && \text{in } (-L, 0) \end{aligned}$$

Important Note: The series expansion of $f(x)$ given by (1) is valid for $f(x)$ only in the interval $(0, L)$ but not outside this interval.

In a similar way, to obtain the half-range Fourier sine series (or half range expansion in sines) for $f(x)$ in $(0, L)$, define $g(x)$ such that

- i. $g(x) = f(x)$ in $(0, L)$ (refer Fig. 17.6) and
- ii. $g(x)$ is an odd function in $(-L, L)$, (refer Fig. 17.7) periodic with period $2L$.

Fig. 17.6

Odd Periodic Continuation (Extensions) of $f(x)$

Fig. 17.7

The new function $g(x)$ is called as an odd periodic continuation of $f(x)$. Now the Fourier sine series of $g(x)$ is given by

$$g(x) = \sum_{n=1}^{\infty} b_n \sin \frac{n\pi x}{L} \quad (4)$$

with

$$b_n = \frac{2}{L} \int_0^L g(x) \sin \frac{n\pi x}{L} dx$$

or

$$b_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx \quad (5)$$

Since $f(x)$ and $g(x)$ are equal in $(0, L)$, the required half range Fourier sine series expansion of $f(x)$ in the interval $(0, L)$ is given by (4) with b_n 's given by (5). This expansion (4) is valid for $f(x)$ only in the interval $(0, L)$. Thus a given non-periodic function $f(x)$ can be expanded in cosine series or sine series.

WORKED OUT EXAMPLES

Example 1: If $f(x) = 1 - \frac{x}{L}$ in $0 < x < L$ find
(a) Fourier cosine series (b) Fourier sine series of

17.16 — HIGHER ENGINEERING MATHEMATICS—V

$f(x)$. Graph the corresponding periodic continuation of $f(x)$.

Solution: The given function $f(x)$ is neither periodic nor even nor odd. In order to obtain

- a.** *Fourier cosine series of a nonperiodic, not even function $f(x)$.* Define (or construct) a new function $g(x)$ such that (i) $g(x) = f(x)$ in $(0, L)$ (ii) $g(x)$ is even periodic function in $(-L, L)$. Now obtain the Fourier cosine series of $g(x)$ in $(-L, L)$ which is the required Fourier cosine series of $f(x)$ in $(0, L)$ since $f(x)$ and $g(x)$ coincide in $(0, L)$. Define

$$g(x) = f(x) = 1 - \frac{x}{L} \quad \text{in } 0 < x < L$$

$$g(x) = 1 + \frac{x}{L} \quad \text{in } -L < x < 0$$

and $g(x + 2L) = g(x)$.

Now $g(x)$ is even in $(-L, L)$ and is periodic with period $2L$. The graph in Fig. 17.9 is the even pe-

Fig. 17.8

Fig. 17.9

riodic continuation (or extension) of $f(x)$ shown in Fig. 17.8. The Fourier cosine series of $g(x)$ is

$$g(x) = \frac{a_0}{2} + \sum a_n \cos \frac{n\pi x}{L}$$

where

$$a_0 = \frac{2}{L} \int_0^L f(x) dx = \frac{2}{L} \int_0^L \left(1 - \frac{x}{L}\right) dx$$

$$a_0 = \frac{2}{L} \left[\left(x - \frac{x^2}{2L}\right) \Big|_0^L \right] = \frac{2}{L} \left[L - \frac{L^2}{2L} \right] = 1$$

$$\begin{aligned} a_n &= \frac{2}{L} \int_0^L f(x) \cos n \frac{\pi x}{L} dx \\ &= \frac{2}{L} \int_0^L \left(1 - \frac{x}{L}\right) \cos n \frac{\pi x}{L} dx \\ &= \frac{2}{L} \left[\left(1 - \frac{x}{L}\right) \cdot \frac{L}{n\pi} \sin \frac{n\pi x}{L} \right. \\ &\quad \left. - \left(-\frac{1}{L}\right) \cdot \frac{L^2}{n^2\pi^2} \cdot \left(-\cos \frac{n\pi x}{L}\right) \right]_0^L \end{aligned}$$

$$a_n = \frac{2}{n^2\pi^2} [1 - (-1)^n]$$

so

$$g(x) = \frac{1}{2} + \frac{2}{\pi^2} \sum \frac{[1 - (-1)^n]}{n^2} \cos \frac{n\pi x}{L}$$

Thus the required Fourier cosine series of $f(x)$ in $(0, L)$ is

$$f(x) = g(x) = \frac{1}{2} + \frac{2}{\pi^2} \sum_{n=1}^{\infty} \frac{[1 - (-1)^n]}{n^2} \cos \left(\frac{n\pi x}{L}\right)$$

(since $f(x)$ equals to $g(x)$ in the interval $(0, L)$).

Note: The above series expansion is valid for $f(x)$ only in $(0, L)$ not outside this interval.

- b.** *Fourier sine series of $f(x)$ in $(0, L)$:* On similar lines, define a new function $h(x)$ such that (i) $h(x) = f(x)$ in $(0, L)$ and (ii) $h(x)$ is odd periodic function. Define

$$h(x) = f(x) = 1 - \frac{x}{L} \quad \text{in } (0, L)$$

$$h(x) = -\left(1 + \frac{x}{L}\right) \quad \text{in } (-L, 0)$$

and $h(x + 2L) = h(x)$ (6)

Thus $h(x)$ is odd periodic function in $(-L, L)$ with period $2L$. The graph in Fig. 17.11 is the odd periodic continuation (or extension) of $f(x)$ shown in Fig. 17.10.

Now the Fourier sine series expansion of $g(x)$ in the interval $(-L, L)$ is

$$h(x) = \sum_{n=1}^{\infty} b_n \sin \frac{n\pi x}{L}$$

Fig. 17.10

Fig. 17.11

where

$$\begin{aligned}
 b_n &= \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx \\
 b_n &= \frac{2}{L} \int_0^L \left(1 - \frac{x}{L}\right) \sin \frac{n\pi x}{L} dx \\
 &= \frac{2}{L} \left[\left(1 - \frac{x}{L}\right) (-1) \left(\cos \frac{n\pi x}{L}\right) \cdot \frac{L}{n\pi} \right. \\
 &\quad \left. - \left(\frac{-1}{L}\right) \frac{L^2}{n^2\pi^2} \sin \frac{n\pi x}{L} \right]_0^L \\
 b_n &= \frac{2}{n\pi}
 \end{aligned}$$

so

$$h(x) = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \sin \left(\frac{n\pi x}{L} \right)$$

Thus the required Fourier sine series of $f(x)$ in the interval $(0, L)$ is

$$f(x) = h(x) = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \sin \left(\frac{n\pi x}{L} \right)$$

Note: Thus a non-periodic function $f(x)$ can be expanded in two different series in $(0, L)$.

Example 2: Represent $f(x) = \sin \frac{\pi x}{L}$ in $0 < x < L$ by a Fourier cosine series. Graph the corresponding periodic continuation of $f(x)$. (See Figs. 17.12 and 17.13)

Solution: In $0 < x < L$, $f(x)$ is neither periodic nor odd nor even. Construct

$$g(x) = f(x) = \sin \frac{\pi x}{L} \quad \text{in } 0 < x < L$$

$$g(x) = -\sin \frac{\pi x}{L} \quad \text{in } -L < x < 0$$

$g(x)$ is even, periodic with period $2L$.

Fig. 17.12

Fig. 17.13

Fourier cosine series of $g(x)$ is

$$g(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi x}{L} \quad \text{where}$$

$$a_0 = \frac{2}{L} \int_0^L f(x) dx = \frac{2}{L} \int_0^L \sin \left(\frac{\pi x}{L} \right) dx$$

$$= \frac{2}{L} \frac{L}{\pi} \left(-\cos \frac{\pi x}{L} \right) \Big|_0^L$$

$$a_0 = \frac{-2}{\pi} [-1 - 1] = \frac{4}{\pi}$$

For $n \neq 1$

$$a_n = \frac{2}{L} \int_0^L f(x) \cos \frac{n\pi x}{L} dx$$

$$= \frac{2}{L} \int_0^L \sin \left(\frac{\pi x}{L} \right) \cdot \cos \left(\frac{n\pi x}{L} \right) dx$$

$$= \frac{2}{L} \frac{1}{2} \int_0^L \left[\sin(1+n) \frac{\pi x}{L} + \sin(1-n) \frac{\pi x}{L} \right] dx$$

$$a_n = \frac{1}{L} \left[\frac{-L}{\pi(n+1)} \cdot \cos(1+n) \frac{\pi x}{L} \right.$$

$$\left. - \frac{L}{\pi(1-n)} \cos(1-n) \frac{\pi x}{L} \right]_0^L$$

17.18 — HIGHER ENGINEERING MATHEMATICS—V

$$= \frac{1}{\pi} \left[\frac{1}{n+1} - \frac{1}{n-1} \right] \{(-1)^n + 1\}$$

$$= -\frac{4}{\pi} \frac{1}{n^2 - 1} \quad \text{if } n \text{ is even}$$

$$= 0 \quad \text{if } n \text{ is odd}$$

$$\text{i.e.,} \quad a_{2n} = -\frac{4}{\pi} \frac{1}{4n^2 - 1} = \frac{-4}{\pi(2n-1)(2n+1)}$$

$$\text{For } n = 1, a_1 = \frac{2}{L} \int_0^L \sin \frac{\pi x}{L} \cdot \cos \frac{\pi x}{L} dx = 0.$$

Thus

$$\begin{aligned} g(x) &= \frac{2}{\pi} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{1}{(2n-1)(2n+1)} \cos 2n \frac{\pi x}{L} \\ &= \frac{2}{\pi} - \frac{4}{\pi} \left(\frac{1}{1.3} \cos \frac{2\pi x}{L} + \frac{1}{3.5} \cos \frac{4\pi x}{L} \right. \\ &\quad \left. + \frac{1}{5.7} \cos \frac{6\pi x}{L} + \dots \right) \end{aligned}$$

Hence the Fourier cosine series representation of $f(x)$ in $(0, L)$ is

$$f(x) = g(x) = \frac{2}{\pi} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{1}{(2n-1)(2n+1)} \cos \left(\frac{2n\pi x}{L} \right)$$

Example 3: Show that in the interval $(0, 1)$

$$\cos \pi x = \frac{8}{\pi} \sum_{n=1}^{\infty} \frac{n}{4n^2 - 1} \sin 2n\pi x$$

(refer Figs. 17.14 and 17.15)

Solution: This is a Fourier sine series representation of $\cos \pi x$ in the interval $0 < x < 1$. Put $\pi x = z$, for $0 < x < 1$, then $0 < z < \pi$. Rewriting

$$\cos z = \frac{8}{\pi} \sum_{n=1}^{\infty} \frac{n}{4n^2 - 1} \sin 2nz$$

To expand $\cos z$ in Fourier sine series in $(0, \pi)$: Define

$$\begin{aligned} g(z) = f(z) &= \cos z & \text{in } 0 < z < \pi \\ g(z) &= -\cos z & \text{in } -\pi < z < 0 \end{aligned}$$

Now $g(z)$ is an odd function in $(-\pi, \pi)$ and is periodic of period 2π . Then

$$g(z) = \sum_{n=1}^{\infty} b_n \sin n z$$

For $n \neq 1$,

$$\begin{aligned} b_n &= \frac{2}{\pi} \int_0^{\pi} g(z) \sin n z dz \\ &= \frac{2}{\pi} \int_0^{\pi} \cos z \cdot \sin n z dz \\ &= \frac{2}{\pi} \int_0^{\pi} \frac{1}{2} [\sin(n+1)z + \sin(n-1)z] dz \\ &= \frac{1}{\pi} \left[\frac{-\cos(n+1)z}{n+1} - \frac{\cos(n-1)z}{(n-1)} \right]_0^{\pi} \end{aligned}$$

$$\begin{aligned} b_n &= -\frac{1}{\pi} \left[\frac{(-1)^{n+1}}{n+1} + \frac{(-1)^{n-1}}{n-1} - \frac{1}{n+1} - \frac{1}{n-1} \right] \\ &= \frac{2n}{\pi(n^2 - 1)} \{(-1)^n + 1\} \end{aligned}$$

$$b_n = 0 \quad \text{for } n \text{ odd}$$

$$b_1 = \frac{2}{\pi} \int_0^{\pi} \cos z \sin z dz = 0.$$

Fig. 17.14

Fig. 17.15

The required Fourier sine series in $(0, \pi)$ is

$$\begin{aligned} f(z) = g(z) &= \sum_{n=1}^{\infty} \frac{2n \{(-1)^n + 1\}}{\pi(n^2 - 1)} \sin n z \\ &= \sum_{n=1}^{\infty} \frac{2(2n) \cdot 2}{\pi[(2n)^2 - 1]} \sin 2nz \\ &= \sum_{n=1}^{\infty} \frac{8n}{\pi(4n^2 - 1)} \sin 2nz \end{aligned}$$

Replacing z by πx

$$\cos z = \cos \pi x = \sum_{n=1}^{\infty} \frac{8n}{\pi(4n^2 - 1)} \sin 2n\pi x \quad \text{in } 0 < x < 1.$$

EXERCISE

1. Expand $f(x) = x$ in $(0, \pi)$ by (a) Fourier sine series (Fig. 17.16) (b) Fourier cosine series (Fig. 17.17).

Ans. a. $g(x) = x \quad \text{in } (0, \pi)$
 $= +x \quad \text{in } (-\pi, 0)$

$$f(x) = x = 2 \left[\frac{\sin x}{1} - \frac{\sin 2x}{3} + \frac{\sin 3x}{5} - \dots \right]$$

$$= \sum_{n=1}^{\infty} \frac{2}{n} (-1)^{n+1} \sin nx$$

Fig. 17.16

b. $g(x) = |x| \quad \text{in } (-\pi, \pi)$

$$f(x) = x = \frac{\pi}{2} - \frac{4}{\pi} \left[\frac{\cos x}{1} + \frac{\cos 3x}{3^2} + \frac{\cos 5x}{5^2} + \dots \right]$$

$$= \frac{\pi}{2} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos(2n-1)x}{(2n-1)^2}$$

Fig. 17.17

2. Find the two half-range expansions of

$$f(x) = \begin{cases} 2kx/L & \text{if } 0 < x < (L/2) \\ 2k(L-x)/L & \text{if } L/2 < x < L. \end{cases}$$

Ans. a. Even periodic extension: (Fourier cosine series) (refer Fig. 17.18).

$$f(x) = \frac{k}{2} + \frac{4k}{\pi^2} \sum_{n=1}^{\infty} \left(\frac{2 \cos \frac{n\pi}{2} - \cos n\pi - 1}{n^2} \right)$$

$$\times \cos \frac{n\pi x}{L}$$

Fig. 17.18

- b. Odd periodic extension: (Fourier sine series) (refer Fig. 17.19)

$$f(x) = \frac{8k}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \sin \frac{n\pi}{2} \cdot \sin \frac{n\pi x}{L}$$

Fig. 17.19

3. Obtain the Fourier cosine series of $f(x) = \sin x$ in the interval $0 < x < \pi$.

Ans. $f(x) = \frac{2}{\pi} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos 2nx}{4n^2 - 1}$

4. Represent $f(x) = \begin{cases} 1 & \text{if } 0 < x < \frac{1}{2} \\ 0 & \text{if } \frac{1}{2} < x < 1 \end{cases}$

in (a) a Fourier sine series (b) Fourier cosine series (c) a Fourier series (with period 1).

Ans. a. $f(x) = \frac{2}{\pi} \sum_{n=1}^{\infty} (1 - \cos \frac{n\pi}{2}) \frac{1}{n} \cdot \sin n\pi x$

b. $f(x) = \frac{1}{2} + \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \cdot \sin \frac{n\pi}{2} \cdot \cos n\pi x$

c. $f(x) = \frac{1}{2} + \frac{1}{\pi} \sum_{n=1}^{\infty} [1 - (-1)^n] \frac{1}{n} \cdot \sin n\pi x$

5. Find the Fourier sine and cosine series of

$$f(x) = \begin{cases} x & \text{when } 0 < x < \frac{\pi}{2} \\ 0 & \text{when } \frac{\pi}{2} < x < \pi. \end{cases}$$

Ans. Fourier sine series

$$f(x) = \frac{2}{\pi} \sum_{n=1}^{\infty} \left[\frac{1}{n^2} \sin \frac{n\pi}{2} - \frac{\pi}{2n} \cdot \cos \frac{n\pi}{2} \right] \sin nx$$

17.20 — HIGHER ENGINEERING MATHEMATICS—V

Fourier cosine series:

$$f(x) = \frac{\pi}{8} + \sum_{n=1}^{\infty} \left[\frac{1}{n} \sin n\pi/2 + \frac{2}{\pi n^2} \left(\cos \frac{n\pi}{2} - 1 \right) \right] \cos nx.$$

6. Obtain the half-range Fourier sine and cosine series for $f(x) = x$ in $0 < x < \frac{\pi}{2}$ and $f(x) = \pi - x$ in $\frac{\pi}{2} < x < \pi$.

Ans. Sine series: $f(x) = \sum_{n=1}^{\infty} \frac{4}{\pi n^2} \sin \frac{n\pi}{2} \cdot \sin nx$

Cosine series:

$$\frac{\pi}{4} + \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{n^2} \left[2 \cos \frac{n\pi}{2} - 1 - (-1)^n \right] \cos nx$$

7. Determine the half-range sine series for $f(x) = e^x$ in $0 < x < 1$.

Ans. $f(x) = 2\pi \sum_{n=1}^{\infty} \frac{n[1 - e(-1)^n]}{1 + n^2\pi^2} \sin n\pi x.$

8. Find the half-range Fourier cosine series of $f(x) = x^3$ in $(0, L)$.

Ans. $f(x) = \frac{L^3}{4} + \frac{6L^3}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \left[(-1)^n + \frac{2}{\pi^2 n^2} \{ 1 - (-1)^n \} \right] \frac{\cos n\pi x}{L}.$

9. Represent $f(x) = x^2$ in $0 < x < L$ by Fourier sine series.

Ans. $\frac{2L^2}{\pi} \sum_{n=1}^{\infty} \left[\frac{2}{n^3\pi^2} \{ (-1)^n - 1 \} - \frac{(-1)^n}{n} \right] \sin \frac{n\pi x}{L}.$

10. Find the two half-range Fourier series of $f(x) = 1$ in $0 < x < L$.

Ans. Sine series:

$$f(x) = 1 = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} [1 - (-1)^n] \sin \frac{n\pi x}{L}.$$

cosine series $f(x) = 1 = \frac{2}{\pi} = 1$

$$(a_0 = 2, a_n = 0 \text{ for } n \geq 1)$$

11. Obtain two half-range Fourier series of $f(x) = x$ in $0 < x < 2$.

Ans. Sine series: $f(x) = \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin \frac{n\pi x}{2}$

$f(x) = 1 + \frac{4}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} [(-1)^n - 1] \cos \frac{n\pi x}{2}$ is cosine series.

12. Expand $f(x) = \frac{1}{4} - x$ if $0 < x < 0.5$
 $= x - \frac{3}{4}$ if $0.5 < x < 1$

as Fourier series of sine terms

Ans. $\sum_{n=1}^{\infty} \left\{ \frac{1}{2n\pi} [1 - (-1)^n] - \frac{4 \sin(n\pi/2)}{n^2\pi^2} \right\} \sin n\pi x$

13. Find the half-range Fourier sine series of $f(x) = \sin x$ when $0 \leq x \leq \frac{\pi}{4}$ and $f(x) = \cos x$ in $(\frac{\pi}{4}, \frac{\pi}{2})$.

Ans. $f(x) = \frac{8}{\pi} \cos \frac{\pi}{4} \left[\frac{\sin 2x}{1.3} - \frac{\sin 6x}{5.7} + \frac{\sin 10x}{9.11} \dots \right]$

14. Expand $x \sin x$ in $(0, \pi)$ as Fourier cosine series. Deduce that $1 + \frac{2}{1.3} - \frac{2}{3.5} + \frac{2}{5.7} \dots = \frac{\pi}{2}$

Ans. $f(x) = 1 - \frac{1}{2} \cos x + 2 \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{(n-1)(n+1)} \cos nx$

put $x = \frac{\pi}{2}$ then $\frac{\pi}{2} \cdot \sin \frac{\pi}{2} = 1 - 0 +$

$$+ 2 \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{(n-1)(n+1)} \cos n \frac{\pi}{2}.$$

17.5 PRACTICAL HARMONIC ANALYSIS

Harmonic analysis is the theory of expanding a given function in Fourier series. We know that the Euler-Fourier coefficients of a function $f(x)$ with period 2π in the interval $(-\pi, \pi)$ are given by

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx \quad (1)$$

$$a_m = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos mx dx \quad (2)$$

$$b_m = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin mx dx. \quad (3)$$

When $f(x)$ is given in analytical form, the integrals in the R.H.S. of (1), (2), (3) can be evaluated and the Fourier coefficients a_0, a_m, b_m 's can be determined completely. However, in many practical problems, the function $f(x)$ is in tabulated form. In such cases, practical harmonic analysis deals with the determination of the approximate values of the Fourier coefficients a_0, a_m, b_m . Divide the interval $[-\pi, \pi]$ into n equal parts with $(n + 1)$ points

$$-\pi = x_0, x_1, x_2, \dots, x_n = \pi$$

and subinterval size $h = \frac{\pi - (-\pi)}{n} = \frac{2\pi}{n}$. Let $y_i = f(x_i)$, for $i = 0, 1, 2, \dots, n$.

Now the integrals on the R.H.S. of (1), (2), (3) are approximately evaluated using, say, rectangular formula (area = sum of n rectangles = $\sum_{i=1}^n$ width $h \times$ ordinate y_i). Then the Fourier coefficients (1), (2), (3) are determined approximately by the following:

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx = \frac{1}{\pi} \left[\sum_{i=1}^n h \cdot y_i \right] = \frac{1}{\pi} \cdot \frac{2\pi}{n} \sum_{i=1}^n y_i$$

$$\text{or} \quad a_0 = \frac{2}{n} \sum_{i=1}^n y_i \quad (4)$$

Also

$$a_m = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx = \frac{1}{\pi} \left[\sum_{i=1}^n h \cdot y_i \cos mx_i \right]$$

$$= \frac{1}{\pi} \cdot \frac{2\pi}{n} \sum_{i=1}^n y_i \cos mx_i. \quad \text{Thus}$$

$$a_m = \frac{2}{n} \sum_{i=1}^n y_i \cos mx_i \quad (5)$$

quadrants. Usual choice $n = 6, 12, 24$ (in which case (4),(5),(6) get simplified).

WORKED OUT EXAMPLES

Example 1: Compute approximately the Fourier coefficients a_0, a_1, a_2, a_3 and b_1, b_2, b_3 in the Fourier series expansion of function tabulated as follows. Find the amplitude of the first harmonic. Calculate $y(3)$

$x :$	0	1	2	3	4	5
$y :$	9	18	24	28	26	20

Solution: Here $n =$ number of sub-intervals $= 6$. The interval $(0, 2\pi)$ is divided into 6 sub-intervals of size $\frac{2\pi}{6} = 60^\circ$.

Table 17.1

x	θ	$\cos \theta$	$\cos 2\theta$	$\cos 3\theta$	y	$y \cos \theta$	$y \cos 2\theta$	$y \cos 3\theta$
0	0°	1	1	1	9	9	9	9
1	60°	$+\frac{1}{2}$	$-\frac{1}{2}$	-1	18	-9	-9	-18
2	120°	$-\frac{1}{2}$	$-\frac{1}{2}$	1	24	-12	-12	24
3	180°	-1	+1	-1	28	-28	28	-28
4	240°	$-\frac{1}{2}$	$-\frac{1}{2}$	1	26	-13	-13	26
5	300°	$+\frac{1}{2}$	$-\frac{1}{2}$	-1	20	10	-10	-20
Totals $\sum$					125	-25	-7	-7

Similarly,

$$b_m = \frac{2}{n} \sum_{i=1}^n y_i \sin mx_i \quad (6)$$

When $f(x)$ is given in the form of a graph, Fourier analyzer instruments determine the approximate values of the Fourier coefficients a_0, a_m 's, b_m 's.

Note: Choose n as a number divisibly by 4 since the values of sine and cosine are repeated in four

Now

$$a_0 = \frac{2}{n} \sum_{i=1}^n y_i = \frac{2}{6}(215) = 41.666$$

$$a_1 = \frac{2}{n} \sum_{i=1}^n y_i \cos x_i = \frac{2}{6}(-25) = -8.333$$

$$a_2 = \frac{2}{n} \sum_{i=1}^n y_i \cos 2x_i = \frac{2}{6}(-7) = -2.333$$

$$a_3 = \frac{2}{n} \sum_{i=1}^n y_i \cos 3x_i = \frac{2}{6}(-7) = -2.337$$

17.22 — HIGHER ENGINEERING MATHEMATICS—V

Similarly

2. Compute $T(\theta = 75^\circ)$ using the first four terms of the Fourier sine series representation of

Table 17.2

x	θ	$\sin \theta$	$\sin 2\theta$	$\sin 3\theta$	y	$y \sin \theta$	$y \sin 2\theta$	$y \sin 3\theta$
0	0	0	0	0	9	0	0	0
1	$\frac{\pi}{3} = 60$	$\frac{\sqrt{3}}{2}$	$\frac{\sqrt{3}}{2}$	0	18	$9\sqrt{3}$	$9\sqrt{3}$	0
2	$\frac{2\pi}{3} = 120$	$\frac{\sqrt{3}}{2}$	$-\frac{\sqrt{3}}{2}$	0	24	$12\sqrt{3}$	$-12\sqrt{3}$	0
3	$\pi = 0$	0	0	0	28	0	0	0
4	$\frac{4\pi}{3} = 240$	$-\frac{\sqrt{3}}{2}$	$\frac{\sqrt{3}}{2}$	0	26	$-13\sqrt{3}$	$13\sqrt{3}$	0
5	$\frac{5\pi}{3} = 300$	$-\frac{\sqrt{3}}{2}$	$-\frac{\sqrt{3}}{2}$	0	20	$-10\sqrt{3}$	$-10\sqrt{3}$	0
Totals					125	$-2\sqrt{3}$	0	0

$$b_1 = \frac{2}{n} \sum_{i=1}^n y_i \sin x_i = \frac{2}{6}(-2\sqrt{3}) = -1.1547$$

$$b_2 = \frac{2}{n} \sum_{i=1}^n y_i \sin 2x_i = \frac{2}{6}(0) = 0, b_3 = 0$$

Amplitude of the first harmonic $= \sqrt{a_1^2 + b_1^2} = \sqrt{(-8.333)^2 + (-1.1547)^2} = 8.4126$.

The Fourier series of $y(x)$ containing the first 4 cos terms and 3 sine terms is

$$y = \frac{41.666}{2} + (-8.333) \cos x - 2.333 \cos 2x - 2.337 \cos 3x + (-1.1547) \sin x + 0 + 0$$

At $x = 3, \theta = \pi, y(3) = y(\theta = \pi) = \frac{41.666}{2} + (-8.333)(-1) - 2.333(1) - (2.337)(-1) = 29.166$
(Exact value: $y(3) = 28$).

EXERCISE

1. Find the direct current part and amplitude of the first harmonic from the following table consisting of the variations periodic current

$t \text{ sec} :$	0	$\frac{T}{6}$	$\frac{T}{3}$	$\frac{T}{2}$	$\frac{2T}{3}$	$\frac{5T}{6}$	T
$A \text{ amp} :$	1.98	1.30	1.05	1.30	-0.88	-0.25	1.98

Ans. Direct current part $= \frac{a_0}{2} = 0.75$, amplitude of the first harmonic $= \sqrt{a_1^2 + b_1^2} = \sqrt{(0.373)^2 + (1.005)^2} = 1.072$

turning moment T given for a series of values of the crank angle $\theta^\circ = 75^\circ$.

$\theta^\circ :$	0	30	60	90	120	150	180
$T :$	0	5224	8097	7850	5499	2626	0

Hint: $T(\theta) = 785 \sin \theta + 150 \sin 2\theta, b_3 = 0, b_4 = 0$

$$b_1 = \frac{2}{6} \left[(5224 + 2626) \left(\frac{1}{2} \right) + (8097 + 5499)(.866) + 7850 \right] = 785$$

$$b_2 = \frac{2}{6} \left[(5224 + 8097)(.866) + (5499 + 2626)(-.866) \right] = 150$$

Ans. 8332

3. Determine the first three coefficients of cosine and two coefficients of sine terms in the Fourier series expansion of the following tabulated function.

$x :$	0	$\frac{\pi}{6}$	$\frac{\pi}{3}$	$\frac{\pi}{2}$	$\frac{2\pi}{3}$	$\frac{5\pi}{6}$
$y :$	0	9.2	14.4	17.8	17.3	11.7

Hint: $y = 11.733 - 7.733 \cos 2x - 2.833 \cos 4x - 1.566 \sin 2x + 0.116 \sin 4x$, Length of interval is $\pi; L = \frac{\pi}{2}$.

Ans. $a_0 = 23.46, a_1 = -7.73, a_2 = -2.83, b_1 = -1.566, b_2 = +.116$

4. Find the harmonics $a_0, a_1, a_2, a_3, b_1, b_2, b_3$ of the Fourier series of the following data

$x :$	0	$\frac{\pi}{3}$	$\frac{2\pi}{3}$	π	$\frac{4\pi}{3}$	$\frac{5\pi}{3}$	2π
$y :$	1.0	1.4	1.9	1.7	1.5	1.2	1.0

Ans. $a_0 = 2.9, a_1 = -.37, a_2 = -0.1, a_3 = 0.03, b_1 = 0.17, b_2 = -0.06, b_3 = 0$

5. Compute a_0, a_1, a_2, a_3 in the Fourier cosine series for y which is tabulated below

$x :$	0	1	2	3	4	5
$y :$	4	8	15	7	6	2

Ans. $a_0 = 14, a_1 = -2.8, a_2 = -1.5, a_3 = 2.7$

6. Compute $a_0, a_1, a_2, a_3, b_1, b_2, b_3$ in the Fourier series expansion $f(\theta)$ tabulated below

$\theta :$	0	30	60	90	120	150	180	210	240	270	300	330
$f(\theta) :$	298	356	373	337	254	155	80	51	60	93	147	221

Ans. $f(\theta) = 202 + 107 \cos \theta - 13 \cos 2\theta + 2 \cos 3\theta + 121 \sin \theta + 9 \sin 2\theta - \sin 3\theta.$

Chapter 18

Partial Differential Equations

INTRODUCTION

Real world problems in general involve functions of several (independent) variables giving rise to partial differential equations more often than ordinary differential equations. Thus most problems in engineering and science abound with first and second order linear non homogeneous partial differential equations. In this chapter, we consider methods of obtaining solutions by Lagrange's and Charpits method for first order. The general solution of non homogeneous second order linear P.D.E. with constant coefficients is obtained as the sum of complementary function and particular integral. Monge's method is also considered for solving nonlinear second order P.D.E.

18.1 PARTIAL DIFFERENTIAL EQUATIONS

A partial differential equation is an equation involving two (or more) independent variables x, y and a dependent variable z and its partial derivatives such as $\frac{\partial z}{\partial x}, \frac{\partial z}{\partial y}, \frac{\partial^2 z}{\partial x^2}, \frac{\partial^2 z}{\partial x \partial y}, \text{etc.}$,

$$\text{i.e., } F\left(x, y, z, \frac{\partial z}{\partial x}, \frac{\partial z}{\partial y}, \frac{\partial^2 z}{\partial x^2}, \dots\right) = 0$$

Standard notation

$$p = \frac{\partial z}{\partial x} = z_x, \quad q = \frac{\partial z}{\partial y} = z_y, \quad r = \frac{\partial^2 z}{\partial x^2} = z_{xx},$$

$$s = \frac{\partial^2 z}{\partial x \partial y} = z_{xy}, \quad t = \frac{\partial^2 z}{\partial y^2} = z_{yy}$$

Order of a partial differential equation (P.D.E.) is the order of the highest ordered derivative appearing in the P.D.E.

Formation of Partial Differential Equation

By elimination of arbitrary constants

Let

$$f(x, y, z, a, b) = 0 \quad (1)$$

be an equation involving two arbitrary constants a and b . Differentiating this equation partially with respect to x and y , we get

$$\frac{\partial f}{\partial x} + \frac{\partial f}{\partial z} \frac{\partial z}{\partial x} = 0 \quad (2)$$

$$\frac{\partial f}{\partial y} + \frac{\partial f}{\partial z} \frac{\partial z}{\partial y} = 0 \quad (3)$$

By eliminating a, b from (1), (2), (3), we get an equation of the form

$$F(x, y, z, p, q) = 0 \quad (4)$$

which is a partial differential equation of first order.

Note 1: If the number of arbitrary constants equals to the number of independent variables in (1), then the P.D.E. obtained by elimination is of first order.

Note 2: If the number of arbitrary constants is more than the number of independent variables then the P.D.E. obtained is of 2nd or higher orders.

18.2 — HIGHER ENGINEERING MATHEMATICS—V

By elimination of arbitrary functions of specific functions

- a. One arbitrary function (resulting in first order P.D.E.):

Consider

$$z = f(u) \quad (5)$$

where $f(u)$ is an arbitrary function of u and u is a given (known) function of x, y, z i.e., $u = u(x, y, z)$.

Differentiating (5) partially w.r.t. x and y by chain rule

$$\frac{\partial z}{\partial x} = \frac{\partial f}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial f}{\partial u} \frac{\partial u}{\partial z} \frac{\partial z}{\partial x} \quad (6)$$

$$\frac{\partial z}{\partial y} = \frac{\partial f}{\partial u} \frac{\partial u}{\partial y} + \frac{\partial f}{\partial u} \frac{\partial u}{\partial z} \frac{\partial z}{\partial y} \quad (7)$$

By eliminating the arbitrary function f from (5), (6), (7) we get a P.D.E. of first order.

- b. Two arbitrary functions:

Differentiating twice or more, the elimination process results in a P.D.E. of 2nd or higher order.

Note: When n is the number of arbitrary functions, one may get several P.D. equations. But generally the one with the least order is chosen.

Example: For $z = x f(y) + y g(x)$ involving two arbitrary functions f and g , $\frac{\partial^2 z}{\partial x^2 \partial y^2} = 0$ is also a P.D.E. obtained by elimination. The other P.D.E. $xys = xp + yq - z$ of second order obtained by elimination may be chosen.

Elimination of Arbitrary Function F

from the equation

$$F(u, v) = 0 \quad (8)$$

where $u = u(x, y, z)$ and $v = v(x, y, z)$ are given functions of x, y, z .

Differentiating the Equation (8) partially w.r.t. x by chain rule, we get

$$\frac{\partial F}{\partial u} \left(\frac{\partial u}{\partial x} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial x} \right) + \frac{\partial F}{\partial v} \left(\frac{\partial v}{\partial x} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial x} \right) = 0 \quad (9)$$

Similarly, differentiating Equation (8) partially w.r.t. y , we get

$$\frac{\partial F}{\partial u} \left(\frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial y} \right) + \frac{\partial F}{\partial v} \left(\frac{\partial v}{\partial y} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial y} \right) = 0 \quad (10)$$

Eliminating $\frac{\partial F}{\partial u}$ and $\frac{\partial F}{\partial v}$ from (9) and (10), we have

$$\begin{vmatrix} \frac{\partial u}{\partial x} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial x} & \frac{\partial v}{\partial x} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial x} \\ \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial y} & \frac{\partial v}{\partial y} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial y} \end{vmatrix} = 0$$

Rewriting

$$\begin{bmatrix} u_x + pu_z & v_x + pv_z \\ u_y + qu_z & v_y + qv_z \end{bmatrix} = 0$$

Expansion of this determinant results in a P.D.E. which is free of the arbitrary function F as

$$(u_x + pu_z)(v_y + qv_z) - (u_y + qu_z)(v_x + pv_z) = 0$$

or

$$Pq + Qq = R$$

which is a first order linear P.D.E. Here

$$P = u_z v_y - u_y v_z = \frac{\partial(u, v)}{\partial(y, z)}$$

$$Q = u_x v_z - u_z v_x = \frac{\partial(u, v)}{\partial(z, x)}$$

$$R = u_y v_x - u_x v_y = \frac{\partial(u, v)}{\partial(x, y)}.$$

WORKED OUT EXAMPLES

Elimination of arbitrary constants

Form (obtain) partial differential equation by eliminating the arbitrary constants/functions:

Example 1: $z = ax^2 + by^2$

Solution: Differentiating partially w.r.t. x and y , we get

$$z_x = 2ax, z_y = 2by \quad \text{or} \quad a = \frac{z_x}{2x}, b = \frac{z_y}{2y}.$$

Eliminating the two arbitrary constants a and b

$$z = \frac{z_x}{2x} \cdot x^2 + \frac{z_y}{2y} \cdot y^2 \quad \text{or} \quad 2z = xz_x + yz_y = xp + yq$$

Example 2: $(x - a)^2 + (y - b)^2 = z^2 \cot^2 \alpha$ where α is a parameter.

Solution: Differentiating partially w.r.t. x and y , we get

$$2(x - a) + 0 = 2z \cdot z_x \cdot \cot^2 \alpha$$

$$2 \cdot 0 + 2(y - b) = 2z z_y \cot^2 \alpha$$

Substituting $(zz_x \cot^2 \alpha)^2 + (zz_y \cot^2 \alpha)^2 = z^2 \cot^2 \alpha$

$$p^2 + q^2 = \tan^2 \alpha$$

Example 3: Find the differential equation of all spheres whose centres lie on the z -axis.

Solution: Equation $x^2 + y^2 + (z - a)^2 = b^2$ where a and b are arbitrary constants.

Differentiating

$$2x + 0 + 2(z - a)z_x = 0 \quad (1)$$

$$2y + 2(z - a)z_y = 0 \quad (2)$$

From (2),

$$(z - a) = -\frac{y}{z_y} \quad (3)$$

Substituting (3) in (1)

$$x + \left(-\frac{y}{z_y}\right) \cdot z_x = 0$$

$$xz_y - yz_x = 0$$

or

$$xq - yp = 0.$$

Example 4: $ax + by + cz = 1$

Solution: Differentiating w.r.t. x , $a + 0 + cz_x = 0$. Differentiating again w.r.t. x , $0 + cz_{xx} = 0$, since $c \neq 0$, $z_{xx} = 0$. Similarly by differentiating w.r.t. y and z twice, we get $z_{yy} = 0$, $z_{xy} = 0$ so $r = 0$ or $s = 0$ or $t = 0$. Thus we get 3 PDE.

Elimination of one arbitrary functions

Example 5:

$$z = (x + y) \phi(x^2 - y^2) \quad (1)$$

Solution: Differentiating

$$z_x = 1 \cdot \phi + (x + y)2x \cdot \phi' \quad (2)$$

$$z_y = 1 \cdot \phi + (x + y)(-2y)\phi' \quad (3)$$

From (3),

$$\phi' = \frac{\phi - z_y}{2y(x + y)} \quad (4)$$

Substituting (4) in (2)

$$z_x = \phi + 2x(x + y) \cdot \left[\frac{\phi - z_y}{2y(x + y)} \right]$$

$$p = \phi + \frac{x}{y}(\phi - q)$$

$$p = \left(\frac{x + y}{y} \right) \phi - \frac{x}{y} q$$

From the given Equation (1), $\phi = \frac{z}{(x + y)}$

Substituting ϕ ,

$$p = \frac{(x + y)}{y} \cdot \frac{z}{x + y} - \frac{x}{y} q = \frac{z}{y} - \frac{x}{y} q$$

or $yp + xq = z$

Example 6: $z = x^n f\left(\frac{y}{x}\right)$

Solution: By differentiation,

$$z_x = nx^{n-1} \cdot f + x^n \cdot \left(-\frac{y}{x^2}\right) \cdot f'$$

$$z_y = x^n \cdot \frac{1}{x} \cdot f' \quad \text{or} \quad f' = \frac{z_y}{x^{n-1}}$$

Eliminating f' ,

$$z_x = nx^{n-1} f - x^{n-2} \cdot y \cdot \frac{z_y}{x^{n-1}}$$

$$xp = nx^n f - yq$$

or

$$xp = nz - yq$$

Example 7: $xyz = f(x + y + z)$

Solution: Differentiating w.r.t. x and y

$$yz + xy z_x = 1 \cdot f' + f' \cdot z_x \quad (1)$$

$$xz + xy z_y = 1 \cdot f' + f' \cdot z_y \quad (2)$$

From (2),

$$f' = \frac{xz + xy z_y}{1 + z_y} = \frac{xz + xy q}{1 + q} \quad (3)$$

18.4 — HIGHER ENGINEERING MATHEMATICS—V

Put (3) in (1)

$$yz + xyp = (1 + p)f' = (1 + p) \left(\frac{xz + xyq}{1 + q} \right)$$

$$(1 + q)(yz + xyp) = (1 + p)(xz + xyq)$$

or $x(y - z)p + y(z - x)q = z(x - y)$

Elimination of two arbitrary functions

Example 8: $z = f(x) g(y)$

Solution: Differentiating w.r.t. x and y , we get
 $z_x = f'g$, $z_y = fg'$

$$z_x \cdot z_y = f'g fg' = fg f'g' = z f'g'$$

But

$$z_{xy} = f'g' \text{ so}$$

$$z_x \cdot z_y = z \cdot z_{xy}$$

or $pq = z \cdot s$.

Example 9: $z = f(x + y) \cdot g(x - y)$

Solution: Differentiating partially w.r.t. x and y , we get

$$p = z_x = f' \cdot 1 \cdot g + f \cdot 1 \cdot g' \quad (1)$$

$$q = z_y = f' \cdot 1 \cdot g + f \cdot (-1)g' \quad (2)$$

$$\begin{aligned} r = z_{xx} &= f''g + f'g' + f'g' + fg'' \\ &= f''g + 2f'g' + fg'' \end{aligned} \quad (3)$$

$$\begin{aligned} t = z_{yy} &= f''g + f'g'(-1) \\ &\quad - f'g' - fg''(-1) \\ &= f''g - 2f'g' + fg'' \end{aligned} \quad (4)$$

$$\begin{aligned} s = z_{xy} &= f''g + f'g'(-1) \\ &\quad + f'g' + fg''(-1) \\ &= f''g - fg'' \end{aligned} \quad (5)$$

Adding (1) and (2),

$$f' = \frac{p + q}{2g} \quad (6)$$

Subtracting (2) from (1),

$$g' = \frac{p - q}{2f} \quad (7)$$

Adding (3) and (4)

$$\begin{aligned} \text{From (5),} \quad & \frac{r + t}{2s} = \frac{2(f''g + fg'')}{2(f''g - fg'')} \\ \text{Adding} \quad & \frac{r + t + 2s}{r + t - 2s} = \frac{4f''g}{4fg''} \end{aligned} \quad (8)$$

$$\text{Subtracting} \quad r + t - 2s = 4fg'' \quad (9)$$

Substituting (6), (7), (8), (9) in (3)

$$\begin{aligned} r &= \left(\frac{r + t + 2s}{4} \right) + 2 \cdot \frac{(p + q)}{2g} \cdot \frac{(p - q)}{2f} \\ &\quad + \left(\frac{r + t - 2s}{4} \right) \\ (r - t)z &= (p + q)(p - q) \end{aligned}$$

Example 10: $z = xf(ax + by) + g(ax + by)$

Solution: Differentiating w.r.t. x and y , we get

$$z_x = f + xaf' + ag'$$

$$\begin{aligned} z_{xx} &= af' + af' + ax f''a + a^2 g'' \\ &= a[2f' + axf'' + ag''] \end{aligned} \quad (1)$$

$$z_y = bx f' + bg'$$

$$z_{yy} = b^2 x f'' + b^2 g'' = b^2 [x f'' + g''] \quad (2)$$

$$\begin{aligned} z_{yx} &= bf' + bx af'' + ba g'' \\ &= b[f' + a(xf'' + g'')] \end{aligned} \quad (3)$$

Substituting (2) in (3)

$$\frac{z_{yx}}{b} = f' + a \cdot \frac{z_{yy}}{b^2}$$

Solving

$$f' = \frac{z_{yx}}{b} - \frac{a}{b^2} z_{yy} \quad (4)$$

Substituting (2) and (4) in (1)

$$\begin{aligned} z_{xx} &= 2af' + a^2 [x f'' + g''] \\ &= 2a \cdot \left[\frac{z_{yx}}{b} - \frac{a}{b^2} z_{yy} \right] + a^2 \left[\frac{z_{yy}}{b^2} \right] \end{aligned}$$

$$b^2 z_{xx} + a^2 z_{yy} = 2ab z_{yx}$$

$$b^2 r + a^2 t = 2abs$$

Elimination of arbitrary function of specific functions

$F(u, v) = 0$ where u and v are given.

Example 11:

$$F(xy + z^2, x + y + z) = 0 \quad (1)$$

Solution:

$$\text{Let } u(x, y, z) = xy + z^2 \quad (2)$$

$$v(x, y, z) = x + y + z \quad (3)$$

Differentiating (1) partially w.r.t. x by chain rule

$$\frac{\partial F}{\partial u} \left[\frac{\partial u}{\partial x} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial x} \right] + \frac{\partial F}{\partial v} \left[\frac{\partial v}{\partial x} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial x} \right] = 0$$

$$\text{i.e., } F_u \cdot (y + 2z z_x) + F_v \cdot (1 + z_x) = 0$$

Differentiating w.r.t. ' y ', we get

$$F_u(x + 2z z_y) + F_v(1 + z_y) = 0$$

Eliminating F_u and F_v (i.e., the coefficient matrix should be singular)

$$\begin{vmatrix} y + 2z z_x & 1 + z_x \\ x + 2z z_y & 1 + z_y \end{vmatrix} = 0$$

$$\text{or } (1 + q)[y + 2zp] - (1 + p)[x + 2zq] = 0$$

$$(2z - x)p + (y - 2z)q = x - y.$$

Example 12: $xyz = f(x + y + z)$

Solution: Put $u = x + y + z$, $v = xyz$ so that the given equation may be written as $F(u, v) = 0$

Differentiating w.r.t. x and y , we get

$$F_u \cdot (1 + z_x) + F_v(yz + xy z_x) = 0$$

$$F_u(1 + z_y) + F_v(xz + xy z_y) = 0$$

Eliminating F_u, F_v , we have

$$\begin{vmatrix} 1 + p & yz + xyp \\ 1 + q & xz + xyq \end{vmatrix} = 0$$

$$\text{or } (xz + xyq)(1 + p) - (1 + q)(yz + xyp) = 0$$

$$x(z - y)p + (x - z)yq + z(x - y) = 0.$$

Example 13: $F(x^2 + y^2 + z^2, z^2 - 2xy) = 0$

Solution: Let $u = x^2 + y^2 + z^2$, $v = z^2 - 2xy$

Differentiating F partially w.r.t. x , we get

$$\frac{\partial F}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial F}{\partial v} \frac{\partial v}{\partial x} = 0$$

$$F_u \cdot 2x + F_v \cdot 2z \cdot p + F_v(-2y) + F_v 2z \cdot p = 0$$

Similarly w.r.t. y , we get

$$\frac{\partial F}{\partial u} \frac{\partial u}{\partial y} + \frac{\partial F}{\partial v} \frac{\partial v}{\partial y} = 0$$

$$F_u \cdot 2y + F_u 2z \cdot q + F_v(-2x) + F_v \cdot 2z \cdot q = 0$$

Solving

$$\begin{vmatrix} x + zp & -y + zp \\ y + zq & -x + zq \end{vmatrix} = 0$$

$$(x + zp)(zq - x) - (zp - y)(y + zq) = 0$$

$$xz(q - p) + yz(q - p) + (y^2 - x^2) = 0$$

$$(x + y)[z(q - p) + (y - x)] = 0.$$

EXERCISE

Form (obtain) partial differential equation by eliminating the arbitrary constants/functions:

Elimination of arbitrary constants

$$1. \ 2z = \frac{x^2}{a^2} + \frac{y^2}{b^2}$$

$$\text{Ans. } 2z = xp + yq$$

$$2. \ z = ax + by + a^2 + b^2$$

$$\text{Ans. } z = px + qy + p^2 + q^2$$

$$3. \ z = (x^2 + a^2)(y^2 + b^2)$$

$$\text{Ans. } 4xyz = pq$$

$$4. \ z = axy + b$$

$$\text{Ans. } px = qy$$

$$5. \ z = axe^y + \frac{1}{2}a^2e^{2y} + b$$

$$\text{Ans. } q = px + p^2$$

$$6. \ z = (x - a)^2 + (y - b)^2 + 1$$

$$\text{Ans. } 4z = p^2 + q^2 + 4$$

$$7. \ z = a(x + y) + b(x - y) + abt + c$$

Hint: Number of independent variables x, y, t are 3 = number of arbitrary constants a, b, c .
So P.D.E. is of 1st order.

$$\text{Ans. } z_x^2 - z_y^2 = 4z_t$$

$$8. \ \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

$$\text{Ans. } pz = xp^2 + xzr$$

18.6 — HIGHER ENGINEERING MATHEMATICS—V

or $qz = yq^2 + zy t$

Note: Number of arbitrary constants a, b, c is three > number of independent variables x, y is two so P.D.E. is of 2nd order.

9. $z = ae^{-b^2t} \cos bx$

Ans. $\frac{\partial z}{\partial t} = \frac{\partial^2 z}{\partial x^2}$

10. $z = ae^{bx} \sin by$

Ans. $\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = 0$

11. $z = xy + y\sqrt{x^2 + a^2} + b$

Ans. $pq = py + qx$

Find the differential equation of:

12. All planes which are at a constant distance b from the origin.

Hint: Equation $lx + my + nz = b$ with $l^2 + m^2 + n^2 = 1$.

Ans. $z = px + qy + b\sqrt{1 + p^2 + q^2}$

13. All planes having equal x and y intercepts.

Hint: Equation $\frac{x}{a} + \frac{y}{a} + \frac{z}{b} = 1$.

Ans. $p = q$

14. All spheres of given radius c having their centres in the xy -plane.

Hint: $(x - a)^2 + (y - b)^2 + z^2 = c^2$; a, b constants.

Ans. $z^2(p^2 + q^2 + 1) = c^2$

15. All cones with their vertices at the origin.

Ans. $px + qy = z$

Elimination of arbitrary functions

16. $z = f(x^2 - y^2)$

Ans. $yp + xq = 0$

17. $x + y + z = f(x^2 + y^2 + z^2)$

Ans. $(y - z)p + (z - x)q = x - y$

18. $z = y f\left(\frac{y}{x}\right)$

Ans. $z = px + qy$

19. $z = f(\sin x + \cos y)$

Ans. $p \sin y + q \cos x = 0$

20. $z = e^{ax+by} \cdot f(ax - by)$

Ans. $bp + aq = 2abz$

21. $z = y^2 + 2f\left(\frac{1}{x} + \ln y\right)$

Ans. $x^2p + yq = 2y^2$

22. $z = x + y + f(xy)$

Ans. $xp - yq = x - y$

23. $z = f\left(\frac{xy}{z}\right)$

Ans. $xp = yq$

24. $z = f(x + at) + g(x - at)$

Ans. $z_{tt} = a^2 z_{xx}$

25. $z = f(x) + e^y g(x)$

Ans. $t = q$

26. $z = f(x + iy) + g(x - iy)$

Ans. $z_{xx} + z_{yy} = 0$

27. $z = yf(x) + xg(y)$

Ans. $xys = px + qy - z$

28. $z = xf\left(\frac{y}{x}\right) + yg(x)$

Ans. $x \frac{\partial^3 z}{\partial x \partial y^2} + \frac{\partial^2 z}{\partial y^2} + y \frac{\partial^3 z}{\partial y^3} = 0$

29. $z = f(xy) + g(x + y)$

Ans. $rx(y - x) - s(y^2 - x^2) + t y(y - x) + (p - q)(x + y) = 0$

30. $z = [f(r - at) + g(r + at)]/r$

Ans. $z_{tt} = \frac{a^2}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial z}{\partial r} \right)$

Elimination of arbitrary function $F(u, v) = 0$

31. $F(x^2 + y^2, z - xy) = 0$

Ans. $xq - yp = x^2 - y^2$

32. $F(x + y + z, x^2 + y^2 - z^2) = 0$

Ans. $(y + z)p - (z + x)q = x - y$

33. $F(x^2 + y^2, x^2 - z^2) = 0$

Ans. $yp - xq = \frac{xy}{z}$

34. $F(ax + by + cz, x^2 + y^2 + z^2) = 0$

Ans. $(bz - cy)p + (cx - az)q = ay - bx$

35. $z = x^2 \phi(x - y)$

Hint: Rewrite the given equation in the form

$$F\left(\frac{z}{x^2}, x - y\right) = 0.$$

Ans. $2z = xp + xq$.

18.2 PARTIAL DIFFERENTIAL EQUATIONS OF FIRST ORDER

The general form of a first order partial differential equation is

$$F(x, y, z, p, q) = 0 \quad (1)$$

where x, y are the two independent variables, z is the dependent variable and $p = z_x, q = z_y$.

Complete Solution

Any function

$$f(x, y, z, a, b) = 0 \quad (2)$$

involving two arbitrary constants a, b and satisfying the P.D.E. (1) is known as complete solution or complete integral or primitive.

General Solution

of P.D.E. (1) is any arbitrary function F of specific (given) functions u, v

$$F(u, v) = 0 \quad (3)$$

satisfying P.D.E. (1).

Here $u = u(x, y, z)$ and $v = v(x, y, z)$ are known functions of x, y, z .

Linear

A partial differential equation is said to be linear (after rationalization and cleared of fractions) if the dependent variable z and its derivatives are of degree (power) one and products of z and its derivatives do not appear in the equation.

Quasi-linear

P.D.E. is said to be quasi-linear if degree of highest ordered derivative is one and no products of partial derivatives of the highest order are present.

Example: $x^2p + y^2q = z$
is linear in z and of first order.

Example: $z z_{xx} + (z_y)^2 = 0$ is a quasi-linear of second order.

Non-linear

A P.D.E. which is not linear is known as non-linear P.D.E.

Example: $\left(\frac{\partial^2 u}{\partial x^2}\right)^2 + u^2 \left(\frac{\partial u}{\partial y}\right) = f(x, y)$

is non-linear in u and of second order.

Homogeneous

if each term contains the dependent variable or its derivatives.

Otherwise non-homogeneous.

18.3 LINEAR PARTIAL DIFFERENTIAL EQUATIONS OF FIRST ORDER

The general form of a quasi-linear partial differential equation of the first order is

$$P(x, y, z)z_x + Q(x, y, z)z_y = R(x, y, z) \quad (1)$$

This Equation (1) is known as “Lagrange’s linear equation”.

If P and Q are independent of z and R is linear in z then (1) is a linear equation. The general solution of the Lagrange’s linear P.D.E.

$$Pp + Qq = R \quad (1)$$

is given by the equation

$$F(u, v) = 0 \quad (2)$$

since the elimination of the arbitrary function F from (2) results in (1).

Here $u = u(x, y, z), v = v(x, y, z)$ are specific (known) functions of x, y, z .

Method of Obtaining General Solution

1. Rewrite the equation in the standard form

$$Pp + Qq = R$$

2. Form the Lagrange’s auxiliary equations (A.E.)

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R} \quad (3)$$

18.8 — HIGHER ENGINEERING MATHEMATICS—V

3. Nature of solution to the simultaneous equations of the form $\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R}$:
 $u(x, y, z) = c_1$ and $v(x, y, z) = c_2$ are said to be the complete solution of the system of simultaneous equations (provided u_1 and u_2 are linearly independent i.e., $u_1/u_2 \neq \text{constant}$).

Case 1: One of the variables is either absent or cancels out from the set of auxiliary equations.

Case 2: If $u = c_1$ is known but $v = c_2$ is not possible by case I, then use $u = c_1$ to get $v = c_2$.

Case 3: Introducing Lagrange's multipliers P_1, Q_1, R_1 , which are functions of x, y, z or constants, each fraction in (3) is equal to

$$\frac{P_1 dx + Q_1 dy + R_1 dz}{P_1 P + Q_1 Q + R_1 R} \quad (4)$$

If P_1, Q_1, R_1 are so chosen that $P_1 P + Q_1 Q + R_1 R = 0$ then $P_1 dx + Q_1 dy + R_1 dz = 0$ which can be integrated.

Case 4: Multipliers may be chosen (more than once) such that the numerator $P_1 dx + Q_1 dy + R_1 dz$ is an exact differential of the denominator $P_1 P + Q_1 Q + R_1 R$. Now combine (4) with a fraction of (3) to get an integral.

4. General solution of (1) is

$$F(u, v) = 0 \quad \text{or} \quad v = \phi(u).$$

WORKED OUT EXAMPLES

Solve the following:

Example 1: $xp + yq = 3z$

Solution: This is a linear P.D.E. of first order $Pp + Qq = R$ with $P = x, Q = y$ and $R = 3z$. The Lagrange's auxiliary equations are

$$\frac{dx}{x} = \frac{dy}{y} = \frac{dz}{3z}$$

Integrating the first two equations (or fractions) $\frac{dx}{x} = \frac{dy}{y}$, we get $\ln x = \ln y + c_1$ or $\frac{x}{y} = c$

Integrating first and the last equations $\frac{dx}{x} = \frac{dz}{3z}$, we have

$$3 \ln x = \ln z + c_2 \quad \therefore x^3 = c_1 z$$

Thus the required solution is $x^3 = zf\left(\frac{x}{y}\right)$. The general solution can also be written as $F(x^3/z, x/y) = 0$.

Note: By integrating 2nd and 3rd equations $\frac{dy}{y} = \frac{dz}{3z}$, we also get $y^3 = c_2 z$ so the general solution is also given by $y^3 = zf\left(\frac{x}{y}\right)$.

Example 2: $yzp - xzq = xy$

Solution: Auxiliary equations are

$$\frac{dx}{yz} = \frac{dy}{-xz} = \frac{dz}{xy}$$

From first and second fractions, we get

$$\frac{dx}{yz} = \frac{dy}{-xz}$$

$$\text{or} \quad \frac{dx}{y} = \frac{dy}{-x}$$

$$\text{or} \quad xdx + ydy = 0$$

$$\text{Integrating } x^2 + y^2 = c_1$$

From first and third fractions

$$\frac{dx}{yz} = \frac{dz}{xy}$$

$$\text{or} \quad \frac{dx}{z} = \frac{dz}{x}$$

$$\text{Integrating } x^2 - z^2 = c_2$$

Thus the general solution is

$$F(x^2 + y^2, x^2 - z^2) = 0.$$

Example 3: $p - q = \ln(x + y)$

Solution: Auxiliary equations are

$$\frac{dx}{1} = \frac{dy}{-1} = \frac{dz}{\ln(x + y)}$$

Integrating the first two fractions $dx + dy = 0$ yields $x + y = c_1$

From first and last fractions $\ln(x + y)dx = dz$

Put $x + y = c_1$, then $\ln c_1 dx = dz$

Integrating $x \ln c_1 = z + c_2$

or $x \cdot \ln(x + y) = z + c_2$

The general solution is

$$F(x + y, x \ln(x + y) - z) = 0.$$

Example 4: $z(z^2 + xy)(px - qy) = x^4$

Solution: Auxiliary equations are

$$\frac{dx}{xz(z^2 + xy)} = \frac{dy}{-yz(z^2 + xy)} = \frac{dz}{x^4}$$

From first and second fractions, we get

$$\frac{dx}{x} = \frac{dy}{-y}$$

on integration $xy = c_1$

From first and third fractions

$$x^3 dx = (z^3 + xyz) dz$$

using $xy = c_1$, $x^3 dx = (z^3 + c_1 z) dz$

$$\text{Integrating } \frac{x^4}{4} = \frac{z^4}{4} + c_1 \frac{z^2}{2} + c_2$$

$$\text{or } x^4 - z^4 - 2c_1 z^2 = c_2$$

$$\text{Substituting for } c_1, x^4 - z^4 - 2(xy)z^2 = c_2$$

The general solution is

$$F(xy, x^4 - z^4 - 2xyz^2) = 0$$

Example 5: $xzp + yzq = xy$

Solution: Auxiliary equations $\frac{dx}{xz} = \frac{dy}{yz} = \frac{dz}{xy}$

From one and two $\frac{dx}{xz} = \frac{dy}{yz}$ or $\frac{dx}{x} = \frac{dy}{y}$

Integrating $x = c_1 y$

Choosing the multipliers as $y, x, 2z$

$$\frac{ydx + xdy}{yxz + xyz} = \frac{2zdz}{2zxy}$$

$$\text{or } ydx + xdy - 2zdz = 0$$

$$d(xy) - d(z^2) = 0$$

$$\text{Integrating } xy - z^2 = c_2$$

The general solution is

$$F\left(\frac{x}{y}, xy - z^2\right) = 0.$$

Example 6: $(z - y)p + (x - z)q = y - x$

Solution: Auxiliary equations are

$$\frac{dx}{z - y} = \frac{dy}{x - z} = \frac{dz}{y - x}$$

Choosing multipliers as, 1, 1, 1

$$dx + dy + dz = (z - y) + (x - z) + (y - x) = 0$$

Integrating $x + y + z = c_1$

Choosing multipliers as x, y, z

$$x dx + y dy + z dz = x(z - y) + y(x - z) + z(y - x) = 0$$

$$\text{Integrating } x^2 + y^2 + z^2 = c_2$$

The general solution is

$$F(x + y + z, x^2 + y^2 + z^2) = 0$$

Example 7: $(y + zx)p - (x + yz)q = x^2 - y^2$

Solution: Auxiliary equations are

$$\frac{dx}{y + zx} = \frac{dy}{-(x + yz)} = \frac{dz}{x^2 - y^2}$$

Choosing multipliers as $x, y, -z$

$$x dx + y dy - z dz$$

$$= x(y + zx) + y(-1)(x + yz) - z(x^2 - y^2) = 0$$

$$\text{Integrating } x^2 + y^2 - z^2 = c_1$$

Choosing multipliers as $y, x, 1$, we get

$$y dx + x dy + dz$$

$$= y(y + zx) + x(-1)(x + yz) + (x^2 - y^2) = 0$$

$$\text{Integrating } xy + z = c_2$$

The general solution is

$$F(x^2 + y^2 - z^2, xy + z) = 0.$$

Example 8: $(y^2 + z^2)p - xyq + zx = 0$

Solution: Auxiliary equations are

$$\frac{dx}{y^2 + z^2} = \frac{dy}{-xy} = \frac{dz}{-zx}$$

From the 2nd and 3rd fractions

$$\frac{dy}{y} = \frac{dz}{z} \quad \text{or} \quad \frac{y}{z} = c_1$$

Choosing multipliers as x, y, z

$$x dx + y dy + z dz = x(y^2 + z^2) + y(-xy) + z(-zx) = 0$$

18.10 — HIGHER ENGINEERING MATHEMATICS—V

Integrating $x^2 + y^2 + z^2 = c_2$

The general solution is

$$F\left(\frac{y}{z}, x^2 + y^2 + z^2\right) = 0.$$

Example 9: $px(x+y) = qy(x+y) - (2x+2y+z)(x-y)$

Solution: Auxiliary equations are

$$\frac{dx}{x(x+y)} = \frac{dy}{-y(x+y)} = \frac{dz}{-(x-y)(2x+2y+z)}$$

From first two fractions, cancelling $(x+y)$, we get

$$\frac{dx}{x} = -\frac{dy}{y} \quad \text{or} \quad d(\ln x) + d(\ln y) = c$$

which on integration gives $xy = c_1$

$$\begin{aligned} \frac{dx+dy}{x(x+y)-y(x+y)} &= \frac{dx+dy}{(x+y)(x-y)} \\ &= \frac{dz}{-(x-y)(2x+2y+z)} \end{aligned}$$

Cancelling the $(x-y)$ term, we get

$$(2x+2y+z)(dx+dy) + (x+y)dz = 0$$

or

$$(x+y+z)(dx+dy) + (x+y)(dx+dy) + (x+y)dz = 0$$

$$(x+y+z)d(x+y) + (x+y)d(x+y+z) = 0$$

$$\text{i.e.,} \quad d((x+y)(x+y+z)) = 0$$

Integrating $(x+y)(x+y+z) = c_2$

Thus the general solution is

$$F(xy, (x+y)(x+y+z)) = 0$$

Example 10: $(x^2 - y^2 - yz)p + (x^2 - y^2 - zx)q = z(x-y)$

Solution: Auxiliary equations are

$$\frac{dx}{x^2 - y^2 - yz} = \frac{dy}{x^2 - y^2 - zx} = \frac{dz}{z(x-y)}$$

$$dx - dy - dz = x^2 - y^2 - yz - (x^2 - y^2 - zx)$$

$$-z(x-y) = 0$$

Integrating $x - y - z = c_1$

From first and second

$$\frac{xdx - ydy}{x^3 - xy^2 - x^2y - y^3} = \frac{dz}{z(x-y)}$$

$$\text{or} \quad \frac{xdx - ydy}{(x^2 - y^2)(x-y)} = \frac{dz}{z(x-y)}$$

$$\text{i.e.,} \quad \frac{1}{2}d(\ln(x^2 - y^2)) = d(\ln z)$$

$$\therefore (x^2 - y^2)/z^2 = c_2.$$

$\therefore$ The general solution is

$$f(x-y-z, (x^2 - y^2)/z^2) = 0$$

EXERCISE

Solve the following:

$$1. \quad y^2zp + x^2zq = xy^2$$

$$\text{Ans.} \quad F(x^3 - y^3, x^2 - z^2) = 0$$

$$2. \quad p \tan x + q \tan y = \tan z$$

$$\text{Ans.} \quad F\left(\frac{\sin x}{\sin y}, \frac{\sin y}{\sin z}\right) = 0$$

$$3. \quad xp + yq = z$$

$$\text{Ans.} \quad F\left(\frac{x}{z}, \frac{y}{z}\right) = 0$$

$$4. \quad 2p + 3q = 1$$

$$\text{Ans.} \quad F(3x - 2y, y - 3z) = 0$$

$$5. \quad x^2p + y^2q = z^2$$

$$\text{Ans.} \quad F\left(\frac{1}{x} - \frac{1}{y}, \frac{1}{y} - \frac{1}{z}\right) = 0$$

$$6. \quad pyz + qzx = xy$$

$$\text{Ans.} \quad F(x^2 - y^2, y^2 - z^2) = 0$$

$$7. \quad x^2p + y^2q = (x+y)z$$

$$\text{Ans.} \quad F\left(\frac{xy}{z}, \frac{x-y}{z}\right) = 0$$

$$8. \quad p + 3q = 5z + \tan(y - 3x)$$

Hint: Use the solution $y - 3x = c$ obtained from $\frac{dx}{1} = \frac{dy}{3}$.

$$\text{Ans.} \quad F(y - 3x, e^{-5x}\{5z + \tan(y - 3x)\}) = 0$$

$$9. \quad z(p - q) = z^2 + (x + y)^2$$

Hint: Use solution $x + y = c$ obtained from $\frac{dx}{1} = \frac{dy}{-1}$.

Ans. $F[x + y, e^{2y}\{z^2 + (x + y)^2\}] = 0$

10. $z(xp - yq) = y^2 - x^2$

Hint: Use x, y, z as multipliers.

Ans. $F(xy, x^2 + y^2 + z^2) = 0$

11. $(x^3 + 3xy^2)p + (y^3 + 3x^2y)q = 2(x^2 + y^2)z$

Hint: Choose multipliers $(1/x, 1/y, 0)$, $(1, 1, 0)$, $(1, -1, 0)$.

Ans. $F[(x - y)^{-2} - (x + y)^{-2}, xy/z^2] = 0$

12. $x^2(y^3 - z^3)p + y^2(z^3 - x^3)q = z^2(x^3 - y^3)$

Ans. $F(x^2 + y^2 + z^2, \frac{1}{x} + \frac{1}{y} + \frac{1}{z}) = 0$

13. $(2x^2 + y^2 + z^2 - 2yz - zx - xy)p + (x^2 + 2y^2 + z - yz - 2zx - xy)q = (x^2 + y^2 + 2z^2 - yz - 2xy)$

Hint: $\frac{dx-dy}{x-y} = \frac{dy-dz}{y-z} = \frac{dz-dx}{z-x}$.

Ans. $F\left(\frac{x-y}{y-z}, \frac{y-z}{z-x}\right) = 0$

14. $(mz - ny)p + (nx - lz)q = ly - mx$

Ans. $F(x^2 + y^2 + z^2, lx + my + nz) = 0$

15. $(x^2 - yz)p + (y^2 - zx)q = z^2 - xy$

Ans. $F\left(\frac{x-y}{y-z}, xy + yz + zx\right) = 0$

16. $(x^2 - y^2 - z^2)p + 2xyq = 2xz$

Ans. $F(x^2 + y^2 + z^2, y/z) = 0$

17. $(x + 2z)p + (4zx - y)q = 2x^2 + y$

Hint: Multipliers $y, x, -2z$ and $2x, -1, -1$.

Ans. $F(xy - z^2, x^2 - y - z) = 0$

18. $x(y - z)p + y(z - x)q = z(x - y)$

Ans. $F(x + y + z, xyz) = 0$

19. $(y - z)p + (x - y)q = (z - x)$

Ans. $F(x + y + z, \frac{x^2}{2} + yz) = 0$

20. $(y + z)p + (z + x)q = x + y$

Ans. $F\left(\frac{x-y}{y-z}, \frac{y-z}{\sqrt{x+y+z}}\right) = 0$

21. $x^2(y - z)p + y^2(z - x)q = z^2(x - y)$.

Hint: Multipliers: $1/x, 1/y, 1/z$ and $1/x^2, 1/y^2, 1/z^2$.

Ans. $F\left(xyz, \frac{1}{x} + \frac{1}{y} + \frac{1}{z}\right) = 0$

22. $(z^2 - 2yz - y^2)p + (xy + zx)q = xy - zx$

Ans. $F(x^2 + y^2 + z^2, y^2 - 2yz - z^2) = 0$

23. $px(z - 2y^2) = (z - qy)(z - y^2 - 2x^3)$

Hint: Multiply A.E. by $(z - y^2 - 2x^3)$, use multipliers $1, 2xy, -x$, divide by x^2 throughout.

Ans. $F\left(y/z, \frac{y^2}{x} - \frac{z}{x} - x^2\right) = 0$

24. $x(y^2 - z^2)p + y(z^2 - x^2)q = z(x^2 - y^2)$

Hint: Multipliers x, y, z and $1/x, 1/y, 1/z$.

Ans. $F(x^2 + y^2 + z^2, xyz) = 0$.

18.4 NON-LINEAR PARTIAL DIFFERENTIAL EQUATIONS OF FIRST ORDER

Non-linear P.D.E. of first order contains p and q of degree (power) other than one and/or product terms of p and q . Its complete solution is given by $f(x, y, z, a, b) = 0$ where a and b are any two arbitrary constants. Some special types of non-linear first order P.D.E. are presented.

Form I: $f(p, q) = 0$

i.e., equation contains only p and q (or x, y, z are absent)

Assume that $p = a$ then $f(a, q) = 0$

Solving $q = \phi(a)$

Consider

$$dz = \frac{\partial z}{\partial x} dx + \frac{\partial z}{\partial y} dy = p dx + q dy$$

$$dz = a dx + \phi(a) dy$$

Integrating $z = ax + \phi(a)y + c$ where a and c are arbitrary constants.

Thus the complete solution is

$$z = ax + by + c$$

where a, b satisfy the equation $f(a, b) = 0$

i.e., $b = \phi(a)$

Form II: $f(z, p, q) = 0$

i.e., equation does not involve the independent variables x and y .

Assume $q = ap$. Substituting q in the given equation $f(z, p, ap) = 0$ and solving for p , we get $p = \phi(z)$. Now

$$dz = p dx + q dy = p dx + ap dy$$

$$dz = p(dx + a dy) = \phi(z)(dx + a dy)$$

Integrating $x + ay = \int \frac{dz}{\phi(z)} + b$ where a and b are two arbitrary constants.

Form III: $f(x, p) = g(y, q)$

i.e., x, p and y, q are separable.

Assume $f(x, p) = g(y, q) = a = \text{constant}$.

Solving each equation for p and q , we get

$$p = f_1(x, a) \quad \text{and} \quad q = g_1(y, a)$$

Now $dz = p dx + q dy = f_1(x, a) dx + g_1(y, a) dy$

Integrating $z = \int f_1(x, a) dx + \int g_1(y, a) dy + b$.

Form IV: Clairaut Equation:

$$z = px + qy + f(p, q)$$

The complete solution of this equation is

$$z = ax + by + f(a, b)$$

which is obtained by replacing p by a and q by b in the given Clairaut equation.

Note: All these four forms can be solved by Charpit's method.

WORKED OUT EXAMPLES

Form I: $f(p, q) = 0$

Solve the following:

Example 1: $p^3 - q^3 = 0$

Solution: The complete solution is

$$z = ax + by + c$$

where a, b are connected by $a^3 - b^3 = 0$ or $a = b$

Thus $z = ax + ay + c$ is the complete integral.

Example 2: $p^2 + q^2 = npq$

Solution: The complete solution is

$$z = ax + by + c$$

where a, b satisfy the equation $a^2 + b^2 = nab$.

Solving for b

$$b = \frac{-na \pm \sqrt{n^2 a^2 - 4a^2}}{2} = +\frac{a}{2} [n \pm \sqrt{n^2 - 4}]$$

so complete integral:

$$z = ax + \frac{a}{2} (n \mp \sqrt{n^2 - 4}) y + c$$

Example 3: $(x + y)(p + q)^2 + (x - y)(p - q)^2 = 1$

Solution: To reduce this equation to $f(P, Q) = 0$ form, put $x + y = X^2$ and $x - y = Y^2$. Then

$$\begin{aligned} X &= \sqrt{x + y}, \quad Y = \sqrt{x - y} \\ p &= z_x = \frac{\partial z}{\partial x} = \frac{\partial z}{\partial X} \frac{\partial X}{\partial x} + \frac{\partial z}{\partial Y} \cdot \frac{\partial Y}{\partial x} \\ &= \frac{1}{2X} \frac{\partial z}{\partial X} + \frac{1}{2Y} \frac{\partial z}{\partial Y} \end{aligned}$$

since

$$\frac{\partial X}{\partial x} = \frac{1}{2} \frac{1}{\sqrt{x + y}} = \frac{1}{2X} \quad \text{and} \quad \frac{\partial Y}{\partial x} = \frac{1}{2} \frac{1}{\sqrt{x - y}} = \frac{1}{2Y}$$

Similarly,

$$q = z_y = \frac{\partial z}{\partial y} = \frac{\partial z}{\partial X} \frac{\partial X}{\partial y} + \frac{\partial z}{\partial Y} \cdot \frac{\partial Y}{\partial y} = \frac{1}{2X} z_x - \frac{1}{2Y} z_y$$

$$\text{Adding } p + q = z_x \cdot \frac{1}{X},$$

$$\text{subtracting } p - q = z_y \cdot \frac{1}{Y}.$$

Thus the given equation reduces to

$$X^2 \cdot \left(z_x \frac{1}{X}\right)^2 + Y^2 \left(z_y \frac{1}{Y}\right)^2 = 1 \quad \text{or} \quad z_x^2 + z_y^2 = 1$$

The complete solution is

$$z = aX + bY + c$$

$$\text{where } a^2 + b^2 = 1 \quad \text{or} \quad b = \sqrt{1 - a^2}$$

$$\text{or} \quad z = a\sqrt{x + y} + \sqrt{1 - a^2}\sqrt{x - y} + c.$$

Example 4: $(x - y)(px - qy) = (p - q)^2$

Solution:

$$\text{Put} \quad x + y = u \quad \text{and} \quad xy = v \quad (1)$$

$$\text{Then} \quad p = \frac{\partial z}{\partial x} = \frac{\partial z}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial z}{\partial v} \frac{\partial v}{\partial x} = z_u + y z_v \quad (2)$$

Since $u_x = 1, u_y = 1, v_x = y, v_y = x$

Similarly, $q = \frac{\partial z}{\partial y} = \frac{\partial z}{\partial u} \frac{\partial u}{\partial y} + \frac{\partial z}{\partial v} \frac{\partial v}{\partial y} = z_u + xz_v$ (3)

From (2) and (3)

$$p - q = (y - x)z_v \quad (4)$$

$$xp - qy = (x - y)z_u \quad (5)$$

Using (4), (5) the given equation transforms to

$$(x - y)(x - y)z_u = (y - x)^2 z_v^2$$

or

$$z_u = z_v^2$$

$$P = Q^2$$

Its complete solution is

$$z = au + bv + c$$

where

$$a = b^2.$$

Using (1), replace u, v then

$$z = b^2(x + y) + bxy + c$$

where b, c are arbitrary constants.

Form II: $f(z, p, q) = 0$

Example 5: $zpq = p + q$

Solution: Assume $q = ap$.

Substituting in the given equation

$$zp \cdot ap = p + ap$$

Solving for p , we get

$$p = \frac{1 + a}{az}$$

We know that $dz = p dx + q dy = p(dx + ady)$

$$dz = \frac{1 + a}{az}(dx + ady) \quad \text{or} \quad az dz = (1 + a)(dx + ady)$$

$$\text{Integrating: } a \frac{z^2}{2} = (1 + a)[x + ay] + b.$$

Example 6: $p^2 z^2 + q^2 = p^2 q$

Solution: Let $q = ap$ then the given equation reduces to

$$p^2 z^2 + a^2 p^2 = p^2 \cdot ap$$

$$\text{Solving } p = (z^2 + a^2)/a.$$

Then

$$dz = p dx + q dy = p(dx + ady)$$

$$dz = \frac{(z^2 + a^2)}{a}(dx + ady)$$

$$\text{or} \quad \frac{adz}{(z^2 + a^2)} = dx + ady$$

Integrating $\tan^{-1}\left(\frac{z}{a}\right) = x + ay + b$. Thus the complete solution is

$$z = a \tan(x + ay + b).$$

Example 7: $p^2 x^2 = z(z - qy)$

Solution: To reduce this equation to $f(z, p, q) = 0$ form, put $X = \ln x, Y = \ln y$ so that

$$dx = \frac{dx}{x}, dy = \frac{dy}{y}$$

Rewriting

$$\left(x \frac{\partial z}{\partial x}\right)^2 = z \left(z - y \frac{\partial z}{\partial y}\right)$$

$$\left(\frac{\partial z}{\partial X}\right)^2 = z \left(z - \frac{\partial z}{\partial Y}\right)$$

Let $P = \frac{\partial z}{\partial X}, Q = \frac{\partial z}{\partial Y}$. Then the given equation reduces to

$$P^2 = z(z - Q)$$

which is of the form $f(z, P, Q) = 0$

Let $Q = aP$. Substituting this in the new equation

$$P^2 = z^2 - zQ = z^2 - zaP$$

or

$$P^2 + azP - z^2 = 0$$

$$\text{Solving } P = \frac{-az \pm \sqrt{a^2 z^2 + 4z^2}}{2} = z \cdot k$$

$$\text{where } k = \left(-a \pm \sqrt{a^2 + 4}\right)/2$$

$$\text{now } dz = P dX + Q dY = P(dX + adY)$$

$$\text{or } dz = k \cdot z(dX + adY) \quad \text{since } P = kz$$

Replacing X and Y by $\ln x$ and $\ln y$

$$\frac{1}{k} \frac{dz}{z} = d \ln x + ad \ln y$$

$$\text{Integrating } z^{\frac{1}{k}} = xy^a b$$

where a, b are arbitrary constants and

$$k = \left(-a \pm \sqrt{a^2 + 4}\right)/2$$

18.14 — HIGHER ENGINEERING MATHEMATICS—V

Form III: $f(x, p) = g(y, q)$

Example 8: $yp + xq + pq = 0$

Solution: Rewriting $(x + p)q = -yp$

$$\text{or } \frac{x + p}{p} = -\frac{y}{q} = a, \quad \text{say}$$

Then solving for p and q

$$p = \frac{x}{a-1} \quad \text{and} \quad q = -\frac{y}{a}$$

$$\text{Now } dz = p dx + q dy = \frac{x}{(a-1)} dx + \left(-\frac{y}{a}\right) dy$$

$$\text{Integrating } z = \frac{1}{(a-1)} \frac{x^2}{2} - \frac{y^2}{2a} + b.$$

Example 9: $p^2 q^2 + x^2 y^2 = x^2 q^2 (x^2 + y^2)$

Solution: To transform this to the standard form, put $x^2 = X$ and $y^2 = Y$ so that

$$2x dx = dX, \quad 2y dy = dY$$

$$\text{Then } p = \frac{\partial z}{\partial x} = \frac{\partial z}{\partial X} \cdot \frac{\partial X}{\partial x} = 2x z_x, \quad q = 2y z_y$$

$$\text{Similarly, } q = \frac{\partial z}{\partial y} = \frac{\partial z}{\partial Y} \cdot \frac{\partial Y}{\partial y} = 2y z_y = 2y Q$$

Substituting these values, the given equation reduces to

$$4x^2 P^2 \cdot 4y^2 Q^2 + x^2 y^2 = x^2 4y^2 Q^2 (x^2 + y^2)$$

$$4X P^2 \cdot 4Y Q^2 + XY = 4XY Q^2 (X + Y)$$

$$\text{or } 16P^2 Q^2 + 1 = 4Q^2 (X + Y)$$

Now rewrite this as

$$16P^2 Q^2 - 4X Q^2 = 4Y Q^2 - 1$$

$$(4P^2 - X) = \frac{4Y Q^2 - 1}{4Q^2} = a^2 \quad \text{say}$$

This is in the standard form

$$f(P, X) = g(Q, Y).$$

Solving for P and Q , we get

$$P = \frac{1}{2}(X + a^2)^{\frac{1}{2}}$$

$$Q = \frac{1}{2} \frac{1}{(Y - a^2)^{\frac{1}{2}}}$$

$$\text{Now } dz = P dX + Q dY$$

$$dz = \frac{1}{2}(X + a^2)^{\frac{1}{2}} dX + \frac{1}{2}(Y - a^2)^{-\frac{1}{2}} dY$$

$$\text{Integrating } z = \frac{1}{3}(X + a^2)^{\frac{3}{2}} + (Y - a^2)^{\frac{1}{2}} + b$$

$$\text{or } z = \frac{1}{3}(x^2 + a^2)^{\frac{3}{2}} + (y^2 - a^2)^{\frac{1}{2}} + b$$

where a, b are arbitrary constants.

Example 10: $zpy^2 = x(y^2 + z^2 q^2)$.

Solution: To get rid of z in the equation, put $Z = \frac{z^2}{2}$ or $dZ = zdz$. Then

$$zp = \frac{z \partial z}{\partial x} = \frac{\partial Z}{\partial x} = P, \quad \text{similarly, } zq = z \frac{\partial z}{\partial y} = \frac{\partial Z}{\partial y} = Q$$

Now the equation gets transformed to

$$Py^2 = x(y^2 + Q^2)$$

$$\text{or } \frac{P}{x} = \frac{Q^2 + y^2}{y^2} = a \quad \text{say}$$

$$\text{Solving } P = ax, \quad Q = \sqrt{a-1}y$$

$$\text{So } dz = P dx + Q dy = ax dx + \sqrt{a-1}y dy$$

$$\text{or } zdz = ax dx + \sqrt{a-1}y dy$$

Integrating $z^2 = ax^2 + \sqrt{a-1}y^2 + b$ where a, b are arbitrary constants.

Form IV: Clairaut's equation

Example 11: $z = px + qy + \ln pq$

Solution: The complete solution of this Clairaut's equation is

$$z = ax + by + \ln ab$$

Example 12: $(p - q)(z - px - qy) = 1$

Solution: Rewriting this in Clairaut's form

$$z = px + qy + \frac{1}{p - q}$$

The complete solution is

$$z = ax + by + \frac{1}{a - b}$$

EXERCISE

Find the complete solution of:

Form I: $f(p, q) = 0$

1. $pq = k$

Ans. $z = ax + k\frac{y}{a} + c$

2. $p^2 + q^2 = m^2$

Ans. $z = ax + \sqrt{m^2 - a^2}y + c$

3. $\sqrt{p} + \sqrt{q} = 1$

Ans. $z = ax + (1 - \sqrt{a})^2y + c$

4. $p^2 - q^2 = 4$

Ans. $z = ax + \sqrt{a^2 - 4}y + c$

5. $p + q = pq$

Ans. $z = ax + ay/(a - 1) + c$

6. $p = e^q$

Ans. $z = ax + y \ln a + c$

7. $2p^2 + 6p + 2q + 4 = 0$

Ans. $z = ax - (2 + 3a + a^2/2)y + c$

8. $x^2p^2 + y^2q^2 = z^2$

Hint: Put $Z = \ln z$, $X = \ln x$, (where $a = \cos \alpha$, $b = \sqrt{1 - a^2} = \sin \alpha$), $Y = \ln y$, which transforms the given equation to $P^2 + Q^2 = 1$.

Ans. $z = c^* x^{\cos \alpha} \cdot y^{\sin \alpha}$

9. $(x^2 + y^2)(p^2 + q^2) = 1$

Hint: Put $x = r \cos \theta$, $y = r \sin \theta$, (where $r = \sqrt{x^2 + y^2}$, $\tan \theta = y/x$, $R = \ln r$, then equation reduces to $(\frac{\partial z}{\partial R})^2 + (\frac{\partial z}{\partial \theta})^2 = 1$)

Ans. $z = a \ln r + \sqrt{1 - a^2} \theta + c$

10. $pq = x^m y^n z^l$

Ans. $z^p = p \left(\frac{ax^q}{q} + \frac{1}{a} \frac{y^r}{r} + c \right)$

where $p = 1 - \frac{l}{2}$, $q = m + 1$, $r = n + 1$

Hint: Put $Z = \frac{z^p}{p}$, $X = \frac{x^q}{q}$, $Y = \frac{y^r}{r}$

Then equation reduces to

$$\frac{\partial Z}{\partial X} \cdot \frac{\partial Z}{\partial Y} = 1.$$

Form II: $f(z, p, q) = 0$

1. $p^2 z^2 + q^2 = 1$

Ans. $az(1 + a^2 z)^{\frac{1}{2}} - \ln \left[az + (1 + a^2 z^2)^{\frac{1}{2}} \right] = 2a(ax + y + b)$

2. $p(1 + q) = qz$

Ans. $\ln (az - 1) = x + ay + b$

3. $q^2 = z^2 p^2 (1 - p^2)$

Ans. $a^2 z^2 = (y + ax + c)^2 + 1$

4. $p^3 + q^3 = 27z$

Ans. $(1 + a^3)z^2 = 8(x + ay + b)^3$

5. $z^2(p^2 + q^2 + 1) = \alpha^2$

Ans. $(1 + b^2)(\alpha^2 - z^2) = (x + by + c)^2$

6. $z^2 = 1 + p^2 + q^2$

Ans. $z = \cosh(x + ay + c/\sqrt{1 + a^2})$

7. $p(1 + q^2) = q(z - \alpha)$

Ans. $4a(z - \alpha) = 4 + (x + ay + c)^2$

8. $9(p^2 z + q^2) = 4$

Ans. $(z + a^2)^3 = (x + ay + b)^2$

9. $z^2(p^2 x^2 + q^2) = 1$

Hint: Put $X = \ln x$, equation reduces to $z^2 \left[\left(\frac{\partial z}{\partial X} \right)^2 + \left(\frac{\partial z}{\partial Y} \right)^2 \right] = 1$.

Ans. $z^2 \sqrt{1 + a^2} = \pm 2 (\ln x + ay) + b$

10. $q^2 y^2 = z(z - px)$

Hint: Put $X = \ln x$, $Y = \ln y$ then equation reduces to $Q^2 = z^2 - zP$

Ans. $xy^a \cdot b = z^{\frac{1}{k}}$

where $k = (-1 \pm \sqrt{1 + 4a^2})/(2a^2)$

Form III: $f(x, p) = g(y, q)$

1. $p^2 \pm q^2 = x \pm y$

Ans. $z = \frac{2}{3}(a + x)^{\frac{3}{2}} + \frac{2}{3}(\mp a + y)^{\frac{3}{2}} + b$

2. $\sqrt{p} + \sqrt{q} = x + y$

$$\text{Ans. } z = \frac{(a+x)^3}{3} + \frac{(y-a)^3}{3} + b$$

$$3. \quad p + q = \sin x + \sin y$$

$$\text{Ans. } z = ax - \cos x - \cos y - ay + b$$

$$4. \quad p^2 y(1 + x^2) = qx^2$$

$$\text{Ans. } z = a\sqrt{1 + x^2} + \frac{1}{2}a^2 y^2 + b$$

$$5. \quad pe^y = qe^x$$

$$\text{Ans. } z = a(e^x + e^y) + b$$

$$6. \quad p - q = x^2 + y^2$$

$$\text{Ans. } z = \frac{1}{3}(x^3 - y^3) + a(x + y) + b$$

$$7. \quad y^2 q^2 - xp + 1 = 0$$

$$\text{Ans. } z = (a^2 + 1) \ln x + a \ln y + b$$

$$8. \quad z^2(p^2 + q^2) = x^2 + y^2$$

Hint: Put $Z = \frac{1}{2}z^2$ equation reduces to $P^2 + Q^2 = x^2 + y^2$ where $P = zp$, $Q = zq$.

$$\text{Ans. } z^2 = x\sqrt{x^2 + a} + y\sqrt{y^2 - a} + a \ln \frac{x + \sqrt{x^2 + a}}{y + \sqrt{y^2 - a}} + 2b$$

$$9. \quad z(xp - yq) = y^2 - x^2$$

Hint: Put $Z = \frac{z^2}{2}$ equation reduces to $xP - yQ = y^2 - x^2$ where $P = \frac{\partial Z}{\partial x}$, $Q = \frac{\partial Z}{\partial y}$.

$$\text{Ans. } z^2 = 2a \ln xy - (x^2 + y^2) + 2b$$

$$10. \quad z(p^2 - q^2) = x - y$$

Hint: Put $Z = \frac{2}{3}z^{\frac{3}{2}}$, equation reduces to $P^2 - Q^2 = x - y$ where $P = \frac{\partial Z}{\partial x}$, $Q = \frac{\partial Z}{\partial y}$.

$$\text{Ans. } z^{\frac{3}{2}} = (a + x)^{\frac{3}{2}} + (a + y)^{\frac{3}{2}} + c.$$

Form IV: $z = px + qy + f(p, q)$:

Clairaut's equation

$$1. \quad 2q(z - px - qy) = 1 + q^2$$

$$\text{Ans. } z = ax + by + \frac{b^2 + 1}{2b}$$

$$2. \quad pqz = p^2(xq + p^2) + q^2(yq + q^2)$$

$$\text{Ans. } z = ax + by + \left(\frac{a^3}{b} + \frac{b^3}{a}\right)$$

$$3. \quad z = px + qy \pm pq$$

$$\text{Ans. } z = ax + by \pm ab$$

$$4. \quad (px + qy - z)^2 = d(1 + p^2 + q^2)$$

$$\text{Ans. } z = ax + by \pm \left(\sqrt{1 + a^2 + b^2}\right) d$$

$$5. \quad (p + q)(z - xp - yq) = 1$$

$$\text{Ans. } z = ax + by + \frac{1}{a+b}$$

$$6. \quad 4xyz = pq + 2px^2y + 2qxy^2$$

Hint: Put $X = x^2$, $Y = y^2$, equation reduces to $z = PX + QY + PQ$.

$$\text{Ans. } z = ax^2 + by^2 + ab.$$

18.5 CHARPIT'S METHOD

Charpit's method is a general method to find the complete solution of the first order non-linear P.D.E. of the form

$$f(x, y, z, p, q) = 0 \quad (1)$$

We know that

$$dz = \frac{\partial z}{\partial x} dx + \frac{\partial z}{\partial y} dy = p dx + q dy \quad (2)$$

Integrating (2), we get the complete solution of (1). In order to integrate (2), we must know p and q in terms of x, y, z . For this purpose, introduce another first order non-linear P.D.E. of the form

$$g(x, y, z, p, q, a) = 0 \quad (3)$$

involving an arbitrary constant "a" compatible with (1). Solving (1) and (3), we get

$$p = p(x, y, z, a), \quad q = q(x, y, z, a) \quad (4)$$

On substitution of (4) in (2), equation (2) becomes integrable, resulting in the complete solution of (1) in the form

$$F(x, y, z, a, b) = 0 \quad (5)$$

containing two arbitrary constants a and b .

Now differentiating (1) and (3) partially w.r.t. x and y and eliminating $\frac{\partial p}{\partial x}$ and $\frac{\partial q}{\partial x}$, we get after simplification, a Lagrange's linear equation of ϕ (as dependent variable) in terms of x, y, z, p, q (as independent variables) as

$$\begin{aligned} f_q \frac{\partial g}{\partial x} + f_q \frac{\partial g}{\partial y} + (pf_p + qf_q) \frac{\partial g}{\partial z} - (f_x + pf_z) \frac{\partial g}{\partial p} \\ - (f_y + qf_z) \frac{\partial g}{\partial q} = 0 \end{aligned} \quad (6)$$

The subsidiary equations of (6) are

$$\begin{aligned}\frac{dx}{f_p} &= \frac{dy}{f_q} = \frac{dz}{pf_p + qf_q} = \frac{dp}{-(f_x + pf_z)} \\ &= \frac{dq}{-(f_y + qf_z)}\end{aligned}\quad (7)$$

These Equations (7) are known as Charpit's equations. Solving (7), we get relations (4) of p and q , using which, the equation (2) is integrated resulting in the complete solution (5) of (1).

Note: Not all of the Charpit's Equations (7) need be used. Choose the simplest of (7) so that p and q are easily obtained.

WORKED OUT EXAMPLES

Example 1: Solve $z^2 = pqxy$.

Solution: Here $f(x, y, z, p, q) = z^2 - pqxy = 0$. Differentiating f partially w.r.t. x, y, z, p, q , form the auxiliary equations

$$\begin{aligned}\frac{dx}{f_p} &= \frac{dy}{f_q} = \frac{dz}{pf_p + qf_q} = \frac{dp}{-(f_x + pf_z)} = \frac{dq}{-(f_y + qf_z)} \\ \frac{dx}{-qxy} &= \frac{dy}{-pxy} = \frac{dz}{-2pqxy} = \frac{dp}{-(-pqy + p2z)} \\ &= \frac{dq}{-(-pqx + 2qz)}\end{aligned}$$

Using the multipliers $p, q, 0, x, y$, we have

$$\begin{aligned}\frac{pdx + xdp}{-pqxy + xpqy - 2pxz} &= \frac{qdy + ydq}{-qpxy + ypqx - 2yqz} \text{ or} \\ \frac{pdx + xdp}{-2xpz} &= \frac{qdy + ydq}{-2yqz} \\ \frac{d(xp)}{(xp)} &= \frac{d(yq)}{(yq)}\end{aligned}$$

Integrating $xp = ayq$.

Solving $q = \frac{xp}{ay}$. Substituting q in given P.D.E.

$$z^2 = p \cdot \left(\frac{xp}{ay}\right)xy = \frac{p^2x^2}{a} \text{ or } p = \sqrt{a} \cdot \frac{z}{x};$$

$$\text{Then } q = \frac{xp}{ay} = \frac{x}{ay} \cdot \sqrt{a} \frac{z}{x} = \frac{z}{\sqrt{ay}}$$

$$\text{Now } dz = pdx + qdy = \sqrt{a} \frac{z}{x} dx + \frac{1}{\sqrt{a}} \frac{z}{y} dy$$

$$\frac{dz}{z} = \sqrt{a} \frac{dx}{x} + \frac{1}{\sqrt{a}} \frac{dy}{y}.$$

Integrating, we get the complete solution as

$$z = bx^a y^{\frac{1}{a}}$$

where a and b are two arbitrary constants.

Example 2: Solve $2(z + xp + yq) = yp^2$.

Solution: Here $f = 2(z + xp + yq) - yp^2$. Forming the auxiliary equations

$$\begin{aligned}\frac{dx}{2x - 2yp} &= \frac{dy}{2y} = \frac{dz}{2xp - 2yp^2 + 2qy} = \frac{dp}{-(2p + 2p)} \\ &= \frac{dq}{-(2q - p^2 + 2q)} \\ \frac{dx}{x - yp} &= \frac{dy}{y} = \frac{dz}{xp - yP^2 + yq} = \frac{dp}{-2p} = \frac{dq}{-(2q - \frac{p^2}{2})}\end{aligned}$$

Using second and fourth

$$\frac{dy}{y} = \frac{dp}{-2p} \quad \text{or} \quad p = ay^{-2} = \frac{a}{y^2}$$

Substituting p in the given P.D.E.

$$\begin{aligned}2yq &= y \left(\frac{a}{y^2}\right)^2 - 2z - 2x \left(\frac{a}{y^2}\right) \quad \text{or} \\ q &= \frac{a^2}{2y^4} - \frac{z}{y} - \frac{ax}{y^3}\end{aligned}$$

$$\text{Now } dz = p dx + q dy = \frac{a}{y^2} dx + \left(\frac{a^2}{2y^4} - \frac{z}{y} - \frac{ax}{y^3}\right) dy$$

Regrouping the terms

$$\left(\frac{ydz + zdy}{y}\right) = \left(\frac{aydx - axdy}{y^3}\right) + \frac{a^2}{2y^4} dy$$

Multiplying throughout by y :

$$d(yz) = ad\left(\frac{x}{y}\right) + \frac{a^2}{2} \frac{dy}{y^3}.$$

$$\text{Integrating } yz = a \frac{x}{y} + \frac{a^2}{2} \cdot \left(\frac{1}{-2y^2}\right) + b$$

$$z = \frac{ax}{y^2} - \frac{a^2}{4y^3} + \frac{b}{y}$$

is the required complete solution involving two arbitrary constants a and b .

EXERCISE

Solve (obtain the complete solution):

$$1. 16p^2z^2 + 9q^2z^2 + 4z^2 - 4 = 0$$

$$\text{Hint: } \frac{dp}{32p^3z + 18pq^2z + 8pz} = \frac{dq}{32p^2qz + 18q^3z + 8qz} = \frac{-dx}{32pz^2} = \frac{-dy}{+18qz^2} = \frac{-dz}{32p^2z^2 - 18q^2z^2}$$

$$4z dp + 0 \cdot dq + 1 \cdot dx + 0 \cdot dy + 4p dz = 0, \quad x + 4pz = a, \quad p = -\frac{x-a}{4z}, \quad q = \frac{2}{3z} \sqrt{1 - z^2 - \frac{1}{4}(x-a)^2}.$$

$$\text{Ans. } \frac{(x-a)^2}{4} + \frac{(y-b)^2}{9/4} + z^2 = 1$$

$$2. p(1 + q^2) + (b - z)q = 0.$$

$$\text{Hint: } \frac{dp}{pq} = \frac{dq}{q^2} = \frac{dz}{3pq^2 + p + (b-z)q} = \frac{dx}{q^2 + 1} = \frac{dy}{-z + b + 2pq} \quad (\text{i}) \quad q = pc, \text{ sub } q = \sqrt{c(z-b)-1}.$$

$$\text{Ans. } 2\sqrt{[c(z-b)-1]} = x + cy + a; a, c \text{ are arbitrary constants.}$$

$$3. 2xz - px^2 - 2qxy + pq = 0.$$

$$\text{Hint: } q = a, \quad p = \frac{2x(z-ay)}{x^2-a}.$$

$$\text{Ans. } z - ay = b(x^2 - a)$$

$$4. q \mp px - p^2 = 0.$$

$$\text{Hint: } q = a, \quad p = \frac{1}{2} [\mp x \pm \sqrt{x^2 + 4a}].$$

$$\text{Ans. } z = \mp \frac{x^2}{4} \pm \frac{1}{2} \left[\frac{x}{2} \sqrt{x^2 + 4a} + 2a \ln \{x + \sqrt{x^2 + 4a}\} \right] + ay + b$$

$$5. px + qy \mp pq = 0.$$

$$\text{Hint: } p = aq, \quad q = -\frac{(y+ax)}{a}, \quad p = -(y+ax).$$

$$\text{Ans. } az = -\frac{1}{2}(y+ax)^2 + b$$

$$6. qz - p^2y - q^2y = 0.$$

$$\text{Hint: } p^2 + q^2 = a, \quad q = \frac{ay}{z}, \quad p^2 = \frac{az^2 - a^2y^2}{z^2}.$$

$$\text{Ans. } z^2 = a(y^2 + (x+b)^2)$$

$$7. \frac{p^2 + qy}{2} = -(z + y^2).$$

$$\text{Hint: } p = -x + a, \quad q = \frac{1}{y} [-2z - 2y^2 - (a-x)^2].$$

$$\text{Ans. } y^2[(x-a)^2 + 2z + y^2] = b$$

$$8. yz - p(xy + q) - qy = 0.$$

$$\text{Hint: } p = a, \quad q = \frac{y(z-ax)}{a+y}.$$

$$\text{Ans. } (z-ax)(y+a)^a = be^y$$

$$9. 2(xy - px - qy) + p^2 + q^2 = 0.$$

$$\text{Hint: } dp + dq = dx + dy, \quad (p-x) + (q-y) = a$$

$$p - x = 2a \pm \frac{\sqrt{4a^2 - 8\{a^2 - (x-y)^2\}}}{4}$$

$$q = y + \frac{1}{2} \left[a \pm \sqrt{2(x-y)^2 - a^2} \right].$$

$$\text{Ans. } z = \frac{x^2}{2} + \frac{y^2}{2} - \frac{a}{2}(x+y) \pm \frac{1}{\sqrt{2}} \left(\frac{x-y}{2} \sqrt{(x-y)^2 - \frac{a^2}{2}} \right) - \frac{a^2}{4} \ln \left[(x-y) + \sqrt{(x-y)^2 - \frac{a^2}{2}} \right]$$

$$10. z - q^2y - p^2x = 0.$$

$$\text{Hint: } 2px dp + p^2 dx = 2qy dq + q^2 dy, \quad p^2 x = q^2 ya, \quad q^2 = \left[\frac{z}{1+a} \right], \quad p^2 = \frac{za}{(1+a)x}.$$

$$\text{Ans. } \sqrt{(1+a)}\sqrt{z} = \sqrt{a}\sqrt{x} + \sqrt{y} + b.$$

18.6 HOMOGENEOUS LINEAR PARTIAL DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

Consider a partial differential equation of the form

$$\left(A_0 \frac{\partial^n z}{\partial x^n} + A_1 \frac{\partial^n z}{\partial x^{n-1} \partial y} + \dots + A_n \frac{\partial^n z}{\partial y^n} \right) + \left(B_0 \frac{\partial^{n-1} z}{\partial x^{n-1}} + B_1 \frac{\partial^{n-1} z}{\partial x^{n-2} \partial y} + \dots + B_{n-1} \frac{\partial^{n-1} z}{\partial y^{n-1}} \right) + \dots + \left(M_0 \frac{\partial z}{\partial x} + M_1 \frac{\partial z}{\partial y} \right) + N_0 z = 0 \quad (1)$$

Here $A_0, A_1, \dots, A_n, B_0, B_1, \dots, B_{n-1}, M_0, M_1, N_0$ are all constants. In this equation the dependent variable z and its derivatives are linear. Since each term (in the LHS) of (1) contains z or its derivatives, equation (1) is known as homogeneous* linear partial differential equation of order n with constant coefficients. Introducing the notation $D_x = \frac{\partial}{\partial x}$ and $D_y = \frac{\partial}{\partial y}$ equation (1) takes the form $(A_0 D_x^n + A_1 D_x^{n-1} D_y + \dots + A_n D_y^n)z + (B_0 D_x^{n-1} + B_1 D_x^{n-2} D_y + \dots + B_{n-1} D_y^{n-1})z +$

* Some authors call an equation homogeneous of each term in the equation is of the same order.

$$\cdots + (M_0 D_x + M_1 D_y)z + N_0 z = 0$$

$$\text{or} \quad F(D_x, D_y)z = 0 \quad (2)$$

where $F(D_x, D_y)$ is a linear differential operator given by

$$F(D_x, D_y) = A_0 D_x^n + \cdots + A_n D_y^n + \cdots + M_0 D_x + M_1 D_y + N_0 \quad (3)$$

Reducible

The differential operator (3) is said to be reducible if (3) can be written as the product of linear factors of the form $(a_i D_x + b_i D_y + c_i)$ where a_i, b_i, c_i are constants. Otherwise (3) is said to be *irreducible*. Here we consider only reducible case. Then the reducible equation (2) can be written as $F(D_x, D_y)z = (a_1 D_x + b_1 D_y + c_1) \cdots (a_n D_x + b_n D_y + c_n)z = 0$

$$= \prod_{i=1}^n (a_i D_x + b_i D_y + c_i)z = 0 \quad (4)$$

Here the order in which the linear factors in the LHS of (4) occurs is immaterial.

Book Work 1: Prove that the general solution (G.S.) of the first order linear homogeneous partial differential equation

$$(aD_x + bD_y + c)z = 0 \quad (5)$$

is given by

$$\boxed{z = e^{-cx/a} \phi(ay - bx), (a \neq 0)} \quad (6)$$

or

$$\boxed{z = e^{-cy/b} \psi(ay - bx), (b \neq 0)} \quad (7)$$

Proof: The given equation is of the form $P(x)p + Q(x)q = R(x)$ where $P(x) = a$, $Q(x) = b$, $R(x) = -cz$. Then the auxiliary system of (5) is

$$\frac{dx}{a} = \frac{dy}{b} = \frac{dz}{-cz}$$

From $\frac{dx}{a} = \frac{dy}{b}$, we get $ay - bx = A = \text{const.}$ From $\frac{dx}{a} = \frac{dz}{-cz}$, we get $\ln z = -\frac{c}{a}x + \ln B$ provided $a \neq$

0. Then $z = Be^{-cx/a}$. Thus the general solution of (5) involving one arbitrary function ϕ is

$$z = e^{-cx/a} \phi(ay - bx), \quad a \neq 0$$

Instead from $\frac{dy}{b} = \frac{dz}{-cz}$, we get $z = ce^{-cy/b}$ provided $b \neq 0$. Thus the general solution of (5) involving one arbitrary function ψ is

$$z = e^{-cy/b} \psi(ay - bx), \quad b \neq 0$$

Corollary 1: If $c = 0$, then the general solution

$$\text{of } (aD_x + bD_y)z = 0 \quad (8)$$

$$\text{is } z = \phi(ay - bx) \quad (9)$$

Corollary 2: If $c \neq 0, a = 0, b \neq 0$, then the general solution of

$$(bD_y + c)z = 0 \quad (10)$$

$$\text{is } z = e^{-cy/b} \psi(x) \quad (11)$$

Corollary 3: If $c \neq 0, a \neq 0, b = 0$. Then G.S. of

$$(aD_x + c)z = 0 \quad (12)$$

$$\text{is } z = e^{-cx/a} \phi(y) \quad (13)$$

Corollary 4: If $c = 0, a = 0, b \neq 0$ then G.S. of

$$bD_y z = 0 \quad (14)$$

$$\text{is } z = \phi(x) \quad (15)$$

Corollary 5: If $c = 0, b = 0, a \neq 0$, then G.S. of

$$aD_x z = 0 \quad (16)$$

$$\text{is } z = \psi(y) \quad (17)$$

Recall the *linearity principle* which states that if $z_1, z_2, \dots, z_n$ are linearly independent solutions of the homogeneous linear partial differential equation

$F(D_x, D_y)z = 0$, then $z = \sum_{i=1}^n c_i z_i$ is also a solution since

$$F(D_x, D_y)z = F(D_x, D_y) \left(\sum_{i=1}^n c_i z_i \right)$$

$$= \sum_{i=1}^n F(D_x, D_y)(c_i z_i)$$

$$= \sum_{i=1}^n c_i F(D_x, D_y) z_i = 0$$

Here $c_1, c_2, \dots, c_n$ are arbitrary constants. Using the linearity principle and book work 1 which provides general solution to each linear factor of the form $(a_i D_x + b_i D_y + c_i)$, we now get the general solution of the linear homogeneous equation (4) as the sum of n arbitrary functions given by $z = e^{-\alpha_1 x} \phi_1(a_1 y - b_1 x) + e^{-\alpha_2 x} \phi_2(a_2 y - b_2 x) + \dots + e^{-\alpha_n x} \phi_n(a_n y - b_n x)$

$$\text{or } z = \sum_{i=1}^n e^{-\alpha_i x} \phi_i(a_i y - b_i x) \quad (18)$$

where $\alpha_i = c_i/a_i$. We can also write the general solution of (4) as

$$\text{or } z = \sum_{i=1}^n e^{-\beta_i y} \psi_i(a_i y - b_i x) \quad (19)$$

where $\beta_i = c_i/b_i$.

Multiple Factors

The solution corresponding to a multiple factor say $(a_i D_x + b_i D_y + c_i)^2$ of multiplicity z , in the decomposition of $F(D_x, D_y)$ into linear factors is given by

$$z = e^{-c_i x/a_i} [\phi_1(a_i y - b_i x) + x \phi_2(a_i y - b_i x)].$$

Extending this to a factor $(a_i D_x + b_i D_y + c_i)^k$ of multiplicity k , the corresponding solution is given by

$$z = e^{-c_i x/a_i} [\phi_1(a_i y - b_i x) + x \phi_2(a_i y - b_i x) + \dots + x^{k-1} \phi_k(a_i y - b_i x)] \quad (20)$$

or

$$z = e^{-c_i x/a_i} \sum_{j=1}^k x^{j-1} \phi_j(a_i y - b_i x).$$

Special case:

When the total degree of each term in $F(D_x, D_y)$ is same (i.e., the derivatives involved are *all* of the same order) then the above analysis gets simplified. Replacing D_x by m and D_y by 1 (or equivalently D_x/D_y by m) in the differential operator $F(D_x, D_y)$ we get an *auxiliary equation* (A.E.) of the form

$$F(m, 1) = 0 \quad (21)$$

which is an n th degree polynomial in m having n roots. Then the general solution (G.S.) of $F(D_x, D_y)z = 0$ is given as follows depending on the nature of the roots of the auxiliary equation (21).

Case i : n distinct real roots: $m_1 \neq m_2 \neq \dots \neq m_n$ then the general solution is

$$z = \phi_1(y + m_1 x) + \phi_2(y + m_2 x) + \dots + \phi_n(y + m_n x).$$

Case ii : One root of multiplicity k , so that

$$m_1 = m_2 = \dots = m_k \neq m_{k+1} \neq \dots \neq m_n.$$

Then G.S. is

$$z = \phi_1(y + m_1 x) + x \phi_2(y + m_1 x) + x^2 \phi_3(y + m_1 x) + \dots + x^{k-1} \phi_k(y + m_1 x) + \phi_{k+1}(y + m_{k+1} x) + \dots + \phi_n(y + m_n x).$$

Case iii : If m_1, m_2 are complex conjugate pair say $m_1 = a + bi, m_2 = a - bi$ then general solution is

$$z = \phi_1(y + ax + ibx) + \phi_1(y + ax - ibx) + i \{\phi_2(y + ax + ibx) - \phi_2(y + ax - ibx)\} + \phi_3(y + m_3 x) + \dots + \phi_n(y + m_n x).$$

WORKED OUT EXAMPLES

Complementary functions

Example 1: Find the complementary function of the following P.D.E. (a to g)

$$(a) (D_x^3 - 3D_x^2 D_y + 2D_y^2 D_x)z = 0$$

Solution: Auxiliary equation (A.E.) is obtained by replacing D_x by m and D_y by 1. So the A.E. is $m^3 - 3m^2 \cdot 1 + 2 \cdot 1^2 \cdot m = 0$ or $m(m-1)(m-2) = 0$ i.e., roots are $m = 0, 1, 2$. Then the complementary function (C.F.) is

$$z = \phi_1(y + 0 \cdot x) + \phi_2(y + x) + \phi_3(y + 2x)$$

$$(b) 25r - 40s + 16t = 0 \text{ or } (25D_x^2 - 40D_x D_y + 16D_y^2)z = 0$$

Solution: A.E.: $25m^2 - 40m + 16 = 0$ or $(5m - 4)^2 = 0$ so double roots are $m = \frac{4}{5}, \frac{4}{5}$. Then C.F. is

$$z = \phi_1 \left(y + \frac{4}{5}x \right) + x \phi_2 \left(y + \frac{4}{5}x \right)$$

or $z = f_1(5y + 4x) + xf_2(5y + 4x)$

$$(c) (D_x^4 + D_x^3 D_y - 3D_x^2 D_y^2 - 5D_x D_y^3 - 2D_y^4)z = 0$$

Solution: A.E. is $m^4 + m^3 - 5m - 2 = 0$, or $(m - 2)(m + 1)^3 = 0$ so roots are $m = 2, -1, -1, -1$ with -1 repeated three times. Then C.F. is

$$z = \phi_1(y + 2x) + \phi_2(y - x) + x\phi_3(y - x) + x^2\phi_4(y - x)$$

$$(d) r + b^2t = 0 \text{ or } (D_x^2 + b^2D_y^2)z = 0$$

Solution: A.E.: $m^2 + b^2 = 0$ with complex conjugate roots $m = \pm bi$. The complementary function is

$$z = \phi_1(y + ax + ibx) + \phi_1(y + ax - ibx) + i[\phi_2(y + ax + ibx) - \phi_2(y + ax - ibx)]$$

Here $a = 0$. So the C.F. is

$$z = \phi_1(y + ibx) + \phi_1(y - ibx) + i[\phi_2(y + ibx) - \phi_2(y - ibx)]$$

$$(e) (D_x + 2D_y - 3)(D_x + D_y - 1)z = 0$$

Solution: If $aD_x + bD_y + c$ is a factor then the solution is $z = e^{-\frac{c}{a}x}\phi(bx - ay)$.

For the first factor $a = 1, b = 2, c = -3$ and for the second factor $a = 1, b = 1, c = -1$. So the C.F. is

$$z = e^{-\left(\frac{-3}{1}\right)x}\phi_1(2x - y) + e^{-\left(\frac{-1}{1}\right)x}\phi_2(x - y).$$

or

$$z = e^{3x}\phi_1(2x - y) + e^x\phi_2(x - y)$$

$$(f) (D_x + 2D_y)(+D_x + 3D_y + 1)(D_x + 2D_y + 2)^2z = 0$$

Solution: Here the last factor is repeated twice. C.F. is

$$z = e^{0 \cdot x}\phi_1(2x - y) + e^{-1 \cdot x}\phi_2(3x - y) + e^{-2x}\{\phi_3(2x - y) + x\phi_4(2x - y)\}$$

(g) Irreducible:

$$(D_x^2 + D_x D_y - D_y^2 + D_x - D_y)z = 0$$

Solution: C.F. is $z = \sum_{i=1}^{\infty} c_i e^{a_i x + b_i y}$ where a_i, b_i satisfy the equation $a_i^2 + a_i b_i - b_i^2 + a_i - b_i = 0$ and c_i are arbitrary constants.

EXERCISE

Solve the following:

$$1. (D_x^2 - D_x D_y - 6D_y^2)z = 0$$

$$\text{Ans. } z = f(y - 2x) + g(y + 3x)$$

Hint: Roots of auxiliary equation are $-2, 3$

$$2. (D_x^3 - D_x^2 D_y - 8D_x D_y^2 + 12D_y^3)z = 0$$

$$\text{Ans. } z = f(y + 2x) + xg(y + 2x) + h(y - 3x)$$

Hint: Roots are $2, 2$ (double), -3

$$3. (D_x^4 - D_x^3 D_y + 2D_x^2 D_y^2 - 5D_x D_y^3 + 3D_y^4)z = 0$$

$$\text{Ans. } z = f_1(y + x) + xf_2(y + x) + f_3\left[y - \frac{1}{2}(1 + i\sqrt{11}x)\right] + f_3\left[y - \frac{1}{2}(1 - i\sqrt{11}x)\right] + i\left[f_4\left\{y - \frac{1}{2}(1 + i\sqrt{11}x)\right\} - f_4\left\{y - \frac{1}{2}(1 - i\sqrt{11}x)\right\}\right]$$

Hint: Roots $1, 1$ (double), $\frac{-1}{2}(1 \pm i\sqrt{11})$ (complex conjugate).

$$4. (2D_x^2 + 5D_x D_y + 2D_y^2)z = 0$$

$$\text{Ans. } z = f(y - 2x) + g\left(y - \frac{1}{2}x\right) \text{ or } = f(y - 2x) + h(2y - x)$$

Hint: Roots $-2, -\frac{1}{2}$

$$5. (D_x^2 + 6D_x D_y + 9D_y^2)z = 0$$

$$\text{Ans. } z = f(y - 3x) + xg(y - 3x)$$

Hint: $m = -3, -3$ (repeated root)

$$6. (D_x^4 - D_y^4)z = 0$$

$$\text{Ans. } z = f_1(y + x) + f_2(y - x) + f_3(y + ix) + f_3(y - ix) + i[f_4(y + ix) - f_4(y - ix)]$$

$$7. (D_x^2 - a^2 D_y^2)z = 0$$

$$\text{Ans. } z = f(y + ax) + g(y - ax)$$

Hint: Roots $\pm a$

$$8. (9D_x^2 + 24D_x D_y + 16D_y^2)z = 0$$

$$\text{Ans. } z = f\left(y - \frac{4}{3}x\right) + xg\left(y - \frac{4}{3}x\right) \text{ or } z = f_1(3y - 4x) + xg_1(3y - 4x)$$

Hint: Roots: $-\frac{4}{3}, -\frac{4}{3}$ (repeated)

$$9. (2D_x + D_y + 1)(D_x^2 + 3D_x D_y - 3D_x)z = 0$$

$$\text{Ans. } z = f_1(y) + e^{-x/2} \cdot f_2(2y - x) + e^{3x} f_3(y - 3x)$$

or

$$z = f_1(y) + e^{-y} f_2(2y - x) + f_3(y - 3x)$$

$$10. (2D_x + D_y + 5)(D_x - 2D_y + 1)^2 z = 0$$

$$\text{Ans. } z = e^{-5y} f_1(2y - x) + e^{-x} [f_2(y + 2x) + x f_3(y + 2x)]$$

$$11. (D_x^2 - D_y^2 + 3D_x - 3D_y)z = 0$$

$$\text{Ans. } z = f_1(y + x) + e^{-3x} f_2(y - x)$$

$$12. (2D_x + 3D_y - 1)^2 (D_x - 3D_y + 3)^3 z = 0$$

$$\text{Ans. } z = e^{\frac{x}{2}} [f_1(2y - 3x) + x f_2(2y - 3x)] + e^y [f_3(y + 3x) + y f_4(y + 3x) + y^2 f_5(y + 3x)]$$

$$13. (D_x^4 + D_y^4 - 2D_x^2 D_y^2)z = 0 \text{ (biharmonic equation)}$$

$$\text{Ans. } z = x f_1(x - y) + f_2(x - y) + x f_3(x + y) + f_4(x + y)$$

Hint: Root 1, -1 (both repeated twice)

$$14. (D_x^3 - 3D_x^2 D_y + 2D_x D_y^2)z = 0$$

$$\text{Ans. } z = f_1(y) + f_2(y + x) + f_3(y + 2x)$$

Hint: Roots: 0, 1, 2

$$15. (D_x^3 - 6D_x^2 D_y + 11D_x D_y^2 - 6D_y^3)z = 0$$

$$\text{Ans. } z = f_1(y + x) + f_2(y + 2x) + f_3(y + 3x)$$

18.7 NON-HOMOGENEOUS LINEAR PARTIAL DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

A partial differential equation of the form

$$F(D_x, D_y) = f(x, y) \quad (1)$$

is known as a non-homogeneous linear equation with constant coefficients. The general solution of the corresponding homogeneous equation

$$F(D_x, D_y) = 0 \quad (2)$$

is known as the “complementary function (C.F.)” of (1). Any solution of (1) is known as the “particular integral” (P.I.) of (1). Then the general solution of the non-homogeneous equation (1) is the sum of the complementary function z_c and the particular integral z_p . Thus

$$\begin{aligned} \text{General solution} &= \text{complementary function} \\ &+ \text{particular integral} \\ (\text{G.S} = \text{C.F.} + \text{P.I.}) \quad (3) \end{aligned}$$

Methods of obtaining complementary function were considered in detail in this section.

Methods of Obtaining Particular Integral

Suppose $F(D_x, D_y)$ is factored into m linear factors so that (1) takes the form

$$\begin{aligned} F(D_x, D_y) &= (D_x - m_1 D_y)(D_x - m_2 D_y) \dots \\ &\dots (D_x - m_n D_y) = f(x, y) \end{aligned}$$

Then the particular integral is

$$z_p = \frac{1}{(D_x - m_1 D_y) \dots (D_x - m_n D_y)} f(x, y) \quad (4)$$

$$\begin{aligned} \text{or } z_p &= \left(\frac{1}{(D_x - m_1 D_y)} \right) \left(\frac{1}{(D_x - m_2 D_y)} \right) \dots \\ &\dots \left(\frac{1}{(D_x - m_{n-1} D_y)} \right) \left(\frac{1}{(D_x - m_n D_y)} \right) f(x, y) \end{aligned}$$

By introducing $u_1 = \frac{1}{D_x - m_n D_y} f(x, y)$, $u_2 = \frac{1}{D_x - m_{n-1} D_y} u_1$, ..., $z = u_n = \frac{1}{D_x - m_1 D_y} u_{n-1}$ the solution of (4) reduces to solution of above n first order equations which can be solved by the following, book work.

Book work: Prove that the particular integral of $p - mq = g(x, y)$ is given by $z = \int g(x, a - mx) dx$ where a is replaced by $y + mx$ after integration. Also the constant of integration is omitted.

Proof: The auxiliary system of the first order linear equation

$$p - mq = g(x, y)$$

$$\text{is } \frac{dx}{1} = \frac{dy}{-m} = \frac{dz}{g(x, y)}$$

From $\frac{dx}{1} = \frac{dy}{-m}$, we get $y + mx = \text{constant} = a$.

From $\frac{dx}{1} = \frac{dz}{g(x,y)}$ we get

$$z = \int g(x, y) dx$$

Substituting $y = a - mx$,

$$z = \int g(x, a - mx) dx$$

Here the constant of integration is omitted and a is replaced by $y + mx$ after integration.

Special case: If $F(D_x, D_y)$ is a homogeneous function of D_x and D_y of degree n and RHS function $f(x, y)$ is of the form $\phi(ax + by)$, then a particular integral of equation

$$F(D_x, D_y) = f(x, y) \quad (1)$$

is given by $z_p = \frac{1}{F(D_x, D_y)} \phi(ax + by)$

$$\text{or } \boxed{z_p = \frac{1}{F(a,b)} \int \int \dots \int \phi(v) dv^n}, F(a, b) \neq 0$$

where $v = ax + by$, i.e., integrate $\phi(v)$ w.r.t v , n times and after integration replace v by $ax + by$, provided $F(a, b) \neq 0$.

If $F(a, b) = 0$ so that

$F(D_x, D_y) = (bD_x - aD_y)^m G(D_x, D_y)$, $G(a, b) \neq 0$, then the particular integral is

$$z_p = \frac{1}{(bD_x - aD_y)^m} \phi(ax + by)$$

$$\boxed{z_p = \frac{x^m}{b^m m!} \phi(ax + by)}$$

Short Methods of Obtaining Particular Integrals

The inverse operator short methods of obtaining particular integrals similar to those used in ordinary differential equations are listed here.

Case 1: $f(x, y) = e^{ax+by}$

$$\text{P.I. : } z = \frac{1}{F(D_x, D_y)} e^{ax+by} = \frac{1}{F(a, b)} e^{ax+by}$$

provided $F(a, b) \neq 0$.

Case 2: If $F(a, b) = 0$ then $F(D_x, D_y) = (D_x -$

$\frac{a}{b} D_y)^r g(D_x, D_y)$ so that $g(a, b) \neq 0$. Thus

$$\begin{aligned} \text{P.I. : } z &= \frac{1}{(D_x - \frac{a}{b} D_y)^r} \frac{1}{g(D_x, D_y)} e^{ax+by} \\ &= \frac{1}{g(a, b)} \cdot \frac{x^r}{r!} e^{ax+by} \end{aligned}$$

provided $g(a, b) \neq 0$.

Case 3: $f(x, y) = \sin(ax + by)$ or $\cos(ax + by)$. Replace D_x^2 by $-a^2$, D_y^2 by $-b^2$ and $D_x \cdot D_y$ by $-ab$. Thus

$$\begin{aligned} &\frac{1}{F(D_x^2, D_x D_y, D_y^2)} \sin(ax + by) \\ &= \frac{1}{F(-a^2, -ab, -b^2)} \sin(ax + by) \end{aligned}$$

and

$$\begin{aligned} &\frac{1}{F(D_x^2, D_x D_y, D_y^2)} \cos(ax + by) \\ &= \frac{1}{F(-a^2, -ab, -b^2)} \cos(ax + by) \end{aligned}$$

provided $F(-a^2, -ab, -b^2) \neq 0$.

Note: If $F(-a^2, -ab, -b^2) = 0$, then use the Book work stated above.

Case 4: $f(x, y) = x^m y^n$ where m and n are positive constants. Then particular integral is

$$z_p = \frac{1}{F(D_x, D_y)} x^m y^n = [F(D_x, D_y)]^{-1} x^m y^n$$

(a) If $n < m$, $\frac{1}{F(D_x, D_y)}$ is expanded in powers of $\frac{D_y}{D_x}$.

(b) If $m < n$, $\frac{1}{F(D_x, D_y)}$ is expanded in powers of $\frac{D_x}{D_y}$.

Note: Although the answers in (a) and (b) are different, the difference can be merged into the arbitrary functions of C.F.

Case 5: Exponential shift: $f(x, y) = e^{ax+by} \cdot V(x, y)$ where $V(x, y)$ is any function of x and y . Then

$$\begin{aligned} z_p &= \frac{1}{F(D_x, D_y)} \{e^{ax+by} \cdot V(x, y)\} \\ &= e^{ax+by} \frac{1}{F(D_x + a, D_y + b)} V(x, y) \end{aligned}$$

WORKED OUT EXAMPLES

Example 1: Obtain the particular solution of $p - 2q = \sin(x + 2y)$

$$\text{Solution: } \frac{dx}{1} = \frac{dy}{-2} = \frac{dz}{\sin(x+2y)}$$

Integrating $y + 2x = c_1$. From (1) and (3), we have $z = \int \sin(x + 2y)dx = \int \sin(x + 2(c_1 - 2x))dx$ since $y = c_1 - 2x$. So

$$z = \int \sin(2c_1 - 3x)dx = \frac{\cos(3x-2c_1)}{3}.$$

$$\text{Replacing } c_1 \text{ by } y + 2x, \quad z = \frac{\cos(3x-2(y+2x))}{-3} = \frac{\cos(x+2y)}{3}.$$

Thus the particular integral is $3z = \cos(x + 2y)$.

Example 2: Solve $(D_x^2 + 5D_x D_y + 6D_y^2)z = e^{x-y}$

Solution: A.E. is $m^2 + 5m + 6 = 0$ or $(m + 2)(m + 3) = 0$. So C.F. is $z_c = \phi_1(y - 2x) + \phi_2(y - 3x)$.

P.I. is $z_p = \frac{1}{f(D_x, D_y)} e^{x-y} = \frac{1}{(D_x^2 + 5D_x D_y + 6D_y^2)} e^{x-y}$. Here $a = 1, b = -1$, so replace D_x by $a = 1, D_y$ by $b = -1$. Then

$$z_p = \frac{1}{1^2 + 5 \cdot 1(-1) + 6(-1)^2} e^{x-y} = \frac{1}{2} e^{x-y}.$$

Then the general solution is

$$z = C.F. + P.I. = \phi_1(y - 2x) + \phi_2(y - 3x) + \frac{1}{2} e^{x-y}$$

Example 3: Solve $4r + 12s + 9t = e^{3x-2y}$

Solution: P.D.E. is $(4D_x^2 + 12D_x D_y + 9D_y^2)z = e^{3x-2y}$.

A.E. is $4m^2 + 12m + 9 = 0$ or $(2m + 3)^2 = 0$ i.e., $m = -\frac{3}{2}, -\frac{3}{2}$. (repeated roots)

So C.F. is $z_c = f_1(y - \frac{3}{2}x) + x f_2(y - \frac{3}{2}x) = \phi_1(2y - 3x) + x \phi_2(2y - 3x)$.

$$\text{P.I.: } z_p = \frac{1}{4D_x^2 + 12D_x D_y + 9D_y^2} e^{3x-2y} = \frac{1}{4[D_x - (-\frac{3}{2})D_y]^2} e^{3x-2y}$$

Here $a = 3, b = -2$. Since $-\frac{3}{2}$ is a (double) root of the A.E. this is a failure case and D_x and D_y can not be replaced by 3 and -2 respectively because $f(+3, -2) = 0$. Applying the B.W. (on page 18.22) we get

$$\text{P.I.: } z_p = \frac{1}{4} \cdot \frac{x^2}{2!} e^{3x-2y}. \text{ Thus G.S. } z = C.F. + P.I. = \phi_1(2y - 3x) + x \phi_2(2y - 3x) + \frac{1}{8} x^2 e^{3x-2y}$$

Aliter: Put $u = (D_x + \frac{3}{2}D_y)z$, then PDE reduces to

$$(4D_x^2 + 12D_x D_y + 9D_y^2)z = 4 \left(D_x + \frac{3}{2}D_y \right)^2 z = 4 \left(D_x + \frac{3}{2}D_y \right) u = e^{3x-2y}.$$

Solution is $u = \int F(x, c - mx)dx$. Here $y - \frac{3}{2}x = c_1$ or $2y - 3x = c$. Then $u = \int e^{3x-2y}dx = \int e^{3x-(c+3x)}dx = e^{-c} \int dx = x e^{-c}$.

Thus $u = x e^{-2y+3x}$. Now $4(D_x + \frac{3}{2}D_y)z = u = x e^{3x-2y}$. Solution by BW (see page 18.22) $z = \frac{1}{4} \int F(x, c - mx)dx$. Here $2y - 3x = c$.

$$z = \frac{1}{4} \int x e^{3x-2y} dx = \frac{1}{4} \int x e^{-c} dx = \frac{e^{-c}}{4} \int x dx = \frac{e^{-c} x^2}{2} = \frac{1}{4} \frac{x^2}{2} \cdot e^{-c} = \frac{x^2}{8} e^{3x-2y}$$

Example 4: Solve $\frac{\partial^2 z}{\partial x^2} - 2 \frac{\partial^2 z}{\partial x \partial y} + \frac{\partial^2 z}{\partial y^2} = \sin x$.

Solution: A.E.: $m^2 - 2m + 1 = 0$ or $(m - 1)^2 = 0$ with repeated (double) roots 1, 1. So C.F. is

$$z_c = \phi_1(y + x) + x \phi_2(y + x).$$

$$\text{P.I.: } z_p = \frac{1}{D_x^2 - 2D_x D_y + D_y^2} \cdot \sin x.$$

Here $a = 1, b = 0$. Replace D_x^2 by $-m^2 = -1^2 = -1, D_y^2 = -n^2 = 0$ and $D_x D_y = -m \cdot n = -1 \cdot 0 = 0$, then

$$P.I.: z_p = \frac{1}{-1 - 0 - 0} \sin x = -\sin x.$$

Thus

$$z = \text{G.S.} = C.F. + P.I. = \phi_1(y + x) + x \phi_2(y + x) - \sin x$$

Example 5: Solve $r - 2s = \sin x \cdot \cos 2y$

Solution: PDE is $\frac{\partial^2 z}{\partial x^2} - 2 \frac{\partial^2 z}{\partial x \partial y} = \sin x \cdot \cos 2y$.

AE is $m^2 - 2m = m(m - 2) = 0$ i.e., $m = 0, 2$

C.F. $z_c = f_1(y + 0x) + f_2(y + 2x)$

P.I. $z_p = \frac{1}{D_x^2 - 2D_x D_y} \sin x \cdot \cos 2y$

$$= \frac{1}{2} \cdot \frac{1}{D_x^2 - 2D_x D_y} [\sin(x + 2y) + \sin(x - 2y)]$$

Using the result (on page 18.23) (with $a = 1, b = 2$ for the first term and $a = 1, b = -2$ for the second term)

$$= \frac{1}{2} \left[\frac{1}{-1^2 - 2 \cdot 0(-2)} \sin(x + 2y) + \frac{1}{-1^2 - 2 \cdot 0(+2)} \sin(x - 2y) \right]$$

$$= \frac{1}{2} \left[\frac{1}{3} (\sin x \cdot \cos 2y + \sin 2y \cdot \cos x) - \frac{1}{5} (\sin x \cdot \cos 2y - \sin 2y \cdot \cos x) \right]$$

$$= \frac{1}{15} \sin x \cdot \cos 2y + \frac{4}{15} \sin 2y \cdot \cos x$$

$$z = \text{G.S.} = \text{C.F.} + \text{P.I.} = f_1(y) + f_2(y + 2x)$$

$$+ \frac{1}{15} (\sin x \cos 2y + 4 \sin 2y \cdot \cos x)$$

Example 6: Solve $(2D_x^2 - 5D_x D_y + 2D_y^2)z = 5 \sin(2x + y)$

Solution: A.E. is $2m^2 - 5m + 2 = 0$ or $(2m - 1)(m - 2) = 0$ i.e., $m = \frac{1}{2}, 2$. So C.F. is $z_c = \phi_1(y + \frac{1}{2}x) + \phi_2(y + 2x)$ or

$z_c = \phi_3(2y + x) + \phi_2(y + 2x)$.

Here $a = 2, b = 1$. Note $a = 2$ is a root of the A.E.

$$\text{P.I.} : z_p = \frac{1}{2D_x^2 - 5D_x D_y + 2D_y^2} 5 \cdot \sin(2x + y)$$

$$= \frac{5}{2} \frac{1}{D_x^2 - \frac{5}{2} D_x D_y + D_y^2} \sin(2x + y)$$

$$= \frac{5}{2} \frac{1}{(D_x - \frac{1}{2} D_y)(D_x - 2D_y)} \sin(2x + y)$$

At $D_x^2 = -a^2 = -4, D_y^2 = -b^2 = -1, D_x D_y = -a \cdot b = -2, f(D_x, D_y) = 2D_x^2 - 5D_x D_y + 2D_y^2 = 0$. So rewriting

$$(2D_x - D_y)(D_x - 2D_y)z = 5 \sin(2x + y)$$

Put $u = (D_x - 2D_y)z$ then $(2D_x - D_y)u = 5 \sin(2x + y)$

$$u = \frac{5}{2D_x - D_y} \cdot \sin(2x + y).$$

Here $2y + x = x$, or $y = \frac{c-x}{2}$.

$$u = 5 \int \sin \left(2x + \frac{c-x}{2} \right) dx$$

$$= 5 \int \sin \left(\frac{3x+c}{2} \right) dx$$

$$\text{Integrating, } u = 5 \cdot \frac{2}{3} (-\cos(\frac{3x+c}{2}))$$

$$= \frac{-10}{3} \cdot \cos \left(\frac{3x+2y+x}{2} \right) = \frac{-10}{3} \cos(2x + y)$$

$$\text{Now P.I.} := z_p = \frac{1}{D_x - 2D_y} [u] =$$

$$\frac{1}{D_x - 2D_y} \left[\frac{-10}{3} \cos(2x + y) \right]$$

Using $y + 2x = c$,

$$z_p = \int \frac{-10}{3} \cdot \cos c dx = \frac{-10}{3} \cos c \int dx$$

$$= \frac{-10}{3} \cdot x \cdot \cos c = \frac{-10}{3} \cdot x \cdot \cos(y + 2x)$$

Thus G.S. = C.F. + P.I.

$$z = f_1(y + 2x) + f_2(2x) - \frac{10}{3} \cdot x \cdot \cos(y + 2x)$$

Example 7: Solve $(D_x^2 + D_y^2)z = x^2 y^2$

Solution: A.E.: $m^2 + 1 = 0$ or $m = \pm i$. So

C.F.: $z_c = \phi_1(y + ix) + \phi_1(y - ix)$

$+ i[\phi_2(y + ix) - \phi_2(y - ix)]$

$$\text{P.I.} : z_p = \frac{1}{D_x^2 + D_y^2} x^2 y^2 = \frac{1}{D_x^2} \left[\frac{1}{1 + \left(\frac{D_y}{D_x} \right)^2} \right] x^2 y^2$$

Expanding by binomial series

$$= \frac{1}{D_x^2} \left[1 - \left(\frac{D_y}{D_x} \right)^2 + \left(\frac{D_y}{D_x} \right)^4 + \dots \right] x^2 y^2$$

$$= \frac{1}{D_x^2} (x^2 y^2) - \frac{1}{D_x^4} D_y^2 (x^2 y^2) + 0 + \dots$$

18.26 — HIGHER ENGINEERING MATHEMATICS—V

Integrating and differentiating

$$= \frac{1}{D_x} \frac{x^3}{4} y^2 - \frac{1}{D_x^4} 2x^2 = \frac{x^4}{12} y^2 - 2 \cdot \frac{x^6}{3 \cdot 4 \cdot 5 \cdot 6}$$

$$z_p = \frac{1}{180} (15x^4 y^2 - x^6).$$

Thus G.S. = C.F. + P.I. = $z_c + z_p$

$$z = \phi_1(y + ix) + \phi_1(y - ix)$$

$$+ i[\phi_2(y + ix) - \phi_2(y - ix)]$$

$$+ \frac{1}{180} (15x^4 y^2 - x^6)$$

Exponential shift

Example 1: Solve $z_{xx} - z_{xy} - 2z_{yy} = (y - 1)e^x$

Solution: $(D_x^2 - D_x D_y - 2D_y^2)z = (y - 1)e^x$

A.E.: $m^2 - m - 2 = 0$ or $(m + 1)(m - 2) = 0$
 $\therefore m = -1, 2$

C.F.: $z_c = f_1(y - x) + f_2(y + 2x)$

P.I.: $z_p = \frac{1}{D_x^2 - D_x D_y - 2D_y^2} (y - 1)e^x$

Applying exponential shift with $a = 1, b = 0$

$$z_p = \frac{e^x}{(D_x + 1)^2 - (D_x + 1)D_y - 2D_y^2} (y - 1)$$

$$= e^x \frac{1}{1 + (D_x^2 + 2D_x - D_x D_y - D_y - 2D_y^2)} (y - 1)$$

$$= e^x [1 - (D_x^2 + 2D_x - D_x D_y - D_y - 2D_y^2)$$

$$+ \dots](y - 1)$$

$$= e^x [(y - 1) - (0 + 0 - 0 - 1 - 0) + \dots] = ye^x$$

$$\therefore \text{G.S.} : z = \text{C.F.} + \text{P.I.} = z_c + z_p = f_1(y - x) +$$

$$+ f_2(y + 2x) + ye^x$$

Method of undetermined coefficients

Example 1: Solve $(D_x^2 + D_x D_y - 6D_y^2)z = x^2 \sin(x + y)$

Solution: A.E.: $m^2 + m - 6 = 0$ or $(m - 2)(m + 3) = 0$ so $m = 2, -3$.

C.F.: $z_c = f_1(y + 2x) + f_2(y - 3x)$.

To find the particular integral, use the method of undetermined coefficients. So assume the P.I. as $z_p = x^2(A \sin(x + y) +$

$B \cos(x + y)) + x(C \sin(x + y) + D \cos(x + y))$
 $+ (E \sin(x + y) + F \cos(x + y))$

or

$z_p = (Ax^2 + Cx + E) \sin(x + y) + (Bx^2 + Dx + F) \cos(x + y)$

Differentiating z partially w.r.t. x and y , we get

$z_x = (2Ax + C - Bx^2 - Dx - F) \sin(x + y) +$
 $(Ax^2 + Cx + E + 2Bx + D) \cos(x + y)$

$z_{xx} = (2A - Ax^2 - Cx - E - 4Bx - 2D) \sin(x + y)$
 $+ (4Ax + 2C + 2B - Bx^2 - Dx - F) \cos(x + y).$

$z_{xy} = -(Ax^2 + Cx + E + 2Bx + D) \sin(x + y) +$
 $+(2Ax + C - Bx^2 - D \cdot x - F) \cos(x + y)$

$z_{yy} = -(Ax^2 + Cx + E) \sin(x + y) - (Bx^2 + D \cdot x$
 $+ F) \cos(x + y).$

Substituting these values in the given PDE, we obtain

$[(2A - Ax^2 - Cx - E - 4Bx - 2D) + (-Ax^2 - Cx - E - 2Bx - D) + 6(Ax^2 + Cx + E)]$
 $\times \sin(x + y) + [(4Ax + 2C + 2B - Bx^2 - Dx - F) + (2Ax + C - Bx^2 - D \cdot x - F) + 6(Bx^2 + Dx + F)] = x^2 \sin(x + y).$

Now equating the coefficients on both sides, we have

$x^2 \sin x : -A - A + 6A = 1 \therefore A = \frac{1}{4}$
 $x \sin x : -C - 4B - C - 2B + 6C = 0$

$\therefore 2C - 3B = 0$

$x^0 \sin x : 2A - E - 2D - E - D + 6E = 0$

$\therefore 3D - 4E = \frac{1}{2}$

$x^2 \cos x : -B - B + 6B = 0 \therefore B = 0 \therefore C = 0$

$x \cos x : 4A - D + 2A - D + 6D = 0 \therefore D = -\frac{3}{8}$

$\therefore E = \frac{-13}{32}$

$x^0 \cos x : 2C + 2B - F + C - F + 6F = 0$

$\therefore F = 0$

Thus $A = \frac{1}{4}, B = C = 0, D = -\frac{3}{8}, E = \frac{-13}{32}, F = 0.$

Hence the P.I. is

$z_p = \frac{1}{4} x^2 \sin(x + y) - \frac{13}{32} \sin(x + y) - \frac{3}{8} x \cos(x + y)$

Thus G.S. = $z = \text{C.F.} + \text{P.I.} = z_c + z_p.$

Example 2: Solve $(D_x^2 - 2D_x D_y + D_y^2)z = \tan(y + x).$

Solution: $(D_x - D_y)^2 z = \tan(y + x).$ So the complementary function is $z_c = \phi_1(y + x) + x\phi_2(y + x).$ Now particular integral is $z_p = \frac{1}{(D_x - D_y)^2} \tan(y + x).$ Since $F(D_x, D_y) = (D_x - D_y)^2 = (1 - 1) = 0.$ So applying the result, on page 18.23 $z_p = \frac{x^2}{2!} \tan(y + x).$ Thus the general solution is $z = \phi_1(y + x) + x\phi_2(y + x) + \frac{x^2}{2} \tan(y + x).$

Example 3: Solve $(D_x^2 + 3D_x D_y + D_x + 2D_y^2 - 2)z = e^{3x+4y} + y(1-2x)$.

Solution: Factorizing the L.H.S. we have $(D_x + D_y - 1)(D_x + 2D_y + 2)z = e^{3x+4y} + y(1-2x)$. For the first factor $(D_x + D_y - 1)$, the associated solution is $e^x \phi_1(y-x)$ with $a = 1, b = 1, c = -1$ and for the second factor $D_x + 2D_y + 2$, the associated solution is $e^{-y} \phi_2(y-2x)$ with $a = 1, b = 2, c = 2$. Then the complementary function z_p is $z_p = e^x \phi_1(y-x) + e^{-y} \phi_2(y-2x)$. Now the particular integral is

$z_p =$

$$\frac{1}{(D_x + D_y - 1)(D_x + 2D_y + 2)} \cdot [e^{3x+4y} + y(1-2x)]$$

$$z_p = I_1 + I_2$$

For $I_1 = \frac{1}{(D_x + D_y - 1)(D_x + 2D_y + 2)} e^{3x+4y}$

$$= \frac{1}{(3+4-1)(3+8+2)} e^{3x+4y}$$

with $a = 3, b = 4$

$$I_1 = \frac{1}{78} e^{3x+4y}$$

Now

$$I_2 = \frac{1}{(D_x + D_y - 1)(D_x + 2D_y + 2)} y(1-2x)$$

Consider $\frac{1}{(D_x + D_y - 1)} y(1-2x) =$

$$\frac{-1}{1 - (D_x + D_y)} y(1-2x) = -[1 + (D_x + D_y) +$$

$$(D_x + D_y)^2 + \dots][y(1-2x)]$$

$$= -[(y-2xy) - 2y + 1 - 2x + 0 + 0 + 2(-2)]$$

$$= (2xy + y + 2x + 3)$$

Then $I_2 = \frac{1}{D_x + 2D_y + 2} (2xy + y + 2x + 3)$

$$= \frac{1}{2} \frac{1}{1 + \left(\frac{D_x}{2} + D_y\right)} (2xy + y + 2x + 3)$$

$$= \frac{1}{2} \left[1 - \left(\frac{D_x}{2} + D_y\right) + \left(\frac{D_x}{2} + D_y\right)^2 + \dots \right]$$

$$[2xy + y + 2x + 3] = \frac{1}{2} [(2xy + y + 2x + 3) -$$

$$\frac{1}{2}(2y+2) - (2x+1) + \frac{1}{4} \cdot 0 + 0 + 2]$$

$$= \frac{1}{2} [2xy + 0 + 0 + 3] = xy + \frac{3}{2}.$$

Thus the particular integral is

$$z_p = \frac{1}{78} e^{3x+4y} + \left(xy + \frac{3}{2}\right)$$

Hence the general solution is

$$z = z_c + z_p = e^x \phi_1(y-x) + e^{-y} \phi_2(y-2x) + \frac{1}{78} e^{3x+4y} + xy + \frac{3}{2}.$$

Example 4: Solve $(3D_x D_y - 2D_y^2 - D_y)z = \cos(3y+2x)$

Solution: Rewriting $D_y(3D_x - 2D_y - 1)z = \cos(3y+2x)$

For D_y the corresponding solution is $\phi_1(x)$ and for $(3D_x - 2D_y - 1)$ the corresponding solution is $e^{y/2} \phi_2(3y+2x)$ with $a = 3, b = -2, c = -1$. Then the complementary function is

$$z_c = \phi_1(x) + e^{y/2} \phi_2(3y+2x).$$

The particular integral is

$$z_p = \frac{1}{3D_x D_y - 2D_y^2 - D_y} \cdot \cos(3y+2x)$$

Here $a = 2, b = 3$. So replace D_y^2 by $-b^2 = -3^2 = -9$ and replace $D_x D_y$ by $-a \cdot b = -2 \cdot 3 = -6$.

Then $z_p = \frac{1}{3(-6) - 2(-9) - D_y} \cos(3y+2x)$

$$= -\frac{1}{D_y} \cos(3y+2x)$$

$$z_p = -\frac{\sin(3y+2x)}{3}$$

Thus the general solution is

$$z = z_c + z_p = \phi_1(x) + e^{y/2} \phi_2(3y+2x) - \frac{1}{3} \sin(3y+2x)$$

Example 5: Solve $(6D_x^2 + 5D_x D_y - 6D_y^2)z = 132 \log(x+3y)$

Solution: Rewriting $(2D_x + 3D_y)(3D_x - 6D_y)z = 132 \log(x+3y)$. For the first factor $a = 2, b = 3$ so the corresponding solution is $\phi_1(2x+3y)$.

For the second factor $a = 3, b = -2$ so the corresponding solution is $\phi_2(3x-2y)$. Thus the complementary function is

$$z_c = \phi_1(2x+3y) + \phi_2(3x-2y).$$

18.28 — HIGHER ENGINEERING MATHEMATICS—V

The particular integral is

$$z_p = \frac{1}{6D_x^2 + 5D_x D_y - 6D_y^2} [132 \log(x + 3y)]$$

Since the operator $F(D_x, D_y) = 6D_x^2 + 5D_x D_y - 6D_y^2$ is homogeneous of degree $n = 2$, the P.I. is obtained by integrating $132 \log v$, twice w.r.t. v and dividing by $F(a, b)$. Here $v = x + 3y$ and $a = 1$, $b = 3$. Thus the particular integral is

$$\begin{aligned} z_p &= \frac{132}{F(1, 3)} \int \int \ln v \, dv \, dv \\ &= \frac{132}{6 \cdot 1^2 + 5 \cdot 1 \cdot 3 - 6 \cdot 3^2 + \dots} \int \int \ln v \, dv \, dv \\ &= \frac{132}{-33} \int [v \ln v - v] \, dv = 4 \left[\frac{v^2}{2} - \int v \ln v \, dv \right] \\ &= 4 \left[\frac{v^2}{2} - \int \ln v \, d \left(\frac{v^2}{2} \right) \right] = 4 \left[\frac{v^2}{2} - \frac{v^2}{2} \cdot \ln v + \frac{1}{2} \frac{v^2}{2} \right] \\ &= v^2 [3 - 2 \ln v] \end{aligned}$$

Replacing v by $x + 3y$, we get P.I. as

$$z_p = (x + 3y)^2 [3 - 2 \ln(x + 3y)]$$

Then the general solution is

$$\begin{aligned} z &= z_c + z_p = \phi_1(2x + 3y) + \phi_2(3x - 2y) \\ &\quad + (x + 3y)^2 [3 - 2 \ln(x + 3y)] \end{aligned}$$

EXERCISE

Solve (obtain the general solution (G.S.))

1. $(D_x^2 - D_y^2)z = x - y$

Ans. $z = f_1(x + y) + f_2(x - y) + \frac{1}{4}x(x - y)^2$

2. $(D_x^2 + 3D_x D_y + 2D_y^2)z = x + y$

Ans. $z = f_1(y - x) + f_2(y - 2x) + \frac{1}{36}(x + y)^2$

3. $(4D_x^2 - 4D_x D_y + D_y^2)z = 16 \log(x + 2y)$

Ans. $z = f_1(2y + x) + x f_2(2y + x) + 2x^2 \log(x + 2y)$

4. $(D_x^2 + D_y^2)z = \cos mx \cdot \cos ny$

Ans. $z = f_1(y + ix) + f_2(y - ix) - \frac{\cos mx \cdot \cos ny}{(m^2 + n^2)}$

5. $(D_x^2 - 6D_x D_y + 9D_y^2)z = 12x^2 + 36xy$

Ans. $z = f_1(y + 3x) + x f_2(y + 3x) + 10x^4 + 6x^3y$

6. $(D_x^2 - D_y^2 + D_x + 3D_y - 2)z = e^{x-y} - x^2y$

Ans. $z = e^{-2x} f_1(y + x) + e^x f_2(y - x) - \frac{1}{4}e^{x-y} + \frac{1}{2} \left(x^2y + xy + \frac{3}{2}x^2 + \frac{3y}{2} + 3x + \frac{21}{4} \right)$

7. $(D_x - 3D_y - 2)^2 z = 2e^{2x} \tan(y + 3x)$

Ans. $z = e^{2x} [f_1(y + 3x) + x f_2(y + 3x)] + x^2 e^{2x} \tan(y + 3x)$

Hint: Use exponential shift.

8. $(D_x^2 + D_x D_y - 6D_y^2)z = y \cos x$

Ans. $z = f_1(y + 2x) + f_2(y - 3x) + \sin x - y \cos x$

9. $(D_x^2 + D_x D_y - 6D_y^2)z = \cos(2x + y)$

Ans. $z = \phi_1(y - 3x) + \phi_2(y + 2x) + \frac{x}{5} \sin(2x + y) + \frac{1}{25} \cos(2x + y)$

10. $(D_x^2 + 2D_x D_y + D_y^2 - 2D_x - 2D_y)z = \sin(x + 2y)$

Ans. $z = f_1(y - x) + e^{2x} f_2(y - x) + \frac{1}{39} [2 \cos(x + 2y) - 3 \sin(x + 2y)]$

11. $D_x^2 + 5D_x D_y + 5D_y^2 z = x \cdot \sin(3x - 2y)$

Ans. $z = f_1(y + (-5 + \sqrt{5})\frac{x}{2}) + f_2(y + (-5 - \sqrt{5})\frac{x}{2}) + x \sin(3x - 2y) + 4 \cos(3x - 2y)$

Hint: Assume P.I. as $Ax \sin(3x - 2y) + Bx \cos(3x - 2y) + C \sin(3x - 2y) + D \cos(3x - 2y)$. By method of undetermined coefficients $A = 1$, $B = C = 0$, $D = 4$.

12. $(D_x^3 + D_x^2 D_y - D_x D_y^2 - D_y^3)z = e^x \cos 2y$

Ans. $z = f_1(y - x) + x f_2(y - x) + f_3(y + x) + \frac{1}{25} e^x \cos 2y + \frac{2}{25} e^x \sin 2y$

Hint: a) Assume P.I. as $Ae^x \cos 2y + Be^x \sin 2y$ then $A = \frac{1}{25}$ and $B = \frac{2}{25}$

(b) Applying exponential shift

P.I. =

$$\begin{aligned} & e^x \frac{1}{(D_x + 1)^3 + (D_x + 1)^2 D_y - (D_x + 1) D_y^2 - D_y^3} \cdot \cos 2y, \\ & \text{(replace } D_x^2 = 0, D_y^2 = -4, D_x D_y = 0) \\ &= e^x \frac{D_y}{D_y(5D_y + 3D_x + 5)} \cos 2y \\ &= -\frac{2}{5} e^x \frac{1}{D_y - 4} \sin 2y = -\frac{2}{5} e^x \frac{D_y + 4}{D_y^2 - 16} \sin 2y \end{aligned}$$

$$= \frac{e^x}{50} (D_y + 4) \sin 2y$$

$$13. (D_x^3 - 7D_x D_y^2 - 6D_y^3)z = \sin(x + 2y) + e^{3x+y}$$

$$\text{Ans. } z = f_1(y - x) + f_2(y - 2x) + f_3(y + 3x) - \frac{1}{75} \cos(x + 2y) + \frac{x}{20} e^{3x+y}$$

$$14. (D_x^2 + 2D_x D_y - 8D_y^2)z = \sqrt{2x + 3y}$$

$$\text{Ans. } z = f_1(y + 2x) + f_2(y - 4x) - \frac{1}{210} (2x + 3y)^{5/2}$$

$$15. (D_x^3 - 7D_x D_y^2 - 6D_y^3)z = \cos(x - y) + x^2 + xy^2 + y^3$$

$$\text{Ans. } z = f_1(y - x) + f_2(y - 2x) + f_3(y + 3x) + \frac{1}{4}x \cos(x - y) + \frac{5}{72}x^6 + \frac{1}{60}x^5(1 + 21y) + \frac{1}{24}x^4y^2 + \frac{1}{6}x^3y^3$$

Find the particular integral (see pages 18.22 and 18.23)

$$16. p + 3q = \cos(2x + y)$$

$$\text{Ans. } z = \frac{1}{5} \sin(2x + y)$$

Hint: $y - 3x = c_1$,

$$z = \int \cos(2x + c_1 + 3x) dx$$

$$17. p - 2q = (y + 1)e^{3x}$$

$$\text{Ans. } z = \frac{1}{3} \left(y + \frac{5}{3} \right) e^{3x}$$

Hint: $y + 2x = c_1$,

$$z = \int [(c_1 - 2x) + 1] e^{3x} dx$$

$$18. (D_x^3 - 3D_x^2 D_y - 4D_x D_y^2 + 12D_y^3)z = \sin(y + 2x)$$

$$\text{Ans. } z = \frac{1}{4}x \sin(y + 2x).$$

$$\text{Hint: P.I.} = \frac{1}{(D_x + 2D_y)(D_x - 3D_y)(D_x - 2D_y)} \cdot \sin(y + 2x)$$

$$= \frac{1}{D_x^2 - D_x D_y - 6D_y^2} \cdot \frac{1}{(D_x - 2D_y)} \cdot \sin(y + 2x)$$

$$= -\frac{1}{4} \left(\frac{1}{D_x - 2D_y} \right) \sin(y + 2x).$$

$$\text{Now } \frac{dx}{1} = \frac{dy}{-2} = \frac{dz}{\sin y + 2x}, \quad y + 2x = c,$$

$$z = \int \sin(y + 2x) dx,$$

$$z = \sin c \int dx = x \cdot \sin c = x \cdot (y + 2x)$$

$$19. (D_x + D_y - 1)(D_x + D_y - 3)(D_x + D_y)z = e^{x+y+z} \cos(2x - y)$$

$$\text{Ans. } z = e^x \phi_1(y - x) + e^{3x} \phi_2(y - x) + \phi_3(y - x) - \frac{1}{10} e^{x+y+z} [\sin(2x - y) + 2 \cos(2x - y)]$$

Hint: Use exponential shift.

$$20. [D_x^2 + D_x D_y - 2D_y^2]z = 8 \ln(x + 5y)$$

$$\text{Ans. } z = \phi_1(2x - y) + \phi_2(x + y) + \frac{1}{22} [3 - 2 \ln(x + 5y)](x + 5y)^2$$

Hint: Since $F(D_x, D_y)$ is homogeneous of degree 2, integrate $8 \ln v$ twice w.r.t. v and divide by $F(1, 5)$. Here $v = x + 5y$.

$$21. (D_x^2 - D_x D_y)z = \cos x \cdot \cos 2y$$

$$\text{Ans. } z = \phi_1(y) + \phi_2(y + x) + \frac{1}{2} \cos(x + 2y) - \frac{1}{6} \cos(x - 2y)$$

$$22. (D_x^3 - 2D_x^2 D_y)z = 2e^{2x} + 3x^2 y$$

$$\text{Ans. } z = \phi_1(y) + x \phi_2(y) + \phi_3(y + 2x) + \frac{1}{60} (15e^{2x} + 3x^5 y + x^6)$$

$$23. (D_x^2 - 4D_x D_y + 4D_y^2)z = e^{2x+y}$$

$$\text{Ans. } z = \phi_1(y + 2x) + x \phi_2(y + 2x) + \frac{1}{2} x^2 e^{2x+y}$$

18.8 CAUCHY TYPE DIFFERENTIAL EQUATION

The partial differential equation of the form

$$F(x D_x, y D_y) = f(x, y)$$

with variable coefficients can be transformed to P.D.E. with constant coefficients by putting $x = e^u$ and $y = e^v$. Then $u = \ln x$, $v = \ln y$, $x \frac{\partial}{\partial x} = \frac{\partial}{\partial u}$, $x^2 \frac{\partial^2}{\partial x^2} = \frac{\partial}{\partial u} \left(\frac{\partial}{\partial u} - 1 \right)$ i.e. $x D_x = D_u$ and $x^2 D_x^2 = D_u (D_u - 1)$. Similarly $y D_y = D_v$ and $y^2 D_y^2 = D_v (D_v - 1)$. Here D_v is $\frac{\partial}{\partial v}$. The transformed equation in the new dependent variables u and v which is a D.E. with constant coefficients, is then solved using the above methods. In the solution $z(u, v)$, replace u by $\ln x$ and v by $\ln y$ to get the general solution $z(x, y)$.

WORKED OUT EXAMPLES

Euler-Cauchy equation

Example 1:

$$\text{Solve } (x^2 D_x^2 - y^2 D_y^2)z = x^2 y.$$

18.30 — HIGHER ENGINEERING MATHEMATICS—V

Solution: Put $x = e^u$, $y = e^v$ then $x^2y = e^{2u+v}$. Also $x D_x = D_u$, $x^2 D_x^2 = D_u(D_u - 1)$. Similarly $y D_y = D_v$, $y^2 D_y^2 = D_v(D_v - 1)$. Then the given D.E. in the new variables u and v is

$$[D_u(D_u - 1) - D_v(D_v - 1)]z = e^{2u+v}$$

$$(D_u - D_v)(D_u + D_v - 1)z = e^{2u+v}$$

The complementary function is

$$z_c = \phi_1(v + u) + e^u \phi_2(v - u)$$

$$\text{or } z_c = \phi_1(\ln y + \ln x) + x \phi_2(\ln y - \ln x)$$

$$z_c = \phi_1(\ln xy) + x \phi_2(\ln(y/x))$$

$$z_c = \psi_1(xy) + x \psi_2\left(\frac{y}{x}\right)$$

Now the particular integral is

$$z_p = \frac{1}{D_u^2 - D_u - D_v^2 + D_v} \cdot e^{2u+v}$$

Here $a = 2$, $b = 1$. Replace D_u by $a = 2$, D_v by $b = 1$.

$$\text{Then } z_p = \frac{1}{4 - 2 - 1 + 1} e^{2u+v} = \frac{1}{2} e^{2u+v}$$

$$\text{or } z_p = \frac{1}{2} x^2 y.$$

Hence the general solution is

$$z = z_c + z_p = \psi_1(xy) + x \psi_2\left(\frac{y}{x}\right) + \frac{1}{2} x^2 y$$

EXERCISE

$$1. (x^2 D_x^2 - 4xy D_x D_y + 4y^2 D_y^2 + 6y D_y)z = x^3 y^4$$

$$\text{Ans. } z = \phi_1(x^2 y) + x \phi_2(x^2 y) + \frac{1}{30} x^3 y^4$$

Hint: Put $x = e^u$, $y = e^v$ then

$$(D_u - 2D_v)(D_u - 2D_v - 1)z = e^{3u+4v}$$

where $D_u = \frac{\partial}{\partial u}$ and $D_v = \frac{\partial}{\partial v}$.

$$2. \left(\frac{1}{x^2} D_x^2 - \frac{1}{x^3} D_x - \frac{1}{y^2} D_y^2 + \frac{1}{y^2} D_y \right) z = 0$$

$$\text{Ans. } z = \phi_1(y^2 + x^2) + \phi_2(y^2 - x^2)$$

Hint: Put $x^2 = 2u$, $y^2 = 2v$, then $(D_u^2 - D_v^2)z = 0$

$$3. (x^2 D_x^2 - y^2 D_y^2 + x D_x - y D_y)z = \log x$$

$$\text{Ans. } z = \phi_1(xy) + \phi_2\left(\frac{y}{x}\right) + \frac{1}{6}(\log x)^3$$

Hint: Put $x = e^u$, $y = e^v$ then $(D_u^2 - D_v^2)z = u$.

$$4. (x D_x^3 D_y^2 - y D_x^2 D_y^3)z = 0$$

$$\text{Ans. } z = \psi_1(y) + \psi_2(x) + x \psi_3(y) + y \psi_4(x) + \psi_5(xy)$$

Hint: Put $x = e^u$, $y = e^v$, $(x^3 y^2 D_x^3 D_y^2 - x^2 y^3 D_x^2 D_y^3)z = 0$

$$D_u D_v (D_u - 1)(D_v - 1)(D_u - D_v)z = 0$$

$$5. (x^2 D_x^2 + xy D_x D_y - 2y^2 D_y^2 - x D_x - 6y D_y)z = 0$$

$$\text{Ans. } z = \phi_1(y/x^2) + x^2 \phi_2(xy)$$

$$6. (x^2 D_x^2 - 2xy D_x D_y - 3y^2 D_y^2 + x D_x - 3y D_y)z = x^2 y \sin(\ln x)^2$$

$$\text{Ans. } z = \phi_1(x^3 y) + \phi_2(y/x) - \frac{1}{65} x^2 y [4 \cos(\ln x)^2 + 7 \sin(\ln x)^2].$$

$$7. (x^2 D_x^2 + y^2 D_y^2 + 2xy D_x D_y - nx D_x - ny D_y + n)z = x^2 + y^2$$

$$\text{Ans. } z = x \phi_1(y/x) + x^n \phi_2(y/x) + \frac{1}{(2-n)}(x^2 + y^2)$$

Hint: Put $x = e^u$, $y = e^v$, then

$$(D_u + D_v - n)(D_u + D_v - 1)z = e^{2u} + e^{2v}$$

18.9 NON-LINEAR PARTIAL DIFFERENTIAL EQUATIONS OF SECOND ORDER: MONGE'S METHOD

The most general second order non-linear partial differential equation in two independent variables x and y , and z as the dependent variable has the form

$$F(x, y, z, p, q, r, s, t) = 0 \quad (1)$$

whose solution can be obtained by Monge's* method in special cases. The first step in Monge's method consists of finding one or two intermediate integrals (also known as first integrals) of the form

$$u_1 = \psi_1(v_1) \quad (2)$$

$$\text{and/or } u_2 = \psi_2(v_2) \quad (3)$$

* Gaspard Monge (1746-1818), Professor at Paris.

Here u_1, u_2, v_1, v_2 are functions of x, y, z, p, q and the functions ψ_1 and ψ_2 are arbitrary. Note that an intermediate integral may not exist for PDE (1).

By differentiating

$$u = \psi(v) \quad (4)$$

w.r.t. x and y and eliminating ψ' we obtain the most general PDE of the form

$$Rr + Ss + Tt + U(rt - s^2) = V \quad (5)$$

which has (4) as an intermediate integral (I.I.). Here R, S, T, U, V are functions of x, y, z, p and q .

When $U = v_p u_q - v_q u_p = 0$ then (5) reduces to

$$Rr + Ss + Tt = V. \quad (6)$$

Since the coefficients R, S, T, V are functions of p and q as well as x, y, z , P.D.E. (6) is non-linear (also referred to as “quasilinear” or “uniform non-linear” equation unlike (5) which is known as “non-uniform” equation).

We know that

$$dz = \frac{\partial z}{\partial x} dx + \frac{\partial z}{\partial y} dy = p dx + q dy \quad (7)$$

$$dp = \frac{\partial p}{\partial x} dx + \frac{\partial p}{\partial y} dy = r dx + s dy \quad (8)$$

$$dq = \frac{\partial q}{\partial x} dx + \frac{\partial q}{\partial y} dy = t dx + u dy \quad (9)$$

Solving (8) and (9), we get

$$r = \frac{dp - s dy}{dx}, \quad t = \frac{dq - s dx}{dy} \quad (10)$$

Using (10) eliminate r and t from (6), we have

$$R \left(\frac{dp - s dy}{dx} \right) + Ss + T \left(\frac{dq - s dx}{dy} \right) = V$$

or

$$s [R(dy)^2 - S dx dy + T(dx)^2] = R dy dp + T dx dq - V dx dy$$

Thus we obtain

$$R(dy)^2 - S dx dy + T(dx)^2 = 0 \quad (11)$$

$$R dy dp + T dx dq - V dx dy = 0 \quad (12)$$

The two simultaneous equations (11) and (12) are known as *Monge's (subsidiary) equations (M.E.)*. By solving the Monge's equations (11) and (12) one or two intermediate integrals of (6) are obtained.

In general, the quadratic (11) can be resolved into two (or one repeated) equations.

Case I: Suppose (11) can be resolved as

$$R(dy)^2 - S dx dy + T(dx)^2 =$$

$$= (A_1 dy + B_1 dx)(A_2 dy + B_2 dx) = 0$$

where $A_1 B_2 \neq A_2 B_1$. Then we have two systems

$$\left. \begin{aligned} A_1 dy + B_1 dx &= 0 \\ \text{and} \\ R dy dp + T dx dq - V dx dy &= 0 \end{aligned} \right\} \quad (13)$$

and

$$\left. \begin{aligned} A_2 dy + B_2 dx &= 0 \\ R dy dp + T dx dq - V dx dy &= 0 \end{aligned} \right\} \quad (14)$$

Integrating (13), we get two integrals $u_1 = a, v_1 = b$. Thus we get an intermediate integral of (6) as

$$u_1 = \psi_1(v_1) \quad (2)$$

Similarly from (14), we get another intermediate integral of (6) as

$$u_2 = \psi_2(v_2). \quad (3)$$

Solving (2) and (3), determine p and q as functions (in terms) of x, y and z . Substituting p and q in

$$dz = p dx + q dy \quad (7)$$

which on integration yields the required general solution of (6) involving two arbitrary functions.

Note 1: Some cases, the second intermediate integral can be obtained from the first one by inspection.

Note 2: When inspection fails, rearrange the first intermediate integral in the form $Pp + Qq = R^*$ and solve by Lagrange's method.

Case II: When (11) is a perfect square, i.e., $R(dy)^2 - S dx dy + T(dx)^2 = (Ady + Bdx)^2 = 0$, then we have only one system

$$\left. \begin{aligned} Ady + Bdx &= 0 \\ \text{and } R dy dp + T dx dq - V dx dy &= 0 \end{aligned} \right\} \quad (15)$$

18.32 — HIGHER ENGINEERING MATHEMATICS—V

Solving (15) we get only one intermediate integral $u = \psi(v)$ of the form $Pp + Qq = R^*$ which is integrated using Lagrange's method. (or Charpit's method).

Note: When equation (11) gives neither two factors nor a perfect square, then use the methods explained in Section 18.7 on page 18.22.

WORKED OUT EXAMPLES

Example 1: Solve $r + (a + b)s + abt = xy$

Solution: Comparing the given equation with

$$Rr + Ss + Tt = V$$

we get $R = 1$, $S = a + b$, $T = ab$, $V = xy$. Then the Monge's subsidiary equations

$$R(dy)^2 - S dx dy + T(dx)^2 = 0$$

$$\text{and } Rdp dy + T dq dx - V dx dy = 0$$

reduces to

$$(dy)^2 - (a + b)dx dy + ab(dx)^2 = 0 \quad (1)$$

$$\text{and } dp dy + ab dq dx - xy dx dy = 0 \quad (2)$$

Factorising equation (1), we get

$$(dy - adx)(dy - bdx) = 0$$

$$\text{which yields } dy - adx = 0 \quad (3)$$

$$\text{and } dy - bdx = 0 \quad (4)$$

Integrating (3) and (4), we get

$$y - ax = c_1 \quad (5)$$

$$y - bx = c_2 \quad (6)$$

Substitute $dy = adx$ from (3) in (2) then

$$dp(ax) + ab dq dx - x y dx(ax) = 0$$

$$\text{or } dp + b dq - xy dx = 0$$

Integrating we get

$$p + bq - y \frac{x^2}{2} = \text{constant} = \psi_1(y - ax) \quad (7)$$

Similarly using $dy = bdx$ from (4) in (2), we get

$$dp(b dx) + ab dq dx - x y dx(b dx) = 0$$

$$\text{or } dp + a dq - xy dx = 0$$

Integrating

$$p + aq - y \frac{x^2}{2} = \text{constant} = \psi_2(y - bx) \quad (8)$$

Now solve (7) and (8) for p and q . Multiply (7) by 'a' and (8) by 'b' and subtract, then

$$(b - a)p - (b - a) \frac{x^2 y}{2} = b\psi_2 - a\psi_1$$

$$\text{or } p = \frac{b\psi_2 - a\psi_1}{b - a} + \frac{x^2 y}{2} \quad (9)$$

Similarly subtracting (8) from (7), we get

$$q = \frac{\psi_2 - \psi_1}{a - b}. \quad (10)$$

We know that

$$dz = p dx + q dy.$$

Substituting p and q from (9) and (10), we have

$$dz = \left(\frac{b\psi_2 - a\psi_1}{b - a} + \frac{x^2 y}{2} \right) dx + \left(\frac{\psi_2 - \psi_1}{a - b} \right) dy$$

Rearranging

$$(a - b)dz = -\psi_1(dy - a dx) + \psi_2(dy - b dx) + (a - b) \frac{x^2 y}{2} dx$$

Integrating

$$z = \phi_1(y - ax) + \phi_2(y - bx) + \frac{x^3 y}{6}$$

which is the required general solution involving two arbitrary functions ϕ_1 and ϕ_2 which are functions of their arguments.

Example 2: Solve $q^2 r - 2pq s + p^2 t = pt - qs$.

Solution: Rewriting the equation in the standard form

$$q^2 r - q(2p - 1)s + p(p - 1)t = 0$$

Here $R = q^2$, $S = q - 2pq$, $T = p^2 - p$, $V = 0$

The first Monge's equation (11) is

$$q^2(dy)^2 + (2pq - q)dx dy + (p^2 - p)(dx)^2 = 0$$

Rewriting

$$q^2(dy)^2 + q(p-1)dxdy + pq dx dy + p(p-1)(dx)^2 = 0$$

$$\text{or } [p dx + q dy][q dy + (p-1)dx] = 0$$

The two factors are

$$p dx + q dy = dz = 0 \text{ or } z = c_1$$

and

$$q dy + (p-1)dx = q dy + p dx - dx = dz - dx = 0$$

$$\text{or } z - x = c_2$$

The second Monge's equation (12) is

$$q^2 dp dy + p(p-1)dq dx = 0.$$

Since $p dx + q dy = 0$, substitute $q dy = -p dx$, then

$$q dp(-p dx) + p(p-1)dq dx = 0$$

$$\text{or } -q dp + p dq - dq = 0$$

$$\text{Rewriting, } \frac{q dp - p dq}{q^2} + \frac{dq}{q^2} = 0$$

$$\text{or } d\left(\frac{p}{q}\right) + d\left(-\frac{1}{q}\right) = 0.$$

$$\text{Integrating } \frac{p}{q} - \frac{1}{q} = \text{constant} = \psi_1(z)$$

$$\text{or } p - \psi_1(z)q = 1$$

which is a Lagrange's equation, with auxiliary equations.

$$\frac{dx}{1} = \frac{dy}{-\psi_1} = \frac{dz}{1}$$

From the first and third, $x - z = \text{constant} = c_2$

From second and third

$$\psi_1(z)dz + dy = 0$$

Integrating

$$\psi_2(z) + y = \text{constant} = \psi_3(x - z).$$

Thus the general solution is

$$y = \psi_2(z) + \psi_3(x - z)$$

where ψ_2, ψ_3 are arbitrary functions.

Example 3: Solve $x^2 r - 2xs + t + q = 0$

Solution: Here $R = x^2, S = -2x, T = 1, V = -q$
The first Monge's equation is

$$x^2(dy)^2 + 2x dx dy + (dx)^2 = 0$$

$$\text{or } (x dy + dx)^2 = 0, \text{ repeated factors.}$$

$$\text{Then } x dy + dx = 0 \text{ or } dy + \frac{dx}{x} = 0$$

Integrating $y + \ln x = c_1$

Now the second Monge's equation is

$$x^2 dp dy + dq dx + q dx dy = 0$$

Substituting $x dy = -dx$

$$x dp(-dx) + dq dx + q dx \left(\frac{dx}{-x}\right) = 0$$

$$\text{or } -x dp + dq - q \frac{dx}{x} = 0$$

$$\text{i.e., } -dp + \frac{dq}{x} - q \frac{dx}{x^2} = 0$$

$$\text{or } -dp + d\left(\frac{q}{x}\right) = 0$$

$$\text{Integrating } p = \frac{q}{x} + c_1(y + \ln x)$$

$$\text{or } p - \frac{q}{x} = c_1$$

which is Lagrange's equation with auxiliary equations

$$\frac{dx}{1} = \frac{dy}{-\frac{1}{x}} = \frac{dz}{c_1}$$

From one and two, $\frac{1}{x}dx + dy = 0$ or $y + \ln x = c$

From one and three, $dz = c_1 dx$ or $z = c_1 x + c_2$.

Thus the general solution involving two arbitrary function is

$$z = x\psi_1(y + \ln x) + \psi_2(y + \ln x)$$

Example 4: Solve $(e^x - 1)(qr - ps) = pqe^x$

Solution: Rewriting in standard form

$$(e^x - 1)q \cdot r + p(1 - e^x)s = pqe^x$$

Here $R = q(e^x - 1), S = p(1 - e^x), T = 0, V = pqe^x$.

Monge's first equation is

$$q(e^x - 1)(dy)^2 - p(1 - e^x)dx dy = 0$$

$$(e^x - 1)dy[q dy + p dx] = 0$$

so $(e^x - 1)dy = 0$, $p dx + q dy = dz = 0$

Integrating $y = c_1$, $z = c_2$.

Now the Monge's second equation is

$$q(e^x - 1)dy dp - p q e^x dx dy = 0$$

Substituting $q dy = -p dx$, we get

$$(e^x - 1)(-p dx) \cdot dp - p q e^x dx dy = 0$$

$$\text{or } (e^x - 1)dp + q e^x dy = 0$$

$$\text{i.e., } (e^x - 1)dp - p e^x dx = 0$$

$$\frac{dp}{p} = \frac{e^x dx}{e^x - 1} = \frac{d(e^x - 1)}{(e^x - 1)}$$

Integrating

$$p = c_1(e^x - 1)$$

$$\text{or } \frac{\partial z}{\partial x} = p = \psi_1(z)(e^x - 1)$$

Integrating

$$\frac{dz}{\psi_1(z)} = (e^x - 1)dx$$

$$\psi_2(z) = e^x - x + \psi_3(y)$$

$$\therefore x = \psi_3(y) - \psi_2(z) + e^x$$

Example 5: Solve $(1 - q)^2 r - 2(2 - p - 2q + pq)s + (2 - p)^2 t = 0$

Solution: Here $R = (1 - q)^2$, $S = -2(2 - p - 2q + pq)$, $T = (2 - p)^2$, $V = 0$.

Monge's first equation is

$$(1 - q)^2(dy)^2 + 2(2 - p - 2q + pq)dxdy + (2 - p)^2(dx)^2 = 0$$

$$[(1 - q)dy + (2 - p)dx]^2 = 0$$

$$\text{or } (1 - q)dy + (2 - p)dx = 0$$

$$dy - q dy + 2dx - p dx = dy + 2dx - (p dx + q dy) = 0$$

$$\text{i.e. } dy + 2dx - dz = 0$$

Since $dz = p dx + q dy$.

Integrating $y + 2x - z = c_1$

Substituting $(1 - q)dy = -(2 - p)dx$ in the Monge's second equation

$$(1 - q)^2 dy dp + (2 - p)^2 dx dq = 0$$

reduces to

$$(1 - q)dp[-(2 - p)dx] + (2 - p)^2 dx dq = 0$$

or

$$(1 - q)dp + (2 - p)dq = 0$$

$$\text{i.e., } \frac{dp}{p - 2} = \frac{dq}{q - 1}$$

$$\text{Integrating } (p - 2) = c_2(q - 1)$$

$$q - 1 = c_3(p - 2) = \psi(y + 2x - z)(p - 2).$$

Then $c_3 p - q = 2c_3 - 1$

which is a Lagrange's equation with subsidiary equations.

$$\frac{dx}{c_3} = \frac{dy}{-1} = \frac{dz}{2c_3 - 1}$$

From first and second

$$dx + c_3 dy = 0$$

which on integration gives

$$x + y \cdot \psi(y + 2x - z) = \phi(y + 2x - z)$$

Example 6: Solve $r - 3s - 10t = -3$.

Solution: Here $R = 1$, $S = -3$, $T = -10$, $V = -3$. Monge's equations are

$$(dy)^2 + 3 dx dy - 10(dx)^2 = 0 \quad (1)$$

$$\text{and } dy dp - 10dx dq + 3dxdy = 0 \quad (2)$$

Equation (1) can be factorized as

$$(dy + 5dx)(dy - 2dx) = 0$$

$$\text{Thus } dy + 5dx = 0 \quad (3)$$

$$\text{and } dy - 2dx = 0 \quad (4)$$

which on integration gives

$$y + 5x = c_1 \quad (5)$$

$$y - 2x = c_2 \quad (6)$$

Substituting $dy = -5dx$ from (3) in (2), we get

$$(-5dx)dp - 10dx dq + 3dx(-5dx) = 0$$

$$\text{or } dp + 2dq + 3dx = 0$$

Integrating we have

$$p + 2q + 3x = c_3 \quad (7)$$

Substituting $dy = 2 dx$ from (4) in (2), we get

$$(2dx)dp - 10 dx dq + 3dx(2dx) = 0$$

$$dp - 5dq + 3dx = 0$$

which on integration gives

$$p - 5q + 3x = c_4 \quad (8)$$

$$\text{Thus } p + 2q + 3x = f(y - 5x) \quad (9)$$

$$\text{and } p - 5q + 3x = g(y - 2x) \quad (10)$$

Solving (9) and (10), we get

$$7p = 5f + 2g - 21x$$

$$7q = f - g.$$

Substituting p and q in

$$dz = p dx + q dy$$

$$7dz = (5f + 2g - 21x)dx + (f - g)dy$$

$$7dz = (5dx + dy)f(5x + y) - (dy - 2dx)g(y - 2x) - 21x dx$$

$$\text{Integrating } z = \phi(5x + y) + \phi(y - 2x) - \frac{3x^2}{2}.$$

EXERCISE

Solve (obtain the general solution (G.S.)) of the following examples by Monge's method.

$$1. qs - pt = q^3$$

$$\text{Ans. G.S.: } y + xz = f(z) + g(x)$$

Hint: Monge's Equations (M.E.) are $q \frac{dx}{dy} + p \frac{dy}{dx} + p(dx)^2 = 0$, $p \frac{dx}{dy} + q \frac{dy}{dx} + q^3 dx dy = 0$; $dz = p dx + q dy = 0$ so $z = c_1$.

Intermediate integral (I.I.): $\frac{1}{q} + x = c_2 = \psi(z)$

$$2. q^2r - 2pq s + p^2t = 0$$

$$\text{Ans. G.S.: } y + x\psi(z) = \phi(z)$$

Hint: M.E.: $(p dx + q dy)^2 = 0$, $q^2 dp dy + p^2 dq dx = 0$; $dz = 0$, $z = c_1$, $q dp = p dq$ or $p = c_2 q$; Lagrange's $\frac{dx}{1} = \frac{dy}{-\psi(z)} = \frac{dz}{0}$, $z = c_1$, $y + x f(c_1) = c_2$

$$3. r - t \cos^2 x + p \tan x = 0$$

$$\text{Ans. G.S.: } z = f(y - \sin x) + g(y + \sin x)$$

Hint: M.E.: $(dy)^2 - \cos^2 x (dx)^2 = 0$, $dp dy - \cos^2 x dq dx + p \tan x \cdot dx dy = 0$; $y - \sin x = c_1$, I.I., $p \sec x - q = c_1 = f(y - \sin x)$, $y + \sin x = c_2$, I.I.: $p \sec x + q = c_2 = g(y + \sin x)$, solving $p = \frac{f+q}{2 \sec x}$, $q = \frac{1}{2}(g - f)$.

$$4. x(r + 2xs + x^2t) = p + 2x^3$$

$$\text{Ans. G.S.: } z = \psi(x^2 - 2y) + \frac{x^2}{2} \phi(x^2 - 2y) + \frac{x^4}{4}$$

Hint: M.E.: $(dy - x dx)^2 = 0$, $x dy dp + x^3 dx dq - (p + 2x^3) dx dy = 0$.

$x^2 - 2y = c_1$, I.F. $\frac{1}{x^2}$, I.I.: $p + xq = x^3 + x f(x^2 - 2y)$.

Lagrange's: $\frac{dx}{1} = \frac{dy}{x} = \frac{dz}{x^3 + x f(x^2 - 2y)}$

$$5. (x - y)(xr - xs - ys + yt) = (x + y)(p - q)$$

$$\text{Ans. G.S.: } Z = f(xy) + g(x + y)$$

Hint: M.E.: $(x dy + y dx)(dx + dy) = 0$, $x dp dy + y dq dx$

$-\frac{x+y}{x-y} \cdot (p - q) dy dx = 0$, $xy = c_1$,

$x + y = c_2$,

I.I.: $dp - dq - \frac{dx - dy}{x - y}(p - q) = 0$

i.e., $p - q = c_3(x - y)$; use Lagrange's

$\frac{dx}{1} = \frac{dy}{-1} = \frac{dz}{(x - y)f(xy)}$

$$6. y^2r - 2ys + t - p - 6y = 0$$

$$\text{Ans. G.S.: } z = y^3 - y f(y^2 + 2x) + g(y^2 + 2x)$$

Hint: M.E.: $(y dy + dx)^2 = 0$, $y^2 + 2x = c_1$, $y dp - dq + (p + 6y) dy = 0$

I.I.: $py - q + 3y^2 = c_2$, use Lagrange's auxiliary equations.

$$7. 2x^2r - 5xys + 2y^2t = -2(px + qy)$$

$$\text{Ans. G.S.: } z = f(yx^2) + g(xy^2)$$

Hint: M.E.: $(x dy + 2y dx)(2x dy + y dx) = 0$, $x^2y = c_1$, $xy^2 = c_2$, $2x^2 dp dy + 2y^2 dq dx + 2(px + qy) dx dy = 0$

I.I.: $2xp - yq = c_3$ use Lagrange's equations $\frac{dx}{2x} = \frac{dy}{-y} = \frac{dz}{f(yx^2)}$

$$8. q(1 + q)r - (1 + 2q)(1 + p)s + (1 + p)^2t = 0$$

$$\text{Ans. G.S.: } x = \psi(x + y + z) + \phi(x + z)$$

Hint: M.E.: $qdy + (1 + p)dx = 0$,
 $q(1 + q)dydp + (1 + p)^2dx dq = 0$
 $x + z = c_1$, I.I.: $\frac{1+p}{\phi} = f(x + z) \cdot (1 + q)$;
M.E.: $(1 + q)dy + (1 + p)dx = 0$,
 $q(1 + q)dy dp + (1 + p)^2dx dq = 0$,
 $x + y + z = c_2$, I.I.: $1 + p = g(x + y + z) \cdot q$. Solving $p = \frac{fg+f-g}{g-f}$, $q = \frac{f}{g-f}$,
 $dz = p dx + q dy$,
 $fgdx = -f(dx + dy + dz) + g(dx + dz)$,

$$dx = -\frac{dx + dy + dz}{g(x + y + z)} + \frac{dx + dz}{f(x + z)}$$

9. $xy(t - r) + (x^2 - y^2)(s - 2) - py + qx = 0$

Ans. G.S.: $z = xy + f(x^2 + y^2) + g\left(\frac{y}{x}\right)$

Hint: M.E.: $(x dy - y dx)(y dy + x dx) = 0$,
 $x^2 + y^2 = c_1$,
 $\frac{y}{x} = c_2$, $-xy dp dy + xy dq dx - [py - qx + 2(x^2 - y^2)]dx dy = 0$

I.I.: $xp + yq = 2xy + \psi(x^2 + y^2)$. Use Lagrange's A.E.

10. $y^2r + 2xys + x^2t + px + qy = 0$

Ans. G.S.: $z = f(x^2 - y^2) + g(x^2 - y^2) \log(x + y)$

Hint: M.E.: $(x dx - y dy)^2 = 0$, $x^2 - y^2 = c_1$, $y^2 dp dy + x^2 dq dx + (px + qy)dx dy = 0$, I.I.: $yp + xq = c_2 = \psi(x^2 - y^2)$. Use Lagrange's A.E.: $\frac{dz}{\psi(x^2 - y^2)} = \frac{dy}{x} = \frac{dy}{\sqrt{y^2 + c_1}}$,
integrating

$$z - \psi(c_1) \log\{y + \sqrt{y^2 + c^2}\} = c_3$$

11. $qs - pt + s - t = 0$

Ans. G.S. $z = f(x) + g(x + y + z)$

Hint: M.E.: $-(p + 1)dq dx = 0$, $-(q + 1)dx dy - (p + 1)(dx)^2 = 0$; $dq = 0$, $dx + dy + p dx + q dy = dx + dy + dz = 0$, $x + y + z = c_1$, integrate $q = c_2 = \psi(x + y + z)$ w.r.t. y .

12. $q^2r - 2pqs + p^2t - pq^2 = 0$

Ans. G.S.: $y = e^x f(z) + g(z)$

Hint: M.E.: $(p dx + q dy)^2 = 0$, $z = c_1$, $q^2 dy dp + p^2 dx dq - pq^2 dx dy = 0$, $-\frac{dp}{p} +$

$\frac{dq}{q} + dx = 0$, I.I.: $e^x q = p\psi(z)$. Use Lagrange's A.E.

13. $x^2r + 2xys + y^2t = 0$

Ans. $z = x\phi(y/x) + \psi(y/x)$

14. $qr - ps = p^3$

Ans. $x = yz - \phi(z) + \psi(y)$.

18.10 SOLUTION OF SECOND ORDER P.D.E.: MISCELLANEOUS

A large class of P.D.E. of first and second order can be integrated by methods similar to integration of O.D.E. . While integrating a P.D.E. partially w.r.t. say one independent variable x , the resulting constant of integration will be a function of the other independent variable(s) say y .

Type I

P.D.E. can be reduced to a linear equation in p and x , p and y , q and x or q and y which can be integrated as a linear first order ordinary D.E.

Type II

P.D.E. may be rewritten as partial derivatives w.r.t. a single independent variable say x which after integration can be solved by Lagrange's method.

Type III

P.D.E. can easily be integrated by inspection. Note that while integration partially w.r.t. one independent variable say x , the other independent variables(s) is (are) held constant.

WORKED OUT EXAMPLES

Reducible to linear equation

Example 1: Solve $yt - q = xy$

Solution: Rewriting the given P.D.E. we get

$$y \frac{\partial q}{\partial y} - q = xy \text{ or } \frac{\partial q}{\partial y} - \frac{q}{y} = x$$

which is linear in q and y . The integration factor for this D.E. is I.F. $= e^{\int -\frac{1}{y} dy} = \frac{1}{y}$. So the solution is $q \cdot \frac{1}{y} = \int x \cdot \frac{1}{y} dy + f(x)$ where $f(x)$ is an arbitrary function of x . Then

$$\frac{q}{y} = x \ln y + f(x)$$

$$\text{or } q = xy \ln y + yf(x)$$

$$\text{i.e., } \frac{\partial z}{\partial y} = xy \ln y + yf(x)$$

Integrating partially w.r.t. 'y', we get

$$z = x \int y \ln y dy + \frac{y^2}{2} f(x) + g(x)$$

where $g(x)$ is an arbitrary function of x . Then

$$z = x \left[y^2 \ln y - \frac{y^2}{2} \right] + \frac{y^2}{2} f(x) + g(x)$$

Use of Lagrange's method

Example 1: Solve $p + r + s = 1$

Solution: Rewriting the given P.D.E.

$$\frac{\partial z}{\partial x} + \frac{\partial p}{\partial x} + \frac{\partial q}{\partial x} = 1$$

which is expressed as partial derivatives w.r.t. x . Integrating partially w.r.t. x , we have

$$z + p + q = x + f(y)$$

where $f(y)$ is an arbitrary function of y . Rewriting this as a linear first order P.D.E.

$$p + q = x + f(y) - z$$

We get the auxiliary equations as

$$\frac{dx}{1} = \frac{dy}{1} = \frac{dz}{x + f(y) - z}$$

Using first two, we get $x = y$ or $x - y = c_1$. From two and three, we get

$$\frac{dz}{dy} = x + f(y) - z$$

$$\text{or } \frac{dz}{dy} + z = x + f(y)$$

which is a first order linear D.E. in z . Its I.F. is $e^{\int dy} = e^y$.

Then

$$e^y \cdot z = \int [x + f(y)] e^y dy + c_2$$

$$e^y \cdot z = x e^y + \int f(y) e^y dy + c_2.$$

Thus the general solution is

$$z = x + F(y) \cdot e^{-y} + c_2 e^{-y} = x + F(y) e^{-y} + e^{-y} \phi(x - y)$$

$$\text{where } F(y) = \int f(y) dy$$

Equations solvable by direct integration

Example 1: Solve

$$\frac{\partial^3 z}{\partial x^2 \partial y} = \cos(2x + 3y)$$

Solution: Integrating partially w.r.t. x , we get

$$\frac{\partial^2 z}{\partial x \partial y} = \int \cos(2x + 3y) dx + f(y) = \frac{\sin(2x + 3y)}{2} + f(y)$$

Integrating again partially w.r.t. x , we have

$$\frac{\partial z}{\partial y} = \int \frac{1}{2} \sin(2x + 3y) dx + \int x f(y) dx + g(y)$$

Here $f(y)$ and $g(y)$ are the arbitrary functions of y . Thus

$$\frac{\partial z}{\partial y} = -\frac{1}{4} \cos(2x + 3y) + \frac{x^2}{2} f(y) + g(y).$$

Now integrating partially w.r.t. 'y', we get

$$z = -\frac{1}{4} \int \cos(2x + 3y) dy + \int \frac{x^2}{2} f(y) dy + \int g(y) dy + h(x)$$

$$z = -\frac{1}{12} \sin(2x + 3y) + \frac{x^2}{2} \psi(y) + n(y) + h(x)$$

where

$$\psi(y) = \int f(y) dy, n(y) = \int g(y) dy \text{ and } h(x)$$

is an arbitrary function of x .

Example 2: Solve $z_x = 6x + 3y$

and

$$z_y = 3x - 4y.$$

Solution: Integrating $z_x = 6x + 3y$ partially w.r.t. x , we have $z = 3x^2 + 3xy + f(y)$ where $f(y)$ is an

18.38 — HIGHER ENGINEERING MATHEMATICS—V

arbitrary function of y . To determine $f(y)$, differentiate the above equation partially w.r.t. y and equate it with the given second equation. Then

$$0 + 3x + \frac{df}{dy} = z_y = 3x - 4y$$

or $\frac{df}{dy} = -4y$. Integrating w.r.t. y , we get

$$f(y) = -2y^2 + c$$

where c is a pure constant. Thus the solution is

$$z = 3x^2 + 3xy - 2y^2 + c$$

Example 3: Solve $\frac{\partial^2 z}{\partial x^2} = a^2 z$ if $\frac{\partial z}{\partial x} = a \sin y$ and $\frac{\partial z}{\partial y} = 0$ when $x = 0$.

Solution: If z is a function of x alone, then

$$\frac{d^2 z}{dx^2} = a^2 z$$

whose auxiliary equation is $m^2 - a^2 = 0$ and general solution is

$$z = c_1 e^{ax} + c_2 e^{-ax} \quad (1)$$

But since z is actually a function of x and y , vary the constants c_1 and c_2 as functions of y . Thus

$$z = f(y)e^{ax} + g(y)e^{-ax}. \quad (2)$$

Use the two conditions, to determine the two unknown functions $f(y)$ and $g(y)$.

$$a \sin y = \left. \frac{\partial z}{\partial x} \right|_{x=0} = af'(y)e^{ax} + g'(y)(-a)e^{-ax} \Big|_{x=0}$$

$$\sin y = f'(y) - g'(y) \quad (3)$$

$$\text{Also } 0 = \left. \frac{\partial z}{\partial y} \right|_{x=0} = f'(y)e^{ax} + g'(y)e^{-ax} \Big|_{x=0}$$

$$0 = f'(y) - g'(y) \quad (4)$$

Solving (3) and (4), we get

$$f'(y) = \frac{1}{2} \cos y \text{ and } g'(y) = -\frac{1}{2} \cos y.$$

Integrating w.r.t. y , we get

$$f(y) = \frac{1}{2} \sin y + c_1, \quad g(y) = -\frac{1}{2} \sin y + c_2 \quad (5)$$

Substituting (5) in (2), we have

$$z = \left(\frac{1}{2} \sin y + c_1 \right) e^{ax} + \left(-\frac{1}{2} \sin y + c_2 \right) e^{-ax}$$

$$= \sin y \cdot \sinh ax + c_1 e^{ax} + c_2 e^{-ax}$$

$$z = \sin y \cdot \sinh ax + c_3 \cosh ax$$

Since $f - g = \left(-\frac{1}{2} \sin y + c_1 \right) -$

$\left(-\frac{1}{2} \sin y + c_2 \right) = \sin y$, so $c_1 = c_2$. Here $c_3 = 2c_1$.

EXERCISE

Solve the following P.D.E.

1. $\frac{\partial^2 z}{\partial x \partial y} = \sin x$

Ans. $z = -y \cos x + g(x) + F(y)$

2. $\frac{\partial^2 z}{\partial x \partial y} = \sin x \cdot \sin y$ given that $\frac{\partial z}{\partial y} = -2 \sin y$ when $x = 0$, and $z = 0$ when y is an odd multiple of $\frac{\pi}{2}$.

Ans. $z = \cos x \cdot \cos y + \cos y$.

Hint: $\frac{\partial z}{\partial y} = -\cos x \cdot \sin y + f(y)$, use B.C. $f(y) = -\sin y$, $z = \cos x \cdot \cos y + \cos y + g(x)$, use B.C., $g(x) = 0$.

3. $z_x = 3x - y$ and $z_y = -x + \cos y$

Ans. $z = \frac{3x^2}{2} - xy + \sin y + c$

Hint: $z = \frac{3x^2}{2} - xy + f(y)$, use 2nd equation, $f' = \cos f(y) = \sin y + c$

4. $ys + p = \cos(x + y) - y \sin(x + y)$

Ans. $zy = y \sin(x + y) + F(y) + \phi(x)$

5. Show that the surface satisfying $t = 6x^3y$ and containing the two lines $y = 0, z = 0$, $y = 1, z = 1$ is $z = x^3y^3 + y(1 - x^3)$

Hint: $z = x^3y^3 + yf(x) + \phi(x)$, use conditions, $\phi(x) = 0$, $1 = x^3 + f + \phi$

6. Prove that the surface $8axz = 4ax - y^2$ passes through the parabolas $z = 0, y^2 = 4ax$ and $z = 1, y^2 = -4ax$ and satisfies the equation $xr + 2p = 0$

7. Solve $\frac{\partial^3 z}{\partial x^2 \partial y} + 18xy^2 + \sin(2x - y) = 0$

Ans. $z = \frac{1}{4} \cos(2x - y) - x^3y^3 + xf(y) + g(y) + h(x)$

8. Solve $\frac{\partial^2 z}{\partial x^2} + z = 0$ if $z = e^y$ and $\frac{\partial z}{\partial x} = 1$ when $x = 0$.

Ans. $z = \sin x + e^y \cos x$

9. Solve $t - xq = x^2$

Ans. $z = -xy + e^{xy} \frac{f(x)}{x} + g(x)$

Hint: Rewrite $\frac{\partial q}{\partial y} - xq = x^2$, I.F.: e^{-xy}

10. Solve $xs + q = 4x + 2y + 2$

Ans. $xyz = 2x^2y + y^2x + 2xy + \int f(y)dy + g(x)$

Hint: Rewrite $x \frac{\partial q}{\partial x} + q = 4x + 2y + z$, I.F.: x

11. Solve $t + s + q = 0$

Ans. $ze^x = F(x) + g(x - y)$ where $F(x) = \int f(x)e^x dx$

Hint: Rewrite $\frac{\partial q}{\partial x} + \frac{\partial p}{\partial y} + \frac{\partial z}{\partial y} = 0$. Integrate w.r.t. y , $p + q = f(x) - z$, $\frac{dx}{1} = \frac{dy}{1} = \frac{dz}{f(x)-z}$, $x - y = c_1$, $\frac{dz}{dx} + z = f(x)$.

12. Show that the equation of the surface satisfying $r + s = 0$ and touching the elliptic paraboloid $z = 4x^2 + y^2$ along its section by the plane $y = 2x + 1$ is $z + 4x^2 + y^2 - 8yx + 8x - 4y + 2 = 0$

Hint: Rewrite $\frac{\partial p}{\partial x} + \frac{\partial q}{\partial x} = 0$, integrate w.r.t. x , $p + q = f(y)$, $y - x = c_1$, $z = F(y) + \phi(y - x)$, $\phi(y - x) = 8(y - x) - 4(y - x)^2 + c_1$, $F(y) = 3y^2 - 4y + c_2$.

Applications of Partial Differential Equations

INTRODUCTION

Several problems in fluid mechanics, solid mechanics, heat transfer, electromagnetic theory and other areas of physics are modeled as Initial Boundary Value Problems (IBVP) consisting of partial differential equations and **initial conditions (I.C.s) specifying the state of the system at some initial time** and/or **boundary conditions (B.Cs) (specifying the state of the system on the boundary say end points of an interval over which the solution is defined)**. Method of separation of variables is a powerful tool to solve such IBVP when PDE is linear and boundary conditions are homogeneous. In this chapter, we derive and solve by separation of variables technique some of the most important PDE's of one-dimensional heat equation, wave equation, Laplace's equation in two dimensions and in polar coordinates, two-dimensional heat equation, wave equation, vibrations of circular membrane, transmission lines. Unlike the ordinary differential equations, the general solution of PDE's involve arbitrary functions which require the knowledge of single and double Fourier series.

19.1 METHOD OF SEPARATION OF VARIABLES

Separation of variables is a powerful technique to solve P.D.E. For a P.D.E. in the function u of two independent variables x and y , assume that the re-

quired solution is separable, i.e.,

$$u(x, y) = X(x)Y(y) \quad (1)$$

where $X(x)$ is a function of x alone and $Y(y)$ is a function of y alone. Then substitution of u from (1) and its derivatives reduces the P.D.E. to the form

$$f(X, X', X'', \dots) = g(Y, Y', Y'', \dots) \quad (2)$$

which is separable in X and Y . Since the L.H.S. of (2) is a function of x alone and R.H.S. of (2) is a function of y alone, then (2) must be equal to a common constant say k . Thus (2) reduces to

$$f(X, X', X'', \dots) = k \quad (3)$$

$$g(X, X', X'', \dots) = k \quad (4)$$

Thus the determination of solution to P.D.E. reduces to the determination of solutions to two O.D.E. (with appropriate conditions).

WORKED OUT EXAMPLES

1. Solve $u_{xx} - u_y = 0$ by separation of variables.

Solution: Assume that $u(x, y) = X(x)Y(y)$. Differentiating w.r.t. x and y , we get

$$u_{xx} = X''Y, u_y = XY' \quad \text{so the P.D.E. reduces to}$$

$$2X''Y - XY' = 0$$

$$\text{or} \quad \frac{2X''}{X} = \frac{Y'}{Y} = 2k = \text{constant}$$

Solving $X'' - kX = 0$, we have A.E.: $m^2 - k = 0$, solution is $X(x) = c_1 e^{\sqrt{k}x} + c_2 e^{-\sqrt{k}x}$

19.2 — HIGHER ENGINEERING MATHEMATICS—V

Solving $Y' - 2kY = 0$, we have solution as

$$Y(y) = c_3 e^{2ky}$$

Hence the required solution is

$$u(x, y) = X(x)Y(y) = \left(c_1 e^{\sqrt{k}x} + c_2 e^{-\sqrt{k}x} \right) (c_3 e^{2ky})$$

$$u(x, y) = \left(A e^{\sqrt{k}x} + B e^{-\sqrt{k}x} \right) e^{2ky}$$

2. Use the separation of variables technique to solve $3u_x + 2u_y = 0$ with $u(x, 0) = 4e^{-x}$.

Solution: Assume $u(x, y) = X(x)Y(y)$. Then P.D.E. becomes $3X'Y + 2XY' = 0$

or
$$\frac{X'}{X} = -\frac{2}{3} \frac{Y'}{Y} = k = \text{constant}$$

Solving $X' - kX = 0$, we get $X(x) = c_1 e^{kx}$

Similarly, $Y' + \frac{3}{2}kY = 0$, we get $Y(y) = c_2 e^{-\frac{3}{2}ky}$

So $u(x, y) = X(x)Y(y) = c_1 e^{kx} \cdot c_2 e^{-\frac{3}{2}ky} = c e^{\frac{k}{2}(2x-3y)}$

Given that $4e^{-x} = u(x, 0) = X(x)Y(0) = c e^{kx}$

Thus $c = 4$, $k = -1$. Hence the required solution is

$$u(x, y) = 4e^{-\frac{1}{2}(2x-3y)}.$$

EXERCISE

Solve the following P.D.E. by the method of separation of variables:

1. $4u_x + u_y = 3u$ and $u(0, y) = e^{-5y}$

Ans. $u(x, y) = e^{2x-5y}$

2. $2xz_x - 3yz_y = 0$

Ans. $z(x, y) = Ax^{3b}y^{2b}$ where $A = c_1 c_2$, $k = 6b$

3. $u_x = 4u_y$, $u(0, y) = 8e^{-3y}$

Ans. $u(x, y) = 8e^{-12x-3y}$

4. $u_{xt} = e^{-t} \cos x$ with $u(x, 0) = 0$ and

$$\frac{\partial u(0, t)}{\partial t} = 0$$

Ans. $u(x, t) = \sin x - e^{-t} \sin x$

5. $y^3 z_x + x^2 z_y = 0$

Ans. $z(x, y) = c e^{k\left(\frac{x^3}{3} - \frac{y^4}{4}\right)}$

6. $u_{xx} = u_y + 2u$, with $u(0, y) = 0$, $\frac{\partial u(0, y)}{\partial x} = 1 + e^{-3y}$

Ans. $u(x, y) = \frac{1}{\sqrt{2}} \sinh \sqrt{2}x + e^{-3y} \sin x$

7. $z_{xx} - 2z_x + z_y = 0$

Ans. $z(x, y) = [c_1 e^{ax} + c_2 e^{bx}] e^{-ky}$ where $a = (1 + \sqrt{1+k})$, $b = (1 - \sqrt{1+k})$

8. $u_x = 2u_t + u$ where $u(x, 0) = 6e^{-3x}$

Ans. $u(x, t) = 6e^{-(3x+2t)}$

19.2 CLASSIFICATION OF PARTIAL DIFFERENTIAL EQUATIONS OF SECOND ORDER

In the fields of wave propagation, heat conduction, vibrations, elasticity, boundary layer theory, etc., second order partial differential equations are of particular interest.

The general form of a second-order P.D.E. in the function u of the two independent variables x, y is given by

$$A(x, y) \frac{\partial^2 u}{\partial x^2} + B(x, y) \frac{\partial^2 u}{\partial x \partial y} + C(x, y) \frac{\partial^2 u}{\partial y^2} + f\left(x, y, u, \frac{\partial u}{\partial x}, \frac{\partial u}{\partial y}\right) = 0 \quad (1)$$

This equation is linear in second order terms. PDE (1) is said to be “linear or quasi-linear” according as f is linear or non-linear.

PDE (1) is classified as *elliptic*, *parabolic* or *hyperbolic* according as $B^2 - 4AC < 0$, $= 0$ or > 0 .

Example:

Elliptic: ($B^2 - 4AC < 0$)

Laplace's equation in two dimensions

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \quad (2)$$

Poisson's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = f(x, y) \quad (3)$$

Parabolic: ($B^2 - 4AC = 0$)

One dimensional heat-flow equation

$$a^2 \frac{\partial^2 u}{\partial x^2} = \frac{\partial u}{\partial t} \quad (4)$$

Hyperbolic: ($B^2 - 4AC > 0$)

One-dimensional wave equation

$$\frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial x^2} \quad (5)$$

P.D.E. (2), (4), (5) are homogeneous while (3) is non-homogeneous.

Note: For an elliptic Equation (2) or (3) boundary conditions are prescribed in a closed region, whereas for parabolic or hyperbolic Equations (4) or (5) boundary conditions and initial conditions are prescribed in an open-ended region.

19.3 DERIVATION OF ONE-DIMENSIONAL HEAT EQUATION

Consider a heat conducting homogeneous rod of length L , placed along the x -axis with one end of the rod at $x = 0$ (origin) and the other end of the rod at $x = L$ (Fig. 19.1). Assume that the rod has constant density ρ and uniform cross section A . Also assume that the lateral surface of the rod is impenetrable to heat transfer i.e., rod is insulated laterally and therefore heat flows only in the x -direction. The rod is sufficiently thin so that the temperature is same at all points of any cross sectional area of the rod. Let $u(x, t)$ be the temperature of the cross section at the point x at any time t .

Fig. 19.1

The amount of heat $Q(t)$ in a small segment of the rod between the cross sections at x and $x + \Delta x$ is

$$Q(t) = \int_x^{x+\Delta x} (c)(\rho A) u(s, t) ds \quad (1)$$

where c is specific heat of the rod. By Fourier law of heat conduction, rate of propagation of heat (i.e., the quantity of heat passing through a cross section at x in unit time) is

$$q = -k \frac{\partial u}{\partial x} \cdot A \quad (2)$$

where k is the coefficient of thermal conductivity. Since heat flows in the direction of decreasing temperature, a negative sign appears in (2). The rate of

heat flow at cross section $x + \Delta x$ is

$$-kA \frac{\partial u}{\partial x} (x + \Delta x, t)$$

The rate of change of heat content in the segment of the rod between x and $x + \Delta x$ must be equal to net heat flow into this segment of the rod. Thus

$$\frac{\partial Q}{\partial t} = kA \left[\frac{\partial u}{\partial x} \Big|_{x+\Delta x} - \frac{\partial u}{\partial x} \Big|_x \right] \quad (3)$$

By mean value theorem,

$$\begin{aligned} \frac{\partial Q}{\partial t} &= \frac{\partial}{\partial t} \int_x^{x+\Delta x} c\rho A u(s, t) ds = \int_x^{x+\Delta x} c\rho A \frac{\partial u}{\partial t} ds \\ &= c\rho A \cdot u_t(\xi, t) \Delta x \end{aligned} \quad (4)$$

where ξ lies between x and $x + \Delta x$. Replacing L.H.S. of (3) by (4)

$$c\rho A \frac{\partial u}{\partial t} (\xi, t) \Delta x = kA \left[\frac{\partial u}{\partial x} \Big|_{x+\Delta x} - \frac{\partial u}{\partial x} \Big|_x \right]$$

Rewriting this and taking the limit as $\Delta x \rightarrow 0$,

$$\frac{\partial u(x, t)}{\partial t} = a^2 \frac{\partial^2 u}{\partial x^2} \quad (5)$$

where $a^2 = \frac{k}{c\rho}$ known as diffusivity constant. Equation (5) is the one-dimensional heat equation which is second order, homogeneous and **parabolic** type.

19.4 SOLUTION OF ONE-DIMENSIONAL HEAT EQUATION

By separation of variables technique

Consider a long thin wire or rod or bar of constant cross section and homogeneous heat conducting material. Let the bar be of length L oriented along the x -axis with one end A coinciding with origin (Fig. 19.2). Suppose that the lateral surface of the bar is perfectly insulated. Then the heat flows in the bar along the x -direction only.

Fig. 19.2

Thus the temperature u of the bar depends only on x and t . This phenomenon is described by the

19.4 — HIGHER ENGINEERING MATHEMATICS—V

initial boundary value problem consisting of one-dimensional heat equation

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2} \quad (1)$$

where c^2 is the thermal diffusivity, the boundary conditions (B.C.'s) prescribed at the end points A and B.

$$x(0, t) = 0, \quad x(L, t) = 0 \quad (2)$$

i.e., the end points are assumed to be at zero temperature and the initial temperature distribution in the bar given by

$$u(x, 0) = f(x) \quad (3)$$

where $f(x)$ is a given (prescribed) function of x . Solution by the separation of variables technique or the method of separating variables or product method reduces the IBVP to the solution of two ordinary differential equations as follows:

Step I. Assume that the solution $u(x, t)$ is separable i.e.,

$$u(x, t) = X(x)T(t) \quad (4)$$

where $X(x)$ is a function of x alone and $T(t)$ is a function of t only.

Differentiating (4) w.r.t. t and x , we get

$$\frac{\partial u}{\partial t} = X\dot{T}, \quad u_x = X'T, \quad u_{xx} = X''T$$

where $'$ denotes differentiation w.r.t x and $\dot{}$ denotes differentiation w.r.t. t . Substituting these in the P.D.E. (1), we get

$$\begin{aligned} X\dot{T} &= c^2 X''T \\ \frac{X''}{X} &= \frac{\dot{T}}{c^2 T} \end{aligned} \quad (5)$$

Since the L.H.S. of (5) is a function of x alone while R.H.S. of (5) is a function of t alone, both sides of (5) must be a constant. Thus

$$\frac{X''}{X} = \frac{\dot{T}}{c^2 T} = k = \text{constant}$$

which results in two ordinary differential equations

$$X'' - kX = 0 \quad (6)$$

$$\text{and} \quad \dot{T} - c^2 kT = 0 \quad (7)$$

Using (4) the boundary conditions (2) reduce to

$$0 = u(0, t) = X(0)T(t) \implies X(0) = 0 \quad (8)$$

$$0 = u(L, t) = X(L)T(t) \implies X(L) = 0 \quad (9)$$

since $T(t) \neq 0$ (otherwise if $T(t) = 0$, $u = 0$ for all t which is a trivial solution).

Step II.

Case 1: $k = 0$, $X'' = 0$

Solution is $X(x) = ax + b$

$$\text{using (8) and (9)} \quad 0 = X(0) = a \cdot 0 + b \quad \therefore b = 0,$$

$$0 = X(L) = a \cdot L \quad \therefore a = 0$$

Thus $X(x) = 0$ for all x or $u = 0$ for all x which is a trivial solution.

Case 2: $k = \lambda^2 > 0$, $X'' - \lambda^2 X = 0$

Solution is $X(x) = Ae^{\lambda x} + Be^{-\lambda x}$

$$\text{using (8)} \quad 0 = X(0) = A + B \quad \text{or} \quad A = -B$$

$$\text{using (9)} \quad 0 = X(L) = A(e^{\lambda L} - e^{-\lambda L})$$

$$\implies A = 0 = B$$

$$\text{since} \quad e^{\lambda L} - e^{-\lambda L} = 2 \sinh \lambda L = 0 \quad \text{only when } \lambda = 0.$$

Thus $X(x) = 0$ for all x or $u = 0$ for all x which is a trivial solution.

Case 3: $k = -\lambda^2$

Equation is $X'' + \lambda^2 X = 0$

Solution is $X(x) = A \cos \lambda x + B \sin \lambda x$

$$\text{using (8)} \quad 0 = X(0) = A + B \cdot 0 \quad \therefore A = 0$$

$$\text{using (9)} \quad 0 = X(L) = B \cdot \sin \lambda L$$

We must take $B \neq 0$ since otherwise $X(x) = 0$.

$$\text{Hence} \quad \sin \lambda L = 0 \quad \text{or} \quad \lambda L = n\pi$$

$$\therefore \quad \lambda = \frac{n\pi}{L}, \quad n \text{ integer} \quad (10)$$

Assuming $B = 1$, we get infinitely many solutions

$$X_n(x) = \sin \frac{n\pi x}{L}, \quad n = 1, 2, 3, \dots \quad (11)$$

Solving (7) $\dot{T} + e^2 \lambda^2 T = 0$, we get

$$T_n(t) = B_n e^{-\lambda_n^2 t} = B_n e^{-n^2 \pi^2 t / L^2} \quad (12)$$

Hence the "eigen functions"

$$\begin{aligned} u_n(x, t) &= X_n(x)T_n(t) \\ &= B_n \frac{\sin n\pi x}{L} \cdot e^{-\lambda_n^2 t}, \quad n = 1, 2, 3, \dots \end{aligned} \quad (13)$$

satisfy Equation (1) and boundary conditions (2).

Step III. In order to satisfy the initial condition (3) we invoke the *superposition* or *linearity principle* which states that

$$\begin{aligned}
 u(x, t) &= \sum_{n=1}^{\infty} u_n(x, t) \\
 &= \sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{L} \cdot e^{-c^2 n^2 \pi^2 t / L^2} \quad (14)
 \end{aligned}$$

satisfies (1) and (2). To determine the unknown constants B_n , use initial condition (3) in (14)

$$f(x) = u(x, 0) = \sum_{n=1}^{\infty} B_n \cdot \sin \frac{n\pi x}{L} \quad (15)$$

Since the R.H.S. of (15) is a half range Fourier sine series expansion of $f(x)$ in the interval $(0, L)$, the Fourier coefficients B_n 's are given by

$$B_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx, \quad n = 1, 2, \dots \quad (16)$$

Thus the temperature distribution in the bar is given by the solution (14) with B_n 's calculated from (16).

Note: Solution (14) is transient contains (negative exponential) i.e., u decreases as t increases which is consistent with physical nature of the heat conduction problem.

Steady-state condition

A condition (phenomena) is said to be steady-state if the (dependent) variables are independent (free) of time t .

Non-homogeneous boundary conditions are boundary conditions which are all not zero.

Non-homogeneous (Non-zero) Boundary Conditions

Suppose a bar AB of length L has its ends A and B maintained at A_0° and B_0° respectively until steady-state condition is reached. Then the temperatures at A and B are suddenly and simultaneously changed to A_1° and B_1° and maintained thereafter. To find the subsequent temperature distribution in the bar:

Step I. Initial temperature distribution in the bar is determined using the steady-state condition in which u will be independent of t

(i.e., $\frac{\partial u}{\partial t} = 0$). Therefore the heat equation reduces to

$$\frac{d^2 u}{dx^2} = 0$$

Its solution is $u(x) = ax + b$

The boundary conditions in the steady-state are $u(0) = A_0$ and $u(L) = B_0$. Using these

$$A_0 = u(0) = a \cdot 0 + b \quad \therefore b = A_0$$

$$B_0 = u(L) = a \cdot L + A_0 \quad \therefore a = (B_0 - A_0)/L$$

Thus the initial temperature distribution in the bar is

$$u(x, 0) = \frac{(B_0 - A_0)}{L} x + A_0 \quad (17)$$

Now the boundary conditions (temperatures) at A and B have been changed to

$$u(0, t) = A_1 \quad \text{and} \quad u(L, t) = B_1 \quad (18)$$

Thus the heat flow problem is to solve the one-dimensional heat equation (1) with B.C.'s (18) and initial condition (17). Unlike the previous problem, here the boundary conditions are non-homogeneous (non-zero). Therefore assume that the required solution $u(x, t)$ as

$$u(x, t) = u_s(x) + u_{tr}(x, t) \quad (19)$$

where $u_s(x)$ is the steady-state solution and $u_{tr}(x, t)$ is the transient solution (containing negative exponential of time t).

Step II. To determine $u_s(x)$:

The equation is $\frac{d^2 u_s(x)}{dx^2} = 0$

Its solution is $u_s(x) = Ax + B$

$$\text{Use (18)} \quad A_1 = u_s(0) = A \cdot 0 + B \quad \therefore B = A_1$$

$$B_1 = u_s(L) = A \cdot L + B \quad \therefore A = \frac{B_1 - A_1}{L}$$

$$\text{Thus} \quad u_s(x) = \frac{B_1 - A_1}{L} x + A_1 \quad (20)$$

Step III. To find $u_{tr}(x, t)$:

$$\text{From (19),} \quad u_{tr}(x, t) = u(x, t) - u_s(x)$$

$$\text{So} \quad u_{tr}(0, t) = u(0, t) - u_s(0) = A_1 - A_1 = 0 \quad (21)$$

$$u_{tr}(L, t) = u(L, t) - u_s(L) = B_1 - B_1 = 0 \quad (22)$$

19.6 — HIGHER ENGINEERING MATHEMATICS—V

Thus the boundary conditions for $u_{tr}(x, t)$ are homogeneous (zero).

The initial condition is

$$\begin{aligned} u_{tr}(x, 0) &= u(x, 0) - u_s(x) \\ &= \left[\frac{B_0 - A_0}{L}x + A_0 \right] - \left[\frac{B_1 - A_1}{L}x + A_1 \right] \\ u_{tr}(x, 0) &= [(A_1 - A_0) + (B_1 - B_0)] \cdot \frac{x}{L} + (A_0 - A_1) \\ &= A_2 \frac{x}{L} + A_3 \end{aligned} \quad (23)$$

where $A_2 = (A_1 - A_0) + B_1 - B_0$, $A_3 = A_0 - A_1$

Therefore $u_{tr}(x, t)$ satisfying one-dimensional heat equation, the zero B.C.'s (21), (22), and the initial condition (23) is given by

$$u_{tr}(x, t) = \sum A_n \sin \frac{n\pi x}{L} \cdot e^{-c^2 n^2 \pi^2 t / L^2} \quad (24)$$

where $A_n = \frac{2}{L} \int_0^L f(x) \cdot \sin \frac{n\pi x}{L} dx$

$$\begin{aligned} A_n &= \frac{2}{L} \int_0^L \left(\frac{A_2 x}{L} + A_3 \right) \sin \frac{n\pi x}{L} dx \\ &= \frac{2}{L} \left[\left(\frac{A_2 x}{L} + A_3 \right) \left(\frac{-L}{n\pi} \right) \cdot \cos \frac{n\pi x}{L} \right. \\ &\quad \left. - \frac{A_2}{L} \cdot \left(\frac{-L^2}{n^2 \pi^2} \right) \cdot \sin \frac{n\pi x}{L} \right]_0^L \\ A_n &= \frac{-2}{n\pi} [(A_2 + A_3) \cos n\pi - A_3] \\ &= \frac{2}{n\pi} [A_3 - (A_2 + A_3)(-1)^n] \end{aligned} \quad (25)$$

Hence the required temperature distribution in bar is given by (19), (20), (24), (25) i.e.,

$$\begin{aligned} u(x, t) &= u_s(x) + u_{tr}(x, t) \\ &= \left[(B_1 - A_1) \frac{x}{L} + A_1 \right] + \\ &\quad + \frac{2}{\pi} \sum \frac{[A_3 - (A_2 + A_3)(-1)^n]}{n} \times \\ &\quad \times \sin \frac{n\pi x}{L} \cdot e^{-c^2 n^2 \pi^2 t / L^2}. \end{aligned}$$

Bar with both ends insulated

When both ends of the bar are insulated, no heat flows through them and then the corresponding boundary

conditions are

$$\left. \frac{\partial u}{\partial x} \right|_{x=0} = u_x(0, t) = 0, \quad \left. \frac{\partial u}{\partial x} \right|_{x=L} = u_x(L, t) = 0 \quad (26)$$

Using (4), these boundary conditions reduce to

$$0 = u_x(0, t) = X'(0)T(t) \quad \therefore X'(0) = 0 \quad (27)$$

$$0 = u_x(L, t) = X'(L)T(t) \quad \therefore X'(L) = 0 \quad (28)$$

Differentiating $X(x) = A \cos \lambda x + B \sin \lambda x$ w.r.t. 'x'

$$X'(x) = -A\lambda \sin \lambda x + B\lambda \cos \lambda x$$

Using (27), $0 = X'(0) = B\lambda$ and then using (28)

$$0 = X'(L) = -A\lambda \sin \lambda L$$

Thus assuming $A = 1$ and $B = 0$, then $\lambda = \frac{n\pi}{L}$, n integer

Hence $X_n(x) = \cos \frac{n\pi x}{L}$, $n = 0, 1, 2, 3, \dots$

No change in the solution for $T(t)$. The required eigen functions are $u_n(x, t) = X_n(x)T_n(t)$, with $n = 0, 1, 2, \dots$

By the linearity principle, the required solution is

$$\begin{aligned} u(x, t) &= \sum_{n=0}^{\infty} u_n(x, t) = \sum_{n=0}^{\infty} X_n(x) \cdot T_n(t) \\ u(x, t) &= \sum_{n=0}^{\infty} A_n \cdot \cos \frac{n\pi x}{L} \cdot e^{-c^2 n^2 \pi^2 t / L^2} \end{aligned}$$

where $A_0 = \frac{2}{L} \int_0^L f(x) dx$

$$A_n = \frac{2}{L} \int_0^L f(x) \cos \frac{n\pi x}{L} dx.$$

WORKED OUT EXAMPLES

Homogeneous (zero) boundary conditions

Example 1: Find the temperature in a bar of length 2 whose ends are kept at zero and lateral surface insulated if the initial temperature is $\sin \frac{\pi x}{2} + 3 \sin \frac{5\pi x}{2}$.

Solution: Let $u(x, t)$ be the temperature in the bar. The boundary conditions are $u(0, t) = u(2, t) = 0$ for any t . The initial condition is $u(x, 0) = \sin \frac{\pi x}{2} + 3 \sin 5\pi \frac{x}{2}$. Then the solution is

$$u(x, t) = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{l} \cdot e^{-n^2\pi^2 c^2 t/l^2}$$

Here l = length of bar = 2 and

$$A_n = \frac{2}{l} \int_0^l f(x) \sin \frac{n\pi x}{l} dx$$

$$A_n = \frac{2}{2} \int_0^2 \left(\sin \frac{\pi x}{2} + 3 \sin \frac{5\pi x}{2} \right) \sin \frac{n\pi x}{2} dx$$

$$A_1 = 1, A_2, 3, 4 = 0, A_5 = 3, A_n = 0 \quad \text{for } n \geq 6$$

Thus

$$u(x, t) = \sin \left(\frac{\pi x}{2} \right) \cdot e^{-c^2\pi^2 t/4} + 3 \sin \left(\frac{5\pi x}{2} \right) \cdot e^{-c^2\pi^2 25t/4}$$

Example 2: Find the temperature $u(x, t)$ in a homogeneous bar of heat conducting material of length L cm with its ends kept at zero temperature and initial temperature given by $dx(L - x)/L^2$.

Solution: The initial boundary value problem consists of

- i. *P.D.E. heat equation:* $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$
- ii. *Boundary conditions:* $u(x, 0) = 0, u(L, 0) = 0$, for any t
- iii. *Initial condition:* $u(x, 0) = dx(L - x)/L^2$, $0 < x < L$

The solution is

$$u(x, t) = \sum_{n=1}^{\infty} A_n \cdot \sin \frac{n\pi x}{L} \cdot e^{-n^2\pi^2 c^2 t/L^2}$$

where

$$A_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx \quad \text{for } n = 1, 2, 3, \dots$$

$$\begin{aligned} A_n &= \frac{2}{L} \int_0^L \frac{dx(L - x)}{L^2} \sin n \frac{\pi x}{L} dx \\ &= \frac{2d}{L^3} \left[x(L - x) \cdot \left(\frac{-L}{n\pi} \right) \cos \frac{n\pi x}{L} \right. \\ &\quad \left. - (L - 2x) \cdot \left(\frac{-L^2}{n^2\pi^2} \right) \cdot \sin \frac{n\pi x}{L} \right. \\ &\quad \left. + (-2) \left(\frac{-L^3}{n^3\pi^3} \right) \left(-\cos \frac{n\pi x}{L} \right) \right]_0^L \end{aligned}$$

$$= \frac{2d}{L^3} \left[0 + 0 - \frac{2L^3}{n^3\pi^3} \{(-1)^n - 1\} \right]$$

$$= \frac{8d}{n^3\pi^3} \quad \text{if } n \text{ is odd}$$

Therefore the temperature distribution in the bar is given by

$$u(x, t) = \frac{8d}{\pi^3} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^3} \sin \frac{(2n-1)\pi x}{L} \times e^{-(2n-1)^2\pi^2 c^2 t/L^2}$$

Steady-state conditions and zero B.C.'s

Example 3: A bar of length L , laterally insulated, has its ends A and B kept at 0° and u_0° respectively until steady-state conditions prevail. If the temperature at B is then suddenly reduced to 0° and kept so while that of A is maintained at 0° find the temperature in the bar at any subsequent time.

Solution: Let $u(x, t)$ be the temperature in the bar AB . The initial temperature distribution in the bar is to be determined from the steady-state condition (in which u will be independent of time t). The equation governing this steady-state condition is

$$\frac{d^2 u}{dx^2} = 0$$

whose solution is

$$u(x) = ax + b$$

with a and b two arbitrary constants. Use the boundary conditions $u(x = 0) = 0$ and $u(x = L) = u_0$ to determine a and b .

$$0 = u(0) = a \cdot 0 + b \quad \therefore b = 0$$

$$u_0 = u(L) = a \cdot L + 0 \quad \therefore a = \frac{u_0}{L}$$

Thus the initial temperature distribution in the bar is

$$u(x, 0) = \frac{u_0}{L} x \quad (1)$$

and the boundary conditions are

$$u(0, t) = 0, \quad u(L, t) = 0 \quad (2)$$

The solution to the one-dimensional heat equation $u_t = c^2 u_{xx}$ with the initial condition (1) and bound-

19.8 — HIGHER ENGINEERING MATHEMATICS—V

ary conditions (2) is

$$u(x, t) = \sum_{n=1}^{\infty} A_n \cdot \sin\left(\frac{n\pi x}{L}\right) \cdot e^{-(n^2\pi^2 c^2 t/L^2)}$$

$$\begin{aligned} \text{where } A_n &= \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx \\ &= \frac{2}{L} \int_0^L \frac{u_0 x}{L} \cdot \sin \frac{n\pi x}{L} dx \\ &= \frac{2u_0}{L^2} \left[-\frac{xL}{n\pi} \cos \frac{n\pi x}{L} + \frac{L^2}{n^2\pi^2} \sin \frac{n\pi x}{L} \right]_0^L \\ &= -\frac{2u_0 L^2}{L^2 n\pi} (-1)^n \end{aligned}$$

Thus the required solution (temperature distribution in the bar) is

$$u(x, t) = \frac{2u_0}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin \frac{n\pi x}{L} \cdot e^{-(n^2\pi^2 c^2 t/L^2)}.$$

Non-homogeneous (non-zero) boundary conditions

Example 4: A bar AB of length 10 cm has its ends A and B kept at 30° and 100° temperatures respectively, until steady-state condition is reached. Then the temperature at A is lowered to 20° and that at B to 40° and these temperatures are maintained. Find the subsequent temperature distribution in the bar.

Solution: In order to find the initial temperature distribution in the bar, make use of the steady-state condition that the temperature $u(x, t)$ is independent of time t .

Then the one-dimensional heat equation

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2} \quad (1)$$

reduces to $\frac{d^2 u}{dx^2} = 0$ whose solution is given by $u(x) = ax + b$. The two arbitrary constants a and b are determined using the boundary conditions $u(0, t) = 30^\circ$ and $u(10, t) = 100^\circ$. Thus

$$30^\circ = u(0, t) = 0 \cdot 0 + b \quad \therefore b = 30^\circ$$

$$100^\circ = u(10, t) = a \cdot 10 + b = a \cdot 10 + 30^\circ \quad \therefore a = 7$$

So the initial temperature distribution in the bar is

$$u(x, 0) = 7x + 30 \quad (2)$$

When steady-state condition is reached, the temperatures at the ends A and B has been changed to 20° and 40° . So the boundary conditions are

$$u(0, t) = 20 \quad \text{and} \quad u(10, t) = 40 \quad (3)$$

which are non-homogeneous. Therefore assume the solution as

$$u(x, t) = u_s(x) + u_{tr}(x, t) \quad (4)$$

To find $u_s(x)$: solve $\frac{d^2 u_s}{dx^2} = 0$ with $u_s(0) = 20$, $u_s(10) = 40$. The solution is $u_s(x) = a_1 x + b_1$. Using boundary conditions, we get

$$20 = u_s(0) = a_1 \cdot 0 + b_1 \quad \therefore b_1 = 20$$

$$40 = u_s(10) = a_1 \cdot 10 + 20 \quad \therefore a_1 = 2$$

$$\text{Thus} \quad u_s(x) = 2x + 20 \quad (5)$$

To find $u_{tr}(x, t)$: From (4)

$$u_{tr}(x, t) = u(x, t) - u_s(x)$$

the boundary conditions are

$$u_{tr}(0, t) = u(0, t) - u_s(0) = 20 - 20 = 0 \quad (6)$$

$$u_{tr}(10, t) = u(10, t) - u_s(10) = 40 - 40 = 0 \quad (7)$$

i.e., boundary conditions are homogeneous. The initial condition is

$$u_{tr}(x, 0) = u(x, 0) - u_s(x) = (7x + 30) - (2x + 20)$$

$$u_{tr}(x, 0) = 5x + 10 \quad (8)$$

Thus to determine $u_{tr}(x, t)$, solve the one-dimensional heat equation

$$\frac{\partial u_{tr}}{\partial t} = c^2 \frac{\partial^2 u_{tr}}{\partial x^2}$$

with the homogeneous boundary conditions (6), (7) and initial condition (8). Hence the required solution $u_{tr}(x, t)$ is given by

$$u_{tr}(x, t) = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{L} \cdot e^{-c^2 n^2 \pi^2 t/L^2}$$

$$\text{where} \quad A_n = \frac{2}{L} \int_0^L f(x) \cdot \sin \frac{n\pi x}{L} dx$$

$$= \frac{2}{L} \int_0^L (5x + 10) \sin \frac{n\pi x}{L} dx$$

$$= \frac{2}{L} \left[(5x + 10) \cdot \left(\frac{-L}{n\pi} \right) \cos \frac{n\pi x}{L} \right]$$

$$-5 \left(\frac{-L^2}{n^2 \pi^2} \right) \cdot \sin \frac{n\pi x}{L} \Bigg|_0^L$$

$$A_n = \frac{20}{n\pi} [1 - 6(-1)^n] \quad \text{with } L = 10$$

Therefore the temperature distribution in bar is

$$u(x, t) = u_s(x) + u_{tr}(x, t)$$

$$= (2x + 20) + \frac{20}{\pi} \sum_{n=1}^{\infty} \left\{ \frac{1 - 6(-1)^n}{n} \right\} \times$$

$$\times \sin \frac{n\pi x}{10} \cdot e^{-c^2 \pi^2 n^2 t / 100}$$

Both ends insulated

Example 5: Find the temperature in a thin metal rod of length L , with both the ends insulated (so that there is no passage of heat through the ends) and with initial temperature in the rod $\sin(\pi x/L)$.

Solution: Let $u(x, t)$ be the temperature in rod. Then the initial boundary value problem is

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}, \quad \text{P.D.E.}$$

$$\frac{\partial u}{\partial x} \Big|_{x=0} = 0, \quad \frac{\partial u}{\partial x} \Big|_{x=L} = 0, \quad \text{B.C.}$$

$$u(x, 0) = \sin \left(\frac{\pi x}{L} \right), \quad \text{I.C.}$$

Its solution is

$$u(x, t) = \frac{c_0}{2} + \sum_{n=1}^{\infty} c_n \cos \frac{n\pi x}{L} \cdot e^{-n^2 \pi^2 c^2 t / L^2}$$

where

$$c_0 = \frac{2}{L} \int_0^L f(x) dx = \frac{2}{L} \int_0^L \sin \frac{n\pi x}{L} dx$$

$$c_0 = \frac{2}{L} \frac{L}{\pi} \left[-\cos \frac{\pi x}{L} \right]_0^L$$

$$= \frac{2}{\pi} [1 + 1] = \frac{4}{\pi}$$

$$c_1 = \frac{2}{L} \int_0^L \sin \frac{\pi x}{L} \cdot \cos \frac{\pi x}{L} dx = 0$$

$$c_n = \frac{2}{L} \int_0^L \sin \frac{\pi x}{L} \cdot \cos \frac{n\pi x}{L} dx \quad \text{for } n \neq 1$$

$$= \frac{2}{L} \frac{1}{2} \int_0^L \left[\sin \left(1 + n \right) \frac{\pi x}{L} \right]$$

$$+ \sin \left(\frac{(1 - n)\pi x}{L} \right) \Bigg] dx$$

$$= \frac{1}{L} \left[\frac{-L}{(n + 1)\pi} \cos(1 + n) \frac{\pi x}{L} \right.$$

$$\left. - \frac{L}{(1 - n)\pi} \cdot \cos(1 - n) \frac{\pi x}{L} \right]_0^L$$

$$= - \frac{[(-1)^{n+1} - 1]}{\pi} \left[\frac{1}{n + 1} - \frac{1}{n - 1} \right]$$

$$= \frac{-2[(-1)^{n+1} - 1]}{\pi(n^2 - 1)}$$

$$= \frac{4}{\pi(n^2 - 1)} \quad \text{where } n \text{ is even.}$$

Thus the temperature $u(x, t)$ in the rod

$$= \frac{2}{\pi} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{1}{(4n^2 - 1)} \cdot \cos \left(\frac{2n\pi x}{L} \right) \cdot e^{-(4n^2 c^2 t \pi^2 / L^2)}.$$

One end insulated

Example 6: Solve $u_t = c^2 u_{xx}$ when

- i. $u \neq \infty$ as $t \rightarrow \infty$
- ii. $u_x = 0$ when $x = 0$ for all t
- iii. $u = 0$ when $x = L$ for all t
- iv. $u = u_0 = \text{constant}$

when $t = 0$ for $0 < x < L$.

Solution: The given equations represent heat flow in a rod of length L whose one end (at $x = 0$) is insulated and the initial temperature in the rod is constant. Assume that the temperature in the rod

$$u(x, t) = X(x)T(t)$$

The P.D.E. reduces to

$$\frac{X''}{X} = \frac{\dot{T}}{c^2 T} = k = \text{constant}$$

$$\text{with } u_x(0, t) = x'(0)T = 0 \Rightarrow X'(0) = 0$$

$$u(L, t) = X(L)T = 0 \Rightarrow X(L) = 0$$

when $k = -\lambda^2 < 0$, non-trivial solutions exist. So

$$X'' + \lambda^2 X = 0, \quad X'(0) = 0, \quad X(L) = 0$$

$$X(x) = A \cos \lambda x + B \sin \lambda x$$

$$X'(x) = -A\lambda \sin \lambda x + B\lambda \cos \lambda x$$

$$0 = X'(0) = 0 + B\lambda \quad \therefore B = 0$$

19.10 — HIGHER ENGINEERING MATHEMATICS—V

$$0 = X(L) = A \cos \lambda L$$

$$\therefore \lambda = \frac{(2n-1)\pi}{L}, \quad n = 1, 2, \dots$$

$$\text{Thus } X_n(x) = \cos \frac{(2n-1)\pi}{L} \cdot x$$

$$T_n(t) = e^{-c^2 \lambda_n^2 t}$$

Hence the general solution (by principle of superposition) is

$$u(x, t) = \sum_{n=1}^{\infty} A_n \cos(\lambda_n x) \cdot e^{-c^2 \lambda_n^2 t}$$

To find A_n 's use the initial condition

$$u_0 = u(x, 0) = \sum_{n=1}^{\infty} A_n \cos(\lambda_n x)$$

$$\text{So } A_n = \frac{2}{L} \int_0^L f(x) \cdot \cos(\lambda_n x) dx$$

$$\begin{aligned} A_n &= \frac{2}{L} \int_0^L u_0 \cdot \cos\left(\frac{(2n-1)\pi}{L} x\right) dx \\ &= \frac{2u_0}{L} \cdot \frac{2L}{(2n-1)\pi} \cdot \sin\left(\frac{(2n-1)\pi x}{2L}\right) \Big|_0^L \\ &= \frac{4u_0(-1)^{n-1}}{(2n-1)\pi} \end{aligned}$$

$$\therefore u(x, t) = \frac{4u_0}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{(2n-1)} \cos\left(\frac{(2n-1)\pi x}{2L}\right) \times e^{-(c^2(2n-1)^2\pi^2 t)/(4L^2)}$$

EXERCISE

Homogeneous B.C.'s

Find the temperature $u(x, t)$ in a laterally insulated heat conducting bar of length L with its ends kept at 0° and with the initial temperature in the bar is $u(x, 0)$:

$$1. u(x, 0) = 100 \sin(\pi x/80); L = 80 \text{ cm}$$

$$\text{Ans. } u(x, t) = 100 \sin(\pi x/80) \cdot e^{-c^2 \pi^2 t/L^2}$$

$$2. u(x, 0) = \sin \frac{\pi x}{2} - 3 \sin 2\pi x; L = 2$$

$$\begin{aligned} \text{Ans. } u(x, t) &= \sin\left(\frac{\pi x}{2}\right) \cdot e^{-\pi^2 c^2 t/4} \\ &- 3 \sin 2\pi x \cdot e^{-4\pi^2 c^2 t/4} \end{aligned}$$

3. "Triangular" temperature:

$$\begin{aligned} u(x, 0) &= \frac{2Tx}{L}, \quad \text{when } 0 \leq x \leq \frac{L}{2} \\ &= \frac{2T}{L}(L-x), \quad \text{when } \frac{L}{2} \leq x \leq L \end{aligned}$$

$$\begin{aligned} \text{Ans. } u(x, t) &= \frac{8T}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2} \sin \frac{(2n-1)\pi}{2} \cdot \sin \frac{(2n-1)\pi x}{L} \\ &\times e^{-(2n-1)^2 \pi^2 c^2 t/L^2} \end{aligned}$$

$$4. u(x, 0) = x(L-x), 0 < x < L$$

$$\begin{aligned} \text{Ans. } u(x, t) &= \sum_{n=1}^{\infty} \frac{8L^2}{(2n-1)^2 \pi^2} \sin\left(\frac{(2n-1)\pi x}{L}\right) \\ &\times e^{-(2n-1)^2 \pi^2 c^2 t/L^2} \end{aligned}$$

$$5. u(x, 0) = u_0 = \text{constant}$$

$$\begin{aligned} \text{Ans. } u(x, t) &= \frac{4u_0}{\pi} \sum_{n=1}^{\infty} \frac{1}{(2n-1)} \cdot \sin\left(\frac{(2n-1)\pi x}{L}\right) \\ &\times e^{-(2n-1)^2 \pi^2 c^2 t/L^2} \end{aligned}$$

$$6. u(x, 0) = bx, 0 < x < L, b = \text{constant}$$

$$\begin{aligned} \text{Ans. } u(x, t) &= \sum_{n=1}^{\infty} \frac{2Lb}{\pi n} (-1)^{n+1} \sin\left(\frac{n\pi x}{L}\right) \\ &\times e^{-\pi^2 c^2 n^2 t/L^2} \end{aligned}$$

$$\begin{aligned} 7. u(x, 0) &= T_1 \quad \text{when } 0 < x < \frac{L}{2} \\ &= T_2 \quad \text{when } \frac{L}{2} < x < L \end{aligned}$$

where T_1, T_2 are constants.

$$\begin{aligned} \text{Ans. } u(x, t) &= \sum_{n=1}^{\infty} \left[\frac{2T_1}{n\pi} (1 - \cos \frac{n\pi}{2}) + \frac{2T_2}{n\pi} \times \right. \\ &\times \left. \left(\cos \frac{n\pi}{2} - \cos n\pi \right) \right] \sin \frac{n\pi x}{L} \\ &\times e^{-n^2 \pi^2 c^2 t/L^2} \end{aligned}$$

8. A bar of 30 cm length has its ends kept at 20° and 80° respectively until steady-state conditions prevail. The temperature at each end is then suddenly reduced to 0° and maintained thereafter. Find the temperature in bar.

Hint: $u(x, 0) = 2x + 20$ obtained from steady-state.

$$\begin{aligned} \text{Ans. } u(x, t) &= \frac{40}{\pi} \sum_{n=1}^{\infty} \left[\frac{1 - 4(-1)^n}{n} \right] \sin\left(\frac{n\pi x}{30}\right) \\ &\times e^{-c^2 n^2 \pi^2 t/900} \end{aligned}$$

Non-homogeneous B.C.'s

9. Solve $u_t = c^2 u_{xx}$, $0 \leq x \leq 1$ with $u(0, t) = 2$, $u(1, t) = 3$, $u(x, 0) = x(1 - x)$.

Ans. $u(x, t) = x + 2 + 2 \sum_{n=1}^{\infty} \left[\frac{3(-1)^n}{n\pi} - \frac{2(-1)^n}{n^3\pi^3} - \frac{2}{n\pi} + \frac{2}{n^3\pi^3} \right] \sin n\pi x \times e^{-n^2\pi^2 c^2 t}$

10. A bar of 10 cm long with its ends A and B kept at 20° and 40° respectively until steady-state conditions prevail. The temperature at A is then suddenly raised to 50° and at the same time at B is lowered to 10° . Find the subsequent temperature distribution. Show that the temperature at the middle point of the bar remains unaltered for all time.

Ans. $u(x, t) = 50 - 4x - \frac{120}{\pi} \sum_{n=1}^{\infty} \frac{1}{2n} \sin \frac{2n\pi x}{10} \times e^{-4n^2\pi^2 c^2 t/100}$

At the mid-point $x = 5$, $u(5, t) = -20 + 50 + 0 = 30 = \text{constant}$.

11. A bar of length L is laterally insulated with its ends A and B kept at 0° and 100° respectively until steady-state condition is reached. Then suddenly the temperature at A is raised to 20° and at B reduced to 80° simultaneously. Find the subsequent temperature distribution in the bar.

Hint: Initial condition $u(x, 0) = 100x/L$. Assume $u(x, t) = u_s(x) + u_{tr}(x, t)$ where $u_s(x) = 20 + 60x/L$.

Ans. $u(x, t) = \frac{60x}{L} + 20 - \frac{40}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \sin \left(\frac{2n\pi x}{L} \right) \times e^{-4c^2 n^2 \pi^2 t/L^2}$

12. A rod of length L has its ends A and B maintained at 0° and 100° respectively until steady-state conditions reached. Then suddenly the temperature at A and B have been changed to 25° and 75° respectively. Find the subsequent temperature in rod.

Hint: $u(x, 0) = \frac{100x}{L}$, $u_s(x) = \frac{50x}{L} + 25$

Ans. $u(x, t) = \frac{50x}{L} + 25 - \frac{50}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \sin \frac{2n\pi x}{L} \times e^{-4c^2 n^2 \pi^2 t/L^2}$.

Both edges insulated

Find the temperature in a laterally insulated bar of length L whose both ends are insulated and

13. with initial temperature $u(x, 0) = x$ if $0 < x < \frac{L}{2}$ and $= L - x$ if $\frac{L}{2} < x < L$

Ans. $u(x, t) = \frac{L}{4} - \frac{2L}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} (2 \cos \frac{n\pi}{2} - \cos n\pi - 1) \times \cos \frac{n\pi x}{L} \cdot e^{-c^2 n^2 \pi^2 t/L^2}$

14. with initial temperature $u(x, 0) = 60$, $0 < x < 50$, $= 40$, $50 < x < 100$; $L = 100$

Ans. $u(x, t) = 50 + \sum_{n=1}^{\infty} \left(\frac{40}{n\pi} \right) \sin \frac{n\pi}{2} \cdot \cos \frac{n\pi x}{100} \times e^{-c^2 n^2 \pi^2 t/L^2}$

15. with initial temperature $u(x, 0) = x(L - x)$

Ans. $u(x, t) = \frac{L^2}{6} - \frac{L^2}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \cos \left(\frac{2n\pi x}{L} \right) \times e^{-4n^2\pi^2 c^2 t/L^2}$

16. A rod of 100 cm length has its ends kept at 0° and 100° until steady-state conditions prevail. The two ends are then suddenly insulated and maintained so. Find the temperature in the rod. Show that the sum of the temperatures at any two points equidistant from the centre is always 100° .

Hint: $u(x, t) + u(l - x, t) = L = 100$ since $\cos \left(\frac{(2n-1)\pi(L-x)}{L} \right) = -\cos \frac{(2n-1)\pi x}{L}$

Ans. $u(x, t) = \frac{L}{2} - \frac{4L}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2} \cos \left(\frac{(2n-1)\pi x}{L} \right) \times e^{-c^2 (2n-1)^2 \pi^2 t/L^2}$

One edge insulated

Obtain the temperature in bar of length L and with one edge insulated:

17. $L = 1$, $u_x(1, t) = 0$, $u(0, t) = 10$, $u(x, 0) = 1 - x$, $0 < x < 1$

19.12 — HIGHER ENGINEERING MATHEMATICS—V

$$\text{Ans. } u(x, t) = 10 + \sum_{n=1}^{\infty} \left[\frac{8(-1)^n}{(2n-1)^2 \pi^2} - \frac{36}{(2n-1)\pi} \right] \\ \times \sin \frac{(2n-1)\pi x}{2} \cdot e^{-(2n-1)^2 \pi^2 c^2 t/4}$$

$$18. \quad u_x(0, t) = 0, u(L, t) = 0, u(x, 0) = x$$

$$\text{Ans. } u(x, t) = \frac{8L}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2} \left[\frac{(2n-1)\pi}{2} (-1)^{n+1} - 1 \right] \\ \times \cos \frac{(2n-1)\pi x}{2L} \cdot e^{-(2n-1)^2 \pi^2 c^2 t/(4L^2)}$$

19.5 DERIVATION OF ONE-DIMENSIONAL WAVE EQUATION

The classical one-dimensional wave equation, which is **hyperbolic**, arises in the study of transverse vibrations of an elastic string or torsional oscillations or longitudinal vibrations of a rod.

Vibrating string:

Consider an elastic string, stretched to its length L and alinged (placed) along the x -axis, with its two ends $x = 0$ and $x = L$ fixed. Let ρ be the constant density of the string (i.e., homogeneous string). Let the function $u(x, t)$ denote the displacement (or deflection) of string at any point x and at any time $t > 0$ from the equilibrium position (x -axis). When the string is distorted, then it vibrates. The small transverse vibrations of such a vibrating string are mathematically modelled by one-dimensional wave equation.

Fig. 19.3

Assume that the string is perfectly flexible and offers no resistance to bending. Applying Newton's second law of motion for a small portion of the string between x and $x + \Delta x$, the equation is derived. Let T_1 and T_2 be tension at the end points P and Q of this portion of the string.

Assuming that points on the string move only in the vertical direction, there is no motion in the horizontal direction. Thus the sum of the forces in the horizontal direction must be zero i.e.,

$$-T_1 \cos \alpha + T_2 \cos \beta = 0$$

$$\text{or} \quad T_1 \cos \alpha = T_2 \cos \beta = T = \text{constant} \quad (1)$$

Neglecting the gravitational force on the string, the only two forces acting on the string are the vertical components of tension $-T_1 \sin \alpha$ at P and $T_2 \sin \beta$ at Q with upward direction takes as positive. By Newton's second law

resultant of forces = mass $\times$ acceleration

$$T_2 \sin \beta - T_1 \sin \alpha = (\rho \Delta x) \left(\frac{\partial^2 u}{\partial t^2} \right) \quad (2)$$

Dividing (2) by (1), we have

$$\frac{T_2 \sin \beta}{T_2 \cos \beta} - \frac{T_1 \sin \alpha}{T_1 \cos \alpha} = \frac{\rho \Delta x}{T} \frac{\partial^2 u}{\partial t^2} \\ \tan \beta - \tan \alpha = \frac{\rho \Delta x}{T} \frac{\partial^2 u}{\partial t^2} \quad (3)$$

Replace $\tan \alpha$ by $\frac{\partial u(x, t)}{\partial x}$ and $\tan \beta$ by $\frac{\partial u(x + \Delta x, t)}{\partial x}$ because they are slopes of the string at x and $x + \Delta x$. Then

$$\frac{\partial u(x + \Delta x, t)}{\partial x} - \frac{\partial u(x, t)}{\partial x} = \frac{\rho \Delta x}{T} \frac{\partial^2 u}{\partial t^2}$$

Rewriting and taking the limit as $\Delta x \rightarrow 0$

$$\lim_{\Delta x \rightarrow 0} \frac{1}{\Delta x} \left[\frac{\partial u}{\partial x} \Big|_{x+\Delta x} - \frac{\partial u}{\partial x} \Big|_x \right] = \frac{\rho}{T} \frac{\partial^2 u}{\partial t^2}$$

Thus

$$\frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2} \quad (4)$$

where $c^2 = \frac{T}{\rho}$. Equation (4) is known as one-dimensional wave equation; which is second order, homogeneous, hyperbolic type.

19.6 SOLUTION OF ONE-DIMENSIONAL WAVE EQUATION BY SEPARATION OF VARIABLES:

Consider an elastic string, placed along the x -axis, stretched to length L between two fixed points $x = 0$ and $x = L$. Let $y(x, t)$ denote the deflection (displacement from equilibrium position). Then the small transverse vibrations of the string is governed by the one-dimensional wave equation

$$\frac{\partial^2 y}{\partial t^2} = a^2 \frac{\partial^2 y}{\partial x^2} \quad (1)$$

with boundary conditions

$$y(0, t) = 0, y(L, t) = 0 \quad (2)$$

The form of motion of the string will depend on the initial displacement (deflection at time $t = 0$)

$$y(x, 0) = f(x) \quad (3)$$

and the initial velocity

$$\left. \frac{\partial y}{\partial t} \right|_{t=0} = g(x) \quad (4)$$

The initial boundary value problem can be solved by the separation of variables techniques.

Step I. Assume that y is separable i.e.,

$$y(x, t) = X(x)T(t) \quad (5)$$

Substituting (5) in (1), we get

$$\frac{X''}{X} = \frac{\ddot{T}}{a^2 T} \quad (6)$$

Since L.H.S. of (6) is a function of x only and R.H.S. of (6) is a function of t only, both sides of (6) must be equal to common constant k . This results in two ordinary differential equations for X and T as

$$X'' - kX = 0 \quad (7)$$

$$\ddot{T} - ka^2 T = 0 \quad (8)$$

The boundary conditions (2) reduce to

$$0 = y(0, t) = X(0)T(t) \quad \text{i.e., } X(0) = 0 \quad (9)$$

$$0 = y(L, t) = X(L)T(t) \quad \text{i.e., } X(L) = 0 \quad (10)$$

It can be shown that for $k \geq 0$, only trivial solutions exist. So for non-trivial solutions consider $k = -\lambda^2 < 0$. Then the solution of $X'' + \lambda^2 X = 0$ is

$$X(x) = A \cos \lambda x + B \sin \lambda x$$

$$\text{using (9), } 0 = X(0) = A + B \cdot 0 \quad \therefore A = 0$$

$$\text{using (10), } 0 = X(L) = B \sin \lambda L$$

Since B should not be zero,

$$\sin \lambda L = 0$$

$$\text{i.e., } \lambda L = n\pi$$

$$\text{or } \lambda_n = \frac{n\pi}{L} \quad \text{for } n = 1, 2, 3, \dots \quad (11)$$

This results in infinitely many solutions to (7) given by

$$X_n(x) = \sin \left(\frac{n\pi x}{L} \right), n = 1, 2, 3, \dots \quad (12)$$

With $k = -\lambda^2 = -\frac{n^2\pi^2}{L^2}$ solve (8). Its solution is

$$T_n(t) = A_n \cos \lambda_n a t + B_n \sin \lambda_n a t \quad (13)$$

The set of solutions satisfying (1) and (2) are

$$y_n(x, t) = X_n(x)T_n(t) \quad n = 1, 2, 3, \dots$$

By the principle of superposition the general solution of (1) is

$$\begin{aligned} y(x, t) &= \sum_{n=1}^{\infty} y_n(x, t) \\ &= \sum_{n=1}^{\infty} (A_n \cos \lambda_n a t + B_n \sin \lambda_n a t) \sin \lambda_n x \quad (14) \end{aligned}$$

The unknown constants A_n and B_n 's are determined using the initial conditions

Case 1: When initial displacement is given: $y(x, 0) = f(x)$.

Put $t = 0$ in (14). Then

$$f(x) = y(x, 0) = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{L} \quad (15)$$

Thus A_n 's are the Fourier coefficients in the half range Fourier sine series expansion of $f(x)$ in the interval $(0, L)$.

Hence

$$A_n = \frac{2}{L} \int_0^L f(x) \sin \left(\frac{n\pi x}{L} \right) dx \quad (16)$$

19.14 — HIGHER ENGINEERING MATHEMATICS—V

with $n = 1, 2, 3, \dots$

Case 2: When initial velocity is given:

$$y_t(x, 0) = g(x).$$

Differentiate (14) w.r.t., t

$$\frac{\partial y}{\partial t} = \sum_{n=1}^{\infty} [-A_n \lambda_n a \sin \lambda_n a t + B_n \lambda_n a \cos \lambda_n a t] \sin \frac{n\pi x}{L}$$

Put $t = 0$

$$g(x) = \frac{\partial y}{\partial t} \Big|_{t=0} = \sum_{n=1}^{\infty} B_n \cdot \lambda_n a \sin \left(\frac{n\pi x}{L} \right)$$

$$\text{Then } B_n \cdot \lambda_n = \frac{2}{L} \int_0^L g(x) \cdot \sin \left(\frac{n\pi x}{L} \right) dx$$

$$\text{or } B_n = \frac{2}{a \cdot n\pi} \int_0^L g(x) \sin \left(\frac{n\pi x}{L} \right) dx \quad (17)$$

Hence the general solution of the one-dimensional wave Equation (1) with boundary conditions (2) and initial conditions (3) and (4) is

$$y(x, t) = \sum_{n=1}^{\infty} \left[A_n \cdot \cos \left(\frac{n\pi a t}{L} \right) + B_n \sin \left(\frac{n\pi a t}{L} \right) \right] \times \sin \left(\frac{n\pi x}{L} \right)$$

where A_n and B_n 's are given by (16) and (17).

Corollary 1: When only displacement is given, $f(x) \neq 0$ and $g(x) = 0$, in which case all B_n 's are zero. Then the general solution is

$$y(x, t) = \sum_{n=1}^{\infty} A_n \cdot \cos \left(\frac{n\pi a t}{L} \right) \cdot \sin \left(\frac{n\pi x}{L} \right)$$

with A_n 's given by (16).

Corollary 2: When only initial velocity is prescribed i.e., $g(x) \neq 0$ and $f(x) = 0$ then the solution is

$$y(x, t) = \sum B_n \cdot \sin \left(\frac{n\pi a t}{L} \right) \cdot \sin \left(\frac{n\pi x}{L} \right)$$

with B_n 's given by (17).

WORKED OUT EXAMPLES

Initial displacement

Example 1: A string of length L is fastened at both ends A and C . At a distance ' b ' from the end A , the

string is transversely displaced to a distance ' d ' and is released from rest when it is in this position. Find the equation of the subsequent motion (refer Fig. 19.4).

Solution: Let $y(x, t)$ denote the displacement of the string. The initial displacement is given by ABC .

Fig. 19.4

Equation of AB is $y = \frac{dx}{b}$.

Equation of BC is $y = \frac{d(x-L)}{(b-L)}$. Thus the problem is to solve the one-dimensional wave equation

$$\frac{\partial^2 y}{\partial t^2} = a^2 \frac{\partial^2 y}{\partial x^2}$$

with boundary conditions

$$y(0, t) = 0, \quad y(L, t) = 0$$

and with initial displacement

$$y(x, 0) = f(x) = \begin{cases} \frac{dx}{b} & \text{if } 0 \leq x \leq b \\ \frac{d(x-L)}{(b-L)} & \text{if } b \leq x \leq L \end{cases}$$

The solution is given by

$$y(x, t) = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{L} \cdot \cos \frac{n\pi a t}{L}$$

$$\text{where } A_n = \frac{2}{L} \int_0^L f(x) \cdot \sin \frac{n\pi x}{L} dx$$

$$\begin{aligned} A_n &= \frac{2}{L} \int_0^b \frac{d}{b} x \cdot \sin \left(\frac{n\pi x}{L} \right) dx + \\ &\quad + \frac{2}{L} \frac{d}{(b-L)} \int_b^L (x-L) \sin \frac{n\pi x}{L} dx \\ &= \frac{2d}{bL} \left[x \cdot \left(\frac{-L}{n\pi} \right) \cdot \cos \frac{n\pi x}{L} - \right. \end{aligned}$$

$$\begin{aligned}
 & - \left(\frac{-L^2}{n^2\pi^2} \right) \cdot \sin \frac{n\pi x}{L} \Bigg|_0^b \\
 & + \frac{2d}{L(b-L)} \left[(x-L) \left(\frac{-L}{n\pi} \right) \cos \frac{n\pi x}{L} - \right. \\
 & \left. - \left(\frac{-L^2}{n^2\pi^2} \right) \cdot \sin \frac{n\pi x}{L} \right]_b^L \\
 & = -\frac{2dbL}{bLn\pi} \cdot \cos \frac{n\pi b}{L} + \frac{2dL^2}{bLn^2\pi^2} \cdot \sin \frac{n\pi b}{L} \\
 & + \frac{2d}{n\pi} \cdot \cos \frac{n\pi b}{L} - \frac{2dL^2}{L(b-L)n^2\pi^2} \cdot \sin \frac{n\pi b}{L}.
 \end{aligned}$$

$$\text{Thus } A_n = \frac{2dL^2}{b(L-b)n^2\pi^2} \cdot \sin \frac{n\pi b}{L}$$

Hence the subsequent displacement of the string is given by the displacement function

$$\begin{aligned}
 y(x, t) &= \frac{2dL^2}{b(L-b)\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \sin \frac{n\pi b}{L} \\
 &\quad \times \sin \frac{n\pi x}{L} \cdot \cos \frac{n\pi at}{L}.
 \end{aligned}$$

Initial velocity

Example 2: Find the displacement of a string stretched between two fixed points at a distance $2c$ apart when the string is initially at rest in equilibrium position and points of the string are given initial velocities v where

$$v = \begin{cases} \frac{x}{c}, & \text{when } 0 < x < c \\ \frac{2c-x}{c}, & \text{when } c < x < 2c \end{cases}$$

x being the distance measured from one end.

Solution: The initial displacement $f(x) = 0$ while the initial velocity $g(x) = v(x)$. The solution is

$$y(x, t) = \frac{2c}{\pi a} \sum_{n=1}^{\infty} \frac{B_n}{n} \sin \left(\frac{n\pi x}{2c} \right) \sin \left(\frac{n\pi at}{2c} \right)$$

$$\text{where } B_n = \frac{2}{2c} \int_0^{2c} f(x) \cdot \sin \left(\left(\frac{n\pi x}{2c} \right) x \right) dx$$

$$\begin{aligned}
 B_n &= \frac{1}{c} \int_0^c \frac{x}{c} \sin \left(\frac{n\pi x}{2c} \right) dx \\
 &\quad + \frac{1}{c} \int_c^{2c} \left(\frac{2c-x}{c} \right) \cdot \sin \left(\frac{n\pi x}{2c} \right) dx
 \end{aligned}$$

$$\begin{aligned}
 &= \frac{1}{c} \left[\frac{x}{c} (-1) \left(\frac{2c}{n\pi} \right) \cos \left(\frac{n\pi x}{2c} \right) \right. \\
 &\quad \left. - \frac{1}{c} (-1) \frac{4c^2}{n^2\pi^2} \cdot \sin \left(\frac{n\pi x}{2c} \right) \right]_0^c \\
 &\quad + \frac{1}{c} \left[\left(\frac{2c-x}{c} \right) \cdot \left(\frac{-2c}{n\pi} \right) \cdot \cos \left(\frac{n\pi x}{2c} \right) \right. \\
 &\quad \left. - \left(\frac{-1}{c} \right) \cdot \left(\frac{-4c^2}{n^2\pi^2} \right) \cdot \sin \left(\frac{n\pi x}{2c} \right) \right]_c^{2c} \\
 &= -\frac{2}{n\pi} \cos \frac{n\pi c}{2c} + \frac{4}{n^2\pi^2} \cdot \sin \frac{n\pi c}{2c} \\
 &\quad + \frac{2}{n\pi} \cos \frac{n\pi}{2} + \frac{4}{n^2\pi^2} \frac{\sin n\pi}{2} \\
 B_n &= \frac{8}{n^2\pi^2} \cdot \sin \frac{n\pi}{2}
 \end{aligned}$$

Hence the displacement function is given by

$$\begin{aligned}
 y(x, t) &= \frac{2c}{\pi a} \cdot \frac{8}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n} \cdot \frac{1}{n^2} \sin \left(\frac{n\pi}{2} \right) \\
 &\quad \times \sin \left(\frac{n\pi x}{2c} \right) \cdot \sin \left(\frac{n\pi at}{2c} \right) \\
 y(x, t) &= \frac{16c}{a\pi^3} \sum_{n=1}^{\infty} \frac{1}{n^3} \sin \left(\frac{n\pi}{2} \right) \\
 &\quad \times \sin \left(\frac{n\pi x}{2c} \right) \cdot \sin \left(\frac{n\pi at}{2c} \right).
 \end{aligned}$$

Note: Here a is the constant appearing in wave equations.

Both initial displacement and initial velocity

Example 3: Solve the vibrating string problem with:

- i. $y(0, t) = 0, y(L, t) = 0$
- ii. $y(x, 0) = x$ when $0 < x < \frac{L}{2}$
 $= L - x$ when $\frac{L}{2} < x < L$
- iii. $y_t(x, 0) = x(x - L)$ when $0 < x < L$

Solution: Here $f(x) = y(x, 0)$ is the initial displacement and $g(x) = y_t(x, 0)$ is the initial velocity. The solution is

$$y(x, t) = \sum_{n=1}^{\infty} \left[A_n \cos \left(\frac{n\pi}{L} at \right) \right]$$

$$\begin{aligned}
 & + B_n \sin \left(\frac{n\pi}{L} at \right) \sin \frac{n\pi x}{L} \\
 \text{where } A_n &= \frac{2}{L} \int_0^L f(x) \sin \left(\frac{n\pi x}{L} \right) dx \\
 A_n &= \frac{2}{L} \left[\int_0^{\frac{L}{2}} x \sin \left(\frac{n\pi x}{L} \right) dx \right. \\
 & \quad \left. + \int_{\frac{L}{2}}^L (L-x) \sin \left(\frac{n\pi x}{L} \right) dx \right] \\
 &= \frac{2}{L} \left[x \cdot \left(\frac{-L}{n\pi} \right) \cdot \cos \left(\frac{n\pi x}{L} \right) \right. \\
 & \quad \left. - 1 \cdot \left(\frac{-L^2}{n^2\pi^2} \right) \cdot \sin \left(\frac{n\pi x}{L} \right) \right]_0^{\frac{L}{2}} \\
 & \quad + \frac{2}{L} \left[(L-x) \left(\frac{-L}{n\pi} \right) \cos \left(\frac{n\pi x}{L} \right) \right. \\
 & \quad \left. - (-1) \left(\frac{-L^2}{n^2\pi^2} \right) \cdot \sin \left(\frac{n\pi x}{L} \right) \right]_{\frac{L}{2}}^L \\
 &= \frac{2}{L} \left[\frac{-L^2}{2n\pi} \cdot \cos \frac{n\pi}{2} + \frac{L^2}{n^2\pi^2} \cdot \sin \frac{n\pi}{2} \right. \\
 & \quad \left. + \frac{L^2}{2n\pi} \cos \frac{n\pi}{2} + \frac{L^2}{n^2\pi^2} \sin \frac{n\pi}{2} \right]
 \end{aligned}$$

$$A_n = \frac{4L}{n^2\pi^2} \sin \frac{n\pi}{2}$$

$$\begin{aligned}
 \text{Now } B_n &= \frac{L}{an\pi} \cdot \frac{2}{L} \int_0^L g(x) \cdot \sin \left(\frac{n\pi x}{L} \right) dx \\
 B_n &= \frac{2}{n\pi a} \left[\int_0^L x(x-L) \sin \left(\frac{n\pi x}{L} \right) dx \right] \\
 &= \frac{2}{n\pi a} \left[x(x-L) \left(\frac{-L}{n\pi} \right) \cos \left(\frac{n\pi x}{L} \right) \right. \\
 & \quad \left. - (2x-L) \left(\frac{-L^2}{n^2\pi^2} \right) \cdot \sin \frac{n\pi x}{L} \right. \\
 & \quad \left. + (2) \left(\frac{-L^3}{n^3\pi^3} \right) \cos \frac{n\pi x}{L} \right]_0^L \\
 B_n &= \frac{2}{n\pi a} \left[-\frac{2L^3}{n^3\pi^3} \{(-1)^n - 1\} \right] \\
 B_n &= \frac{8L^3}{an^4\pi^4} \quad \text{when } n \text{ is odd.}
 \end{aligned}$$

Thus the required solution is

$$\begin{aligned}
 y(x, t) &= \frac{4L}{\pi^2} \sum_{n=1}^{\infty} \left[\frac{1}{n^2} \cdot \sin \frac{n\pi}{2} \cdot \cos \left(\frac{n\pi at}{L} \right) \cdot \sin \left(\frac{n\pi x}{L} \right) \right] \\
 & \quad + \frac{8L^3}{a\pi^4} \sum_{n=1}^{\infty} \left[\frac{1}{(2n-1)^4} \cdot \sin \left(\frac{(2n-1)\pi at}{L} \right) \right. \\
 & \quad \left. \times \sin \frac{(2n-1)\pi x}{L} \right]
 \end{aligned}$$

Example 4: Find the displacement of a string stretched between the fixed points (0, 0) and (1, 0) and released from rest from the position $A \sin \pi x + B \sin 2\pi x$.

Solution: Here initial deflection $y(x, 0) = f(x) = A \sin \pi x + B \sin 2\pi x$

$$\text{So } A_n = \frac{2}{1} \int_0^1 (A \sin \pi x + B \sin 2\pi x) \sin \frac{n\pi x}{1} \cdot dx$$

On integration, $A_1 = A$, $A_2 = B$, $A_n = 0$ for $n \geq 3$. So the displacement is given by

$$y(x, t) = A \sin \pi x \cdot \cos \pi at + B \sin 2\pi x \cdot \cos 2\pi at.$$

EXERCISE

A string of length L is stretched and fastened to two fixed points. Find the solution of the wave equation $y_{tt} = a^2 y_{xx}$ when:

1. Initial displacement $y(x, 0) = f(x) = b \sin \left(\frac{\pi x}{L} \right)$

Ans. $y(x, t) = b \sin \left(\frac{\pi x}{L} \right) \cdot \cos \left(\frac{\pi at}{L} \right)$

2. Initial displacement $y(x, 0) = f(x)$ where

$$f(x) = \begin{cases} \frac{3b}{L}x & \text{if } 0 \leq x \leq \frac{L}{3} \\ \frac{3b}{L}(L-2x) & \text{if } \frac{L}{3} \leq x \leq \frac{2L}{3} \\ \frac{3b}{L}(x-L) & \text{if } \frac{2L}{3} \leq x \leq L \end{cases}$$

$$\begin{aligned}
 \text{Ans. } y(x, t) &= \frac{9b}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \sin \left(\frac{2n\pi}{3} \right) \cdot \sin \left(\frac{2n\pi x}{L} \right) \\
 & \quad \times \cos \left(\frac{2n\pi at}{L} \right)
 \end{aligned}$$

3. Triangular initial deflection

$$f(x) = \begin{cases} \frac{2kx}{L}, & \text{if } 0 < x < \frac{L}{2} \\ \frac{2k(L-x)}{L}, & \text{if } \frac{L}{2} < x < L \end{cases}$$

$$\text{Ans. } y(x, t) = \frac{8k}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \sin\left(\frac{n\pi}{2}\right) \cdot \sin\left(\frac{n\pi x}{L}\right) \times \cos\left(\frac{n\pi at}{L}\right)$$

4. Initial displacement $y(x, 0) = f(x) = b_0 \sin^3\left(\frac{\pi x}{L}\right)$

$$\text{Ans. } y(x, t) = \frac{3}{4} \sin\left(\frac{\pi x}{L}\right) \cdot \cos\left(\frac{\pi at}{L}\right) - \frac{1}{4} \sin\left(\frac{3\pi x}{L}\right) \times \cos\left(\frac{3\pi at}{L}\right)$$

5. Initial displacement $y(x, 0) = f(x) = \frac{4bx(L-x)}{L^2}$

$$\text{Ans. } y(x, t) = \frac{32b}{\pi^3} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^3} \sin\left(\frac{(2n-1)\pi x}{L}\right) \times \cos\left(\frac{(2n-1)\pi at}{L}\right)$$

6. Initial displacement $y(x, 0) = f(x) = k(Lx - x^2)$

$$\text{Ans. } y(x, t) = \frac{8kL^2}{\pi^3} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^3} \sin\left(\frac{(2n-1)\pi x}{L}\right) \times \cos\left(\frac{(2n-1)\pi at}{L}\right)$$

7. Initial displacement $y(x, 0) = f(x)$

$$f(x) = \begin{cases} 0 & \text{if } 0 < x < \frac{1}{4} \\ 4h\left(\frac{x}{L} - \frac{1}{4}\right) & \text{if } \frac{1}{4} < x < \frac{L}{2} \\ 4h\left(\frac{3}{4} - \frac{x}{L}\right) & \text{if } \frac{L}{2} < x < \frac{3L}{4} \\ 0 & \text{if } \frac{3L}{4} < x < L \end{cases}$$

$$\text{Ans. } y(x, t) = \frac{32h}{\pi^2} \sum_{n=1}^{\infty} \sin\left(\frac{n\pi}{2}\right) \sin^2\left(\frac{n\pi}{8}\right) \frac{1}{n^2} \sin\left(\frac{n\pi x}{L}\right) \times \cos\left(\frac{n\pi at}{L}\right)$$

8. Initial velocity $\left(\frac{\partial y}{\partial t}\right)_{t=0} = g(x) = b_0 \sin^3\left(\frac{\pi x}{L}\right)$

$$\text{Ans. } y(x, t) = \frac{Lb_0}{12a\pi} \left[9 \sin\left(\frac{\pi x}{L}\right) \sin\left(\frac{a\pi t}{L}\right) - \sin\left(\frac{3\pi x}{L}\right) \times \sin\left(\frac{3a\pi t}{L}\right) \right]$$

9. Initial velocity $\left(\frac{\partial y}{\partial t}\right)_{t=0} = g(x) = bx(L-x)$

$$\text{Ans. } y(x, t) = \frac{8bL^3}{a\pi^4} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^4} \sin\left(\frac{(2n-1)\pi x}{L}\right) \times \sin\left(\frac{(2n-1)\pi at}{L}\right)$$

10. Initial velocity $\left(\frac{\partial y}{\partial t}\right)_{t=0} = g(x) = b \sin\left(\frac{3\pi x}{L}\right) \times \cos\left(\frac{2\pi x}{L}\right)$

$$\text{Ans. } y(x, t) = \frac{Lb}{2a\pi} \sin\left(\frac{\pi x}{L}\right) \cdot \sin\left(\frac{\pi at}{L}\right) + \frac{Lb}{5a\pi} \sin\left(\frac{5\pi x}{L}\right) \cdot \sin\left(\frac{5\pi at}{L}\right)$$

11. Initial velocity $\left(\frac{\partial y}{\partial t}\right)_{t=0} = g(x)$

$$= \begin{cases} cx, & 0 \leq x \leq \frac{L}{2} \\ c(L-x), & \frac{L}{2} \leq x \leq L \end{cases}$$

$$\text{Ans. } y(x, t) = \frac{4cL^2}{a\pi^3} \sum_{n=1}^{\infty} \frac{1}{n^3} \sin\left(\frac{n\pi}{2}\right) \cdot \sin\left(\frac{n\pi x}{L}\right) \times \sin\left(\frac{n\pi at}{L}\right)$$

12. Initial velocity $y_t(x, 0) = g(x) = 1, L = 1$

$$\text{Ans. } y(x, t) = \frac{4}{a\pi^2} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2} \sin((2n-1)\pi x) \times \sin((2n-1)\pi at)$$

19.7 LAPLACE'S EQUATION or POTENTIAL EQUATION or TWO-DIMENSIONAL STEADY-STATE HEAT FLOW

The two-dimensional heat equation

$$\frac{\partial u}{\partial t} = a^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$

reduces to Laplace's equation or potential equation in two dimensions given by

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \quad (1)$$

when the heat-flow is in the steady-state (i.e., $\frac{\partial u}{\partial t} = 0$). The solution $u(x, y)$ of the Laplace's Equation (1) in a rectangular region can be obtained by the separation of variables technique both in the Dirichlet problem (where u is prescribed on the boundary) and in the Neumann problem (where derivative of u in the normal direction to the boundary is prescribed). A rectangular thin plate, with its two surfaces (faces) insulated, is considered so that the heat flow is purely two-dimensional. The boundary conditions are prescribed on the four edges of the plate. The steady-state heat flow in such a plate is obtained by solving Laplace's equation in two-dimensions.

WORKED OUT EXAMPLES

Example 1: Solve the Laplace's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \quad (1)$$

in a rectangle in the xy -plane, $0 < x < a$ and $0 < y < b$ (Fig. 19.5) satisfying the following boundary conditions

Fig. 19.5

$$u(x, 0) = 0 \quad (\text{on } OA) \quad (2)$$

$$u(x, b) = 0 \quad (\text{on } BC) \quad (3)$$

$$u(0, y) = 0 \quad (\text{on } OB) \quad (4)$$

$$u(a, y) = f(y) \quad (\text{on } AC) \quad (5)$$

i.e., u is zero on three sides OA , OB , BC and is prescribed by given function $f(y)$ on the fourth side AC of the rectangle $OACB$.

Solution: By separation of variables:

Step I. Assume that u is separable i.e.,

$$u(x, y) = X(x) \cdot Y(y) \quad (6)$$

Substituting (6) in (1), we get

$$X''X + X\ddot{Y} = 0$$

where ' denotes differentiation w.r.t., x and $\cdot$ denotes differentiation w.r.t., y .

so
$$\frac{\ddot{Y}}{Y} = -\frac{X''}{X} \quad (7)$$

Both sides of (7) must be equal to a constant k since L.H.S. of (7) is a function of y only and the R.H.S. of (7) is a function of x only. Then

$$\frac{\ddot{Y}}{Y} = -\frac{X''}{X} = k$$

or the boundary value problem reduces to two ordinary differential equations in X and Y .

$$\ddot{Y} - kY = 0 \quad (8)$$

$$X'' + kX = 0 \quad (9)$$

The boundary conditions (2) (3) (4) reduces to

$$0 = u(x, 0) = X(x)Y(0) \quad \text{i.e., } Y(0) = 0 \quad (10)$$

$$0 = u(x, b) = X(x)Y(b) \quad \text{i.e., } Y(b) = 0 \quad (11)$$

$$0 = u(0, y) = X(0)Y(y) \quad \text{i.e., } X(0) = 0 \quad (12)$$

If $k \geq 0$, (8) will have only trivial solutions. So assume $k = -\lambda^2 < 0$. Then the Equation (8)

$$\ddot{Y} + \lambda^2 Y = 0$$

has the general solution

$$Y(y) = A \cos \lambda y + B \sin \lambda y$$

$$\text{Using (10), } 0 = Y(0) = A \cdot 1 + B \cdot 0 \quad \text{i.e., } A = 0$$

$$\text{Using (11), } 0 = Y(b) = B \sin \lambda b$$

Since $B \neq 0$, $\sin \lambda b = 0$ i.e., $\lambda b = n\pi$

$$\text{or } \lambda_n = \frac{n\pi}{b}, \quad \text{for } n = 1, 2, 3, \dots \quad (13)$$

Thus we get infinitely many solutions

$$Y_n(y) = \sin \frac{n\pi y}{b} \quad (14)$$

(assuming $B = 1$). Now the solution of (9) is

$$X(x) = A^* e^{-\lambda x} + B^* e^{\lambda x}$$

$$\text{Using (12), } 0 = X(0) = A^* + B^* \quad \text{i.e., } A^* = -B^*$$

$$\text{or } X(x) = 2B^* \frac{(e^{+\lambda x} - e^{-\lambda x})}{2} = B \sinh \lambda x$$

$$\text{Thus } X_n(x) = B_n \sinh \left(\frac{n\pi x}{b} \right) \quad (15)$$

Hence the solution to (1) with boundary conditions (2) (3) (4) is

$$u_n(x, y) = B_n \sinh \left(\frac{n\pi x}{b} \right) \cdot \sin \left(\frac{n\pi y}{b} \right)$$

By superposition principle:

$$\begin{aligned} u(x, y) &= \sum u_n(x, y) \\ &= \sum_{n=1}^{\infty} B_n \sinh\left(\frac{n\pi x}{b}\right) \sin\left(\frac{n\pi y}{b}\right) \quad (16) \end{aligned}$$

To find the unknown constants B_n , use the fourth boundary condition (5)

$$f(y) = u(a, y) = \sum \left[B_n \cdot \sinh\left(\frac{n\pi a}{b}\right) \right] \cdot \sin\left(\frac{n\pi y}{b}\right)$$

Thus B_n 's are the Fourier coefficients of the Fourier half range sine series of $f(y)$ in the interval $(0, b)$ and are given by

$$\begin{aligned} B_n \cdot \sinh\left(\frac{n\pi a}{b}\right) &= \frac{2}{b} \int_0^b f(y) \cdot \sin\left(\frac{n\pi y}{b}\right) dy \\ \text{or } B_n &= \frac{2}{b \cdot \sinh\left(\frac{n\pi a}{b}\right)} \int_0^b f(y) \sin\left(\frac{n\pi y}{b}\right) dy, \\ &\text{for } n = 1, 2, 3, \dots \quad (17) \end{aligned}$$

Hence the harmonic function $u(x, y)$ satisfying the Laplace's equation (1) and the four boundary conditions (2), (3), (4), (5) is given by (16) with B_n 's determined by (17).

Example 2: Solve the above problem when

$$f(y) = ky(b - y), 0 < y < b$$

and k is a constant.

Solution: Consider

$$\begin{aligned} I &= \int_0^b f(y) \sin\left(\frac{n\pi y}{b}\right) dy \\ &= \int_0^b ky(b - y) \sin\left(\frac{n\pi y}{b}\right) dy \\ &= \left[ky(b - y) \cdot \left(\frac{-b}{n\pi}\right) \cos\left(\frac{n\pi y}{b}\right) \right. \\ &\quad \left. - k(b - 2y) \left(\frac{-b^2}{n^2\pi^2}\right) \cdot \sin\frac{n\pi y}{b} \right. \\ &\quad \left. + k(-2) \left(\frac{-b^3}{n^3\pi^3}\right) \cos\left(\frac{n\pi y}{b}\right) \right]_0^b \\ &= \frac{2b^3k}{n^3\pi^3} [(-1)^n - 1] = \frac{-4kb^3}{n^3\pi^3} \text{ when } n \text{ is odd.} \end{aligned}$$

Now substituting I in (17)

$$\begin{aligned} B_n &= \frac{2}{b \sinh\left(\frac{n\pi a}{b}\right)} \int_0^b f(y) \sin\left(\frac{n\pi y}{b}\right) dy \\ &= \frac{2}{b \cdot \sinh\left(\frac{n\pi a}{b}\right)} \left(\frac{-4kb^3}{n^3\pi^3} \right) \text{ for } n \text{ odd} \\ B_n &= \frac{-8kb^2}{n^3\pi^3 \sinh\left(\frac{n\pi a}{b}\right)} \text{ with } n \text{ odd} \end{aligned}$$

Hence the required solution (16) becomes

$$\begin{aligned} u(x, y) &= \sum_{n=\text{odd}} \frac{-8kb^2}{n^3\pi^3 \sinh\left(\frac{n\pi a}{b}\right)} \times \\ &\quad \times \sinh\left(\frac{n\pi x}{b}\right) \cdot \sin\left(\frac{n\pi y}{b}\right) \\ u(x, y) &= \frac{-8kb^2}{\pi^3} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^3 \sinh\left(\frac{(2n-1)\pi a}{b}\right)} \times \\ &\quad \times \sinh\left(\frac{(2n-1)\pi x}{b}\right) \cdot \sin\left(\frac{(2n-1)\pi y}{b}\right). \end{aligned}$$

Example 3: Solve Laplace's equation in rectangle with $u(0, y) = 0$, $u(a, y) = 0$, $u(x, b) = 0$ and $u(x, 0) = f(x)$ (on OA) (refer Fig. 19.6).

Solution: Boundary conditions are

$$0 = u(0, y) = X(0) Y(y) \quad \text{i.e., } X(0) = 0$$

$$0 = u(a, y) = X(a) Y(y) \quad \text{i.e., } X(a) = 0$$

$$0 = u(x, b) = X(x) Y(b) \quad \text{i.e., } Y(b) = 0$$

Fig. 19.6

19.20 — HIGHER ENGINEERING MATHEMATICS—V

The Equation (7) is taken as

$$\frac{X''}{X} = -\frac{Y}{Y} = k = -\lambda^2 < 0$$

Thus the problem reduces to solving

$$X'' + \lambda^2 X = 0 \quad \text{with } X(0) = 0, X(a) = 0$$

and $Y - \lambda^2 Y = 0 \quad \text{with } Y(b) = 0$

Solving $X_n(x) = \sin \frac{n\pi x}{a}, \quad \text{with } n = 1, 2, \dots$

$$Y(y) = A^* e^{\lambda y} + B^* e^{-\lambda y} \quad \text{with } Y(b) = 0$$

$$0 = Y(b) = A^* e^{\lambda b} + B^* e^{-\lambda b}$$

or $A^* = \frac{-B^* e^{-\lambda b}}{e^{\lambda b}}$

Rewriting

$$Y(y) = \frac{-B^* e^{-\lambda b}}{e^{\lambda b}} \cdot e^{\lambda y} + B^* e^{-\lambda y}$$

$$Y(y) = \frac{B^*}{e^{\lambda b}} \left[e^{\lambda b} e^{-\lambda y} - e^{-\lambda b} e^{\lambda y} \right]$$

$$= B \sinh \{ \lambda(b - y) \}$$

Thus $Y_n(y) = B_n \cdot \sinh \left\{ \frac{n\pi}{a}(b - y) \right\}$

The required solution is

$$u(x, y) = \sum_{n=1}^{\infty} B_n \sin \left(\frac{n\pi x}{a} \right) \cdot \sinh \left(\frac{n\pi(b - y)}{a} \right)$$

Use the condition on side OA to find B_n 's.

$$f(x) = u(x, 0) = \sum_{n=1}^{\infty} B_n \cdot \sin \left(\frac{n\pi x}{a} \right) \cdot \sinh n\pi \frac{(b)}{a}$$

Then $B_n = \frac{2}{a \cdot \sinh \left(\frac{n\pi b}{a} \right)} \int_0^a f(x) \sin \left(\frac{n\pi x}{a} \right) dx.$

Example 4: Solve the above problem in a square of length π and $f(x) = \sin^2 x, 0 < x < \pi$.

Solution: Consider

$$I = \int_0^a f(x) \sin \frac{n\pi x}{a} dx = \int_0^{\pi} \sin^2 x \cdot \sin nx dx$$

$$= \int_0^{\pi} \left(\frac{1 - \cos 2x}{2} \right) \sin nx dx = \frac{1}{2} \int_0^{\pi} \sin nx dx$$

$$- \frac{1}{4} \int_0^{\pi} [\sin(n+2)x + \sin(n-2)x]$$

$$= \frac{1}{2} \left[\frac{-\cos nx}{n} \right]_0^{\pi} + \frac{1}{4} \left[\frac{\cos(n+2)x}{n+2} \right. \\ \left. + \frac{\cos(n-2)x}{(n-2)} \right]_0^{\pi} \quad \text{for } n \neq 2$$

$$= \frac{1}{2n} [1 - (-1)^n] + \frac{1}{4} \{ (-1)^{n+2} - 1 \} \times \\ \times \left[\frac{1}{n+2} - \frac{1}{n-2} \right]$$

$$I = -\frac{4}{n(n^2 - 4)} \quad \text{for } n \text{ odd.}$$

(Note for $n = 2$, even, $I = 0$)

Thus $B_n = \frac{2}{\pi \sinh \left(n\pi \cdot \frac{\pi}{\pi} \right)} \int_0^{\pi} \sin^2 x \cdot \sin nx dx$

$$= \frac{2}{\pi \sinh n\pi} \left(\frac{-4}{n(n^2 - 4)} \right)$$

$$= \frac{-8}{n\pi(n^2 - 4) \sinh n\pi}$$

Hence the solution is

$$u(x, y) = -\frac{8}{\pi} \sum_{n=\text{odd}} \frac{\sin nx \cdot \sinh \left(\frac{n(\pi - y)}{\pi} \right)}{(\sinh n\pi) \cdot n(n^2 - 4)}.$$

Example 5: Find the steady-state temperature distribution in a rectangular thin plate with its two surfaces insulated and with the conditions. (Fig. 19.7)

$$u(0, y) = 0, u(x, 0) = 0, u(a, y) = g(y), u(x, b) = f(x)$$

Solution: Superposition applied to boundary conditions dismantles the given problem to solution of two simpler problems each of which can readily be solved by separation of variables.

Fig. 19.7

Assume $u(x, y) = u_1(x, y) + u_2(x, y)$. Then

Fig. 19.8

Thus the two boundary value problems are to be solved. (Actually if one problem is solved, the other can be obtained by interchanging x by y , a by b and $f(x)$ by $g(y)$.)

$$\text{I. } \frac{\partial^2 u_1}{\partial x^2} + \frac{\partial^2 u_1}{\partial y^2} = 0$$

$$u_1(0, y) = 0, u_1(a, y) = 0$$

$$u_1(x, 0) = 0, u_1(x, b) = f(x)$$

$$\text{II. } \frac{\partial^2 u_2}{\partial x^2} + \frac{\partial^2 u_2}{\partial y^2} = 0$$

$$u_2(0, y) = 0, u_2(x, 0) = 0$$

$$u_2(x, b) = 0, u_2(a, y) = g(y)$$

Problem I: $X'' + \lambda X = 0, X(0) = X(a) = 0$

$$X_n(x) = \sin \frac{n\pi x}{a}$$

$$Y'' - \lambda Y = 0, Y(0) = 0,$$

$$Y(y) = c_1 e^{\lambda y} + c_2 e^{-\lambda y} \quad \therefore c_1 = -c_2$$

$$Y_n(y) = A_n \cdot \sinh \frac{n\pi y}{a}$$

$$\text{Thus } u_1(x, y) = \sum A_n \sin \left(\frac{n\pi x}{a} \right) \cdot \sinh \left(\frac{n\pi y}{a} \right)$$

$$\begin{aligned} \text{Since } f(x) = u_1(x, b) &= \sum \left[A_n \cdot \sinh \left(\frac{n\pi b}{a} \right) \right] \\ &\times \sin \left(\frac{n\pi x}{a} \right) \end{aligned}$$

$$\text{Therefore } A_n = \frac{2}{a \cdot \sinh \left(\frac{n\pi b}{a} \right)} \int_0^a f(x) \cdot \sin \left(\frac{n\pi x}{a} \right) dx.$$

In a similar way, the solution to problem II is obtained (by swapping x by y , a by b , $f(x)$ by $g(y)$)

$$u_2(x, y) = \sum_{n=1}^{\infty} B_n \cdot \sin \left(\frac{n\pi y}{b} \right) \cdot \sinh \left(\frac{n\pi x}{b} \right)$$

$$\text{where } B_n = \frac{2}{b \cdot \sinh \left(\frac{n\pi a}{b} \right)} \int_0^b g(y) \sin \left(\frac{n\pi y}{b} \right) dy.$$

The required solution is

$$u(x, y) = u_1(x, y) + u_2(x, y).$$

Example 6: Solve the above problem when $u(a, y) = g(y) = 0$ and $u(x, b) = f(x) = \frac{2x}{a}$ when $0 < x < \frac{a}{2}$ and $f(x) = \frac{2(a-x)}{a}$ when $\frac{a}{2} < x < a$.

Solution: Since $g(y) = 0$, all B_n 's are zero, $u_2(x, y) = 0$

Consider

$$I = \int_0^a f(x) \sin \left(\frac{n\pi x}{a} \right) dx$$

$$= \int_0^{\frac{a}{2}} \frac{2x}{a} \cdot \sin \left(\frac{n\pi x}{a} \right) dx + \int_{\frac{a}{2}}^a \frac{2(a-x)}{a} \sin \left(\frac{n\pi x}{a} \right) dx$$

$$\begin{aligned} I &= \frac{2}{a} \left[x \cdot \left(\frac{-a}{n\pi} \right) \cos \left(\frac{n\pi x}{a} \right) - 1 \left(\frac{-a^2}{n^2\pi^2} \right) \sin \left(\frac{n\pi x}{a} \right) \right]_{\frac{a}{2}}^{\frac{a}{2}} \\ &\quad + \frac{2}{a} \left[(a-x) \left(\frac{-a}{n\pi} \right) \cos \left(\frac{n\pi x}{a} \right) \right. \\ &\quad \left. - (-1) \left(\frac{-a^2}{n^2\pi^2} \right) \sin \left(\frac{n\pi x}{a} \right) \right]_{\frac{a}{2}}^a \\ &= \frac{2}{a} \left[\left\{ \frac{a}{2} \cdot \left(\frac{-a}{n\pi} \right) \cos \frac{n\pi}{2} + \frac{a^2}{n^2\pi^2} \sin \frac{n\pi}{2} \right\} \right. \\ &\quad \left. - \left\{ \frac{a}{2} \left(\frac{-a}{n\pi} \right) \cos \frac{n\pi}{2} - \frac{a^2}{n^2\pi^2} \sin \left(\frac{n\pi}{2} \right) \right\} \right] \\ &= \frac{4a}{n^2\pi^2} \sin \left(\frac{n\pi}{2} \right). \end{aligned}$$

Substituting I in A_n , we get

$$A_n = \frac{2}{a \sinh \left(\frac{n\pi b}{a} \right)} \cdot \frac{4a}{n^2\pi^2} \sin \left(\frac{n\pi}{2} \right)$$

19.22 — HIGHER ENGINEERING MATHEMATICS—V

$$= \frac{8}{n^2 \pi^2} \frac{(-1)^n}{\sinh\left(\frac{n\pi b}{a}\right)}$$

when n is odd.

Hence solution is

$$u(x, y) = \frac{8}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^n}{(2n-1)^2} \times \frac{\sinh\left(\frac{(2n-1)\pi y}{a}\right) \cdot \sin\left(\frac{(2n-1)\pi x}{a}\right)}{\sinh\left(\frac{(2n-1)\pi b}{a}\right)}.$$

Insulated edges

Example 7: Find the steady-state temperature in a rectangular plate $0 < x < a$, $0 < y < b$ when the sides $x = 0$, $x = a$, $y = b$ are insulated while the edge $y = 0$ is kept at temperature $k \frac{\cos \pi x}{a}$ (Fig. 19.9).

Solution: The boundary conditions are

$$\frac{\partial u}{\partial x} \Big|_{x=0} = 0; \frac{\partial u}{\partial x} \Big|_{x=a} = 0, \frac{\partial u}{\partial y} \Big|_{y=b} = 0$$

$$u(x, 0) = f(x) = k \cos\left(\frac{\pi x}{a}\right).$$

Fig. 19.9

The boundary conditions reduce to

$$X'(0) = 0, X'(a) = 0, Y'(b) = 0.$$

Differentiating the solution

$$X(x) = A \cos \lambda x + B \sin \lambda x$$

$$X'(x) = -A\lambda \sin \lambda x + B\lambda \cos \lambda x$$

$$\text{Using, } 0 = X'(0) = 0 + B\lambda \therefore B = 0$$

$$0 = X'(a) = -A\lambda \sin \lambda a \therefore \lambda = \frac{n\pi}{a}$$

$$\text{So } X_n(x) = A_n \cdot \cos \frac{n\pi x}{a}, n = 0, 1, 2, \dots$$

Differentiating the solution

$$Y(y) = c_1 e^{\lambda y} + c_2 e^{-\lambda y}$$

$$Y'(y) = \lambda c_1 e^{\lambda y} - c_2 \lambda e^{-\lambda y}$$

$$\text{Using, } 0 = Y'(b) = \lambda(c_1 e^{\lambda b} - c_2 e^{-\lambda b})$$

$$\text{or } c_1 = \frac{c_2 e^{-\lambda b}}{e^{\lambda b}}$$

$$\begin{aligned} \text{Thus } Y(y) &= c_2 \left(\frac{e^{\lambda(b-y)} + e^{-\lambda(b-y)}}{2} \right) \\ &= c_3 \cosh\left(\frac{n\pi(b-y)}{a}\right) \end{aligned}$$

Hence the solution is

$$u(x, y) = \sum_{n=0}^{\infty} A_n \cos\left(\frac{n\pi x}{a}\right) \cdot \cosh\left(\frac{n\pi(b-y)}{a}\right)$$

$$\text{where } A_n = \frac{2}{a \cosh\left(\frac{n\pi b}{a}\right)} \int_0^a f(x) \cos\left(\frac{n\pi x}{a}\right) dx$$

$$\begin{aligned} A_n &= \frac{2}{a \cosh\left(\frac{n\pi b}{a}\right)} \int_0^a k \cdot \cos \frac{\pi x}{a} \\ &\quad \times \cos\left(\frac{n\pi x}{a}\right) dx \end{aligned}$$

$$A_1 = \frac{2k}{a \cosh\left(\frac{\pi b}{a}\right)} \cdot \frac{\pi}{2} \cdot \frac{a}{\pi},$$

$$A_n = 0 \text{ for } n = 0, n \geq 2$$

$$\begin{aligned} u(x, y) &= k \operatorname{sech}\left(\frac{\pi b}{a}\right) \cdot \cos\left(\frac{\pi x}{a}\right) \\ &\quad \times \cosh\left(\frac{\pi(b-y)}{a}\right). \end{aligned}$$

Example 8: Find the steady-state temperature distribution in a thin sheet of metal plate which

occupies the semi-infinite strip, $0 \leq x \leq L$ and $0 \leq y < \infty$ when the edge $y = 0$ is kept at temperature $u(x, 0) = f(x) = kx(L - x)$, $0 < x < L$ while

- i. The edges $x = 0$ and $x = L$ are kept at zero temperature.
- ii. The edges $x = 0$ and $x = L$ are insulated.
Assume that $u(x, \infty) = 0$.

Solution:

Case 1: $u(0, y) = 0$, $u(L, y) = 0$ for every y : (Fig. 19.10)

Solution of $X'' + \lambda^2 X = 0$, $X(0) = X(L) = 0$ is

$$X_n(x) = \sin \frac{n\pi x}{L}, n = 1, 2, 3, \dots$$

Solution of $Y'' - \lambda^2 Y = 0$ is $Y(y) = Ae^{\lambda y} + Be^{-\lambda y}$.
 A must be zero since $y(\infty) = 0$. So

Fig. 19.10

$$Y(y) = B_n e^{-\lambda y}$$

Thus
$$u(x, y) = \sum_{n=1}^{\infty} B_n e^{-n\pi y/L} \cdot \sin \frac{n\pi x}{L}$$

$$\begin{aligned} \text{where } B_n &= \frac{2}{L} \int_0^L kx(L-x) \cdot \sin \frac{n\pi x}{L} dx \\ &= \frac{2k}{L} \left[x(L-x) \cdot \left(\frac{-L}{n\pi} \right) \cos \frac{n\pi x}{L} - \right. \\ &\quad \left. - (L-2x) \left(\frac{-L^2}{n^2\pi^2} \right) \sin \frac{n\pi x}{L} \right. \\ &\quad \left. + \frac{2L^3}{n^3\pi^3} \cos \frac{n\pi x}{L} \right]_0^L \end{aligned}$$

$$B_n = \frac{2k}{L} \frac{2L^3}{n^3\pi^3} [(-1)^n - 1]$$

$$= \frac{-8kL^2}{n^3\pi^3} \text{ when } n \text{ is odd}$$

$$u(x, y) = \frac{-8kL^2}{\pi^3} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^3} e^{-(2n-1)\pi y/L} \times \sin \left(\frac{(2n-1)\pi x}{L} \right).$$

Case 2: Both edges insulated (Fig. 19.11):

$$\frac{\partial u}{\partial x} \Big|_{x=0} = 0, \frac{\partial u}{\partial x} \Big|_{x=L} = 0$$

the solution of $X'' + \lambda^2 X = 0$ with the boundary conditions $X'(0) = 0$ and $X'(L) = 0$ is

$$X_n(x) = A \cos \frac{n\pi x}{L}, n = 0, 1, 2, \dots$$

The solution of $Y'' - \lambda^2 Y = 0$ with $Y(\infty) = 0$ is

$$Y_n(y) = e^{-n\pi y/L}$$

Thus the solution to the problem is

Fig. 19.11

$$u(x, y) = \sum_{n=0}^{\infty} A_n e^{-n\pi y/L} \cdot \cos \left(\frac{n\pi x}{L} \right)$$

$$\text{where } A_0 = \frac{1}{L} \int_0^L kx(L-x) dx = \frac{k}{L} \left[\frac{Lx^2}{2} - \frac{x^3}{3} \right]_0^L$$

$$A_0 = \frac{kL^2}{6}$$

$$\begin{aligned} A_n &= \frac{2}{L} \int_0^L kx(L-x) \cdot \cos \left(\frac{n\pi x}{L} \right) dx \\ &= \frac{2k}{L} \left[x(L-x) \cdot \left(\frac{-L}{n\pi} \right) \sin \frac{n\pi x}{L} \right. \end{aligned}$$

$$-(L-2x) \cdot \left(\frac{-L^2}{n^2\pi^2} \right) \cdot \cos \frac{n\pi x}{L} \\ + (-2) \left(\frac{-L^3}{n^3\pi^3} \right) \cdot \sin \left(\frac{n\pi x}{L} \right) \Bigg]_0^L$$

$$A_n = \frac{2k}{L} \frac{L^3}{n^2\pi^2} [(-1)^n + 1] \\ = \frac{4kL^2}{n^2\pi^2} \text{ where } n \text{ is even}$$

Hence the required solution is

$$u(x, y) = \frac{kL^2}{6} + \frac{4kL^2}{\pi^2} \sum \frac{1}{4n^2} e^{-(2n\pi y/L)} \cdot \cos \left(\frac{2n\pi x}{L} \right).$$

EXERCISE

Rectangular plate

Find the steady-state temperature distribution in a thin rectangular metal plate $0 < x < a$, $0 < y < b$ with its two-faces insulated (so that the flow is two dimensional) (or solve the two-dimensional Laplace's equation $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$) with the following (temperatures) boundary conditions prescribed on the four edges.

1. $u(0, y) = u(x, 0) = u(x, b) = 0$,
 $u(a, y) = g(y)$, $0 < y < b$

$$\text{Ans. } u(x, y) = \sum_{n=1}^{\infty} B_n \sinh \left(\frac{n\pi x}{b} \right) \cdot \sin \left(\frac{n\pi y}{b} \right)$$

where

$$B_n = \frac{2}{b} \operatorname{cosech} \left(\frac{n\pi a}{b} \right) \int_0^b g(y) \sin \left(\frac{n\pi y}{b} \right) dy$$

2. Solve problem 1, with $g(y) = 100$.

$$\text{Ans. } B_n = \frac{400}{(n\pi \sinh \left(\frac{n\pi a}{b} \right))} \text{ for } n \text{ odd.}$$

3. $u(0, y) = u(a, y) = u(x, 0) = 0$, $u(x, b) = f(x)$, $0 < x < a$

$$\text{Ans. } u(x, y) = \sum_{n=1}^{\infty} A_n \sin \left(\frac{n\pi x}{a} \right) \cdot \sinh \left(\frac{n\pi y}{a} \right) \text{ with}$$

$$A_n = \frac{2}{a \sinh \left(\frac{n\pi b}{a} \right)} \int_0^a f(x) \sin \left(\frac{n\pi x}{a} \right) dx.$$

4. Solve problem 3 with $a = b = L$, $u(x, L) = f(x) = x(L - x)$ for $0 \leq x \leq L$.

$$\text{Ans. } u(x, y) = \frac{8L^2}{\pi^2} \sum_{n=\text{odd}} \frac{\sinh \left(\frac{n\pi y}{L} \right) \cdot \sin \left(\frac{n\pi x}{L} \right)}{n^3 \sinh n\pi}$$

5. Solve problem 3 with $u(x, b) = f(x) = 100$

$$\text{Ans. } u(x, y) = \frac{400}{\pi} \sum_{n=\text{odd}} \frac{1}{n} \sin \left(\frac{n\pi x}{a} \right) \cdot \sinh \left(\frac{n\pi y}{a} \right) \\ \times \operatorname{cosech} \left(\frac{n\pi b}{a} \right).$$

6. Solve problem 3 with $u(x, b) = f(x) = \sin \frac{n\pi x}{a}$.

$$\text{Ans. } u(x, y) = \sin \left(\frac{n\pi x}{a} \right) \cdot \sinh \left(\frac{n\pi y}{a} \right) \\ \times \operatorname{cosech} \left(\frac{n\pi b}{a} \right)$$

7. $u(0, y) = u(a, y) = u(x, b) = 0$, $u(x, 0) = f(x) = x(a - x)$, $0 < x < a$

$$\text{Ans. } u(x, y) = \frac{8a^2}{\pi^3} \sum_{n=0}^{\infty} \frac{1}{m^3} \sin \left(\frac{m\pi x}{a} \right) \cdot \sinh \left(\frac{m\pi(b-y)}{a} \right)$$

$$\times \operatorname{cosech} \left(\frac{m\pi b}{a} \right) \text{ where } m = 2n + 1$$

8. $u(0, y) = u(a, y) = u(x, b) = 0$, $u(x, 0) = 5 \sin \frac{4\pi x}{a} + 3 \sin \frac{3\pi x}{a}$.

$$\text{Ans. } u(x, y) = 3 \cdot \operatorname{cosech} \left(\frac{3\pi b}{a} \right) \cdot \sin \left(\frac{3\pi x}{a} \right) \times \\ \times \sinh \left(\frac{3\pi(b-y)}{a} \right) + 5 \cdot \operatorname{cosech} \left(\frac{4\pi b}{a} \right) \times$$

$$\times \sin\left(\frac{4\pi x}{a}\right) \cdot \sinh\left(\frac{4\pi(b-y)}{a}\right)$$

$$9. \quad u(0, y) = u(a, y) = 0, \quad \left(\frac{\partial u}{\partial y}\right)\bigg|_{y=b} = 0$$

(i.e., $y = b$ is insulated) $u(x, 0) = f(x)$

$$\text{Ans. } u(x, y) = \sum B_n \cdot \sin\left(\frac{n\pi x}{a}\right) \cdot \cosh\left(\frac{n\pi(b-y)}{a}\right) \times \\ \times \operatorname{sech}\left(\frac{n\pi b}{a}\right) \text{ where}$$

$$B_n = \frac{2}{a} \int_0^a f(x) \sin\left(\frac{n\pi x}{a}\right) dx$$

$$10. \quad u_x(0, y) = u_x(L, y) = 0 = u_y(x, 0), \quad u(x, z_0) = gz_0 + gcx \text{ (three faces insulated)}$$

$$\text{Ans. } u(x, y) = \left(gz_0 + \frac{gcL}{2}\right) - \\ - \frac{4gcL}{\pi^2} \sum_{n=0}^{\infty} \frac{\cos\left(\frac{m\pi x}{L}\right) \cdot \cosh\left(\frac{m\pi y}{L}\right)}{m^2 \cosh\left(\frac{m\pi z_0}{L}\right)} \quad \text{where} \\ m=2n+1.$$

Semi infinite strip

Find the steady-state temperature distribution in a thin sheet of metal plate which occupies the semi-infinite strip, $0 \leq x \leq L$ and $0 \leq y < \infty$ with the boundary conditions

$$11. \quad u(0, y) = 0, \quad u(\pi, y) = 0 \text{ for all } y, \quad L = \pi \\ u(x, \infty) = 0, \quad u(x, 0) = u_0 \text{ in } 0 < x < \pi$$

$$\text{Ans. } u(x, y) = \frac{4u_0}{\pi} \sum_{n=1}^{\infty} \frac{1}{(2n-1)} \cdot \sin(2n-1)x \\ \times e^{-(2n-1)y}$$

$$12. \quad u(0, y) = 0, \quad u(a, y) = 100 \text{ for all } y, \quad L = a \\ u(x, \infty) = 0, \quad u(x, 0) = f(x) \text{ for } 0 < x < a$$

$$\text{Ans. } u(x, y) = 100 \frac{x}{a} + \sum_{n=1}^{\infty} B_n e^{-n\pi y/a} \cdot \sin\left(\frac{n\pi x}{a}\right) \\ \text{where } B_n = \frac{2}{a} \int_0^a \left[f(x) - \frac{100x}{a}\right] \cdot \sin\left(\frac{n\pi x}{a}\right) dx$$

$$13. \quad u(0, y) = 0, \quad u(10, y) = 0 \text{ for all } y; \quad L = 10$$

$$u(x, \infty) = 0, \quad u(x, 0) =$$

$$f(x) = \begin{cases} 20x, & 0 \leq x \leq 5 \\ 20(10-x), & 5 \leq x \leq 10 \end{cases}$$

$$\text{Ans. } u(x, y) = \frac{800}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{(2n-1)^2} \cdot \sin\left(\frac{(2n-1)\pi x}{10}\right) \\ \times e^{-(2n-1)\pi y/10}$$

$$14. \quad u(x, 0) = 0, \quad u(x, L) = 0 \text{ for all } x,$$

$$u(\infty, y) = 0, \quad u(0, y) = g(y) \text{ for } 0 \leq y \leq L$$

$$\text{Ans. } u(x, y) = \sum_{n=1}^{\infty} B_n \sin \frac{n\pi y}{L} \cdot e^{-\frac{n\pi x}{L}} \text{ where}$$

$$B_n = \frac{2}{L} \int_0^L g(y) \sin\left(\frac{n\pi y}{L}\right) dy$$

$$15. \quad u(0, y) = 0, \quad u(8, y) = 0 \text{ for all } y, \quad L = 8$$

$$u(x, \infty) = 0, \quad u(x, 0) = f(x) = 100 \sin \frac{\pi x}{8}$$

$$\text{Ans. } u(x, y) = 100 \sin\left(\frac{\pi x}{8}\right) \cdot e^{-\frac{\pi y}{8}}$$

19.8 LAPLACE EQUATION IN POLAR COORDINATES

The two dimensional Laplace equation in Cartesian coordinates

$$\nabla^2 u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

gets transformed to the Laplace equation in polar coordinates r, θ as

$$\nabla^2 u = \frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} + \frac{1}{r^2} \frac{\partial^2 u}{\partial \theta^2} = 0 \quad (1)$$

by the transformations

$$x = r \cos \theta, \quad y = r \sin \theta$$

(see WE6 on page 15.25)

Consider the problem of solving Laplace equation (1), by the method of separation of variables in the plane region $a < r < b$, $0 < \theta < \alpha$ with the

following boundary conditions

$$\text{on } QR : u(r, 0) = c, a < r < b \quad (2)$$

$$\text{on } TS : u(r, \alpha) = d, a < r < b \quad (3)$$

$$\text{on } TQ : u(a, \theta) = 0, 0 < \theta < \alpha \quad (4)$$

$$\text{on } SR : u(b, \theta) = f(\theta), 0 < \theta < \alpha \quad (5)$$

$$\text{Assume that } u(r, \theta) = R(r)\phi(\theta) \quad (6)$$

Fig. 19.12

Substituting (6) in (1), we get

$$\frac{r^2 R'' + r R'}{R} + \frac{\ddot{\phi}}{\phi} = 0$$

Here ' denotes differentiation w.r.t. r and $(\cdot)$ denotes differentiation w.r.t. θ .

or

$$\frac{r^2 R'' + r R'}{R} = -\frac{\ddot{\phi}}{\phi} = \text{constant} = \lambda \quad (7)$$

since the R.H.S. is a function of ϕ alone and the L.H.S. is a function of ' r ' alone, the equality holds good only when both of them are constant.

In order to have physically meaningful solutions satisfying the given boundary conditions choose the unknown constant $\lambda = +p^2$. This (7) given rise to two ordinary differential equations

$$r^2 R'' + r R' - p^2 R = 0 \quad (8)$$

$$\text{and} \quad \ddot{\phi} + p^2 \phi = 0 \quad (9)$$

Equation (8) is Euler-Cauchy equation which can be solved by substitution $x = e^t$. For $p = 0$, the general solutions of (8) and (9) are

$$R(r) = c_1 + c_2 \ln r$$

$$\phi(\theta) = c_3 + c_4 \theta$$

For $p \neq 0$, the general solutions of (8) and (9) are

$$R(r) = c_5 r^p + c_6 r^{-p}$$

$$\phi(\theta) = c_7 \cos p\theta + c_8 \sin p\theta$$

Using the principle of superposition, we get

$$u(r, \theta) = (c_1 + c_2 \ln r)(c_3 + c_4 \theta) + (c_5 r^p + c_6 r^{-p})(c_7 \cos p\theta + c_8 \sin p\theta) \quad (10)$$

The arbitrary constants $c_1, c_2, \dots, c_8$ will be determined using the boundary conditions (2), (3), (4) and (5). Using (2) in (10), we have

$$c = u(r, 0) = (c_1 + c_2 \ln r)(c_3) + (c_5 r^p + c_6 r^{-p})c_7$$

Then $c_1 c_3 = c$, $c_2 = 0$, $c_7 = 0$. Then (10) reduces to

$$u(r, \theta) = c + c_9 \theta + (c_{10} r^p + c_{11} r^{-p}) \sin p\theta \quad (11)$$

where $c = c_1 c_3$, $c_9 = c_1 c_4$, $c_{10} = c_5 \cdot c_8$, $c_{11} = c_6 \cdot c_8$. Using (3) in (11), we have

$$d = u(r, \alpha) = c + c_9 \alpha + (c_{10} r^p + c_{11} r^{-p}) \sin p\alpha$$

Then $d = c + c_9 \alpha$ and $\sin p\alpha = 0$ or $c_9 = \frac{d-c}{\alpha}$ and $p\alpha = n\pi$ i.e., $p = \frac{n\pi}{\alpha}$, $n = 1, 2, \dots$

Thus (11) reduces to

$$u(r, \theta) = c + \frac{(d-c)}{\alpha} \alpha \theta + \sum_{n=1}^{\infty} (A_n r^{n\pi/\alpha} + B_n r^{-n\pi/\alpha}) \sin \left(\frac{n\pi\theta}{\alpha} \right) \quad (12)$$

Using (4) in (12), we get

$$0 = u(a, \theta) = c + \left(\frac{d-c}{\alpha} \right) \theta + \sum_{n=1}^{\infty} (A_n a^{n\pi/\alpha} + B_n a^{-n\pi/\alpha}) \sin \left(\frac{n\pi\theta}{\alpha} \right) \quad (13)$$

Therefore the third term in the R.H.S. of (13) is a half range Fourier series expansion of the function $-c - \frac{(d-c)\theta}{\alpha}$ in the interval $0 < \theta < \alpha$. From Fourier series, we have

$$(A_n a^p + B_n a^{-p}) = \frac{2}{\alpha} \int_0^{\alpha} \left[-c - \frac{(d-c)}{\alpha} \theta \right] \cdot \sin p\theta d\theta \quad (14)$$

Finally using (5) in (12), we get

$$f(\theta) = u(b, \theta) = c + \left(\frac{d-c}{\alpha} \right) \theta + \sum (A_n b^p + B_n b^{-p}) \sin p\theta$$

By similar analysis

$$(A_n b^p + B_n b^{-p}) = \frac{2}{\alpha} \int_0^\alpha \left[f(\theta) - c - \frac{(d-c)}{\alpha} \theta \right] \sin p\theta d\theta \quad (15)$$

For given $c, d, \alpha, f(\theta)$, equations (14) and (15) constitute two equations for the two unknowns A_n and B_n . A non-trivial unique solution exists because the coefficient determinant is zero i.e.,

$$\begin{vmatrix} a^p & a^{-p} \\ b^p & b^{-p} \end{vmatrix} = \left(\frac{a}{b} \right)^p - \left(\frac{b}{a} \right)^p \neq 0 \quad \because b \neq a$$

Thus the general solution to the Laplace equation (1) with boundary conditions (2), (3), (4), (5) is given by (12) with the coefficients A_n 's and B_n 's obtained by solving (14) and (15).

Dirichlet Problem for Circular Disk

Consider a thin circular disk of radius 'b' with the two faces insulated and the temperature on the circumference is prescribed as

$$u(b, \theta) = f(\theta), \quad (-\infty < \theta < \infty) \quad (16)$$

Fig. 19.13

By the method of separation of variables the solution to the Laplace equation (1) is given by (10) (of

the previous section)

$$u(r, \theta) = (c_1 + c_2 \ln r)(c_3 + c_4 \theta) + (c_5 r^p + c_6 r^{-p})(c_7 \cos p\theta + c_8 \sin p\theta) \quad (10)$$

Apparently there is only one boundary condition (16) in the circular disk problem, unlike the previous problem where four boundary conditions (2), (3), (4), (5) are available. The circular disk (Fig. 19.13) may be considered as the limiting case of the region (Fig. 19.12) as $a \rightarrow 0$ and $\alpha \rightarrow 2\pi$. So assume that $u(r, \theta)$ is bounded as $r \rightarrow 0$. Using this in (10), as $r \rightarrow 0$, c_2 and c_6 must be zero (because $\ln r \rightarrow \infty, r^{-p} \rightarrow \infty$) as $r \rightarrow 0$. Thus

$$u(r, \theta) = c_9 + c_{10}\theta + r^p(c_{11} \cos p\theta + c_{12} \sin p\theta) \quad (17)$$

where $c_9 = c_1 c_3, c_{10} = c_1 c_4, c_{11} = c_5 c_7, c_{12} = c_5 c_8$. Note that the domain of θ is infinite in the present problem ($-\infty < \theta < \infty$) unlike the previous problem where θ is finite ($0 < \theta < \alpha$). So we assume that $u(r, \theta)$ is periodic, i.e., $u(r, \theta + 2\pi) = u(r, \theta)$ in order that $u(r, \theta)$ is single-valued function of θ . In equation (17), since $c_{10}\theta$ is not periodic, we take $c_{10} = 0$. The constant c_9 is anyway periodic. Finally in order that the remaining two terms $\cos p\theta$ and $\sin p\theta$ are periodic, we must have

$$\cos p(\theta + 2\pi) = \cos p\theta \quad (18)$$

and

$$\sin p(\theta + 2\pi) = \sin p\theta \quad (19)$$

Expanding equation (18), we have $\cos p\theta \cdot \cos 2\pi p - \sin p\theta \cdot \sin 2\pi p = \cos p\theta$. Then $\cos 2\pi p = 1$ for $k = 1, 2, 3, \dots$ and $\sin 2\pi p = 0$ for $k = \frac{1}{2}, 1, \frac{3}{2}, 2, \dots$. Thus equation (18) is satisfied for the common values $k = 1, 2, 3, \dots$. Similar result holds good for equation (19) also. Now with $c_{10} = 0$ and $p = n$, the equation (17) reduces to

$$u(r, \theta) = \frac{A_0}{2} + \sum_{n=1}^{\infty} r^n (A_n \cos n\theta + B_n \sin n\theta) \quad (20)$$

Here $c_9 = \frac{A_0}{2}$

19.28 — HIGHER ENGINEERING MATHEMATICS—V

Now making use of the only boundary condition of the present problem (16) in (20), we have

$$f(\theta) = u(b, \theta) = \frac{A_0}{2} + \sum_{n=1}^{\infty} b^n (A_n \cos n\theta + B_n \sin n\theta) \quad (21)$$

Observe that the R.H.S. of equation (21) is the (full) Fourier series expansion of the periodic function $f(\theta)$ of period 2π . Then the Fourier coefficients are given by

$$A_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(\theta) d\theta \quad (22)$$

$$A_n = \frac{1}{\pi b^n} \int_{-\pi}^{\pi} f(\theta) \cos n\theta d\theta \quad (23)$$

$$B_n = \frac{1}{\pi b^n} \int_{-\pi}^{\pi} f(\theta) \sin n\theta d\theta \quad (24)$$

Thus the solution to the circular disk problem is given by equation (20) where the coefficient A_0, A_n, B_n are determined by equation (22), (23) and (24).

Note: Putting $r = 0$ in equation (20), we get the value of u at the centre of the disk which equals to $\frac{A_0}{2}$.

WORKED OUT EXAMPLES

Determine the steady-state temperature distribution $u(r, \theta)$ in a semi-circular plate of radius ' b ' cm with insulated faces. The bounding diameter is kept at 0°C and the temperature on the circumference is prescribed by $u(b, \theta) = k\theta(\pi - \theta)$ when $0 \leq \theta \leq \pi$.

Solution The boundary value problem consists of the two-dimensional Laplace equation in polar coordinates

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} + \frac{1}{r^2} \frac{\partial^2 u}{\partial \theta^2} = 0, \quad 0 < r < b \quad (1)$$

with boundary conditions

$$u(r, 0) = 0, \quad u(r, \pi) = 0, \quad 0 < r < b \quad (2)$$

$$u(b, \theta) = f(\theta) = k\theta(\pi - \theta), \quad 0 \leq \theta \leq \pi \quad (3)$$

$$\text{Assume } u(r, \theta) = R(r)\phi(\theta) \quad (4)$$

Fig. 19.14

Using (4) equation (1) takes the form

$$\frac{r^2 R'' + r R'}{R} = -\frac{\ddot{\phi}}{\phi} = \lambda = \text{constant}$$

consider $\frac{d^2 \phi}{d\theta^2} + \lambda \phi = 0$, (5)
with boundary conditions $u(r, 0) = R(r)\phi(0) = 0$
 $\therefore \phi(0) = 0$ and

$$u(r, \pi) = R(r)\phi(\pi) = 0 \quad \therefore \quad \phi(\pi) = 0$$

For $\lambda \leq 0$, we get trivial solutions.

For $\lambda = 0$, the solution of (5) is $\phi(\theta) = c_1 \theta + c_2$

$$\text{Since } 0 = \phi(0) = c_1 \cdot 0 + c_2 \quad \therefore \quad c_2 = 0$$

$$\text{Since } 0 = \phi(\pi) = c_1 \cdot \pi \quad \therefore \quad c_1 = 0.$$

Thus $\phi(\theta) = 0$ for any θ .

Similarly for $\lambda = -p^2$, the solution of (5) is

$$\phi(\theta) = c_1 e^{p\theta} + c_2 e^{-p\theta}$$

$$\text{since } 0 = \phi(0) = c_1 + c_2 \quad \text{or} \quad c_1 = -c_2$$

$$\text{since } 0 = \phi(\pi) = c_1 e^{p\pi} + c_2 e^{-p\pi} = c_1 (e^{p\pi} - e^{-p\pi}) \quad \therefore \quad c_1 = 0 \text{ and } c_2 = -c_1 = 0.$$

Again $\phi(\theta) = 0$ for any θ .

So consider $\lambda = p^2 > 0$ to obtain non-trivial solutions. In this case the solution of (5) is

$$\phi(\theta) = c_1 \cos p\theta + c_2 \sin p\theta$$

$$\text{using } 0 = \phi(0) = c_1 \cdot 1 + c_2 \cdot 0 \quad \therefore \quad c_1 = 0$$

$$\text{using } 0 = \phi(\pi) = c_2 \cdot \sin p\pi$$

$$\text{since } c_2 \neq 0, \text{ therefore } \sin p\pi = 0$$

$$\text{or} \quad p\pi = n\pi$$

$$\text{or} \quad p = n \text{ for } n = 1, 2, 3, \dots \quad (6)$$

Thus $\phi_n(\theta) = \sin n\theta$ where the constant c_2 is taken as unity.

Now the D.E. in R is

$$r^2 \frac{d^2 R}{dr^2} + r \frac{dR}{dr} - p^2 R = 0$$

which is Euler-Cauchy equation.

Put $r = e^z$. Then $r^2 \frac{d^2 R}{dr^2} = \frac{dR^2}{dz^2} - \frac{dR}{dz}$ and $r \frac{dR}{dr} = \frac{dR}{dz}$

Then the D.E. reduces to

$$\frac{d^2 R}{dz^2} - \frac{dR}{dz} + \frac{dR}{dz} - n^2 R = 0 \quad \because p = n.$$

The general solution of this equation is

$$R(z) = c_1 e^{nz} + c_2 e^{-nz}$$

$$\text{or } R(r) = c_1 r^n + c_2 r^{-n}$$

since $u(r, \theta)$ is bounded, $\lim_{r \rightarrow 0} u(r, \theta) = \text{finite}$

Now since n is a positive integer $\lim_{r \rightarrow 0} R(r)$ is finite provided $c_2 = 0$

Thus $R_n(r) = c_1 r^n$

Then by superposition principle

$$u(r, \theta) = \sum_{n=1}^{\infty} B_n r^n \sin n\theta \quad (7)$$

To determine the unknown coefficients B_n 's use the boundary condition $u(b, \theta)$, in (7). So

$$K\theta(\pi - \theta) = u(b, \theta) = \sum_{n=1}^{\infty} B_n b^n \sin n\theta$$

which is a half range Fourier sine series expansion of $K\theta(\pi - \theta)$ in the interval $(0, \pi)$. Then the Fourier coefficients are given by

$$b^n B_n = \frac{2}{\pi} \int_0^{\pi} K\theta(\pi - \theta) \sin n\theta d\theta$$

Integrating by parts

$$\begin{aligned} b^n B_n &= \frac{2K}{\pi} \left[\theta(\pi - \theta) \cdot \left(-\frac{1}{n} \cos n\theta \right) \right. \\ &\quad \left. - (\pi - 2\theta) \left(\frac{-1}{n^2} \right) \sin n\theta \right. \\ &\quad \left. + (-2) \cdot \left(\frac{1}{n^3} \right) \cos n\theta \right] \Bigg|_{\theta=0}^{\pi} \\ b^n B_n &= \frac{2K}{\pi} \left[\frac{2}{n^3} (1 - \cos n\pi) \right] \end{aligned}$$

$$= \frac{4K}{\pi n^3} (1 - (-1)^n)$$

Thus the steady-state temperature distribution in the circular plate is

$$u(r, \theta) = \frac{4K}{\pi} \sum_{n=1}^{\infty} \frac{[1 - (-1)^n]}{b^n n^3} r^n \sin n\theta$$

EXERCISE

1. A plate having the shape of a quadrant of a circle of radius 10 cm has insulated faces. The bounding radii $\theta = 0$ and $\theta = \frac{\pi}{2}$ are kept at 0°C while the temperature along the circular quadrant is kept at $100(\pi\theta - 2\theta^2)$ when $0 \leq \theta \leq \frac{\pi}{2}$ until steady-state conditions prevail. Find the temperature at the centroid of the plate having coordinates $\left(\frac{4\theta\sqrt{2}}{3\pi}, \frac{\pi}{4}\right)$.

Ans. 45.8

Hint: $\phi(0) = \phi\left(\frac{\pi}{2}\right) = 0$, $p = 2n$, $u(r, \theta) = \sum_{n=1}^{\infty} c_n r^{2n} \sin 2n\theta$, $u(10, \theta) = 100(\pi\theta - 2\theta^2)$,

$$\begin{aligned} c_n &= \frac{-400}{\pi n^3 (10)^{2n}}, \text{ for } n = 1, \text{ at centroid, } u \\ &= \frac{400}{\pi} \left(\frac{4\sqrt{2}}{3\pi} \right)^2 \end{aligned}$$

2. The bounding diameter of a semi-circular plate of radius 'b' cm, with insulated faces, is kept at 0°C . The semi-circumference is maintained at a temperature given by $\frac{K\theta}{\pi}$ in $0 \leq \theta \leq \frac{\pi}{2}$ and $\frac{K}{\pi}(\pi - \theta)$ in $\frac{\pi}{2} \leq \theta \leq \pi$. Determine the steady-state temperature distribution in the plate.

Ans: $u(r, \theta) = \frac{4K}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{(2n-1)^2} \left(\frac{r}{b}\right)^{2n-1} \cdot \sin(2n - 1)\theta$.

3. Find the steady-state temperature distribution in a semi-circular plate of radius 'b' cm with the bounding diameter kept at 0°C and with a constant temperature K on the semicircular boundary.

Ans. $u(r, \theta) = \frac{4K}{\pi} \sum_{n=1}^{\infty} \frac{1}{(2n-1)} \left(\frac{r}{b}\right)^{2n-1} \sin(2n - 1)\theta$

19.30 — HIGHER ENGINEERING MATHEMATICS—V

4. Solve the Laplace equation in two dimensions for $u(r, \theta)$ defined in the region $a \leq r \leq b$, $0 \leq \theta \leq \frac{\pi}{2}$ and with boundary conditions $u(r, 0) = u(r, \frac{\pi}{2}) = 0$, $u(b, \theta) = 0$, $u(a, \theta) = \theta(\frac{\pi}{2} - \theta)$.

Ans.
$$u(r, \theta) = \frac{2}{\pi} \sum_{m=1}^{\infty} \frac{\left(\frac{r}{b}\right)^n - \left(\frac{b}{r}\right)^n}{\left(\frac{a}{b}\right)^n - \left(\frac{b}{a}\right)^n} \frac{\sin n\theta}{(2m-1)}$$
 where $n = 4m - 2$

5. Solve the Dirichlet problem:

$$u_{rr} + \frac{1}{r}u_r + \frac{1}{r^2}u_{\theta\theta} = 0$$

$$a < r < b, 0 < \theta < \alpha$$

$$u(r, 0) = 0, \quad u(r, \alpha) = 0, \quad (a < r < b)$$

$$u(a, \theta) = 0, \quad u(b, \theta) = 100, \quad (0 < \theta < \alpha)$$

Ans.
$$u(r, \theta) = \frac{400}{\pi} \sum_{n=1}^{\infty} \frac{1}{m} \frac{\left(\frac{r}{a}\right)^{\lambda} - \left(\frac{a}{r}\right)^{\lambda}}{\left(\frac{b}{a}\right)^{\lambda} - \left(\frac{a}{b}\right)^{\lambda}} \cdot \sin \lambda \theta$$
 Here $m = 2n - 1$, $\lambda = (2n - 1)\pi/\alpha$

6. Determine the steady-state temperature $u(r, \theta)$ in the annulus region $2 < r < 4$ with the temperatures along the boundaries given by $u(2, \theta) = 6 \cos \theta + 10 \sin \theta$, $u(4, \theta) = 15 \cos \theta + 17 \sin \theta$.

Ans.
$$u(r, \theta) = 4\left(r - \frac{1}{r}\right) \cos \theta + 4\left(r + \frac{1}{r}\right) \sin \theta.$$

Hint: $u(r, \theta) = (a_0 + b_0 \log r)$

$$+ \sum_{n=1}^{\infty} (a_n r^n + b_n r^{-n}) \cos n\theta + \sum_{n=1}^{\infty} (c_n r^n + d_n r^{-n}) \sin n\theta$$

Dirichlet Problem for Disk

7. Find the steady-state temperature distribution in a circular plate of radius 'b', with insulated faces and with the temperature on circumference prescribed by

$$f(\theta) = u(a, \theta) = \begin{cases} 100, & 0 \leq \theta \leq \pi \\ 0, & \pi \leq \theta \leq 2\pi \end{cases}$$

Ans.
$$u(r, \theta) = 50 + \frac{200}{\pi} \sum_{n=1}^{\infty} \frac{1}{(2n-1)} \left(\frac{r}{b}\right)^{2n-1} \sin(2n-1)\theta$$

Hint:
$$u(r, \theta) = \frac{a_0}{2} + \sum_{n=1}^{\infty} r^n (a_n \cos n\theta + b_n \sin n\theta)$$

$$a_0 = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(\theta) d\theta, \quad a_n = \frac{1}{\pi b^n} \int_{-\pi}^{\pi} f(\theta) \cos n\theta d\theta$$

$$b_n = \frac{1}{\pi b^n} \int_{-\pi}^{\pi} f(\theta) \sin n\theta d\theta$$

Solve the Laplace equation $\nabla^2 u = 0$ for $u(r, \theta)$ with the following boundary conditions in the region specified.

8. $1 < r < 2$, $0 < \theta < \pi$, $u(r, \pi) = 100$, $u(r, 0) = u_r(1, \theta) = u(2, \theta) = 0$

Ans.
$$u(r, \theta) = \frac{100\theta}{\pi} + \frac{200}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \frac{(-1)^n}{2^{n+2}-n} (r^n + r^{-n}) \sin n\theta$$

9. $1 < r < 2$, $0 < \theta < \pi$, $u(1, \theta) = u_{\theta}(r, 0) = u_{\theta}(r, \pi) = 0$, $u(2, \theta) = 100$

Ans.
$$u(r, \theta) = \frac{100 \ln r}{\ln 2}$$

10. $r < 1$, u bounded, $u(1, 0) = 50 + 20 \cos \theta$

Ans.
$$u(r, \theta) = 50 + 20r \cos \theta$$

19.9 DERIVATION AND SOLUTION OF TWO-DIMENSIONAL HEAT EQUATION

Consider a thin flat metal rectangular plate of uniform thickness θ (cm) of a heat conducting material sandwiched between sheets of insulation. Choose the coordinate system such that one face of the plate is taken as the XOY -plane as shown in Fig. 19.15. Assume that the temperature u at any point of the plate depends on the position in the xy -plane and time t and is independent of the z -coordinate so that u is function of x, y, t i.e. $u = u(x, y, t)$. Thus, the flow is two-dimensional. Let r denote the rate of heat generation per unit volume, ρ (gr/cm³) be the density s (cal/gr deg) be the heat capacity and k (cal/cm sec deg) be the thermal conductivity of the plate. Let $q_x(x, y)$, $q_y(x, y)$ denote the heat flow rates in the x and y directions.

Fig. 19.15

Now the two-dimensional heat equation is derived by applying the law of conservation of energy in the rate form to a small rectangle $ABCD$ with sides Δx and Δy . The conservation of energy states that rate in + rate of generation = rate out + rate of storage or rate in – rate out = rate of storage – rate of generation

$$\begin{aligned} & \left[q_x \left(x, y + \frac{1}{2} \Delta y \right) - q_x \left(x + \Delta x, y + \frac{1}{2} \Delta y \right) \right] \theta \Delta y \\ & + \left[q_x \left(x + \frac{1}{2} \Delta x, y \right) - q_x \left(x + \frac{1}{2} \Delta x, y + \Delta y \right) \right] \theta \Delta x \\ & = \left(-r + \rho s \frac{\partial u}{\partial t} \right) \Delta x \cdot \Delta y \cdot \theta. \end{aligned}$$

Dividing throughout by $\theta \Delta x \Delta y$ and taking the limit as Δx and Δy tend to zero, we get

$$-\frac{\partial q_x}{\partial x} - \frac{\partial q_y}{\partial y} = -r + \rho s \frac{\partial u}{\partial t}$$

Using Fourier law,

$$\frac{\partial}{\partial x} \left(\kappa_x \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial y} \left(\kappa_y \frac{\partial u}{\partial y} \right) = \rho s \frac{\partial u}{\partial t} - r$$

Assuming that the material is isotropic, we have $\kappa_x = \kappa_y = \kappa$ we have the 2-dimensional heat equation

$$\kappa \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) = \rho s \frac{\partial u}{\partial t} - r$$

In the absence of source of heat generation, $r = 0$. The flow of thermal energy in a two-dimensional region is given by

$$\boxed{\frac{\partial u}{\partial t} = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)} \quad (1)$$

Here $c^2 = \frac{\kappa}{\rho s}$, is a positive constant, is the diffusivity. The temperature distribution $u(x, y, t)$ in the metal plate at any time in the transient state is described by equation (1). In addition to (1), specification of temperature on the boundary (condition) of the plate and initial temperature distribution is required.

Steady-state

When u is independent of time t , temperature distribution is said to be in the steady-state and in this case the equation (1) reduces to

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \quad (2)$$

Equation (2) is known as two-dimensional Laplace's equation or steady-state heat equation.

Solution of Two-dimensional Heat Equation by the Method of Separation of Variables

The diffusion of heat in a rectangular metal plate of uniform, isotropic material, with both faces insulated and with the four edges kept at zero temperature is given by the transient temperature $u(x, y, t)$ which satisfies the following initial boundary value problem (IBVP) consisting of

1. Partial Differential Equation (P.D.E.)

$$\frac{\partial u}{\partial t} = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) \quad (1)$$

in the region of the plate

$$0 \leq x \leq a, \quad 0 \leq y \leq b, \quad 0 < t$$

2. With Boundary Conditions (B.C.)

$$\begin{aligned} u(x, 0, t) = 0, \quad u(x, b, t) = 0, \\ 0 < x < a, \quad 0 < t \end{aligned} \quad (2)$$

$$\begin{aligned} u(0, y, t) = 0, \quad u(a, y, t), \\ 0 < y < b, \quad 0 < t \end{aligned} \quad (3)$$

3. Initial Conditions (I.C.)

$$u(x, y, 0) = f(x, y), \quad 0 < x < a, \quad 0 < y < b \quad (4)$$

19.32 — HIGHER ENGINEERING MATHEMATICS—V

We can apply separation of variables technique to the above IBVP because both the P.D.E. (1) and the B.C. (2) and (3) are homogeneous. Assume that

$$u(x, y, t) = \phi(x, y)T(t)$$

substituting u in (1), we have

$$\left(\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} \right) T = \frac{1}{c^2} \phi \dot{T}$$

or

$$\left(\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} \right) \frac{1}{\phi} = \frac{\dot{T}}{c^2 T}$$

The mutual value of the L.H.S. and R.H.S. of the above equation must be a constant. Since the time-dependent part of the product solution exponentially decays (if $\lambda > 0$), a separation constant in the form of $-\lambda^2$ may be introduced. Then the resulting equations are

$$\dot{T} + \lambda^2 c^2 T = 0, \quad t > 0 \quad (5)$$

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = -\lambda^2 \phi, \quad 0 < x < a, \quad 0 < y < b \quad (6)$$

The eigen value λ relates to the decay of the time-dependent part. The boundary conditions (2), (3) take the form

$$\phi(x, 0)T(t) = 0, \quad \phi(x, b)T(t) = 0$$

$$\phi(0, y)T(t) = 0, \quad \phi(a, y)T(t) = 0$$

If $T(t) = 0$, we get trivial solution that $u = 0$ for all t . Thus, the required boundary conditions are

$$\phi(x, 0) = 0, \quad \phi(x, b) = 0, \quad 0 < x < a \quad (7)$$

$$\phi(0, y) = 0, \quad \phi(a, y) = 0, \quad 0 < y < b \quad (8)$$

In the new two-dimensional eigen value problem consisting of equations (6), (7), (8) the P.D.E. and B.C. are linear and homogeneous. So separation of variable can be applied again. Assuming

$$\phi(x, y) = X(x)Y(y)$$

equation (6) becomes

$$\frac{X''}{X} + \frac{Y''}{Y} = -\lambda^2, \quad 0 < x < a, \quad 0 < y < b$$

The ratios $\frac{X''}{X}$ and $\frac{Y''}{Y}$ should be a negative constant, denoted by $-\mu^2$ and $-v^2$ respectively

because the sum of a function of x and a function of y can be a constant only if each of these two functions are individually constants. The separate equations for x and y are

$$X'' + \mu^2 X = 0, \quad 0 < x < a \quad (9)$$

$$Y'' + v^2 Y = 0, \quad 0 < y < b \quad (10)$$

The three separation constants are connected by the relation

$$\lambda^2 = \mu^2 + v^2 \quad (11)$$

the boundary conditions (7) and (8) takes the form

$$X(x)Y(0) = 0, \quad X(x)Y(b) = 0, \quad 0 < x < a$$

$$X(0)Y(y) = 0, \quad X(a)Y(y) = 0, \quad 0 < y < b$$

Again $X(x) = 0$ for all x or $Y(y) = 0$ for all y , leads to trivial solution $u = 0$. Thus, the appropriate boundary conditions are

$$Y(0) = 0, \quad Y(b) = 0 \quad (12)$$

$$X(0) = 0, \quad X(a) = 0 \quad (13)$$

Equations (9) and (13) and Eqns (10) and (12) form two independent eigen value problems, with the following solutions:

$$X_m(x) = \sin\left(\frac{m\pi x}{a}\right), \quad \mu_m^2 = \left(\frac{m\pi}{a}\right)^2$$

and

$$Y_n(y) = \sin\left(\frac{n\pi y}{b}\right), \quad v_n^2 = \left(\frac{n\pi}{b}\right)^2$$

Here the indices n and m are independent. The solutions of the two-dimensional eigen value problems (6), (7), (8) are

$$\phi_{mn}(x, y) = X_m(x)Y_n(y)$$

$$\text{with} \quad \lambda_{mn}^2 = \mu_m^2 + v_n^2$$

and the corresponding solution of (5) is

$$T_{mn} = \exp(-\lambda_{mn}^2 c^2 t)$$

The P.D.E. (1) and B.C. (2), (3) are satisfied by the function

$$\begin{aligned} u_{mn}(x, y, t) &= \phi_{mn}(x, y) \cdot T_{mn}(t) \\ &= \sin\left(\frac{m\pi x}{a}\right) \cdot \sin\left(\frac{n\pi y}{b}\right) \exp(-\lambda_{mn}^2 c^2 t) \end{aligned}$$

for each pair of indices m, n (with $m = 1, 2, 3, \dots$ and $n = 1, 2, 3, \dots$).

Using the superposition principle, we obtain the double series

$$u(x, y, t) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{mn} \phi_{mn}(x, y) T_{mn}(t) \quad (14)$$

which satisfies equations (1), (2), (3). The unknown coefficients A_{mn} are determined using the initial condition (4) as follows:

The key idea here is the double Fourier series (also known as double trigonometric series).

In a problem involving a rectangle $0 < x < a$, $0 < y < b$, a double Fourier sine series is given by

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{mn} \sin\left(\frac{m\pi x}{a}\right) \cdot \sin\left(\frac{n\pi y}{b}\right)$$

Similarly a double Fourier cosine series is given by

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{mn} \cdot \cos\left(\frac{m\pi x}{a}\right) \cdot \cos\left(\frac{n\pi y}{b}\right)$$

clearly other combinations of sines and cosines could be considered.

All these double series are of the form

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \phi_m(x) \psi_n(y)$$

where ϕ_m, ψ_n are the eigen functions of a Sturm-Liouville problem, satisfying the orthogonality relations. For example, in the case of double Fourier sine series, the orthogonality relation is

$$\begin{aligned} & \int_0^a \int_0^b \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right) \sin\left(\frac{p\pi x}{a}\right) \sin\left(\frac{q\pi y}{b}\right) dx dy \\ &= \begin{cases} \frac{ab}{4}, & \text{if both } m = p \text{ and } n = q \\ 0, & \text{otherwise} \end{cases} \end{aligned}$$

Thus, many functions can be expressed as sums of multiple Fourier series. The expansion formula in the case of double Fourier sine series in the rectangle $0 < x < a$, $0 < y < b$ is

$$f(x, y) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{mn} \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right)$$

Here the unknown coefficients A_{mn} are given by the *generalized Euler Formula*.

$$A_{mn} = \frac{4}{ab} \int_0^b \int_0^a f(x, y) \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right) dx dy \quad (15)$$

with $m = 1, 2, 3, \dots$ and $n = 1, 2, 3, \dots$

Now consider the general solution given by equation (14) as

$$\begin{aligned} u(x, y, t) &= \\ & \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{mn} \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right) \exp(-\lambda_{mn}^2 c^2 t). \end{aligned} \quad (16)$$

Using the initial condition (4) in (16) we have

$$\begin{aligned} f(x, y) &= u(x, y, 0) \\ &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{mn} \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right) \end{aligned}$$

which is a double Fourier sine series. Here A_{mn} are determined by (15). Thus, the complete solution to the IBVP (1), (2), (3), (4) is given by (16) with coefficients A_{mn} determined by (15).

WORKED OUT EXAMPLES

Edges at zero temperature

Example 1: Determine the transient temperature in a rectangular metal plate of uniform isotropic material with both faces insulated, with the four edges maintained at zero temperature and with initial temperature distribution given by xy .

Solution: Here the initial condition is

$$u(x, y, 0) = f(x, y) = xy$$

Then from (15),

$$\begin{aligned} A_{mn} &= \frac{4}{ab} \int_0^b \int_0^a xy \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right) dx dy \\ &= \frac{4}{ab} \left[\int_0^b \sin\left(\frac{n\pi y}{b}\right) dy \right] \left[\int_0^a x \sin\left(\frac{m\pi x}{a}\right) dx \right] \end{aligned}$$

19.34 — HIGHER ENGINEERING MATHEMATICS—V

Integrating by parts

$$\begin{aligned}
 A_{mn} &= \frac{4}{ab} \left[y \left(\frac{b}{n\pi} \right) (-1) \cos \frac{m\pi y}{b} \right. \\
 &\quad \left. - 1 \frac{b^2}{n^2\pi^2} (-1) \sin \frac{n\pi y}{b} \right] \Bigg|_{y=0}^b \times \\
 &\quad \times \left[x \left(\frac{a}{m\pi} \right) (-1) \cos \left(\frac{n\pi x}{a} \right) \right. \\
 &\quad \left. - 1 \frac{a^2}{m^2\pi^2} (-1) \sin \left(\frac{n\pi x}{a} \right) \right] \Bigg|_{x=0}^a \\
 &= \frac{4}{ab} \left[\frac{-b^2}{m\pi} \cos m\pi \right] \left[\frac{-a^2}{n\pi} \cos n\pi \right] \\
 &= \frac{4ab}{mn\pi^2} \cos m\pi \cos n\pi
 \end{aligned}$$

Thus, the required solution is

$$\begin{aligned}
 u(x, y, t) &= \frac{4ab}{\pi^2} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{(-1)^{m+n}}{mn} \sin \frac{n\pi x}{a} \\
 &\quad \sin \frac{m\pi y}{a} e^{-\lambda_{mn}^2 c^2 t}
 \end{aligned}$$

where $\lambda_{mn}^2 = \mu_m^2 + \nu_n^2$.

Two edges insulated

Example 1: Find the temperature distribution in a rectangular plate $0 < x < 1$, $0 < y < 2$, with both its faces insulated, top and bottom edges insulated and right and left edges kept at zero temperature. The initial temperature distribution is given by

$$\begin{aligned}
 u(x, y, 0) &= x(1-x)y^2(3-y), \\
 0 < x < 1, \quad 0 < y < 2. \text{ Refer Fig. 19.16.}
 \end{aligned}$$

Solution: The initial boundary value problem consists of PDE

$$\frac{\partial u}{\partial t} = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) \quad (1)$$

$$\begin{aligned}
 \text{B.C : Left edge OC : } u(0, y, t) &= 0, \quad 0 < y < 2, \\
 &\text{all } t \quad (2)
 \end{aligned}$$

$$\begin{aligned}
 \text{Right edge AB } u(1, y, t) &= 0, \quad 0 < y < 2, \\
 &\text{all } t \quad (3)
 \end{aligned}$$

$$\text{Bottom edge OA : } u_y(x, 0, t) = 0, \quad 0 < x < 1,$$

Fig. 19.16

$$\text{all } t \quad (4)$$

$$\begin{aligned}
 \text{Top edge CB : } u_y(x, 2, t) &= 0, \quad 0 < x < 1, \\
 &\text{all } t \quad (5)
 \end{aligned}$$

$$\begin{aligned}
 \text{I.C. : } u(x, y, 0) &= x(1-x)y^2(3-y), \quad 0 < x < 1, \\
 &0 < y < 2 \quad (6)
 \end{aligned}$$

substitution of

$$u(x, y, t) = X(x)Y(y)T(t) \quad (7)$$

into the P.D.E. (1) gives

$$XY\dot{T} = c^2(X''YT + XY''T)$$

or

$$\frac{X''}{X} = \frac{\dot{T}}{c^2 T} - \frac{Y''}{Y}$$

Assuming the common value of the two sides of this equation as a constant $-\lambda^2$, we get

$$\frac{X''}{X} + \frac{Y''}{Y} = -\lambda^2 = \frac{\dot{T}}{c^2 T}$$

Assuming the ratios $\frac{X''}{X}$ and $\frac{Y''}{Y}$ as negative constants $-\mu^2$ and $-\nu^2$ respectively, we get the following three ordinary differential equations.

$$X'' + \mu^2 X = 0 \quad (8)$$

$$Y'' + \nu^2 Y = 0 \quad (9)$$

$$\dot{T} + c^2 \lambda^2 T = 0 \quad (10)$$

Using (7) in the boundary conditions (2), (3), (4), (5), we get

$$X(0) = X(1) = 0 \quad (11)$$

$$Y'(0) = Y'(2) = 0 \quad (12)$$

The non-trivial solutions to the eigenvalue problem (8), (11) are given by constant multiples of

$$X_m = \sin \frac{m\pi x}{1}$$

with $\mu_m = m^2\pi^2$, and m a positive integer. Similarly the corresponding non trivial solutions of (9), (12) are constant multiples of

$$Y_n = \cos \frac{n\pi y}{2}$$

with $\nu_n = \frac{n^2\pi^2}{4}$, and n a positive integer (here $y_0 = \cos 0 = 1$)

with $\lambda_{mn}^2 = \mu_m^2 + \nu_n^2 = m^2\frac{\pi^2}{1^2} + \frac{n^2\pi^2}{4}$, the equation (10) becomes

$$\dot{T} + \lambda_{mn}^2 c^2 T = 0$$

with solutions as constant multiples of

$$T_{mn}(t) = \exp(-\lambda_{mn}^2 c^2 t)$$

Then the most general solution satisfying (1), (2), (3), (4), (5) is given by

$$u(x, y, t) = \sum_{m=1}^{\infty} \sum_{n=0}^{\infty} A_{mn} \sin \frac{m\pi x}{1} \cdot \cos \frac{n\pi y}{2} \cdot e^{-\lambda_{mn}^2 c^2 t} \quad (13)$$

The unknown coefficients A_{mn} are now determined by using the initial condition (6) in (13).

So, $u(x, y, 0) = \sum_{m=1}^{\infty} \sum_{n=0}^{\infty} A_{mn} \sin m\pi x \cdot \cos \frac{n\pi y}{2}$

$= x(1-x)y^2(3-y)$

which is a double trigonometric series. Now for each fixed value of y , express the initial temperature distribution as a sine series in x . Put

$$A_m(y) = \sum_{n=0}^{\infty} A_{mn} \cos \frac{n\pi y}{2}$$

Then

$$x(1-x)y^2(3-y) = \sum_{m=1}^{\infty} A_m(y) \cdot \sin m\pi x$$

with y treated as constant, we have

$$\begin{aligned} A_m(y) &= \frac{2}{1} \int_{x=0}^1 x(1-x)y^2(3-y) \cdot \sin m\pi x \, dx \\ &= 2y^2(3-y) \int_0^1 x(1-x) \sin m\pi x \, dx \end{aligned}$$

Integrating by parts

$$A_m(y) = 2y^2(3-y) \left[x(1-x) \left(\frac{-1}{m\pi} \right) \cos m\pi x \right.$$

$$\begin{aligned} & - (1-2x)(-1) \frac{1}{m^2\pi^2} \sin m\pi x \\ & \left. + (-2)(-1)(-1) \frac{1}{m^3\pi^3} \cdot \cos m\pi x \right]_{x=0}^1 \end{aligned}$$

$$= -\frac{2}{m^3\pi^3} [\cos m\pi - 1] 2y^2(3-y)$$

$$A_m(y) = +\frac{8y^2(3-y)}{m^3\pi^3} \text{ when } m \text{ is odd}$$

$$= 0 \quad \text{when } m \text{ is even}$$

Now expand each function $A_m(y)$ in a cosine series of the form

$$A_m(y) = \sum_{n=0}^{\infty} A_{mn} \cos \frac{n\pi y}{2}$$

If m is even then $A_m(y) = 0$ so

$$a_{mn} = 0 \text{ for all } n.$$

If m is odd, then for $n = 0$, we have

$$A_{m0} = \frac{1}{2} \int_{y=0}^2 \frac{8y^2(3-y)}{m^3\pi^3} dy$$

$$2A_{m0} = \frac{1}{m^3\pi^3} \left[24 \frac{y^3}{3} - 8 \frac{y^4}{4} \right]_{y=0}^2 = \frac{32}{m^3\pi^3}.$$

For $n > 0$,

$$A_{mn} = \frac{2}{2} \int_{y=0}^2 \frac{8y^2(3-y)}{m^3\pi^3} \cos \frac{n\pi y}{2} dy$$

$$A_{mn} = \frac{8}{m^3\pi^3} \left[y^2(3-y) \left(\frac{2}{n\pi} \right) \sin \frac{n\pi y}{2} \right.$$

$$\left. - (6y - 3y^2) \left(\frac{-2^2}{n^2\pi^2} \right) \cos \frac{n\pi y}{2} \right.$$

$$\left. + (6 - 6y) \left(\frac{-2^2}{n^2\pi^2} \right) \left(\frac{2}{n\pi} \right) \cdot \sin \frac{n\pi y}{2} \right.$$

$$\left. - (6)(-1) \frac{2^4}{n^4\pi^4} (-1) \cdot \cos \frac{n\pi y}{2} \right]_{y=0}^2$$

$$= \frac{8}{m^3\pi^3} \left[(-1) \frac{16.6}{n^4\pi^4} (\cos n\pi - 1) \right]$$

$$= \begin{cases} \frac{1536}{m^3 n^4 \pi^7} & \text{if } n \text{ is odd} \\ 0 & \text{if } n \text{ is even} \end{cases}$$

19.36 — HIGHER ENGINEERING MATHEMATICS—V

Thus, the required solution is

$$u(x, y, t) = \sum_{m=1}^{\infty} \sum_{n=0}^{\infty} A_{mn} \sin m\pi x \cdot \cos \frac{n\pi y}{2} e^{-c^2 \lambda_{mn}^2 t}$$

where

$$A_{mn} = \begin{cases} 0 & \text{if } n \text{ is even or if } m > 0 \text{ is even} \\ \frac{16}{m^3 \pi^3} & \text{if } n \text{ is odd and } m = 0 \\ \frac{1536}{m^3 n^4 \pi^7} & \text{if } n \text{ and } m \text{ are both odd} \end{cases}$$

EXERCISE

- Find the temperature $u(x, y, t)$ in a rectangular plate $0 \leq x \leq 2, 0 \leq y \leq 3$ with both faces insulated and the four edges kept at zero temperature and with initial temperature given by

$$u(x, y, 0) = 4 \sin \left(\frac{3\pi x}{2} \right) \sin \pi y - 2 \sin \pi x \cdot \sin \frac{2\pi y}{3}$$

Ans. $u(x, y, t) = 4 \exp \left[-\pi^2 \left\{ \left(\frac{3}{2} \right)^2 + 1^2 \right\} c^2 t \right] \sin \frac{3\pi x}{2} \times \sin \pi y - 2 \cdot \exp \left[-\pi^2 \left\{ 1^2 + \left(\frac{2}{3} \right)^2 \right\} c^2 t \right] \sin \pi x \times \sin \frac{2\pi y}{3}.$

- Solve the problem (*two edges insulated*)

D.E. : $u_t = u_{xx} + u_{yy}, 0 \leq x \leq 1, 0 \leq y \leq 1, t \geq 0$

B.C. : $u(x, 0, t) = 0, u_y(x, 1, t) = 0, u_x(0, y, t)$

$= 0, u(1, y, t) = 0$

I.C. : $u(x, y, 0) = \sin \left(\pi \frac{(3x + y)}{2} \right)$

$-\sin \left(\frac{3\pi x}{2} \right) \cdot \cos \left(\frac{\pi y}{2} \right)$

Ans. $u(x, y, t) = \exp \left[-\pi^2 \left\{ \left(\frac{3}{2} \right)^2 + \left(\frac{1}{2} \right)^2 \right\} t \right] \cos \left(\frac{3\pi x}{2} \right) \times \sin \left(\frac{\pi y}{2} \right).$

- Solve the two-dimensional heat conduction problem in a rectangle $0 < x < a, 0 < y < b$ if all the four edges are insulated and with initial temperature distribution given as

(a) $u(x, y, 0) = 1$

(b) $u(x, y, 0) = x + y$

(c) $u(x, y, 0) = xy$

Ans. (a) $u(x, y, t) = 1$

The solution for (b) and (c) is of the form

$$u(x, y, t) = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} A_{mn} \cos \frac{m\pi x}{a} \times \cos \left(\frac{n\pi y}{b} \right) \exp \left(-\lambda_{mn}^2 c^2 t \right)$$

with $\lambda_{mn}^2 = \left(\frac{m\pi}{a} \right)^2 + \left(\frac{n\pi}{b} \right)^2$ and m and n varying from 0 to ∞ .

(b) $A_{00} = \frac{a+b}{2}, A_{m0} = \frac{-2b(1 - \cos m\pi)}{m^2 \pi^2},$

$A_{0n} = \frac{-2a(1 - \cos n\pi)}{n^2 \pi^2},$

$A_{mn} = 0, \text{ otherwise}$

(c) $A_{00} = \frac{ab}{4}, A_{m0} = \frac{-ab(1 - \cos m\pi)}{m^2 \pi^2},$

$A_{0n} = \frac{-(ab)(1 - \cos n\pi)}{n^2 \pi^2},$

$A_{mn} = \frac{4ab(1 - \cos n\pi)(1 - \cos m\pi)}{m^2 n^2 \pi^2}$
when m and n are greater than zero.

- Solve the two-dimensional heat conduction problem in $0 \leq x \leq L, 0 \leq y \leq M, t \geq 0$. With

B.C. : $u(x, 0, t) = 0, u_y(x, M, t) = 0$

$u_x(0, y, t) = 0, u_x(L, y, t) = 0$

(three edges insulated) and with

I.C. : $u(x, y, 0) = \cos \left(\frac{2\pi x}{L} \right) \cdot \sin \left(\frac{3\pi y}{2M} \right)$

Ans. $u(x, y, t) = \cos \left(\frac{2\pi x}{L} \right) \cdot \sin \left(\frac{3\pi y}{2M} \right) \times \exp \left[- \left\{ \left(\frac{2}{L} \right)^2 + \left(\frac{3}{2M} \right)^2 \right\} \pi^2 c^2 t \right]$

- Solve the two-dimensional heat equation in a rectangular plate $0 < x < L_1, 0 < y < L_2$ with all the four edges maintained at zero temperature and with prescribed initial temperature distribution given by $u(x, y, 0) = 1$. Find the relaxation time.

Ans. $u(x, y, t) = \frac{4}{\pi^2} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \left[\frac{1 - (-1)^m}{m} \right] \left[\frac{1 - (-1)^n}{n} \right] \times$

$$\sin \frac{m\pi x}{L_1} \times \sin \frac{n\pi y}{L_2} \cdot e^{-\lambda_{mn} c^2 t}$$

$$\text{Relaxation time } \tau \text{ is } L_1^2 L_2^2 / [c^2 \pi^2 (L_1^2 + L_2^2)]$$

6. Solve the initial value problem for the heat equation in $0 < x < a$, $0 < y < b$ with BC's $u_x(0, y, t) = 0$, $u_x(a, y, t) = 0$, $u(x, 0, t) = T_1$, $u(x, b, t) = T_2$ and IC $u(x, y, 0) = T_3$ where T_1 , T_2 , T_3 are constants.

Ans. $u(x, y, t) = \frac{T_2 y}{b} + \frac{(b-y)T_1}{a} + \sum_{n=1}^{\infty} A_n \sin \frac{n\pi y}{b} \cdot \exp \left[-\left(\frac{n\pi}{b} \right)^2 c^2 t \right]$
 with $A_n = \frac{2(T_3 - T_1)[1 - (-1)^n]}{n\pi} + \frac{2(T_1 - T_2)(-1)^n}{bn\pi}$

7. Solve the heat equation in a square plate of length a , with left, right, bottom edges at zero temperature and top edge at T_1 constant temperature and with zero initial temperature distribution.

Ans. $u(x, y, t) = \frac{T_1 y}{a} - \frac{4T_1}{\pi^2 a^2} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \left[\frac{1 - (-1)^m}{m} \right] \left[\frac{1 - (-1)^{n+1}}{n} \right] \times \sin \left(\frac{m\pi x}{a} \right) \times \sin \left(\frac{n\pi y}{a} \right) e^{-\lambda_{mn} c^2 t}$
 with $\lambda_{mn} = \frac{(m^2 + n^2)\pi^2}{a^2}$

19.10 DERIVATION AND SOLUTION OF TWO-DIMENSIONAL WAVE EQUATION

The small transverse vibrations of a membrane tightly stretched over a flat frame (in the xy -plane) are governed by the two-dimensional wave equation. Let $u(x, y, t)$ denote the transverse displacement of the membrane from its equilibrium position at time t . Assume that (a) surface tension T is constant and is independent of position (b) membrane is homogeneous with ρ surface density (mass/unit area) constant (c) deflections are small so that all angles of inclination are small. The wave equation is derived by applying Newton's law of motion to a small rectangle of dimensions Δx and Δy of the membrane. On each edge of the rectangle a concentrated force of magnitude $T \Delta x$ or $T \Delta y$ is exerted. Refer Fig. 19.17.

Looking at the projections on the xu - and yu -planes (Figs. 19.18a and b), the resultant of horizontal forces in x -direction is $T \Delta y (\cos \beta - \cos \alpha)$

Fig.19.17 Vibrating membrane

and in the y -direction is $T \Delta x (\cos \delta - \cos \gamma)$. For small $\alpha, \beta, \delta, \gamma$, their cosines are close to 1 and hence, the horizontal components at opposite sides are equal.

Equating the sum of the forces in the vertical direction to mass times acceleration, we get

$$T \Delta y (\sin \beta - \sin \alpha) + T \Delta x (\sin \delta - \sin \gamma) = \rho \Delta x \Delta y \cdot \frac{\partial^2 u}{\partial t^2}$$

Assuming $\alpha, \beta, \delta, \gamma$ to be small, we have

(a)

(b)

Fig. 19.18

$$\sin \alpha \simeq \tan \alpha = \left. \frac{\partial u}{\partial x} \right|_{\text{at } (x, y, t)}$$

$$\sin \beta \simeq \tan \beta = \left. \frac{\partial u}{\partial x} \right|_{\text{at } (x + \Delta x, y, t)}$$

etc. then the above equation becomes

$$\begin{aligned} & T \Delta y \left[\frac{\partial u}{\partial x}(x + \Delta x, y, t) - \frac{\partial u}{\partial x}(x, y, t) \right] \\ & + T \Delta x \left[\frac{\partial u}{\partial y}(x, y, t + \Delta y) - \frac{\partial u}{\partial y}(x, y, t) \right] \\ & = \rho \Delta x \Delta y \frac{\partial^2 u}{\partial t^2} \end{aligned}$$

Now dividing throughout by $\Delta x \Delta y$ and taking the limit as $\Delta x \rightarrow 0$ and $\Delta y \rightarrow 0$, we get

$$T \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) = \rho \frac{\partial^2 u}{\partial t^2}$$

or

$$\frac{\partial^2 u}{\partial t^2} = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$

This equation is known as two-dimensional wave equation.

Here $c^2 = \frac{T}{\rho}$ is a positive constant.

Vibrating Rectangular Membrane

To analyze the transverse vibrations of a rectangular membrane $0 < x < a$, $0 < y < b$, determine the vertical displacement (or deflection) $u(x, y, t)$ of the vibrating membrane as a solution of the IBVP. (Refer Fig. 19.19).

Fig. 19.19 Rectangular membrane

$$\text{P.D.E. : } \frac{\partial^2 u}{\partial t^2} = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) \quad (1)$$

B.C.: Membrane is fixed to a flat frame so that all four sides are having zero displacement

$$u(0, y, t) = 0, u(x, 0, t) = 0 \quad (2)$$

$$u(a, y, t) = 0, u(x, b, t) = 0 \quad (3)$$

$$\text{I.C. : } u(x, y, 0) = \alpha(x, y) \quad (4)$$

where $\alpha(x, y)$ is the given initial displacement and

$$\frac{\partial u}{\partial t}(x, y, 0) = \beta(x, y) \quad (5)$$

where $\beta(x, y)$ is the given initial velocity. We apply the method of separation of variables since both the P.D.E. and B.C.'s are linear and homogeneous. First we separate only the time variable by seeking a product solution of the form

$$u(x, y, t) = h(t)\phi(x, y) \quad (6)$$

substituting (6) into wave equation (1), we get

$$\ddot{h}\phi = c^2(h\phi_{xx} + h\phi_{yy})$$

or

$$\frac{\ddot{h}}{c^2 h} = \frac{\phi_{xx} + \phi_{yy}}{\phi} = -\lambda^2$$

where we have introduced a separation constant $-\lambda^2$.

This results in an O.D.E.

$$\ddot{h} + c^2 \lambda^2 h = 0 \quad (7)$$

for the time function $h(t)$ and a P.D.E.

$$\phi_{xx} + \phi_{yy} + \lambda^2 \phi = 0 \quad (8)$$

for the amplitude function $\phi(x, y)$. Equation (8) is known as two-dimensional Helmholtz equation. Substitution of (6) in B.C.'s (2), (3) gives

$$\phi(0, y) = 0, \quad \phi(x, 0) = 0 \quad (9)$$

$$\phi(a, y) = 0, \quad \phi(x, b) = 0 \quad (10)$$

i.e., $\phi = 0$ along the entire boundary. Equation (8) and B.C.'s (9) (10) constitute a two-dimensional eigen value problem. Since this eigen value problem has a linear homogeneous P.D.E. in two independent variables with homogeneous B.C.'s we can again apply the method of separation of variables. So we assume that

$$\phi(x, y) = f(x)g(y) \quad (11)$$

a product of functions of *each* independent variable. Using (11) in (8), we get

$$g(y) \frac{d^2 f}{dx^2} + f(x) \frac{d^2 g}{dy^2} = -\lambda^2 f(x)g(y)$$

or

$$\frac{1}{f} \frac{d^2 f}{dx^2} = -\lambda^2 - \frac{1}{g} \frac{d^2 g}{dy^2} = -\mu^2$$

where we have introduced a *second* separation constant $-\mu^2$. If $\mu > 0$, we get oscillatory solutions. Thus, we get

$$\frac{d^2 f}{dx^2} + \mu^2 f = 0 \quad (12)$$

$$\frac{d^2 g}{dy^2} + (\lambda^2 - \mu^2)g = 0 \quad (13)$$

with the assumption of separability for the function $u(x, y, t) = f(x)g(y)h(t)$, for the P.D.E. in three variables, we obtain three O.D.E. one function for each independent variable, with only two separation constants. Using (11), the B.C.'s (9), (10) reduce to

$$f(0) = 0, \quad f(a) = 0 \quad (14)$$

$$g(0) = 0, \quad g(b) = 0 \quad (15)$$

Thus, we have one Sturm-Liouville eigen value problem in the x -variable namely (12), (14) with μ^2 as the eigen value and $f(x)$ as the eigen function. Similarly, we have another Sturm-Liouville eigen value problem in the y -variable namely (13), (15) with $\lambda^2 - \mu^2$ as the eigen value and $g(y)$ as the eigen function. In the familiar way, for the first eigen value problem, we obtain the eigen value as

$$\mu_n^2 = \left(\frac{n\pi}{L}\right)^2, \quad n = 1, 2, 3, \dots \quad (16)$$

with corresponding eigen functions as

$$f_n(x) = \sin\left(\frac{n\pi x}{a}\right) \quad (17)$$

For each value of μ_n in (16), There are an infinite number of eigen values λ . Thus, for the second eigen value problem we get the eigen values as

$$\lambda_{mn}^2 - \mu_n^2 = \left(\frac{m\pi}{b}\right)^2, \quad m = 1, 2, 3, \dots \quad (18)$$

with corresponding eigen functions as

$$g_{nm}(y) = \sin\left(\frac{m\pi y}{b}\right) \quad (19)$$

then

$$\lambda_{nm}^2 = \mu_n^2 + \left(\frac{m\pi}{b}\right)^2 = \left(\frac{n\pi}{a}\right)^2 + \left(\frac{m\pi}{b}\right)^2 \quad (20)$$

where $n = 1, 2, 3, \dots$ and $m = 1, 2, 3, \dots$. Thus, $\phi_{mn}(x, y) = \sin\left(\frac{n\pi x}{a}\right) \cdot \sin\left(\frac{m\pi y}{b}\right)$ with $n = 1, 2, 3, \dots$ and $m = 1, 2, 3, \dots$ solving (7) we get the time-dependent part of the product solutions as $\sin c\lambda_{nm}t$ and $\cos c\lambda_{nm}(t)$ oscillations with natural frequencies $c\lambda_{nm} = c\sqrt{\left(\frac{n\pi}{a}\right)^2 + \left(\frac{m\pi}{b}\right)^2}$ with $n = 1, 2, 3, \dots$ and $m = 1, 2, 3, \dots$. The two doubly infinite families of product solutions

$$\sin\left(\frac{n\pi x}{a}\right) \sin\left(\frac{m\pi y}{b}\right) \sin(c\lambda_{mn}t)$$

and

$$\sin\left(\frac{n\pi x}{a}\right) \cdot \sin\left(\frac{m\pi y}{b}\right) \cdot \cos(c\lambda_{mn}t)$$

are known as modes of vibration. As time varies, the shape remains the same but only the amplitude varies periodically.

Applying the principle of superposition, we get the displacement function as

$$\begin{aligned} u(x, y, t) &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} u_{n,m}(x, y, t) \\ &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \sin\left(\frac{n\pi x}{a}\right) \cdot \sin\left(\frac{m\pi y}{b}\right) \times \\ &\quad \times [A_{mn} \cos(c\lambda_{mn}t) + B_{nm} \sin(c\lambda_{nm}t)] \end{aligned} \quad (21)$$

The function $u_{nm}(x, y, t)$ is known as the (n, m) -th harmonic of the rectangular drum.

Using the two initial conditions (4) and (5), the two families of coefficients A_{nm} and B_{nm} are determined. Putting $t = 0$ in (21) and using IC(4) we have a double Fourier series

$$\begin{aligned} \alpha(x, y) &= u(x, y, 0) \\ &= \sum_{m=1}^{\infty} \left(\sum_{n=1}^{\infty} A_{nm} \sin\left(\frac{n\pi x}{a}\right) \right) \sin\left(\frac{m\pi y}{b}\right) \end{aligned} \quad (22)$$

Put

$$A_m^*(x) = \sum_{n=1}^{\infty} A_{mn} \sin\left(\frac{n\pi x}{a}\right). \quad (23)$$

19.40 — HIGHER ENGINEERING MATHEMATICS—V

For fixed x , $A_m^*(x)$ depends only on m . Now from (22)

$$\alpha(x, y) = \sum_{m=1}^{\infty} A_m^*(x) \sin\left(\frac{m\pi y}{b}\right).$$

From the above observation that $A_m^*(x)$ is the coefficients of the Fourier sine series in y of $\alpha(x, y)$ in $0 < y < b$. Thus, the Fourier sine coefficients are given by

$$A_m^*(x) = \frac{2}{b} \int_0^b \alpha(x, y) \cdot \sin\left(\frac{m\pi y}{b}\right) dy \quad (24)$$

for each m . R.H.S. of (24) is a function of x alone (since integration wrt y is performed) and is valid for all x . Then from (23)

$$\sum_{n=1}^{\infty} A_{nm} \sin\left(\frac{n\pi x}{a}\right) = A_m^*(x)$$

In other words A_{nm} are the coefficients in the Fourier sine series in x of $A_m^*(x)$ in $0 < x < a$. Then

$$A_{nm} = \frac{2}{a} \int_0^a A_m^*(x) \cdot \sin\left(\frac{n\pi x}{a}\right) dx \quad (25)$$

substituting $A_m^*(x)$ from (24) in (25), we get

$$A_{nm} = \frac{2}{a} \int_0^a \left[\frac{2}{b} \int_0^b \alpha(x, y) \sin\left(\frac{m\pi y}{b}\right) dy \right] \times \sin\left(\frac{n\pi x}{a}\right) dx$$

or as a double integral

$$A_{nm} = \frac{4}{ab} \int_0^a \int_0^b \alpha(x, y) \sin\left(\frac{m\pi y}{b}\right) dy \cdot \sin\left(\frac{n\pi x}{a}\right) dx \quad (26)$$

To obtain the coefficients B_{nm} , differentiate (21) w.r.t. t and put $t = 0$ and use the IC (5). Then

$$\begin{aligned} \beta(x, y) = \frac{\partial u}{\partial t} \Big|_{(x, y, 0)} &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \sin\left(\frac{n\pi x}{a}\right) \cdot \sin\left(\frac{m\pi y}{b}\right) \times \\ &\times [-c\lambda_{nm} A_{nm} \sin(c\lambda_{nm} \cdot 0) \\ &+ B_{nm} \cdot c\lambda_{nm} \cos(c\lambda_{nm} \cdot 0)] \end{aligned}$$

or

$$\beta(x, y) = \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} c\lambda_{nm} B_{nm} \sin\left(\frac{n\pi x}{a}\right) \cdot \sin\left(\frac{m\pi y}{b}\right)$$

The coefficients in this double Fourier series are given by

$$c \cdot \lambda_{nm} \cdot B_{nm} = \frac{4}{ab} \int_0^a \int_0^b B(x, y) \cdot \sin\left(\frac{m\pi y}{b}\right) \cdot \sin\left(\frac{n\pi x}{a}\right) dy dx \quad (27)$$

Thus, the solution to the IBVP (1), (2), (3), (4), (5) is the doubly infinite series given by (21) with the coefficients A_{nm} and B_{nm} determined by (26) and (27) respectively.

Corollary 1: If the membrane starts from rest, then $B(x, y) = 0$ so all B_{nm} are zero. The solution (21) reduces to

$$\begin{aligned} u(x, y, t) &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{nm} \sin\left(\frac{n\pi x}{a}\right) \times \\ &\times \sin\left(\frac{m\pi y}{b}\right) \times \cos(c\lambda_{nm} t) \end{aligned} \quad (28)$$

with A_{nm} 's determined by (26).

Corollary 2: If the initial displacement is zero, then $\alpha(x, y) = 0$ so all A_{nm} 's are zero. Then (21) reduced to

$$\begin{aligned} u(x, y, t) &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} B_{nm} \sin\left(\frac{n\pi x}{a}\right) \times \\ &\times \sin\left(\frac{m\pi y}{b}\right) \cdot \sin(c\lambda_{nm} t) \end{aligned} \quad (29)$$

with B_{nm} 's determined by (27).

WORKED OUT EXAMPLES

Initial Displacement

Example 1: Find the deflection $u(x, y, t)$ of a rectangular membrane $0 < x < a$, $0 < y < b$ given that its entire boundary is fixed, initial velocity is zero (starts from rest) and initial deflection $\alpha(x, y) = \kappa xy(a-x)(b-y)$.

Solution: Here $\beta(x, y) = 0$ since membrane starts from rest. Therefore B_{nm} are all zero. The displacement (or deflection) function $u(x, y, t)$ is given by (28)

$$\begin{aligned} u(x, y, t) &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{nm} \cdot \sin\left(\frac{n\pi x}{a}\right) \cdot \sin\left(\frac{m\pi y}{b}\right) \times \\ &\times \cos(c\lambda_{nm} t) \end{aligned}$$

where the coefficients A_{nm} 's are determined by

$$A_{nm} = \frac{4}{ab} \int_0^a \int_0^b \kappa x y (a-x)(b-y) \sin\left(\frac{n\pi x}{a}\right) \times \\ \times \sin\left(\frac{m\pi y}{b}\right) dy \cdot dx \\ \frac{ab}{4\kappa} A_{nm} = \left[\int_0^a x(a-x) \sin\left(\frac{n\pi x}{a}\right) dx \right] \times \\ \times \left[\int_0^b y(b-y) \sin\left(\frac{m\pi y}{b}\right) dy \right] \\ = I_1 \times I_2$$

Integrating by parts,

$$I_1 = \left[x(a-x) \left(\frac{a}{n\pi} \right) \left(-\cos\left(\frac{n\pi x}{a}\right) \right) \right. \\ \left. - (a-2x) \cdot \left(\frac{-a^2}{n^2\pi^2} \right) \cdot \sin\left(\frac{n\pi x}{a}\right) \right. \\ \left. + (-2)(-1) \frac{a^3}{n^3\pi^3} (-1) \cdot \cos\frac{n\pi x}{a} \right] \Bigg|_{x=0}^a \\ I_1 = 0 + 0 - \frac{2a^3}{n^3\pi^3} \cdot [\cos n\pi - 1]$$

similarly

$$I_2 = \frac{-2b^3}{m^3\pi^3} [\cos m\pi - 1]$$

Then

$$\frac{ab}{4\kappa} A_{nm} = I_1 I_2 = \\ \left\{ \frac{-2a^3}{n^3\pi^3} [(-1)^n - 1] \right\} \left\{ \frac{-2b^3}{m^3\pi^3} [(-1)^m - 1] \right\}$$

Thus,

$$A_{nm} = \begin{cases} \frac{64a^2b^2}{\pi^6 n^3 m^3}, & \text{when both } m \text{ and } n \text{ are odd} \\ 0, & \text{otherwise} \end{cases}$$

The required deflection is

$$u(x, y, t) = \frac{64a^2b^2}{\pi^6} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{1}{n^3} \sin\left(\frac{n\pi x}{a}\right) \\ \times \frac{1}{m^3} \cdot \sin\left(\frac{m\pi y}{b}\right) \cdot \cos(c\lambda_{nm}t)$$

where

$$\lambda_{nm}^2 = \left(\frac{n\pi}{a}\right)^2 + \left(\frac{m\pi}{b}\right)^2$$

Initial Velocity

Example 2: Determine the displacement function $u(x, y, t)$ of a rectangular membrane $0 < x < L_1$, $0 < y < L_2$ with the entire boundary fixed and with initial conditions $u(x, y, 0) = \alpha(x, y) = 0$ and $u_t(x, y, 0) = \beta(x, y) = 1$.

Solution: In this problem the initial displacement is zero, so the solution is given by (29)

$$u(x, y, t) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} B_{nm} \sin\left(\frac{n\pi x}{L_1}\right) \cdot \sin\left(\frac{m\pi y}{L_2}\right) \\ \times \sin(c\lambda_{nm}t)$$

with the coefficients B_{nm} given by (27) as

$$c\lambda_{nm} B_{nm} = \frac{4}{L_1 \cdot L_2} \int_0^{L_1} \int_0^{L_2} 1 \cdot \sin\left(\frac{m\pi y}{L_2}\right) \times \\ \times \sin\left(\frac{n\pi x}{L_1}\right) dy dx \\ = \frac{4}{L_1 L_2} \left[\left(\frac{-L_2}{m\pi} \right) \cos\left(\frac{m\pi y}{L_2}\right) \right]_{y=0}^{L_2} \times \\ \left[\left(\frac{-L_1}{n\pi} \right) \cos\left(\frac{n\pi x}{L_1}\right) \right]_{x=0}^{L_1} \\ = \frac{4}{mn\pi^2} [(-1)^m - 1] [(-1)^n - 1]$$

So

$$B_{nm} = \begin{cases} \frac{16}{mn\pi^2 c\lambda_{nm}} & \text{if both } m \text{ and } n \text{ are odd} \\ 0 & \text{otherwise} \end{cases}$$

the required solution is

$$u(x, y, t) = \frac{16}{\pi^2 c} \sum_{m=\text{odd}}^{\infty} \sum_{n=\text{odd}}^{\infty} \sin\left(\frac{n\pi x}{L_1}\right) \cdot \sin\left(\frac{m\pi y}{L_2}\right) \\ \times \frac{1}{mn\lambda_{nm}} \cdot \sin(c\lambda_{nm}t)$$

where

$$\lambda_{nm}^2 = \left(\frac{n\pi}{L_1}\right)^2 + \left(\frac{m\pi}{L_2}\right)^2$$

19.42 — HIGHER ENGINEERING MATHEMATICS—V

Example 3: Find the deflection at any time is a unit square membrane, tightly stretched. If the membrane starts from rest and has initial displacement $\alpha(x, y) = k \cdot \sin 2\pi x \cdot \sin \pi y$.

Solution: Here $\beta(x, y) = 0$ so all B_{nm} are zero. The solution is given by (28)

$$u(x, y, t) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{nm} \sin\left(\frac{n\pi x}{1}\right) \cdot \sin\left(\frac{m\pi y}{1}\right) \times \cos(c\lambda_{nm}t)$$

where

$$A_{nm} = \frac{4}{1.1} \int_0^1 \int_0^1 \left(\sin \frac{m\pi y}{1} \cdot \sin \frac{n\pi x}{1} \right) \times k \cdot \sin 2\pi x \cdot \sin \pi y \, dy \, dx$$

$$A_{21} = 4k \cdot \frac{1}{2} \cdot \frac{1}{2} = k,$$

$$\lambda_{21}^2 = \left(\frac{2\pi}{1}\right)^2 + \left(\frac{1 \cdot \pi}{1}\right)^2 = 5\pi^2$$

All other coefficients A_{nm} are zero for $m \neq 2, n \neq 1$. Thus, the deflection function is

$$u(x, y, t) = k \cdot \sin 2\pi x \cdot \sin \pi y \cdot \cos(c\sqrt{5}\pi t)$$

EXERCISE

- Find the deflection $u(x, y, t)$ of the square membrane with $a = b = 1$ and $c = 1$ if the initial velocity is zero and the initial deflection is $\alpha(x, y)$ where

- $k \sin \pi x \cdot \sin 2\pi y$
- $k \sin 3\pi x \cdot \sin 4\pi y$

Ans: 1. $k \cdot \cos \pi \sqrt{5}t \cdot \sin \pi x \cdot \sin 2\pi y$
2. $k \cdot \cos 5\pi t \cdot \sin 3\pi x \cdot \sin 4\pi y$

- Solve the IVBP for the vibrating membrane in the square $0 < x < L, 0 < y < L$, with the initial condition

$$u(x, y, 0) = 3 \sin \frac{\pi x}{L} \cdot \sin \frac{2\pi y}{L} + 4 \sin \frac{3\pi x}{L} \cdot \sin \frac{5\pi y}{L}, u_t(x, y, 0) = 0$$

Ans: $u(x, y, t) = 3 \sin \frac{\pi x}{L} \cdot \sin \frac{2\pi y}{L} \times \cos(\pi ct \sqrt{5}/L) + 4 \sin \left(\frac{3\pi x}{L}\right) \cdot \sin \left(\frac{5\pi y}{L}\right) \times$

$$\cos(\pi ct \sqrt{34}/L)$$

- Find the separated solutions of the wave equation $u_{tt} = c^2(u_{xx} + u_{yy})$ in the square $0 < x < L, 0 < y < L$ with the B.C.'s $u_x(0, y, t) = 0, u_x(L, y, t) = 0, u_y(x, 0, t) = 0, u_y(x, L, t) = 0$ and I.C. $u(x, y, 0) = 0$.

Ans: $u_{mn}(x, y, t) = \cos\left(\frac{m\pi x}{L}\right) \cos\left(\frac{n\pi y}{L}\right) \cdot \sin\left(\lambda_{nm} \frac{\pi ct}{L}\right)$ with $\lambda_{nm}^2 = m^2 + n^2$ with $m, n = 0, 1, 2, \dots$

- Solve IBVP: $u_{tt} = c^2(u_{xx} + u_{yy}), 0 \leq x \leq 1, 0 \leq y \leq 1$.

$$\text{B.C. : } u(x, 0, t) = 0, u(x, 1, t) = 0, u(0, y, t) = 0, u(1, y, t) = 0$$

$$\text{I.C. : } u(x, y, 0) = 0, u_t(x, y, 0) = x(x-1)y(y-1)$$

Ans: $u(x, y, t) = \sum_{m=\text{odd}} \sum_{n=\text{odd}} \left[\frac{4}{mn\pi^2} \right]^3 \left[\pi c^2(n^2 + m^2)^{\frac{1}{2}} \right]^{-1} \times \sin[\pi c(n^2 + m^2)^{\frac{1}{2}} t] \sin(n\pi x) \cdot \sin(m\pi y)$

- Solve the IBVP for a vibrating rectangular membrane $0 < x < a, 0 < y < b$ subject to $u(x, y, 0) = 0$ and $\frac{\partial u}{\partial t}(x, y, 0) = \beta(x, y)$ and $u_x(0, y, t) = 0, u_y(x, 0, t) = 0, u_x(a, y, t) = 0, u_y(x, b, t) = 0$.

Ans: $u(x, y, t) = \sum_{n=0}^{\infty} \sum_{m=0}^{\infty} A_{nm} \cos \frac{n\pi x}{a} \cdot \cos \frac{m\pi y}{b} \times \phi_{nm}(t)$

where

$$\phi_{nm}(t) = \begin{cases} t, & \text{for } n = 0, m = 0 \\ \sin \lambda_{nm} t & \text{otherwise} \end{cases}$$

$$\text{Here } \lambda_{nm}^2 = c^2 \left[\left(\frac{n\pi}{a}\right)^2 + \left(\frac{m\pi}{b}\right)^2 \right]$$

$$A_{nm} \phi'_{nm}(0) = \frac{\int \int \beta(x, y) \cos \frac{n\pi x}{a} \cdot \cos \frac{m\pi y}{b} \, dx \, dy}{\int \int \cos^2 \left(\frac{n\pi x}{a}\right) \cdot \cos^2 \left(\frac{m\pi y}{b}\right) \, dx \, dy}$$

19.11 VIBRATIONS OF CIRCULAR MEMBRANE

In engineering, circular membranes, which occur in drums, pumps, microphones, telephones and so on, are of great importance. The vibrations (or displacement) of a plane, thin elastic membrane, offering no resistance to bending, stretched tightly and fixed to a circular frame of radius R are modelled by the two-dimensional wave equation in polar coordinates given by

$$\frac{\partial^2 u}{\partial t^2} = c^2 \left(\frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} + \frac{1}{r^2} \frac{\partial^2 u}{\partial \theta^2} \right)$$

Fig. 19.20 Circular membrane

Assume that the initial conditions are circularly symmetric, (or radially or rotationally symmetric, Fig. 19.20). Then the displacement function $u = u(r, t)$ is independent of θ . Therefore, the above equation reduces to

$$\frac{\partial^2 u}{\partial t^2} = c^2 \left(\frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} \right), \quad 0 < r < R \quad (1)$$

with boundary condition (fixed along its entire boundary)

$$u(R, t) = 0, \quad \text{for } t > 0 \quad (2)$$

and with initial conditions

$$u(r, 0) = \alpha(r), \quad 0 < r < R \quad (3)$$

$$\frac{\partial u}{\partial t}(r, 0) = \beta(r), \quad 0 < r < R \quad (4)$$

Here $\alpha(r)$ is the initial deflection and $\beta(r)$ is the initial velocity.

Applying the method of separation of variables, we look for product solutions of the form

$$u(r, t) = \phi(r)h(t) \quad (5)$$

substitution of (5) in (1) yields

$$\frac{1}{c^2} \frac{1}{h} \frac{d^2 h}{dt^2} = \frac{1}{r\phi} \frac{d}{dr} \left(r \frac{d\phi}{dr} \right) = -\lambda^2$$

Here we have introduced a separation constant $-\lambda^2$ since displacement oscillates in time for $\lambda > 0$. The time dependent equation is

$$\frac{d^2 h}{dt^2} + \lambda^2 c^2 h = 0 \quad (6)$$

having solutions $\sin c\lambda t$ and $\cos c\lambda t$ when $\lambda > 0$. The eigen value problem for the separation constant λ is

$$\frac{d}{dr} \left(r + \frac{d\phi}{dr} \right) + \lambda^2 r \phi = 0$$

or

$$r \frac{d^2 \phi}{dr^2} + \frac{d\phi}{dr} + \lambda^2 r \phi = 0 \quad (7)$$

$$\text{with B.C.} \quad \phi(R) = 0 \quad (8)$$

since $r = 0$ is a singular point of D.E. (7) we add the requirement that $|\phi(r)|$ is bounded at $r = 0$

$$\text{i.e.,} \quad |\phi(0)| < \infty \quad (9)$$

(7), (8), (9) form a Sturm-Liouville problem, with eigen functions orthogonal wrt weight r . Using the transformation

$$z = \lambda r$$

The O.D.E. (7) becomes

$$z^2 \frac{d^2 \phi}{dz^2} + z \frac{d\phi}{dz} + z^2 \phi = 0$$

which is a Bessel's equation of order zero, with the general solution

$$\phi = A J_0(z) + B Y_0(z) = A J_0(\lambda r) + B Y_0(\lambda r)$$

a linear combination of the zeroth-order Bessel functions. Since $Y_0(\lambda r)$ has a logarithmic singularity at $r = 0$, the boundedness condition (9) demands that $B = 0$. Then

$$\phi(r) = A J_0(\lambda r)$$

Now using the B.C. (8) at $r = R$ we have

$$J_0(\lambda R) = 0$$

19.44 — HIGHER ENGINEERING MATHEMATICS—V

Thus, λ_R must be a zero of the zeroth Bessel function. We thus obtain an infinite number of eigen values $\lambda_1, \lambda_2, \lambda_3, \dots$. Using the principle of superposition, we have

$$u(r, t) = \sum_{n=1}^{\infty} A_n J_0(\lambda_n r) \cos(c\lambda_n t) + \sum_{n=1}^{\infty} B_n J_0(\lambda_n r) \sin(c\lambda_n t) \quad (10)$$

The I.C. (3) and (4) are satisfied if

$$u(r, 0) = \sum_{n=1}^{\infty} A_n J_0(\lambda_n r) = \alpha(r) \quad (11)$$

for $0 < r < R$

and

$$\frac{\partial u}{\partial t}(r, 0) = \sum_{n=1}^{\infty} B_n \lambda_n C J_0(\lambda_n r) = \beta(r) \quad (12)$$

for $0 < r < R$

Thus, (11) and (12) are the Fourier-Bessel series representation of $\alpha(r)$ and $\beta(r)$ in $0 < r < R$ respectively. The Fourier-Bessel coefficients of order zero of these series are given by the integral formulas

$$A_n = \frac{1}{I_n} \int_0^R r \cdot \alpha(r) J_0(\lambda_n r) dr \quad (13)$$

$$B_n = \frac{1}{c \cdot \lambda_n \cdot I_n} \int_0^R r \cdot \beta(r) J_0(\lambda_n r) dr \quad (14)$$

where

$$I_n = \int_0^R r \cdot [J_0(\lambda_n r)]^2 dr \quad (15)$$

Using the orthogonality relation

$$\int_0^R r \cdot [J_m(\lambda r)]^2 dr = \frac{R^2}{2} [J_{m+1}(R\lambda)]^2 \quad (16)$$

with $m = 0$, we have

$$I_n = \frac{R^2}{2} [J_1(R\lambda)]^2 \quad (17)$$

Thus, the displacement function $u(r, t)$ of the vibrating circular membrane is given by (10) with

coefficients A_n 's and B_n 's determined by (13), (14), (17).

WORKED OUT EXAMPLES

Initial Displacement and Initial Velocity

Example 1: Determine the displacement $u(r, t)$ of circular membrane tightly stretched and fixed to a circular frame of radius R with initial displacement $\alpha(r) = 3J_0(r\lambda_1) + J_0(r\lambda_3)$ and initial velocity $\beta(r) = J_0(r\lambda_2)$.

Solution: The displacement $u(r, t)$ is given by

$$u(r, t) = \sum_{n=1}^{\infty} A_n J_0(\lambda_n r) \cos(c\lambda_n t) + \sum_{n=1}^{\infty} B_n J_0(\lambda_n r) \sin(c\lambda_n t)$$

Here the initial conditions are

$$u(r, 0) = \alpha(r) = 3J_0(r\lambda_1) + J_0(r\lambda_3)$$

and

$$\frac{\partial u}{\partial t}(r, 0) = \beta(r) = J_0(r\lambda_2).$$

So the Fourier-Bessel coefficients are given by (13) and (14) as

$$A_n = \frac{1}{I_n} \int_0^R r \cdot [3J_0(\lambda_1 r) + J_0(\lambda_3 r)] J_0(\lambda_n r) dr$$

Using the orthogonality relation (16) we have $A_1 = 3$, $A_2 = 0$, $A_3 = 1$ and $A_n = 0$ for $n > 3$. From

$$B_n = \frac{1}{c\lambda_n I_n} \int_0^R r J_0(r\lambda_2) J_0(\lambda_n r) dr$$

We have $B_1 = 0$, $B_2 = 1$, $B_n = 0$ for $n > 2$. Thus, the required displacement function is

$$u(r, t) = 3(J_0\lambda_1) \cdot \cos(c\lambda_1 t) + J_0(r\lambda_3) \cdot \cos(c\lambda_3 t) + \frac{1}{c\lambda_2} J_0(r\lambda_2) \sin(c\lambda_2 t)$$

EXERCISE

- Find the deflection $u(r, t)$ of a unit circular membrane (with $c = 1$) and with initial velocity zero and initial displacement $\alpha(r) = k(1 - r^2)$.

Ans: $u(r, t) = 4k \sum_{n=1}^{\infty} \frac{J_2(\lambda_n)}{\lambda_n^2 J_1^2(\lambda_n)} \cos(\lambda_n t) \cdot J_0(\lambda_n r)$

Note: $J_2(\lambda_n) = [2 J_1(\lambda_n)]/\lambda_n$

- Determine the displacement $u(r, t)$ of a unit circular membrane (with $c = 1$) and with initial displacement zero and initial velocity $\beta(r) = k(1 - r^2)$.

Ans: $u(r, t) = 4k \sum_{n=1}^{\infty} \frac{J_2(\lambda_n)}{\lambda_n^3 J_1^2(\lambda_n)} \sin(\lambda_n t) \cdot J_0(\lambda_n r)$

19.12 TRANSMISSION LINE EQUATIONS

The purpose of transmission lines network is to transfer electric energy from generating units at various locations to the distribution system which ultimately supplies the load. All transmission lines in a power system exhibit the electrical properties of resistance R (ohms/km), inductance L (henries/km), capacitance to ground C (farads/km), and conductance to ground G (mhos/km) of the cable per unit length. Consider a long cable or telephone wire (see Fig. 19.21) that is imperfectly insulated so that leaks occur along the entire length l km of the cable (Fig. 19.21). The source S (the sending end) be at $x = 0$ and the terminal T (the receiving end) be at $x = l$. Let P be any point x km from the source S . The instantaneous current and voltage (or potential) at point P be $i(x, t)$ and $v(x, t)$, where t is time.

Fig. 19.21 Transmission line

Derivation of Transmission Line Equations

Let Q be at a distance Δx from P . Applying Kirchhoff's voltage law to a small portion PQ of the cable between x and $x + \Delta x$, we have difference of potentials (voltage) at x and $x + \Delta x$ = resistive drop + inductive drop, i.e.

$$-\Delta v = iR\Delta x + L\Delta x \cdot \frac{\partial i}{\partial t}$$

After dividing by Δx and taking limit as $\Delta x \rightarrow 0$ we have

$$-\frac{\partial v}{\partial x} = Ri + L \frac{\partial i}{\partial t} \quad (1)$$

known as *first transmission line equation*.

Similarly applying Kirchhoff's current law: difference of the current at x and $x + \Delta x$ = Loss due to leakage to: ground + captive loss,

$$\text{i.e.,} \quad -\Delta i = Gv\Delta x + C \frac{\partial v}{\partial t} \Delta x$$

After dividing by Δx and taking limit as $\Delta x \rightarrow 0$ we have

$$-\frac{\partial i}{\partial x} = Gv + C \frac{\partial v}{\partial t} \quad (2)$$

known as *second transmission line equation*.

Telephone Equations

Elimination of i or v from the two transmission line equations (1) and (2) leads to a second order P.D.E. in i or v known as telephone equations as follows:

Rewrite (1) and (2) as

$$\left(R + L \frac{\partial}{\partial t}\right) i + \frac{\partial v}{\partial x} = 0 \quad (3)$$

$$\left(G + C \frac{\partial}{\partial t}\right) v + \frac{\partial i}{\partial x} = 0 \quad (4)$$

Operate (3) by $\frac{\partial}{\partial x}$ and (4) by $\left(R + L \frac{\partial}{\partial t}\right)$ and subtracting results in

$$\frac{\partial^2 v}{\partial x^2} - \left(R + L \frac{\partial}{\partial t}\right) \left(G + C \frac{\partial}{\partial t}\right) v = 0$$

or

$$v_{xx} = Lc v_{tt} + (RC + GL)v_t + RGv \quad (5)$$

Similarly operate (3) by $\left(G + C \frac{\partial}{\partial t}\right)$ and (4) by $\frac{\partial}{\partial x}$ and subtracting leads to

$$\left(G + C \frac{\partial}{\partial t}\right) \left(R + L \frac{\partial}{\partial t}\right) i - \frac{\partial^2 i}{\partial x^2} = 0$$

or

$$i_{xx} = LCi_{tt} + (RC + GL)i_t + RGi \quad (6)$$

Replacement of v by i in (5) results in (6) and vice versa.

Telegraph Equations

For a submarine cable, leakages are negligible so $G = 0$ and frequencies are low so $L = 0$. In this case with $G = 0$, $L = 0$, equations (5) and (6) reduces to

$$v_{xx} = RCv_t \quad (7)$$

and

$$i_{xx} = RCi_t \quad (8)$$

known as *submarine cable equations or telegraph equations*. Equations (7) and (8) are similar to one-dimensional heat equation.

High Frequency Line Equations

In the case of alternating currents of high frequencies we can neglect leakages and resistance. Thus, with $G = 0$ and $R = 0$, equations (5) and (6) reduces to

$$v_{xx} = LCv_{tt} \quad (9)$$

and

$$i_{xx} = LCi_{tt} \quad (10)$$

known as *high-frequency line equations or radio equation*.

Equations (9) and (10) are similar to one dimensional wave equation $u_{tt} = a^2 u_{xx}$ where $a^2 = \frac{1}{LC}$. Thus, the general solution of (9) is

$$v(x, t) = f(x + at) + g(x - at)$$

$$v(x, t) = c_1 e^{\alpha x} \cos(\omega t + \beta x) + c_2 e^{-\alpha x} \cdot \cos(\omega t - \beta x)$$

So at any point along the lossless transmission line, the voltage $v(x, t)$ can be considered as the sum of an incident wave (progressive wave for which $e^{\alpha x}$ increases as x increases) and a reflected wave (receding wave for which $e^{-\alpha x}$ decreases as x increases) travelling with equal velocity a . Similarly current $i(x, t)$ can also be considered as the superposition of incident and reflected waves which behave like travelling waves similar to disturbance in water at some sending point.

WORKED OUT EXAMPLES

Radio equation

Example 1: Assuming R and G are negligible, find the voltage $v(x, t)$ and current $i(x, t)$ in a transmission line of length l , t seconds after the ends are suddenly grounded. The initial conditions are $v(x, 0) = v_0 \sin\left(\frac{\pi x}{l}\right)$ and $i(x, 0) = i_0$.

Solution: When $R = 0$ and $G = 0$, for v , we have P.D.E. the radio equation

$$v_{xx} = LC v_{tt} \quad (1)$$

the boundary conditions are

$$v(0, t) = 0 \quad \text{and} \quad v(l, t) = 0 \quad (2)$$

since the ends are suddenly grounded. The given initial condition is

$$v(x, 0) = v_0 \sin\left(\frac{\pi x}{l}\right) \quad (3)$$

we use the separation of variables technique. Assume that

$$v(x, t) = X(x)T(t) \quad (4)$$

Substituting (4) in (1), we get

$$\frac{X''}{X} = LC \frac{T''}{T} = -\lambda^2$$

where we have taken the separation constant as $-\lambda^2$, results in the two ordinary differential equations

$$X'' + \lambda^2 X = 0 \quad (5)$$

and

$$\ddot{T} + \frac{\lambda^2}{LC} T = 0 \quad (6)$$

General solution of (5) is

$$X(x) = A \cos \lambda x + B \sin \lambda x$$

Use B.C. (2) which take the form

$$X(0) = 0, \quad X(l) = 0$$

$$\text{So} \quad 0 = X(0) = A \cdot 1 + B \cdot 0 \quad \therefore \quad A = 0$$

$$0 = X(l) = B \cdot \sin \lambda l$$

$$\text{or} \quad \lambda l = n\pi,$$

i.e. $\lambda = \frac{n\pi}{l}$

General solution of (6) is

$$T(t) = C \cos \frac{\lambda}{\sqrt{LC}} t + D \cdot \sin \frac{\lambda}{\sqrt{LC}} t$$

Using superposition principle, the most general solution of IBVP is

$$v(x, t) = \sum_{n=1}^{\infty} \sin \frac{n\pi x}{l} \cdot (A_n \cdot \cos \mu t + B_n \sin \mu t) \quad (7)$$

where $\mu = \frac{n\pi}{l\sqrt{LC}}$

From equation

$$-\frac{\partial i}{\partial x} = C \frac{\partial v}{\partial t} + Gv$$

with $G = 0$, we have

$$\frac{\partial v}{\partial t} = -\frac{1}{C} \frac{\partial i}{\partial x}$$

or

$$\left. \frac{\partial v}{\partial t} \right|_{(x,0)} = -\frac{1}{C} \frac{\partial i(x,0)}{\partial x} = -\frac{1}{C} \frac{\partial i_0}{\partial x} = 0 \quad (8)$$

This is another initial condition. Differentiating (7) w.r.t. t , we get

$$\frac{\partial v}{\partial t} = \sum_{n=1}^{\infty} \sin \left(\frac{n\pi x}{l} \right) \cdot [-\mu A_n \cdot \sin \mu t + \mu B_n \cos \mu t]$$

Using (8)

$$0 = \left. \frac{\partial v}{\partial t} \right|_{(x,0)} = \sum_{n=1}^{\infty} \mu B_n \cdot \sin \frac{n\pi x}{l}$$

Thus, $B_n = 0$ for all n . Now (7) reduces to

$$v(x, t) = \sum_{n=1}^{\infty} A_n \sin \left(\frac{n\pi x}{l} \right) \cdot \cos \frac{n\pi t}{l\sqrt{LC}} \quad (9)$$

The unknown coefficient A_n 's are determined using the initial condition (3). Putting $t = 0$ in (9), we have

$$v_0 \sin \left(\frac{\pi x}{l} \right) = v(x, 0) = \sum_{n=1}^{\infty} A_n \sin \left(\frac{n\pi x}{l} \right) \cdot 1$$

so $A_1 = v_0$ and $A_n = 0$ for $n > 1$. Thus, the required voltage is

$$v(x, t) = v_0 \cdot \sin \left(\frac{\pi x}{l} \right) \cdot \cos \left(\frac{\pi t}{l\sqrt{LC}} \right) \quad (10)$$

To determine the current $i(x, t)$, use

$$-\frac{\partial i}{\partial x} = Gv + C \frac{\partial v}{\partial t}$$

with $G = 0$. So

$$\frac{\partial i}{\partial x} = -C \frac{\partial v}{\partial t} = -C \frac{\partial}{\partial t} \left[v_0 \cdot \sin \left(\frac{\pi x}{l} \right) \cdot \cos \left(\frac{\pi t}{l\sqrt{LC}} \right) \right]$$

$$\frac{\partial i}{\partial x} = C \cdot v_0 \cdot \sin \left(\frac{\pi x}{l} \right) \cdot \frac{\pi}{l\sqrt{LC}} \cdot \sin \left(\frac{\pi t}{l\sqrt{LC}} \right)$$

Integrating partially w.r.t. x we get

$$i(x, t) = C v_0 \cdot \frac{\pi}{l\sqrt{LC}} \cdot \sin \frac{\pi t}{l\sqrt{LC}} \cdot \left(\frac{-l}{\pi} \right) \cos \frac{\pi x}{l} + C_1$$

where C_1 is the constant of integration.

Using the initial condition

$$i_0 = i(x, 0) = 0 + C_1 \quad \therefore \quad C_1 = i_0$$

then the current

$$i(x, t) = i_0 - v_0 \sqrt{\frac{C}{L}} \cdot \cos \left(\frac{\pi x}{l} \right) \cdot \sin \left(\frac{\pi t}{l\sqrt{LC}} \right).$$

Telegraph Line

Example 1: In a telephone wire of length l , a steady voltage distribution of 20 volts at the source end and 12 volts at the terminal end is maintained. At time $t = 0$, the terminal end is grounded. Determine the voltage and current. Assume that $L = 0$ and $G = 0$.

Solution: The equation of telegraph line is

$$v_{xx} = RCv_t$$

or

$$v_t = \frac{1}{RC} \cdot v_{xx}$$

In steady-state voltage distribution, v is independent of time t , so that the above equation reduces to

$$\frac{\partial^2 v}{\partial x^2} = 0$$

19.48 — HIGHER ENGINEERING MATHEMATICS—V

with solution $v(x) = ax + b$.

At the source end, $x = 0$, $v = 20$

At the terminal end, $x = l$, $v = 12$

Using these boundary conditions, we get

$$20 = v(0) = a \cdot 0 + b$$

$$\therefore b = 20$$

$$12 = v(l) = a \cdot l + b = a \cdot l + 20$$

$$\therefore a = \frac{12 - 20}{l} = \frac{-8}{l}.$$

Thus, initial steady-state voltage is given by

$$v_s(x) = \frac{-8}{l}x + 20 \quad (1)$$

Now, at time $t = 0$ the terminal end is grounded. So the boundary conditions change to $v = 20$ at $x = 0$ and $v = 0$ at $x = l$. Using these new boundary conditions we have the steady-state voltage (after grounding the terminal end) as

$$v_s^*(x) = ax + b$$

$$\text{Then } 20 = a \cdot 0 + b \quad \therefore b = 20$$

$$0 = a \cdot l + b = a \cdot l + 20 \quad \therefore a = \frac{-20}{l}$$

Thus, $v_s^*(x) = \frac{-20}{l}x + 20 = \frac{20}{l}(l - x)$. Assume that

$$v(x, t) = v_s^*(x) + v^{**}(x, t)$$

Here $v^{**}(x, t)$ is the transient solution of the IBVP consisting of telegraph equation (similar to one-dimensional heat equation with $\frac{1}{RC}$ as a^2) and zero boundary conditions i.e. both ends grounded and is given by

$$v^{**}(x, t) = \sum_{n=1}^{\infty} A_n \cdot \sin\left(\frac{n\pi x}{l}\right) e^{-[n^2\pi^2 / (l^2 RC)]t}$$

Thus

$$v(x, t) = \frac{20}{l}(l - x) + \sum_{n=1}^{\infty} A_n \cdot \sin\left(\frac{n\pi x}{l}\right) \times e^{-[n^2\pi^2 / (l^2 RC)]t} \quad (2)$$

The unknown coefficients A_n 's are determined using the initial condition (1). Thus, putting $t = 0$ in (2), we have

$$\frac{-8}{l}x + 20 = v_s(x) = v(x, 0)$$

$$= \frac{20}{l}(l - x) + \sum_{n=1}^{\infty} A_n \cdot \sin\left(\frac{n\pi x}{l}\right)$$

or

$$\frac{12x}{l} = \sum_{n=1}^{\infty} A_n \cdot \sin\left(\frac{n\pi x}{l}\right)$$

so

$$A_n = \frac{2}{l} \int_0^l \left(\frac{12x}{l}\right) \sin\left(\frac{n\pi x}{l}\right) dx$$

$$\begin{aligned} A_n &= \frac{24}{l^2} \left[x \cdot \left(\frac{-l}{n\pi}\right) \cos\frac{n\pi x}{l} - 1 \cdot \left(\frac{-l^2}{n^2\pi^2}\right) \sin\frac{n\pi x}{l} \right] \Bigg|_{x=0}^l \\ &= \frac{24}{l^2} \left[l \cdot \left(\frac{-l}{n\pi}\right) \cos n\pi \right] \\ &= \frac{24}{n\pi} (-1)^{n+1} \end{aligned}$$

Thus, the required voltage distribution is

$$\begin{aligned} v(x, t) &= \frac{20(l - x)}{l} + \\ &+ \frac{24}{\pi} \sum \frac{(-1)^{n+1}}{n} \sin\left(\frac{n\pi x}{l}\right) e^{-[n^2\pi^2 / (l^2 RC)]t} \end{aligned}$$

To obtain current $i(x, t)$, use the equation

$$-\frac{\partial v}{\partial x} = Ri + L \frac{\partial i}{\partial t}$$

with $L = 0$, then

$$i(x, t) = -\frac{1}{R} \frac{\partial v}{\partial x}$$

$$\begin{aligned} i(x, t) &= -\frac{1}{R} \frac{\partial}{\partial x} \left[\frac{20(l - x)}{l} + \frac{24}{\pi} \sum \frac{(-1)^{n+1}}{n} \sin\frac{n\pi x}{l} \times e^{-[n^2\pi^2 / (l^2 RC)]t} \right] \\ &= -\frac{1}{R} \left[-\frac{20}{l} + \frac{24}{\pi} \sum \frac{(-1)^{n+1}}{n} \frac{n\pi}{l} \cos\left(\frac{n\pi x}{l}\right) \times e^{-[n^2\pi^2 / (l^2 RC)]t} \right] \end{aligned}$$

Thus,

$$i(x, t) = \frac{20}{Rl} + \frac{24}{lR} \sum (-1)^n \cos\left(\frac{n\pi x}{l}\right) \times e^{-[n^2\pi^2 / (l^2 RC)]t}$$

EXERCISE

1. Solve $v_{xx} = LC v_{tt}$ assuming that the initial voltage is $v_0 \cdot \sin \frac{\pi x}{l}$, $v_t(x, 0) = 0$ and $v = 0$ at the ends, $x = 0$ and $x = l$ for all t .

Ans: $v(x, t) = v_0 \cos \left(\frac{\pi t}{l\sqrt{LC}} \right) \cdot \sin \left(\frac{\pi x}{l} \right)$

2. In the case of a submarine cable, assuming $L = C = 0$, find the voltage and current given that $v(0) = v_0$ and $i(0) = i_0$.

Ans: $v(x) = v_0 \cosh \alpha x - i_0 z_0 \sinh \alpha x$,
 $i(x) = i_0 \cosh \alpha x - \frac{v_0}{z_0} \cdot \sinh \alpha x$

where $\alpha = \sqrt{GR}$, $z_0 = \sqrt{\frac{R}{G}}$

Hint: Solve $v_{xx} = GRv$ and use $Ri = \frac{-\partial v}{\partial x}$ to find $i(x)$.

3. Determine the electromotive force $v(x, t)$ in a transmission line of length l , t seconds after the ends were suddenly grounded. Assume that R and G are negligible and initial conditions are $v(x, 0) = a_1 \sin \frac{\pi x}{l} + a_5 \sin \frac{5\pi x}{l}$ and $i(x, 0) = i_0$.

Ans: $v(x, t) = a_1 \sin \frac{\pi x}{l} \cdot \cos \frac{\pi t}{l\sqrt{LC}} + a_5 \sin \frac{5\pi x}{l} \cdot \cos \frac{5\pi t}{l\sqrt{LC}}$

4. Consider a telephone line 3000 km long with resistance 4 ohms/km and capacitance of 5×10^{-7} farad/km. Assume that $L = 0$ and $G = 0$. Initially both the ends are grounded so that the transmission line is not charged. At time $t = 0$, a constant emf E_0 is applied at one end while the other end is left grounded. Find the steady state current at the grounded end after 1 second.

Ans: $i = (0.053)i_\infty = 5.3\%$ of i_∞

Hint: Solve $v_{xx} = RC v_t$, obtaining $v(x, t) =$

$$\frac{E_0 x}{l} + \frac{2E_0}{\pi} \sum_{n=1}^{\infty} \sin \frac{n\pi x}{l} \cdot e^{-n^2 \pi^2 t / (RC l^2)} \cdot \frac{(-1)^n}{n}$$

to compute, i , use $i = -\frac{1}{R} \frac{\partial v}{\partial x}$ obtaining

$$i = -\frac{E_0}{lR} - \frac{2E_0}{lR} \sum_{n=1}^{\infty} (-1)^n e^{-n^2 \pi^2 t / (RC l^2)}$$

Put $t = 1$

Note: $e^{-\pi^2 / (RC l^2)} = e^{-0.548} = 0.578$

5. Assuming $L = 0$, $G = 0$, find the potential $v(x, t)$ in a transmission line of 1000 km long which is initially under steady-state conditions with potential 1300 volts at the source end ($x = 0$) and 1200 volts at the terminal end ($x = 1000$). The terminal end of the line is suddenly grounded, while the potential at the source end is maintained at 1300 volts.

Ans: $v(x, t) = 1300 - 1.3x +$

$$\frac{2400}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin \frac{n\pi x}{1000} e^{-[n^2 \pi^2 t / (l^2 RC)]}$$

Chapter 20

Fourier Integral, Fourier Transforms and Integral Transforms

INTRODUCTION

Just as the Fourier series decomposes a periodic function into a discrete set of contributions of various frequencies (all multiples of one fundamental frequency), the Fourier transform provides a continuous frequency resolution of a (possibly nonperiodic) function. Fourier transform is useful in the study of frequency response of a filter, solution of PDE, discrete Fourier transform and Fast Fourier transform in signal analysis.

Two more integral transforms Hankel transforms* useful in problems involving Bessel functions and Hilbert transform are considered.

20.1 FOURIER INTEGRAL THEOREM

A periodic function $f(x)$ defined in a finite interval $(-L, L)$ can be expressed in Fourier series. By extending this concept, non-periodic functions defined in $-\infty < x < \infty$ (for all x) can be expressed as a Fourier integral, since in practice periodic functions are fairly rare.

Theorem: A function $f(x)$, which is piecewise continuous in every finite interval and is absolutely integrable on the x -axis, can be represented by a Fourier integral

$$f(x) = \int_0^\infty [A(\alpha) \cos \alpha x + B(\alpha) \sin \alpha x] d\alpha \quad (1)$$

which is valid at all points of continuity.

At a point of discontinuity x_0 , the Fourier integral $= \frac{1}{2} [f(x_0 - 0) + f(x_0 + 0)]$ i.e., average of the left and right hand limits.

Proof: Consider the Fourier series expansion of $f(x)$ in any interval $[-L, L]$ given by

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} \left(a_n \cos \frac{n\pi x}{L} + b_n \sin \frac{n\pi x}{L} \right) \quad (2)$$

$$\text{where } a_n = \frac{1}{L} \int_{-L}^L f(t) \cos \left(\frac{n\pi t}{L} \right) dt \quad (3)$$

$$b_n = \frac{1}{L} \int_{-L}^L f(t) \sin \left(\frac{n\pi t}{L} \right) dt \quad (4)$$

By substituting the coefficients a_n and b_n from (3) and (4), the Fourier series (1) takes the form

$$\begin{aligned} f(x) &= \frac{1}{2L} \int_{-L}^L f(t) dt + \\ &+ \frac{1}{L} \sum_{n=1}^{\infty} \left[\int_{-L}^L f(t) \cos \left(\frac{n\pi t}{L} \right) dt \right] \cos \frac{n\pi x}{L} \\ &+ \frac{1}{L} \sum_{n=1}^{\infty} \left[\int_{-L}^L f(t) \sin \left(\frac{n\pi t}{L} \right) dt \right] \sin \left(\frac{n\pi x}{L} \right) \\ &= \frac{1}{2L} \int_{-L}^L f(t) dt + \frac{1}{L} \sum_{n=1}^{\infty} \int_{-L}^L f(t) \left[\cos \left(\frac{n\pi t}{L} \right) \right. \\ &\quad \times \cos \left(\frac{n\pi x}{L} \right) + \sin \left(\frac{n\pi t}{L} \right) \cdot \sin \left(\frac{n\pi x}{L} \right) \left. \right] dt \\ f(x) &= \frac{1}{2L} \int_{-L}^L f(t) dt \\ &+ \frac{1}{L} \sum_{n=1}^{\infty} \int_{-L}^L f(t) \cos \left(\frac{n\pi(t-x)}{L} \right) dt \quad (5) \end{aligned}$$

*Available on our Web site <http://www.mhhe.com/ramanahem>

20.2 — HIGHER ENGINEERING MATHEMATICS—V

Put $\alpha_n = \frac{n\pi}{L}$ and $\Delta\alpha_n = \alpha_{n+1} - \alpha_n$

$$= (n+1)\frac{\pi}{L} - \frac{n\pi}{L} = \frac{\pi}{L} \quad (6)$$

Then

$$f(x) = \frac{1}{2L} \int_{-L}^L f(t) dt + \frac{1}{\pi} \sum_{n=1}^{\infty} \left[\int_{-L}^L f(t) \cos(\alpha_n(t-x)) dt \right] \Delta\alpha_n \quad (7)$$

As $L \rightarrow \infty$, $\frac{1}{L} \rightarrow 0$ and $\Delta\alpha_n = \frac{\pi}{L} \rightarrow 0$, the infinite series in (7) becomes an integral from 0 to ∞ . Thus

$$f(x) = \frac{1}{\pi} \int_0^{\infty} \left[\int_{-\infty}^{\infty} f(t) \cdot \cos(\alpha(t-x)) dt \right] d\alpha \quad (8)$$

since the first term in the right hand side of (7) becomes zero because $f(x)$ is absolutely integrable. Thus as $L \rightarrow \infty$ the Fourier series becomes a Fourier Integral.

Expanding $\cos(\alpha(t-x))$, (8) is rewritten as

$$f(x) = \frac{1}{\pi} \int_0^{\infty} \left(\int_{-\infty}^{\infty} f(t) \cos \alpha t dt \right) \cos \alpha x d\alpha + \frac{1}{\pi} \int_{\alpha=0}^{\infty} \left(\int_{-\infty}^{\infty} f(t) \sin \alpha t dt \right) \sin \alpha x d\alpha \quad (9)$$

The **Fourier integral** expansion of $f(x)$ is the right side (expression) of (8) or (9).

Introducing

$$A(\alpha) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(t) \cos(\alpha t) dt \quad (10)$$

$$B(\alpha) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(t) \sin(\alpha t) dt \quad (11)$$

(9) can be rewritten as

$$f(x) = \int_0^{\infty} [A(\alpha) \cos(\alpha x) + B(\alpha) \sin(\alpha x)] d\alpha \quad (1)$$

Note: Fourier integral is very useful in solving differential equations and integral equations.

Particular cases of Fourier integral (10):

Fourier Cosine Integral

When $f(x)$ is an even function, then $B(\alpha) = 0$ and

$$A(\alpha) = \frac{2}{\pi} \int_0^{\infty} f(t) \cos(\alpha t) dt \quad (12)$$

Then the Fourier integral (1) reduces to the Fourier cosine integral

$$f(x) = \int_0^{\infty} A(\alpha) \cos(\alpha x) d\alpha \quad (13)$$

Fourier Sine Integral

When $f(x)$ is odd function, then $A(\alpha) = 0$ and

$$B(\alpha) = \frac{2}{\pi} \int_0^{\infty} f(t) \sin(\alpha t) dt \quad (14)$$

Then the Fourier integral (1) reduces to the Fourier sine integral

$$f(x) = \int_0^{\infty} B(\alpha) \sin \alpha x d\alpha \quad (15)$$

Suppose $f(x)$ is defined in the interval $(0, \infty)$. Then for $x > 0$, $f(x)$ can be represented by Fourier cosine integral (13) by redefining $f(x)$ in $(-\infty, 0)$ such that $f(x)$ is even function in $(-\infty, \infty)$.

Similarly, by redefining $f(x)$ in $(-\infty, 0)$ such that $f(x)$ is an odd function in $(-\infty, \infty)$, the given function $f(x)$ can be represented by the Fourier sine integral (15) valid for $x > 0$.

Fourier Integral in Complex Form

Since $\cos(\alpha(t-x))$ is an even function of α , then (8) can be written as

$$f(x) = \frac{1}{2} \cdot \frac{1}{\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(t) \cos(\alpha(t-x)) dt \right] d\alpha \quad (16)$$

Since $\sin(\alpha(t-x))$ is an odd function of α , then

$$0 = \frac{1}{2} \cdot \frac{1}{\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(t) \sin(\alpha(t-x)) dt \right] d\alpha \quad (17)$$

Multiplying (17) by $-\frac{i}{2\pi}$ and adding it to (16), we get

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(t) \cdot \cos(\alpha(t-x)) - i \sin(\alpha(t-x)) dt \right] d\alpha$$

$$f(x) = \int_{-\infty}^{\infty} \left[\frac{1}{2\pi} \int_{-\infty}^{\infty} f(t) \cdot e^{-i\alpha t} dt \right] e^{i\alpha x} d\alpha \quad (18)$$

$$\text{or } f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \left[\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(t) e^{-i\alpha t} dt \right] e^{i\alpha x} d\alpha$$

Note: A list of standard results which are very often used are given below:

Standard Results

1. $\int e^{ax} \cdot \sin bx dx = \frac{e^{ax}}{a^2+b^2} (a \sin bx - b \cos bx)$
2. $\int_0^\infty e^{-ax} \cdot \sin bx dx = \frac{b}{a^2+b^2}$
3. $\int e^{ax} \cdot \cos bx dx = \frac{e^{ax}}{a^2+b^2} (a \cos bx + b \sin bx)$
4. $\int_0^\infty e^{-ax} \cos bx dx = \frac{a}{a^2+b^2}$
5. $\int_{-\infty}^\infty e^{-x^2} dx = \sqrt{\pi}$
6. $\int_0^\infty \frac{e^{ax} - e^{-ax}}{e^{\pi x} - e^{-\pi x}} dx = \frac{1}{2} \tan \frac{a}{2}$
7. $\int_0^\infty \frac{e^{ax} + e^{-ax}}{e^{\pi x} - e^{-\pi x}} dx = \frac{1}{2} \sec \frac{a}{2}$
8. $\int_0^\infty \frac{e^{-ax}}{x} \sin bx dx = \tan^{-1} \frac{b}{c}, c > 0, b > 0$
9. $\int_0^\infty \frac{\sin ax}{x} dx = \frac{\pi}{2}$ if $a > 0$.

20.2 FOURIER TRANSFORM

From the Fourier integral representations (18), (13) and (15), we get Fourier transform, (which is complex), Fourier cosine transform (which is real) and Fourier sine transform (which is real) of $f(x)$ as follows:

Fourier Transform of $f(x)$

The Fourier integral of $f(x)$ in the complex form given by (18)

$$f(x) = \int_{-\infty}^\infty \left[\frac{1}{2\pi} \int_{-\infty}^\infty f(t) e^{-iat} dt \right] e^{iax} d\alpha \quad (18)$$

can be written as

$$f(x) = \int_{-\infty}^\infty F(\alpha) e^{i\alpha x} d\alpha \quad (19)$$

where
$$F(\alpha) = \frac{1}{2\pi} \int_{-\infty}^\infty f(x) e^{-i\alpha x} dx \quad (20)$$

$F(\alpha)$ defined by (20) is known as the Fourier transform of $f(x)$.

$f(x)$ defined by (19) is known as the inverse Fourier transform of $F(\alpha)$. $F(\alpha)$ and $f(x)$ are known as Fourier transform pair which differ in form only in the sign of the exponent.

Note: The factor $\frac{1}{2\pi}$ can multiply the $f(x)$ integral (19) instead of the $F(\alpha)$ integral (20). Alternatively the factor $\frac{1}{\sqrt{2\pi}}$ can multiply each of the integrals in (19) and (20).

Fourier transform breaks up the function into a continuous spectrum of frequencies α .

Fourier transform method is the process of obtaining $F(\alpha)$ for a given function $f(x)$.

Fourier Cosine Transform of $f(x)$

The Fourier integral of an even function $f(x)$ reduces to Fourier cosine integral given by (13)

$$f(x) = \frac{2}{\pi} \int_0^\infty \left[\int_0^\infty f(t) \cos(\alpha t) dt \right] \cos(\alpha x) d\alpha$$

Put
$$F_c(\alpha) = \int_0^\infty f(x) \cos \alpha x dx \quad (21)$$

Then
$$f(x) = \frac{2}{\pi} \int_0^\infty F_c(\alpha) \cos(\alpha x) d\alpha \quad (22)$$

$F_c(\alpha)$ given by (21) is called the Fourier cosine transform of $f(x)$ in the interval $0 < x < \infty$ and $f(x)$ given by (22) as the inverse Fourier cosine transform of $F_c(\alpha)$.

Fourier Sine Transform of $f(x)$

The Fourier integral of an odd function $f(x)$ reduces to the Fourier sine integral given by (15)

$$f(x) = \frac{2}{\pi} \int_0^\infty \left[\int_0^\infty f(t) \sin(\alpha t) dt \right] \sin(\alpha x) d\alpha$$

Take
$$F_s(\alpha) = \int_0^\infty f(x) \sin(\alpha x) dx \quad (23)$$

Then
$$f(x) = \frac{2}{\pi} \int_0^\infty F_s(\alpha) \sin(\alpha x) d\alpha \quad (24)$$

The function $F_s(\alpha)$ defined by (23) is known as the Fourier sine transform of $f(x)$ in $0 < x < \infty$. The function $f(x)$ given by (24) is known as the **inverse Fourier sine transform** of $F_s(\alpha)$.

Linearity Property

Fourier transform, Fourier cosine transform and Fourier sine transform are all linear operations (since the integral operation is linear). For example for any two functions $f(x)$ and $g(x)$ and for any two constants a and b , the Fourier transform of $af(x) + bg(x)$ is given by

$$\begin{aligned} F(af(x) + bg(x)) &= \frac{1}{2\pi} \int_{-\infty}^\infty [af(x) + bg(x)] e^{-i\alpha x} dx \\ &= a \cdot \frac{1}{2\pi} \int_{-\infty}^\infty f(x) e^{-i\alpha x} dx \\ &\quad + \frac{b}{2\pi} \int_{-\infty}^\infty g(x) e^{-i\alpha x} dx \\ &= aF(f(x)) + bF(g(x)) \end{aligned}$$

20.4 — HIGHER ENGINEERING MATHEMATICS—V

In a similar way

$$\begin{aligned}
 F_c(af(x) + bg(x)) &= \int_0^\infty (af + bg) \cos \alpha x d\alpha \\
 &= a \int_0^\infty f \cos \alpha x d\alpha + b \int_0^\infty g \cos \alpha x d\alpha \\
 &= aF_c(f) + bF_c(g).
 \end{aligned}$$

Fourier Transform of Derivatives

Fourier transform of a derivative of a function $f(x)$ corresponds to multiplication of the Fourier transform by $i\alpha$ i.e.,

$$F\left\{f'(x)\right\} = F\left\{\frac{df}{dx}\right\} = (i\alpha)F\left\{f(x)\right\}$$

Proof: By definition

$$F\left\{f'(x)\right\} = \frac{1}{2\pi} \int_{-\infty}^{\infty} f'(x) e^{-i\alpha x} dx$$

Integrating by parts

$$= \frac{1}{2\pi} \left[f \cdot e^{-i\alpha x} \Big|_{-\infty}^{\infty} - (-i\alpha) \int_{-\infty}^{\infty} f \cdot e^{-i\alpha x} dx \right]$$

Assuming that $f(x) \rightarrow 0$ as $|x| \rightarrow \infty$, we have

$$F\left\{f'(x)\right\} = (i\alpha)F\left\{f(x)\right\}$$

$$\text{In general } F\left\{\frac{d^n f}{dx^n}\right\} = (i\alpha)^n F\{f\}.$$

In particular

$$F\left\{\frac{d^2 f}{dx^2}\right\} = -\alpha^2 F\{f\}. \quad (25)$$

Fourier Cosine and Sine Transforms of Derivatives

Prove that

$$\text{a. } F_c\left\{f'(x)\right\} = \alpha F_s\left\{f(x)\right\} - f(0)$$

$$\text{b. } F_s\left\{f'(x)\right\} = -\alpha F_c\left\{f(x)\right\}$$

Proof:

a. By definition and applying integration by parts

$$\begin{aligned}
 F_c\{f'\} &= \int_0^\infty f' \cos(\alpha x) dx = f \cdot \cos \alpha x \Big|_0^\infty \\
 &\quad + \int_0^\infty f \cdot \sin \alpha x dx \\
 F_c\{f'\} &= -f(0) + \alpha F_s\{f\}
 \end{aligned}$$

b. Similarly,

$$\begin{aligned}
 F_s\{f'\} &= \int_0^\infty f' \sin(\alpha x) d\alpha = f \sin \alpha x \Big|_0^\infty \\
 &\quad - \alpha \int_0^\infty f \cos \alpha x dx \\
 &= 0 - \alpha F_c\{f\}.
 \end{aligned}$$

Corollary 1:

$$\begin{aligned}
 F_c\{f''\} &= \alpha F_s\{f'\} - f'(0) \\
 &= \alpha(-\alpha F_c\{f\}) - f'(0) \\
 F_c\{f''\} &= -\alpha^2 F_c\{f\} - f'(0) \quad (26)
 \end{aligned}$$

Corollary 2:

$$\begin{aligned}
 F_s\{f''\} &= -\alpha F_c\{f'\} = -\alpha \left[\alpha F_s\{f\} - f(0) \right] \\
 F_s\{f''\} &= -\alpha^2 F_s\{f\} + \alpha f(0) \quad (27)
 \end{aligned}$$

Application to Initial Boundary Value Problem (IBVP)

The solution of a IBVP consisting of a partial differential equation together with boundary and initial conditions can be solved by the Fourier transform method. If the boundary conditions are of the Dirichlet type where the function value is prescribed on the boundary, then the Fourier sine transform is used. If the boundary conditions are of the Neumann type where the derivative of function is prescribed on boundary, then Fourier cosine transform is applied. In either case, the P.D.E. reduces to an O.D.E. in Fourier transform which is solved. Then the inverse Fourier sine (or cosine) transform will give the solution to the problem.

20.3 CONVOLUTION

Convolution of two functions $f(x)$ and $g(x)$ denoted by $f * g$ is defined as

$$\begin{aligned}
 h(x) &= (f * g)(x) = \int_{-\infty}^{\infty} f(s)g(x-s)ds \\
 &= \int_{-\infty}^{\infty} f(x-s)g(s)ds
 \end{aligned}$$

Theorem: The Fourier transform of the convolution of f and g is the product of their Fourier transforms.

Proof: By definition

$$\begin{aligned} F\{f * g\} &= \frac{1}{2\pi} \int_{-\infty}^{\infty} (f * g) e^{-i\alpha x} dx \\ &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(s)g(x-s)ds \right] e^{-i\alpha x} dx \end{aligned}$$

Interchange the order of integration

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(s)g(x-s)e^{-i\alpha x} dx \right] ds$$

Now put $x - s = q$, so $x = s + q$, with q as the new variable of integration instead of x .

$$\begin{aligned} &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(s)g(q)e^{-i\alpha(s+q)} dq ds \\ &= \left[\frac{1}{2\pi} \int_{-\infty}^{\infty} f(s)e^{-i\alpha s} ds \right] \left[\frac{2\pi}{2\pi} \int_{-\infty}^{\infty} g(q)e^{-i\alpha q} dq \right] \\ &= 2\pi \cdot F\{f\} \cdot F\{g\}. \end{aligned}$$

Note: Convolution is commutative $f * g = g * f$, associative $f * (g * h) = (f * g) * h$.

WORKED OUT EXAMPLES

Fourier integral

Example 1: Using Fourier integral representation show that

$$\int_0^{\infty} \frac{\cos x\alpha + \alpha \sin x\alpha}{1 + \alpha^2} d\alpha = \begin{cases} 0 & \text{if } x < 0 \\ \frac{\pi}{2} & \text{if } x = 0 \\ \pi e^{-x} & \text{if } x > 0. \end{cases}$$

Solution: Consider the function defined by

$$f(x) = \begin{cases} 0 & \text{if } x < 0 \\ \frac{1}{2} & \text{if } x = 0 \\ e^{-x} & \text{if } x > 0. \end{cases}$$

Now find the Fourier integral representation of $f(x)$ in the exponential form: By definition

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(t) \cdot e^{-i\alpha t} dt \right] e^{i\alpha x} d\alpha$$

$$\begin{aligned} \text{Consider } I &= \int_{-\infty}^{\infty} f(t)e^{-i\alpha t} dt \\ &= \int_{-\infty}^0 0 + \int_0^{\infty} e^{-x} e^{-i\alpha t} dt \\ &= \frac{e^{-t(1+i\alpha)}}{-(1+i\alpha)} \Big|_{t=0}^{\infty} = \frac{1}{1+i\alpha} = \frac{1-i\alpha}{1+\alpha^2} \end{aligned}$$

$$\begin{aligned} \text{So } f(x) &= \frac{1}{2\pi} \int_{-\infty}^{\infty} I e^{i\alpha x} d\alpha \\ &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \left(\frac{1-i\alpha}{1+\alpha^2} \right) e^{i\alpha x} d\alpha \\ &= \int_{-\infty}^{\infty} \frac{1}{2\pi(1+\alpha^2)} (1-i\alpha) \times \\ &\quad \times (\cos \alpha x + i \sin \alpha x) d\alpha \\ &= \int_{-\infty}^{\infty} \frac{1}{2\pi(1+\alpha^2)} \left[(\cos \alpha x + \alpha \sin \alpha x) + i(\sin \alpha x - \alpha \cos \alpha x) \right] d\alpha \end{aligned}$$

The second integral on the right side is zero because the integrand is an odd function.

$$f(x) = \frac{2}{2\pi(1+\alpha^2)} \int_0^{\infty} (\cos \alpha x + \alpha \sin \alpha x) d\alpha$$

For $x > 0$, $f(x) = e^{-x}$ so

$$e^{-x} = \frac{1}{\pi} \int_0^{\infty} \frac{\cos \alpha x + \alpha \sin \alpha x}{1 + \alpha^2} d\alpha \quad (1)$$

For $x < 0$, $f(x) = 0$ so

$$0 = \frac{1}{\pi} \int_0^{\infty} \frac{\cos \alpha x + \alpha \sin \alpha x}{1 + \alpha^2} d\alpha \quad (2)$$

At $x = 0$, $f(x)$ has a discontinuity. So

$$f(x) = \frac{1}{2} \left[f(x+0) + f(x-0) \right] = \frac{1}{2} [1+0] = \frac{1}{2}$$

For $x = 0$

$$\frac{1}{2} = \frac{1}{\pi} \int_0^{\infty} \frac{\cos \alpha x + \alpha \sin \alpha x}{1 + \alpha^2} d\alpha. \quad (3)$$

From (1), (2), (3) the result follows.

Example 2: Find the (a) Fourier cosine integral and (b) Fourier sine integral (representation) of

$$\begin{aligned} f(x) &= \sin x & \text{if } 0 \leq x \leq \pi \\ &= 0 & \text{if } x > \pi \end{aligned}$$

20.6 — HIGHER ENGINEERING MATHEMATICS—V

Solution: a. The Fourier cosine integral of

$$f(x) = \int_0^{\infty} A(\alpha) \cos \alpha x d\alpha \quad \text{where}$$

$$A(\alpha) = \frac{2}{\pi} \int_0^{\infty} f(t) \cos \alpha t dt$$

$$\begin{aligned} A(\alpha) &= \frac{2}{\pi} \left[\int_0^{\pi} \sin t \cdot \cos \alpha t dt + \int_{\pi}^{\infty} 0 \right] \\ &= \frac{2}{\pi} \int_0^{\pi} [\sin(1+\alpha)t + \sin(1-\alpha)t] dt \\ &= -\frac{1}{\pi} \left[\frac{\cos(1+\alpha)t}{1+\alpha} + \frac{\cos(1-\alpha)t}{1-\alpha} \right]_{t=0}^{\pi} \\ &= +\frac{1}{\pi} \left[\frac{1 - \cos(1+\alpha)\pi}{1+\alpha} + \frac{1 - \cos(1-\alpha)\pi}{1-\alpha} \right] \end{aligned}$$

$$\begin{aligned} A(\alpha) &= \frac{1}{\pi} \left[\frac{1 + \cos \alpha \pi}{1+\alpha} + \frac{1 + \cos \alpha \pi}{1-\alpha} \right] \\ &= \frac{2(1 + \cos \alpha \pi)}{\pi(1 - \alpha^2)} \end{aligned}$$

For $\alpha = 1$, $A(1) = 0$.

Substituting $A(\alpha)$, we get the Fourier cosine integral of $f(x)$ as

$$\begin{aligned} f(x) &= \int_0^{\infty} \frac{2(1 + \cos \alpha \pi)}{\pi(1 - \alpha^2)} \cdot \cos \alpha x d\alpha \\ &= \frac{2}{\pi} \int_0^{\infty} \frac{1 + \cos \alpha \pi}{1 - \alpha^2} \cos \alpha x d\alpha \end{aligned}$$

b. Fourier sine integral of $f(x)$:

$$f(x) = \int_0^{\infty} B(\alpha) \sin \alpha x d\alpha, \quad \text{where}$$

$$\begin{aligned} B(\alpha) &= \frac{2}{\pi} \int_0^{\infty} f(t) \cdot \sin \alpha t dt \\ &= \frac{2}{\pi} \left[\int_0^{\pi} \sin t \cdot \sin \alpha t dt + \int_{\pi}^{\infty} 0 \right] \\ &= \frac{2}{\pi} \int_0^{\pi} [\cos(1-\alpha)t - \cos(1+\alpha)t] dt \\ &= \frac{1}{\pi} \left[\frac{\sin(1-\alpha)t}{1-\alpha} - \frac{\sin(1+\alpha)t}{1+\alpha} \right]_{t=0}^{\pi} \\ &= \frac{1}{\pi} \left[\frac{\sin \alpha \pi}{1-\alpha} + \frac{\sin \alpha \pi}{1+\alpha} \right] = \frac{2 \sin \alpha \pi}{\pi(1 - \alpha^2)} \end{aligned}$$

For $\alpha = 1$, $B(1) = 1$.

$$\begin{aligned} \text{Thus } f(x) &= \int_0^{\infty} \frac{2 \sin \alpha \pi}{\pi(1 - \alpha^2)} \cdot \sin \alpha x d\alpha \\ &= \frac{2}{\pi} \int_0^{\infty} \frac{\sin \alpha \pi}{(1 - \alpha^2)} \sin \alpha x d\alpha. \end{aligned}$$

Fourier transform

Example 3: Represent $f(x)$ as an exponential Fourier transform when

$$f(x) = \begin{cases} \sin x, & 0 < x < \pi \\ 0, & \text{otherwise} \end{cases}$$

show that the result can be written as

$$f(x) = \frac{1}{\pi} \int_0^{\infty} \frac{\cos \alpha x + \cos \alpha(x - \pi)}{1 - \alpha^2} d\alpha$$

Solution: Fourier transform in the exponential form is given by

$$\begin{aligned} F\{f(x)\} &= F(\alpha) = \frac{1}{2\pi} \int_{-\infty}^{\infty} f(x) \cdot e^{-i\alpha x} dx \\ &= \frac{1}{2\pi} \left[\int_{-\infty}^0 0 + \int_0^{\pi} \sin x \cdot e^{-i\alpha x} dx + \int_{\pi}^{\infty} 0 \right] \\ &= \frac{1}{2\pi} \int_0^{\pi} \left(\frac{e^{ix} - e^{-ix}}{2i} \right) e^{-i\alpha x} dx \end{aligned}$$

$$\text{since } \sin x = \frac{(e^{ix} - e^{-ix})}{2i}$$

$$\begin{aligned} &= \frac{1}{4\pi i} \int_0^{\pi} [e^{i(1-\alpha)x} - e^{-i(1+\alpha)x}] dx \\ &= \frac{1}{4\pi i} \left[\frac{e^{i(1-\alpha)x}}{i(1-\alpha)} - \frac{e^{-i(1+\alpha)x}}{-i(1+\alpha)} \right]_0^{\pi} \\ &= \frac{1}{4\pi i} \left[\frac{e^{i(1-\alpha)\pi}}{i(1-\alpha)} + \frac{e^{-i(1+\alpha)\pi}}{i(1+\alpha)} - \frac{1}{i(1-\alpha)} - \frac{1}{i(1+\alpha)} \right] \\ &= \frac{1}{2\pi} \frac{e^{-i\pi\alpha} + 1}{1 - \alpha^2} \quad \text{since } e^{\pm i\pi} = -1 \end{aligned}$$

$$\begin{aligned} \text{Then } f(x) &= \int_{-\infty}^{\infty} F(\alpha) e^{i\alpha x} d\alpha \\ &= \int_{-\infty}^{\infty} \frac{1}{2\pi} \left(\frac{e^{-i\pi\alpha} + 1}{1 - \alpha^2} \right) e^{i\alpha x} d\alpha \end{aligned}$$

is the required exponential Fourier transform representation. Expanding the integrand

$$\begin{aligned} (1 + e^{-i\pi\alpha})e^{i\alpha x} &= [1 + \cos \alpha\pi - i \sin \alpha\pi][\cos \alpha x + i \sin \alpha x] \\ &= \cos \alpha x + \cos \alpha(\pi - x) + i[+\sin \alpha x \cdot \sin \alpha\pi] \\ f(x) &= \frac{2}{2\pi} \int_0^\infty \frac{\cos \alpha x + \cos \alpha(\pi - x)}{(1 - \alpha^2)^2} d\alpha \\ &\quad + \frac{1}{2\pi} \int_{-\infty}^\infty \frac{\sin \alpha\pi \cdot \sin \alpha x}{1 - \alpha^2} d\alpha. \end{aligned}$$

Since the 2nd integral is zero (odd function), result follows.

Example 4: Find the Fourier transform of

$$\begin{aligned} f(x) &= \frac{1}{2a}, \quad \text{if } |x| \leq a \\ &= 0, \quad \text{if } |x| > a \end{aligned}$$

Solution: By definition, the Fourier transform of $f(x)$ is

$$\begin{aligned} F\{f(x)\} &= \frac{1}{2\pi} \int_{-\infty}^\infty f(x) \cdot e^{-i\alpha x} dx \\ &= \frac{1}{2\pi} \left[\int_{-\infty}^{-a} 0 + \int_{-a}^a \frac{1}{2a} e^{-i\alpha x} dx + \int_a^\infty 0 \right] \\ &= \frac{1}{2\pi} \left[\int_{-\infty}^{-a} 0 + \int_{-a}^a \frac{1}{2a} e^{-i\alpha x} dx + \int_a^\infty 0 \right] \\ &= \frac{1}{4\pi a} \left. \frac{e^{-i\alpha x}}{-i\alpha} \right|_{x=-a}^a \\ &= \frac{-1}{4\pi a i} [e^{-i\alpha a} - e^{+i\alpha a}] \\ &= \frac{1}{2\pi a \alpha} \left[\frac{e^{i\alpha a} - e^{-i\alpha a}}{2i} \right] = \frac{\sin(\alpha a)}{2\pi a \alpha}. \end{aligned}$$

Example 5: Find the (a) Fourier cosine and (b) sine transform of $f(x) = e^{-ax}$ for $x \geq 0$ and $a > 0$. Deduce the integrals known as "Laplace integrals" $\int_0^\infty \frac{\cos \alpha x}{a^2 + \alpha^2} d\alpha$ and $\int_0^\infty \frac{\alpha \sin \alpha x}{a^2 + \alpha^2} d\alpha$.

Solution: **a.** By definition Fourier cosine transform of $f(x)$ is

$$\begin{aligned} F_c\{f(x)\} &= F_c(\alpha) = \int_0^\infty f(x) \cos \alpha x dx \\ F_c\{f\} &= \int_0^\infty e^{-ax} \cos \alpha x dx = \frac{a}{a^2 + \alpha^2} \end{aligned}$$

The inverse Fourier cosine transform

$$\begin{aligned} f(x) &= \frac{2}{\pi} \int_0^\infty F_c(\alpha) \cos \alpha x d\alpha \\ &= \frac{2}{\pi} \int_0^\infty \frac{a}{a^2 + \alpha^2} \cos \alpha x d\alpha \end{aligned}$$

Since $f(x) = e^{-ax}$, the above integral can be rewritten as

$$\int_0^\infty \frac{\cos \alpha x}{a^2 + \alpha^2} d\alpha = \frac{\pi e^{-ax}}{2a}$$

b. The Fourier sine transform of $f(x)$ is

$$\begin{aligned} F_s\{f(x)\} &= F_s(\alpha) = \int_0^\infty f(x) \sin \alpha x dx \\ &= \int_0^\infty e^{-ax} \sin \alpha x dx = \frac{\alpha}{a^2 + \alpha^2} \end{aligned}$$

Now the inverse Fourier sine transform

$$\begin{aligned} f(x) &= \frac{2}{\pi} \int_0^\infty F_s(\alpha) \sin \alpha x d\alpha \\ &= \frac{2}{\pi} \int_0^\infty \frac{\alpha}{a^2 + \alpha^2} \sin \alpha x d\alpha \end{aligned}$$

with $f(x) = e^{-ax}$, this above integral takes the form

$$\int_0^\infty \frac{\alpha \sin \alpha x}{a^2 + \alpha^2} d\alpha = \frac{\pi e^{-ax}}{2}$$

Note: For $a = 0$, $\int_0^\infty \frac{\alpha \sin \alpha x}{a^2 + \alpha^2} d\alpha = \int_0^\infty \frac{\sin \alpha x}{\alpha} d\alpha = \frac{\pi}{2}$.

Example 6: Find the inverse Fourier sine transform of $\frac{1}{s} e^{-as}$.

Solution:

$$\begin{aligned} f(x) &= F_s^{-1} \left\{ \frac{e^{-as}}{s} \right\} \\ f &= \frac{2}{\pi} \int_0^\infty \frac{e^{-as}}{s} \sin sx ds \end{aligned} \quad (1)$$

Differentiating w.r.t., x

$$\begin{aligned} \frac{df}{dx} &= \frac{2}{\pi} \int_0^\infty \frac{e^{-as}}{s} \frac{d}{dx} (\sin sx) ds \\ &= \frac{2}{\pi} \int_0^\infty \frac{e^{-as}}{s} \cdot s \cdot \cos sx ds \\ \frac{df}{dx} &= \frac{2}{\pi} \int_0^\infty e^{-as} \cos sx ds = \frac{2}{\pi} \frac{a}{x^2 + a^2} \end{aligned}$$

20.8 — HIGHER ENGINEERING MATHEMATICS—V

Integrating
$$f(x) = \frac{2}{\pi} \int a \frac{dx}{x^2 + a^2}$$
$$= \frac{2}{\pi} \tan^{-1} \frac{x}{a} + A \quad (2)$$

From (1) at $x = 0$, $f(0) = 0$. Using this in (2)

$$0 = f(0) = 0 + A \quad \therefore A = 0$$

Thus
$$f(x) = \frac{2}{\pi} \tan^{-1} \frac{x}{a}$$

is the required inverse Fourier sine transform.

Note: When $a = 0$, $f(x) = F_s^{-1} \left\{ \frac{1}{s} \right\}$
 $= \frac{2}{\pi} \tan^{-1} \infty = 1$

Example 7: Find $f(x)$ whose Fourier cosine transform is $\frac{\sin as}{s}$.

Solution: It is given $F_c\{f(x)\} = \frac{\sin as}{s}$.

$$\begin{aligned} f(x) &= F_c^{-1} \left\{ \frac{\sin sa}{s} \right\} = \frac{2}{\pi} \int_0^\infty \frac{\sin sa}{s} \cos sxdx \\ &= \frac{2}{\pi} \frac{1}{2} \int_0^\infty \frac{\sin(s(a+x)) + \sin(s(a-x))}{s} ds \\ &= \frac{1}{\pi} \int_0^\infty \frac{\sin s(a+x)}{s} ds + \frac{1}{\pi} \int_0^\infty \frac{\sin s(a-x)}{s} ds \\ &= \frac{1}{\pi} \left(\frac{\pi}{2} + \frac{\pi}{2} \right) \quad \text{if } a-x > 0 \text{ i.e., } x < a \\ &= \frac{1}{\pi} \left(\frac{\pi}{2} - \frac{\pi}{2} \right) \quad \text{if } x-a > 0 \text{ i.e., } x > a \end{aligned}$$

since $\int_0^\infty \frac{\sin ax}{x} dx = \frac{\pi}{2}$ when $a > 0$. (See note of WE 5 on page 20.7)

Thus

$$f(x) = \begin{cases} 1 & \text{if } x < a \\ 0 & \text{if } x > a. \end{cases}$$

Example 8: Solve for $f(x)$ the integral equation

$$\int_0^\infty f(x) \sin xt dx = \begin{cases} 1, & 0 \leq t < 1 \\ 2, & 1 \leq t < 2 \\ 0, & t \geq 2 \end{cases}$$

Solution: By definition

$$F_s(t) = F_s \left\{ f(x) \right\} = \int_0^\infty f(x) \sin xt dx = \begin{cases} 1, & 0 \leq t < 1 \\ 2, & 1 \leq t < 2 \\ 0, & t \geq 2 \end{cases}$$

$$f(x) = \frac{2}{\pi} \int_0^\infty F_s(t) \sin txdx$$

$$= \frac{2}{\pi} \left[\int_0^1 1 \cdot \sin txdx + \int_1^2 2 \sin txdx + \int_2^\infty 0 \right]$$

$$= \frac{2}{\pi} \left[\left. -\frac{\cos tx}{x} \right|_{t=0}^1 - 2 \left. \frac{\cos tx}{x} \right|_{t=1}^2 \right]$$

$$f(x) = \frac{2}{\pi x} [1 + \cos x - 2 \cos 2x].$$

Example 9: Find the temperature distribution in semi-infinite bar with its end point and lateral surface insulated and with initial temperature distribution in the bar is prescribed by $f(x)$. Deduce the solution when $f(x) = e^{-ax}$.

Solution: This problem is represented by the one-dimensional heat equation

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$$

for $0 < x < \infty$, $t > 0$ with boundary condition

$$u_x(0, t) = 0 \quad (\text{insulated})$$

and with initial condition

$$u(x, 0) = f(x) \quad (\text{given}) \quad \text{for } 0 < x < \infty$$

Since the boundary condition is of the Neumann (derivative) type, apply Fourier cosine transformation to the equation

$$\int_0^\infty \frac{\partial u}{\partial t} \cos sxdx = c^2 \int_0^\infty \frac{\partial^2 u}{\partial x^2} \cos sxdx$$

Integrating the R.H.S. by parts

$$\begin{aligned} \frac{\partial}{\partial t} \int_0^\infty u \cos sxdx &= c^2 \left[\left. \frac{\partial u}{\partial x} \cos sx \right|_0^\infty \right. \\ &\quad \left. + \int_0^\infty s \sin sx \cdot \frac{\partial u}{\partial x} dx \right] \end{aligned}$$

Assuming $\frac{\partial u}{\partial x} \rightarrow 0$ as $x \rightarrow \infty$ and using the boundary condition $\left. \frac{\partial u}{\partial x} \right|_{x=0} = 0$, the first term in R.H.S. becomes zero. Integrating by parts again

$$\begin{aligned} \frac{\partial}{\partial t} \int_0^\infty u \cdot \cos sxdx &= c^2 s \left[\left. u \cdot \sin sx \right|_0^\infty - \int_0^\infty us \cdot \cos sxdx \right] \end{aligned}$$

Assuming that u is bounded i.e., $u \rightarrow 0$ as $x \rightarrow \infty$ the first term is R.H.S. becomes zero.

Put $U(t, s) = F_c \left\{ u(x, t) \right\} = \int_0^\infty u(x, t) \cdot \cos sx dx$

Then $\frac{d}{dt}U = -s^2 c^2 U$

Note that the result of Fourier transforming on x is to eliminate derivatives of x from the heat equation, thus leaving an ordinary differential equation w.r.t., ' t '.

Integrating by separation of variables

$$U(s, t) = A e^{-c^2 s^2 t}$$

At $t = 0, U(s, 0) = A$

Thus $A = U(s, 0) = \int_0^\infty u(x, 0) \cdot \cos(sx) dx$

From the initial condition $u(x, 0) = f(x)$,

then $A = \int_0^\infty f(x) \cos(sx) dx$

Taking inverse Fourier cosine transform

$$\begin{aligned} u(x, t) &= F_c^{-1} \{U\} = F_c^{-1} \left\{ A e^{-c^2 s^2 t} \right\} \\ &= \frac{2}{\pi} \int_0^\infty A e^{-c^2 s^2 t} \cdot \cos(sx) ds \end{aligned}$$

Special Case: when $f(x) = e^{-ax}$ then

$$A = \int_0^\infty e^{-ax} \cos(sx) dx = \frac{a}{a^2 + b^2}$$

Thus the solution in this case is

$$\begin{aligned} u(x, t) &= F_c^{-1} \left\{ \frac{a}{a^2 + b^2} e^{-c^2 s^2 t} \right\} \\ u(x, t) &= \frac{2}{\pi} \int_0^\infty \frac{a}{a^2 + b^2} \cdot e^{-c^2 s^2 t} \cdot \cos(sx) ds \end{aligned}$$

Example 10: Solve the Laplace's equation in the semi infinite strip shown in Fig. 20.1.

Fig. 20.1

Solution: To solve the Laplace's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \quad (1)$$

with the boundary conditions

$$u(0, y) = 0, \quad \text{for } 0 < y < b \quad (2)$$

$$u(x, b) = 0 \quad \text{for } 0 < x < \infty \quad (3)$$

$$u(x, 0) = e^{-ax} \quad \text{with } a > 0. \quad (4)$$

Region is: $0 < x < \infty, 0 < y < b$.

Applying Fourier sine transform of (1) on both sides

$$\int_0^\infty \frac{\partial^2 u}{\partial x^2} \sin sx dx + \int_0^\infty \frac{\partial^2 u}{\partial y^2} \sin sx dx = 0 \quad (5)$$

The first integral is simplified by successive integration by parts and gives

$$\begin{aligned} \int_0^\infty \frac{\partial^2 u}{\partial x^2} \sin sx dx &= \frac{\partial u}{\partial x} \cdot \sin sx \Big|_0^\infty \\ &\quad - \int_0^\infty \frac{\partial u}{\partial x} \cdot s \cdot \cos sx dx \end{aligned}$$

Assuming that $\frac{\partial u}{\partial x} \rightarrow 0$ as $x \rightarrow \infty$

$$= -s \left[u \cdot \cos sx \Big|_0^\infty - \int_0^\infty u \cdot s \cdot (-\sin sx) dx \right]$$

using the boundary condition (2), $u(0, y) = 0$ and assuming u is bounded i.e., $u \rightarrow 0$ as $x \rightarrow \infty$

$$= -s^2 \int_0^\infty u \sin sx dx$$

Put $U(s, y) = F_s \{ u(x, y) \} = \int_0^\infty u(x, y) \sin sx dx$
Thus

$$\int_0^\infty \frac{\partial^2 u}{\partial x^2} \sin sx dx = -s^2 U. \quad (6)$$

Substituting (6) in (5) and rewriting

$$\begin{aligned} -s^2 U + \frac{d^2}{dy^2} \left[\int_0^\infty u(x, y) \sin sx dx \right] &= 0 \\ -s^2 U + \frac{d^2 U}{dy^2} &= 0 \end{aligned} \quad (7)$$

Thus Laplace Equation (1) has been reduced to an ordinary differential equation in y (with s as a parameter). Solution of (7) is

$$U(s, y) = A \cosh sy + B \sinh sy \quad (8)$$

20.10 — HIGHER ENGINEERING MATHEMATICS—V

when $y = b$, $U(s, b) = F_s \{ u(x, b) \} = F_s \{ 0 \} = 0$
since from (3), $u(x, b) = 0$. From (8), at $y = b$,

$$0 = U(s, b) = A \cosh sb + B \sinh sb \quad (9)$$

When $y = 0$, $U(s, 0) = \int_0^\infty u(x, 0) \sin sx dx$

From (4), $u(x, 0) = e^{-ax}$ so

$$U(s, 0) = \int_0^\infty e^{-ax} \sin sx dx = \frac{s}{a^2 + s^2} \quad (10)$$

Putting $y = 0$ in (8)

$$\frac{s}{a^2 + s^2} = U(s, 0) = A + B \cdot 0$$

$$\text{or} \quad A = \frac{s}{a^2 + s^2} \quad (11)$$

Substituting (11) in (9)

$$B = -\frac{s}{a^2 + s^2} \coth sb \quad (12)$$

Thus the solution (8) becomes

$$U(s, y) = \frac{s}{a^2 + s^2} \cosh sy - \frac{s}{a^2 + s^2} \coth sb \sinh sy \quad (13)$$

Taking inverse Fourier sine transform of (12)

$$\begin{aligned} u(x, y) &= F_s^{-1} \{ U(s, y) \} \\ &= \frac{2}{\pi} \int_0^\infty \frac{s}{a^2 + s^2} (\cosh sy - \coth sb \cdot \sinh sy) \sin sx ds. \end{aligned}$$

EXERCISE

Fourier integrals

Find the Fourier integral representation of $f(x)$:

$$1. \quad f(x) = \begin{cases} x, & |x| < 1 \\ 0, & |x| > 1 \end{cases}$$

$$\text{Ans. } f(x) = \int_{-\infty}^\infty \frac{\sin \alpha - \alpha \cos \alpha}{i\pi \alpha^2} e^{i\alpha x} d\alpha$$

$$2. \quad f(x) = \begin{cases} \cos x, & -\frac{\pi}{2} < x < \frac{\pi}{2} \\ 0, & |x| > \frac{\pi}{2} \end{cases}$$

$$\text{Ans. } f(x) = \frac{1}{\pi} \int_{-\infty}^\infty \frac{\cos(\alpha\pi/2)}{1-\alpha^2} e^{i\alpha x} d\alpha$$

$$3. \quad f(x) = \begin{cases} 1, & |x| \leq 1 \\ 0, & |x| > 1 \end{cases}. \text{ Hence evaluate}$$

$$\int_0^\infty \frac{\sin \lambda \cos \lambda x}{\lambda} d\lambda = \begin{cases} \frac{\pi}{2}, & \text{if } |x| < 1 \\ \frac{\pi}{4}, & \text{if } |x| = 1 \\ 0, & \text{if } |x| > 1 \end{cases}$$

$$\text{Ans. } f(x) = \frac{2}{\pi} \int_0^\infty \frac{\sin \lambda \cos \lambda x}{\lambda} d\lambda.$$

$$4. \text{ Find the Fourier cosine and sine integrals of } f(x) = e^{-kx}, \text{ for } x > 0, k > 0.$$

Ans. Fourier cosine integral (F.C.I.)

$$f(x) = e^{-kx} = \frac{2k}{\pi} \int_0^\infty \frac{\cos sx}{k^2 + s^2} ds$$

$$\text{Fourier sine integral (F.S.I.)} = f(x) = e^{-kx} = \frac{2}{\pi} \int_0^\infty \frac{s \sin sx}{k^2 + s^2} ds.$$

$$5. \text{ Find the Fourier cosine integral of } f(x) = e^{-x} \cos x.$$

$$\text{Ans. } f(x) = e^{-x} \cos x = \frac{2}{\pi} \int_0^\infty \frac{(s^2+2) \cos sx ds}{s^4+4}$$

$$6. \text{ Find the Fourier sine integral of } f(x) = e^{-ax} - e^{-bx}.$$

$$\text{Ans. } f(x) = e^{-ax} - e^{-bx} = \frac{2}{\pi} \int_0^\infty \frac{(b^2-a^2)s \sin sx ds}{(a^2+s^2)(b^2+s^2)}, \quad a > 0, b > 0$$

$$7. \text{ Using Fourier integral representation, show that}$$

$$\int_0^\infty \frac{\sin s \cdot \cos xs}{s} ds = \begin{cases} \frac{\pi}{2}, & \text{if } 0 \leq x < 1 \\ \frac{\pi}{4}, & \text{if } x = 1 \\ 0, & \text{if } x > 1. \end{cases}$$

Hint: Find Fourier integral of

$$f(x) = \begin{cases} 1, & \text{if } 0 \leq x < 1 \\ 0, & \text{if } x \geq 1. \end{cases}$$

Fourier transforms

Find the Fourier transform of $f(x)$:

$$8. \quad f(x) = \begin{cases} 1, & \text{for } |x| < a \\ 0, & \text{for } |x| > a \end{cases}.$$

Hence evaluate $\int_0^\infty \frac{\sin ax}{x} dx$

$$\text{Ans. } F \{ f(x) \} = \frac{2 \sin sa}{s}, \text{ for } s \neq 0, \text{ For } s = 0, F(s) = 2, \text{ Integral} = \frac{\pi}{2}$$

$$9. f(x) = \begin{cases} 1 - x^2, & \text{if } |x| \leq 1 \\ 0, & \text{if } |x| > 1 \end{cases}. \text{Hence evaluate} \\ \int_0^\infty \frac{x \cos x - \sin x}{x^3} \cos \frac{x}{2} dx$$

$$\text{Ans. } F\{f(x)\} = -4(s \cos s - \sin s)/s^3, \\ \text{Integral} = \frac{-3\pi}{16}$$

$$10. f(x) = \begin{cases} x, & \text{for } |x| \leq a \\ 0, & \text{for } |x| > a \end{cases}$$

$$\text{Ans. } \frac{2i}{s^2}(as \cos sa - \sin sa)$$

$$11. f(x) = e^{-\frac{x^2}{2}}, -\infty < x < \infty$$

$$\text{Ans. } \sqrt{2\pi} e^{-\frac{s^2}{2}}$$

$$12. f(x) = \begin{cases} 0, & -\infty < x < a \\ x, & a \leq x \leq b \\ 0, & x > b \end{cases}$$

$$\text{Ans. } \frac{1}{s}(ae^{isa} - be^{isb}) + \frac{1}{s^2}(e^{isb} - e^{isa})$$

$$13. f(x) = xe^{-x}, 0 \leq x < \infty$$

$$\text{Ans. } \frac{1}{2\pi} \cdot \frac{(1+is)^2}{(1+s^2)^2}$$

$$14. f(x) = \begin{cases} \cos x, & \text{if } 0 < x < 1 \\ 0, & \text{otherwise} \end{cases}$$

$$\text{Ans. } \frac{1}{4\pi} \left[\frac{\sin(s+1)}{s+1} + \frac{\sin(s-1)}{s-1} + \right. \\ \left. + i \left[\frac{1-\cos(s+1)}{s+1} + \frac{1-\cos(s-1)}{s-1} \right] \right].$$

Fourier cosine and sine transforms

15. Find F.C.T. and F.S.T. of

$$f(x) = \begin{cases} k, & \text{if } 0 < x < a \\ 0, & \text{if } x > a. \end{cases}$$

$$\text{Ans. } F_c\{f(x)\} = k \cdot \frac{\sin as}{s}, F_s\{f(x)\} = \frac{k(1-\cos as)}{s}$$

16. Find F.S.T. of $e^{-|x|}$. Hence show that

$$\int_0^\infty \frac{x \sin mx}{1+x^2} dx = \frac{\pi e^{-m}}{2}, m > 0.$$

$$\text{Ans. } F.S.T. = \frac{s}{1+s^2}$$

17. Find F.S.T. of $\frac{e^{-ax}}{x}$.

$$\text{Ans. } \tan^{-1} \frac{s}{a} + c$$

$$18. \text{Find F.C.T. of } f(x) = \begin{cases} x, & 0 < x < 1 \\ 2-x, & 1 < x < 2 \\ 0, & x > 2. \end{cases}$$

$$\text{Ans. } \frac{(2 \cos s - \cos 2s - 1)}{s^2}$$

19. Find F.S.T. and F.C.T. of $2e^{-5x} + 5e^{-2x}$.

$$\text{Ans. } F.S.T.: \frac{2s}{s^2+25} + \frac{5s}{s^2+4}, F.C.T.: \frac{10}{s^2+4} + \frac{10}{s^2+25}$$

20. Find F.C.T. of $f(x) = e^{-ax} \cos ax$.

$$\text{Ans. } \frac{a(s^2+2a^2)}{s^4+4a^4}.$$

Inverse Fourier transform

21. Find $f(x)$ if its F.C.T. is $\frac{1}{1+s^2}$ and F.S.T. is $\frac{s}{1+s^2}$.

$$\text{Ans. } f(x) = e^{-x}, f(x) = e^{-x}$$

22. Find $f(x)$ if its F.C.T. is $\frac{1}{2\pi} \left(a - \frac{s}{2}\right)$ if $s < 2a$ and zero if $s \geq 2a$.

$$\text{Ans. } (2 \sin^2 ax)/\pi^2 x^2$$

23. Find the inverse F.S.T. of $s^n e^{-as}$

$$\text{Ans. } \frac{2 \cdot n! \sin[(n+1)x]}{\pi \cdot (a^2+x^2)^{\frac{n+1}{2}}}$$

24. Find the inverse Fourier transform of $e^{-|s|y}$

$$\text{Ans. } \frac{y}{[\pi(y^2+x^2)]}.$$

Integral equations

Solve the integral equations:

$$25. \int_0^\infty f(x) \cdot \sin \alpha x dx = \begin{cases} 1-\alpha, & 0 \leq \alpha \leq 1 \\ 0, & \alpha > 1 \end{cases}$$

$$\text{Ans. } f(x) = \frac{2(x-\sin x)}{(\pi x^2)}$$

$$26. \int_{-\infty}^\infty \frac{f(u)du}{(x-u)^2+a^2} = \frac{1}{x^2+b^2}, 0 < a < b$$

$$\text{Ans. } f(x) = \frac{(b-a)\alpha}{b\pi[x^2+(b-a)^2]}$$

$$27. \int_0^\infty f(x) \cos \alpha x dx = \begin{cases} 1-\alpha, & 0 \leq \alpha < 1 \\ 0, & \alpha > 1. \end{cases}$$

$$\text{Hence evaluate } \int_0^\infty \frac{\sin^2 t}{t^2} dt$$

$$\text{Ans. } f(x) = 2 \frac{(1-\cos x)}{(\pi x^2)}$$

$$28. \int_0^\infty f(x) \cos \alpha x dx = e^{-\alpha}$$

$$\text{Ans. } \frac{2}{\pi(1+x^2)}.$$

20.12 — HIGHER ENGINEERING MATHEMATICS—V

Solution to boundary value problems
(B.V.P.): Laplace's equation

29. Find the steady-state temperature distribution $u(x, y)$ in an infinite metal plate covering the first quadrant with the edge along the y -axis held at 0° and the edge along the x -axis held at $u(x, 0) = \begin{cases} 100, & 0 < x < 1 \\ 0, & x > 1 \end{cases}$.

Hint: Use F.S.T. to solve Laplace's equation.

Ans. $u(x, y) = \frac{200}{\pi} \int_0^\infty \frac{1 - \cos s}{s} e^{-sy} \sin sxdx$

or $u(x, y) = \frac{200}{\pi} \left[\arctan \left(\frac{x}{y} \right) - \frac{1}{2} \arctan \left(\frac{x+1}{y} \right) - \frac{1}{2} \arctan \left(\frac{x-1}{y} \right) \right]$

30. Solve $u_{xx} + u_{yy} = 0$ in the upper half-plane when the temperature along the x -axis $u(x, 0) = f(x)$. Deduce (a) when $u(x, 0) = 1$

if $|x| < 1$ (b) $u(x, 0) = \begin{cases} 2u_0, & x < -1 \\ u_0, & -1 < x < 1 \\ 0, & x > 1 \end{cases}$

Ans. $u(x, y) = \frac{1}{\pi} \int_{-\infty}^\infty \frac{yf(s)}{(x-s)^2 + y^2} ds$ known as Poisson integral formula for the half-plane $y > 0$ or Schwarz integral formula.

a. $u(x, y) = \frac{1}{\pi} \left[\tan^{-1} \left(\frac{1-x}{y} \right) + \tan^{-1} \left(\frac{x+1}{y} \right) \right]$

b. $u(x, y) = \frac{u_0}{\pi} \left[\pi - \tan^{-1} \left(\frac{1+x}{y} \right) + \tan^{-1} \left(\frac{1-x}{y} \right) \right]$.

One-dimensional heat equation

31. Find the temperature distribution $u(x, t)$ in a semi-infinite metal bar with the end $x = 0$ at zero temperature and initial temperature distribution $f(x)$. Deduce when $f(x) = e^{-x}$.

Ans. $u(x, t) = \frac{2}{\pi} \int_0^\infty U(s, 0) e^{-c^2 s^2 t} \sin sxdx$

where $U(s, 0) = \int_0^\infty u(x, 0) \cdot \sin sxdx = \int_0^\infty f(x) \sin sxdx$

when $f(x) = e^{-x} : U(s, 0) = \frac{s}{1+s^2}$;

$u(x, t) = \frac{2}{\pi} \int_0^\infty \frac{se^{-c^2 s^2 t}}{1+s^2} \sin sxdx$

32. Find the temperature $u(x, t)$ in a semi-infinite bar with $\frac{\partial u}{\partial x} = \mu$ when $x = 0$ and with initial temperature 0. Assume that $\frac{\partial u}{\partial x} \rightarrow 0$ as $x \rightarrow \infty$ and is bounded.

Ans. $u(x, t) = \frac{2}{\pi} \int_0^\infty \frac{\mu}{s^2} (1 - e^{-s^2 c^2 t}) \cos sxdx$

33. Solve $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$, $x > 0, t > 0$ with $\frac{\partial u}{\partial x} \Big|_{x=0} = 0$ and $u(x, 0) = \begin{cases} x, & 0 \leq x \leq 1 \\ 0, & x > 1 \end{cases}$.

Ans. $u(x, t) = \frac{2}{\pi} \int_0^\infty \left[\frac{\sin s}{s} + \frac{1}{s^2} (\cos s - 1) \right] e^{-s^2 c^2 t} \times \cos sxdx$

34. Solve $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$, $x > 0, t > 0$ with $u(x, 0) = 0, x > 0$ and $u(0, t) = u_0$ for $t > 0$.

Ans. $u(x, t) = u_0 \left[1 - \frac{2}{\pi} \int_0^\infty \frac{e^{-s^2 c^2 t}}{s} \cdot \sin sxdx \right]$.

Vibrating string

35. An infinite string is initially at rest and has an initial transverse displacement $y(x, 0) = f(x)$, $-\infty < x < \infty$. Show that the displacement $y(x, t)$ of the string is $y(x, t) = \frac{1}{2} [f(x+ct) + f(x-ct)]$.

20.4 FINITE FOURIER SINE AND COSINE TRANSFORMS

Let $f(x)$ be a function defined in a finite interval $0 < x < L$ i.e., when the range of one of the variables say x is finite. Suppose $f(x)$ is neither periodic nor even nor odd. Now by redefining $f(x)$ as an odd function in $-L < x < L$, the half range Fourier sine series expansion of $f(x)$ can be obtained as

$$f(x) = \sum_{n=1}^{\infty} b_n \sin \left(\frac{n\pi x}{L} \right)$$

where $b_n = \frac{2}{L} \int_0^L f(x) \sin \left(\frac{n\pi x}{L} \right) dx$.

Then the finite Fourier sine transform of $f(x)$ in $0 < x < L$ is defined as

$$F_s(n) = \int_0^L f(x) \sin \left(\frac{n\pi x}{L} \right) dx$$

which is a function of n , an integer.

The inverse finite Fourier sine transform of $F_s(n)$ is given by

$$f(x) = \frac{2}{L} \sum F_s(n) \cdot \sin\left(\frac{n\pi x}{L}\right)$$

In a similar way, the finite Fourier cosine transform of $f(x)$ in $0 < x < L$ is defined as

$$F_c(n) = \int_0^L f(x) \cos\left(\frac{n\pi x}{L}\right) dx$$

The inverse finite Fourier cosine transform of $F_c(n)$ is given by

$$f(x) = \frac{1}{L} F_c(0) + \frac{2}{L} \sum_{n=1}^{\infty} F_c(n) \cos \frac{n\pi x}{L}.$$

Result 1:

$$F_s \left\{ \frac{\partial^2 f}{\partial x^2} \right\} = \frac{-n^2 \pi^2}{L^2} F_s(f) - \frac{-n\pi}{L} [(-1)^n f(L, T) - f(0, t)]$$

By definition

$$\begin{aligned} F_s \left\{ \frac{\partial^2 f}{\partial x^2} \right\} &= \int_0^L \left(\frac{\partial^2 f}{\partial x^2} \right) \cdot \sin \frac{n\pi x}{L} dx, \\ &\text{integrating by parts} \\ &= \frac{\partial f}{\partial x} \cdot \sin \frac{n\pi x}{L} \Big|_0^L - \frac{n\pi}{L} \int_0^L \frac{\partial f}{\partial x} \cos \frac{n\pi x}{L} dx \\ &= 0 - \frac{n\pi}{L} \left\{ \left[f(x, t) \cdot \cos\left(\frac{n\pi x}{L}\right) \right]_0^L \right. \\ &\quad \left. + \frac{n\pi}{L} \int_0^L f(x, t) \cdot \sin\left(\frac{n\pi x}{L}\right) dx \right\} \\ F_s \left\{ \frac{\partial^2 f}{\partial x^2} \right\} &= -\frac{n\pi}{L} [(-1)^n f(L, t) - f(0, t)] \\ &\quad - \frac{n^2 \pi^2}{L^2} F_s(f). \end{aligned}$$

Similarly,

Result 2:

$$F_c \left\{ \frac{\partial^2 f}{\partial x^2} \right\} = -[f_x(0, t) - (-1)^n f_x(L, t)] - \frac{n^2 \pi^2}{L^2} F_c(f).$$

By definition

$$\begin{aligned} F_c \left\{ \frac{\partial^2 f}{\partial x^2} \right\} &= \int_0^L \frac{\partial^2 f}{\partial x^2} \cdot \cos\left(\frac{n\pi x}{L}\right) dx, \\ &\text{integrating by parts} \\ &= \frac{\partial f}{\partial x} \cdot \cos \frac{n\pi x}{L} \Big|_0^L + \frac{n\pi}{L} \int_0^L \frac{\partial f}{\partial x} \cdot \sin \frac{n\pi x}{L} dx \\ &= [-f_x(0, t) + (-1)^n f_x(L, t)] \\ &\quad + \frac{n\pi}{L} \left[f \cdot \sin \frac{n\pi x}{L} \Big|_0^L - \right. \\ &\quad \left. - \frac{n\pi}{L} \int_0^L f \cos \frac{n\pi x}{L} dx \right] \end{aligned}$$

$$F_c \left\{ \frac{\partial^2 f}{\partial x^2} \right\} = [(-1)^n f_x(L, t) - f_x(0, t)] - \frac{n^2 \pi^2}{L^2} F_c(f).$$

Note 3:

1. Apply finite Fourier sine transform when the boundary condition f prescribed.
2. Apply finite Fourier cosine transform when the boundary condition f_x prescribed.

WORKED OUT EXAMPLES

Example 1: Find the finite Fourier sine and cosine transform of $f(x) = x(\pi - x)$ in $0 < x < \pi$.

Solution: Finite Fourier sine transform of $f(x)$ is

$$\begin{aligned} F_s(n) &= \int_0^L f(x) \sin \frac{n\pi x}{L} dx \\ &= \int_0^\pi x(\pi - x) \cdot \sin nx dx \\ &= x(\pi - x) \cdot \left[\frac{-\cos nx}{n} \right]_0^\pi - \\ &\quad -(\pi - 2x) \cdot \left[\frac{-\sin nx}{n^2} \right]_0^\pi + (-2) \cdot \left[\frac{\cos nx}{n^3} \right]_0^\pi \\ F_s(n) &= 0 + 0 + \frac{2}{n^3} [1 - \cos n\pi] \\ &= \frac{2}{n^3} [1 - (-1)^n] \end{aligned}$$

20.14 — HIGHER ENGINEERING MATHEMATICS—V

Finite Fourier cosine transform of $f(x)$ is

$$\begin{aligned}
 F_c(n) &= \int_0^L f(x) \cos \frac{n\pi x}{L} dx \\
 &= \int_0^\pi x(\pi - x) \cdot \cos nx dx \\
 &= \left[x(\pi - x) \cdot \frac{\sin nx}{n} - \right. \\
 &\quad \left. -(\pi - 2x) \left(\frac{-\cos nx}{n^2} \right) + (-2) \frac{-\sin nx}{n^3} \right]_0^\pi \\
 F_c(n) &= 0 - \frac{(\pi \cos n\pi + \pi)}{n^2} = \frac{-\pi}{n^2} [1 + (-1)^n].
 \end{aligned}$$

Example 2: Find the inverse finite Fourier cosine transform $f(x)$ if $F_c(n) = \frac{\sin(\frac{n\pi}{2})}{2n}$ for $n = 1, 2, 3, \dots$ and $= \frac{\pi}{4}$ when $n = 0$ in $0 < x < \pi$

Solution:

$$\begin{aligned}
 f(x) &= \text{Inverse finite Fourier cosine transform of } F_c(n) \\
 &= \frac{1}{\pi} F_c(0) + \frac{2}{\pi} \sum_{n=1}^{\infty} F_c(n) \cdot \cos \left(\frac{n\pi x}{L} \right) \\
 &= \frac{1}{\pi} \cdot \frac{\pi}{4} + \frac{2}{\pi} \sum_{n=1}^{\infty} \sin \left(\frac{n\pi}{2} \right) \cdot \left(\frac{1}{2n} \right) \cdot \cos \left(\frac{n\pi x}{\pi} \right) \\
 f(x) &= \frac{1}{4} + \frac{1}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \cdot \sin \left(\frac{n\pi}{2} \right) \cdot \cos nx.
 \end{aligned}$$

Example 3: Find the inverse finite Fourier sine transform $f(x)$ if $f_s(n) = \frac{2\pi(-1)^{n-1}}{n^2}$, $n = 1, 2, \dots$ when $0 < x < \pi$.

Solution:

$$\begin{aligned}
 f(x) &= f_s^{-1} \{F_s(n)\} = \frac{2}{L} \sum_{n=1}^{\infty} F_s(n) \cdot \sin \left(\frac{n\pi x}{L} \right) \\
 &= \frac{2}{\pi} \sum_{n=1}^{\infty} \left\{ \frac{2\pi(-1)^{n-1}}{n^2} \right\} \cdot \sin nx \\
 f(x) &= 4 \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^2} \sin nx.
 \end{aligned}$$

Example 4: Find the temperature distribution in a bar of length L , with its both ends and lateral surface insulated when the initial temperature in the bar is $f(x)$. Deduce when $f(x) = x^2$ and $L = 10$.

Solution: This problem is to solve the one-dimensional heat equation $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$ for $0 < x < L$, with boundary conditions $u_x(0, t) = u_x(L, t) = 0$ and with initial condition $u(x, 0) = f(x)$. Since the boundary conditions are of the Neumann type (derivatives) apply finite Fourier cosine transform to both sides of the equation.

$$\int_0^L \frac{\partial u}{\partial t} \cdot \cos \left(\frac{n\pi x}{L} \right) dx = c^2 \int_0^L \frac{\partial^2 u}{\partial x^2} \cos \left(\frac{n\pi x}{L} \right) dx \quad (1)$$

Put $U = F_c \{u(x, t)\}$ and use (2)

$$F_c \left\{ \frac{\partial^2 u}{\partial x^2} \right\} = [(-1)^n u_x(L, t) - u_x(0, t)] - \frac{n^2 \pi^2}{L^2} F_c(u)$$

the equation (1) reduces to

$$\begin{aligned}
 \frac{d}{dt} \int_0^L u \cdot \cos \left(\frac{n\pi x}{L} \right) dx \\
 = c^2 \left\{ [(-1)^n u_x(L, t) - u_x(0, t)] - \frac{n^2 \pi^2}{L^2} F_c(u) \right\}
 \end{aligned}$$

$$\text{or} \quad \frac{dU}{dt} = c^2 \left(\frac{-n^2 \pi^2}{L^2} \right) U \quad (3)$$

since the first term in the R.H.S. is zero because of the zero boundary conditions ($u_x(L, t) = u_x(0, t) = 0$)

Here $U = U(n, t)$.

Solving (3), we get

$$U(n, t) = A e^{-\left(\frac{n^2 \pi^2 c^2 t}{L^2} \right)} \quad (4)$$

To determine the arbitrary constant A in (4) use the initial condition.

Put $t = 0$ in (4) this yields

$$\begin{aligned}
 A &= U(n, 0) = F_c \{u(x, 0)\} = F_c \{f(x)\} \\
 &= \int_0^L f(x) \cdot \cos \left(\frac{n\pi x}{L} \right) dx
 \end{aligned} \quad (5)$$

$$\therefore U(n, t) = \left[\int_0^L f(x) \cdot \cos \left(\frac{n\pi x}{L} \right) dx \right] e^{-n^2 \pi^2 c^2 t / L^2} \quad (6)$$

Taking inverse finite Fourier cosine transform

$$\begin{aligned}
 u(x, t) &= F_c^{-1} \{U(n, t)\} \\
 &= \frac{1}{L} F_c(0) + \frac{2}{L} \sum_{n=1}^{\infty} F_c(n) \cos \left(\frac{n\pi x}{L} \right)
 \end{aligned}$$

where $F_c(0) = \int_0^L f(x) dx$

and $F_c(n) = F_c\{u(x, t)\} = U(n, t)$ given by (6)

Thus
$$u(x, t) = \frac{1}{L} \int_0^L f(x) dx + \frac{2}{L} \sum_{n=1}^{\infty} \left[\int_0^L f(x) \cos\left(\frac{n\pi x}{L}\right) dx \right] \times \cos \frac{n\pi x}{L} e^{-(n^2\pi^2 c^2 t/L^2)} \quad (7)$$

When $f(x) = x^2$, and $L = 10$,

$$F_c(0) = \int_0^{10} x^2 dx = \frac{x^3}{3} \Big|_0^{10} = \frac{1000}{3}$$

$$\begin{aligned} U(n, 0) &= F_c\{u(x, 0)\} = \int_0^{10} x^2 \cdot \cos\left(\frac{n\pi x}{10}\right) dx \\ &= x^2 \cdot \left(\frac{10}{n\pi}\right) \cdot \sin\left(\frac{n\pi x}{10}\right) - 2x \cdot \left(\frac{-10^2}{n^2\pi^2}\right) \\ &\quad \times \cos\left(\frac{n\pi x}{10}\right) + 2 \left(\frac{-10^3}{n^3\pi^3}\right) \sin \frac{n\pi x}{10} \Big|_0^{10} \\ &= \frac{2000}{n^2\pi^2} (-1)^n. \end{aligned}$$

Thus
$$u(x, t) = \frac{100}{3} + \frac{2}{10} \cdot \frac{2000}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2} \times e^{-(n^2\pi^2 c^2 t/100)} \cdot \cos\left(\frac{n\pi x}{10}\right).$$

Example 5: Solve the Laplace's equation $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$ in square plate of length L with the following conditions $u(0, y) = u(L, y) = 0$, $u(x, 0) = 0$, $u(x, L) = f(x)$. Deduce when $f(x) = x^2$ and $L = \pi$.

Solution: Since the boundary conditions are Dirichlet type (u prescribed), take finite Fourier sine transform of the Laplace equation on both sides

$$\int_0^L \frac{\partial^2 u}{\partial x^2} \sin\left(\frac{n\pi x}{L}\right) dx + \int_0^L \frac{\partial^2 u}{\partial y^2} \sin\left(\frac{n\pi x}{L}\right) dx = 0$$

Integrating by parts

$$\begin{aligned} \frac{\partial u}{\partial x} \cdot \sin\left(\frac{n\pi x}{L}\right) \Big|_0^L - \frac{n\pi}{L} \int_0^L \frac{\partial u}{\partial x} \cdot \cos\left(\frac{n\pi x}{L}\right) dx \\ + \frac{\partial^2}{\partial y^2} \int_0^L u(x, y) \sin\left(\frac{n\pi x}{L}\right) dx = 0 \end{aligned}$$

Put $U = F_s\{u(x, y)\} = \int_0^L u(x, y) \sin\left(\frac{n\pi x}{L}\right) dx$
 $= U(n, y)$

Then
$$\frac{d^2 U}{dy^2} + 0 - \frac{n\pi}{L} \left[u(x, y) \cdot \cos \frac{n\pi x}{L} \Big|_0^L + \frac{n\pi}{L} \int_0^L u(x, y) \cdot \sin\left(\frac{n\pi x}{L}\right) dx \right] = 0$$

$$\frac{d^2 U}{dy^2} - \frac{n\pi}{L} [u(L, y)(-1)^n - u(0, y)] - \frac{n^2\pi^2}{L^2} U = 0$$

Using the boundary condition $u(L, y) = u(0, y) = 0$,

$$\frac{d^2 U}{dy^2} - \lambda^2 U = 0 \quad \text{where } \lambda = \frac{n\pi}{L} \quad (1)$$

The solution of this 2nd order ordinary differential equation is

$$U(n, y) = A \cosh \lambda y + B \sinh \lambda y \quad (2)$$

Using the boundary condition $u(x, 0) = 0$

$$0 = U(n, 0) = A \cdot 1 + B \cdot 0 \quad \therefore A = 0 \quad (3)$$

Using $u(x, L) = f(x)$

$$\begin{aligned} U(n, L) &= F_s\{u(x, L)\} = F_s\{f(x)\} \\ &= \int_0^L f(x) \sin\left(\frac{n\pi x}{L}\right) dx \end{aligned} \quad (4)$$

Substituting (3), (4) in (2)

$$\begin{aligned} U(n, L) &= B \cdot \sinh \lambda L \\ \therefore B &= \frac{U(n, L)}{\sinh \lambda L} \end{aligned} \quad (5)$$

Thus (2) reduces to

$$U(n, y) = B \cdot \sinh \lambda y \quad (6)$$

where B and λ are given by (5) and (1).

Taking the inverse finite Fourier sine transform of (6), we get

$$\begin{aligned} u(x, y) &= F_s^{-1}\{U\} = \frac{2}{L} \sum_{n=1}^{\infty} U(n, y) \cdot \sin \frac{n\pi x}{L} \\ u(x, y) &= \frac{2}{L} \sum_{n=1}^{\infty} B \cdot \sinh\left(\frac{n\pi y}{L}\right) \cdot \sin\left(\frac{n\pi x}{L}\right) \end{aligned} \quad (7)$$

20.16 — HIGHER ENGINEERING MATHEMATICS—V

When $f(x) = x^2$ and $L = \pi$, from (4), we get

$$\begin{aligned} U(n, L) &= \int_0^L f(x) \sin\left(\frac{n\pi x}{L}\right) dx = \int_0^\pi x^2 \sin nx dx \\ &= x^2 \cdot \left(\frac{-\cos nx}{n}\right) - 2x \cdot \left(-\frac{1}{n^2} \sin nx\right) \\ &\quad + 2 \left(\frac{1}{n^3}\right) \cdot \cos nx \Bigg|_0^\pi \\ U(n, L) &= \frac{-\pi^2(-1)^n}{n} + \frac{2}{n^3}(-1)^n - \frac{2}{n^3} \end{aligned} \quad (8)$$

Substituting (5), (8) in (7), we get

$$\begin{aligned} u(x, y) &= \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{\sinh n\pi} \left[(-1)^n \left(\frac{2}{n^3} - \pi^2 \right) - \frac{2}{n^3} \right] \\ &\quad \times \sinh ny \cdot \sin nx \end{aligned}$$

EXERCISE

Find the finite Fourier sine transform (F.F.S.T.) and finite Fourier cosine transform (F.F.C.T.) of $f(x)$:

1. $f(x) = 2x$ in $0 < x < 4$

Ans. F.F.S.T.: $\frac{32}{s\pi}(-1)^{n+1}$, F.F.C.T.: $\frac{32}{s\pi}((-1)^n - 1)$

2. $f(x) \begin{cases} 1, & 0 < x < \pi/2 \\ -1, & \pi/2 < x < \pi \end{cases}$

Ans. F.F.S.T. = $(-2 \cos(s\pi/2) + 1 + \cos s\pi/2)/s$

F.F.C.T. = $2 \sin(s\pi/2)/2$, $s = 1, 2, 3, \dots$

3. $f(x) = x^2$ in $0 < x < L$

Ans. F.F.S.T.: $\frac{-L^3 \cos n\pi}{n\pi} + \frac{2L^3}{n^3\pi^3}(\cos n\pi - 1)$, $n = 1, 2, 3, \dots$

F.F.C.T.: $2L^3(\cos n\pi - 1)/n^2\pi^2$

4. Find F.F.S.T. of $f(x) = e^{ax}$ in $(0, L)$

Ans. $s\pi L [(-1)^{s+1} \cdot e^{aL} + 1] / [a^2 L^2 + s^2 \pi^2]$

5. Find F.F.C.T. of $f(x) = \frac{x^2}{2\pi} - \frac{\pi}{6}$ in $(0, \pi)$

Ans. $(-1)^n/n^2$ for $n = 1, 2, 3$ and zero for $n = 0$

6. Determine the inverse F.F.S.T. of $\frac{16(-1)^{n-1}}{n^3}$, $n = 1, 2, 3, \dots$ and $0 < x < 8$

Ans. $f(x) = \frac{2}{8} \sum_{n=1}^{\infty} \frac{16(-1)^{n-1}}{n^3} \sin \frac{n\pi x}{8}$

7. Determine the inverse F.F.C.T. of $\frac{6 \sin \frac{n\pi}{2} - \cos n\pi}{(2n+1)\pi}$ for $n = 1, 2, 3, \dots$ and equals to $\frac{2}{\pi}$ for $n = 0$ in $0 < x < 4$

Ans. $f(x) = \frac{1}{4} \cdot \frac{2}{\pi} + \frac{2}{4} \sum_{n=1}^{\infty} \frac{6(\sin(n\pi/2) - \cos n\pi)}{(2n+1)\pi} \cos\left(\frac{n\pi}{4}\right)$

8. Determine F.F.S.T. of $(1 - \cos n\pi)/n^2\pi^2$ where $0 < x < \pi$

Ans. $f(x) = \frac{2}{\pi^3} \sum_{n=1}^{\infty} \left(\frac{1 - \cos n\pi}{n^2} \right) \sin nx$

Solve the one-dimensional heat equation $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$ with

9. $u(0, t) = u(4, t) = 0$, $u(x, 0) = 2x$

Ans. $u(x, t) = \frac{2}{4} \sum_{n=1}^{\infty} \frac{32(-1)^{n+1}}{n\pi} e^{-n^2\pi^2 c^2 t/16} \cdot \sin \frac{n\pi x}{4}$

10. $u_x(0, t) = u_x(6, t) = 0$, $u(x, 0) = 2x$

Ans. $u(x, t) = 6 + \frac{2\pi}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^n - 1}{n^2} e^{-n^2\pi^2 c^2 t/36} \times \cos \frac{n\pi x}{6}$

11. Solve the Laplace's equation $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$ in square metal plate of side π with $u(x, \pi) = u_0$, $u(0, y) = 0$, $u(\pi, y) = 0$, $u(x, 0) = 0$. Assume $u(x, y)$ is bounded

Ans. $u(x, y) = \frac{4u_0}{\pi} \sum_{n=0}^{\infty} \frac{\sin h((2n+1)y) \sin(2n+1)x}{(2n+1) \cdot \sinh((2n+1)\pi)}$

12. Find the displacement $y(x, t)$ of a string of length π governed by the wave equation $\frac{\partial^2 y}{\partial t^2} = \frac{c^2 \partial^2 y}{\partial x^2}$ with one end fixed $y(\pi, t) = 0$, initially at rest $y(x, 0) = 0$, with initial displacement $u(0, t) = a \sin wt$.

Ans. $y(x, t) = a \sin wt \cdot \sin w \frac{(\pi-x)}{c} \operatorname{cosec}\left(\frac{\pi w}{c}\right) + \left(\frac{2awc}{\pi}\right) \sum_{n=1}^{\infty} (w^2 - n^2 c^2)^{-1} \sin nx \sin nct$.

20.5 PARSEVAL'S* IDENTITY FOR FOURIER TRANSFORMS

Let $F(\alpha)$ and $G(\alpha)$ be respectively the Fourier transforms of $f(x)$ and $g(x)$. Then

$$\int_{-\infty}^{\infty} F(\alpha) \overline{G(\alpha)} d\alpha = \frac{1}{2\pi} \int_{-\infty}^{\infty} f(x) \overline{g(x)} dx \quad (1)$$

where bar implies the complex conjugate.

Proof: Using the inversion formula for Fourier transform for $\overline{g(x)}$ in the R.H.S. of (1),

$$\int_{-\infty}^{\infty} f(x) \overline{g(x)} dx = \int_{-\infty}^{\infty} f(x) \left\{ \int_{-\infty}^{\infty} \overline{G(\alpha)} e^{i\alpha x} d\alpha \right\} dx$$

Interchanging the order of integrand in R.H.S.

$$= \int_{-\infty}^{\infty} \overline{G(\alpha)} \left\{ \int_{-\infty}^{\infty} f(x) e^{i\alpha x} dx \right\} d\alpha$$

Observing that inner most integral is the Fourier transform of $f(x)$, we have

$$= \int_{-\infty}^{\infty} \overline{G(\alpha)} \{2\pi F(\alpha)\} d\alpha = 2\pi \int_{-\infty}^{\infty} F(\alpha) \overline{G(\alpha)} d\alpha$$

Thus $\frac{1}{2\pi} \int_{-\infty}^{\infty} f(x) \overline{g(x)} dx = \int_{-\infty}^{\infty} F(\alpha) \overline{G(\alpha)} d\alpha$.

Corollary 1: Put $g(x) = f(x)$ and note that $z\overline{z} = |z|^2$. Then (1) reduces to

$$\begin{aligned} \int_{-\infty}^{\infty} F(\alpha) \overline{F(\alpha)} d\alpha &= \int_{-\infty}^{\infty} |F(\alpha)|^2 d\alpha \\ &= \frac{1}{2\pi} \int_{-\infty}^{\infty} f(x) \overline{f(x)} dx \\ &= \frac{1}{2\pi} \int_{-\infty}^{\infty} |f(x)|^2 dx \end{aligned}$$

$$\text{i.e., } \boxed{\int_{-\infty}^{\infty} |F(\alpha)|^2 d\alpha = \frac{1}{2\pi} \int_{-\infty}^{\infty} |f(x)|^2 dx} \quad (2)$$

Results (2) and its generalization (1) are known as **Parseval's identity for Fourier transforms (integrals)**.

Corollary 2: The Parseval's identity for Fourier cosine sine transform are

$$(a) \quad \frac{2}{\pi} \int_0^{\infty} F_c(\alpha) G_c(\alpha) d\alpha = \int_0^{\infty} f(x) g(x) dx$$

$$(b) \quad \frac{2}{\pi} \int_0^{\infty} |F_c(\alpha)|^2 d\alpha = \int_0^{\infty} |f(x)|^2 dx$$

Parseval's identity for Fourier sine transform are

$$(c) \quad \frac{2}{\pi} \int_0^{\infty} F_s(\alpha) G_s(\alpha) d\alpha = \int_0^{\infty} f(x) g(x) dx$$

$$(d) \quad \frac{2}{\pi} \int_0^{\infty} |F_s(\alpha)|^2 d\alpha = \int_0^{\infty} |f(x)|^2 dx$$

These results can be proved on similar lines as above.

WORKED OUT EXAMPLES

Example 1: Prove that $\int_0^{\infty} \frac{(x \cos x - \sin x)^2}{x^6} dx = \frac{\pi}{15}$.

Solution: Consider the function $f(x)$ defined as

$$f(x) = \begin{cases} a^2 - x^2 & \text{if } |x| \leq a \\ 0 & \text{if } |x| > a \end{cases}$$

Fourier transform of $f(x) = F\{f(x)\} = F(\alpha) = \frac{1}{2\pi} \int_{-\infty}^{\infty} f(x) e^{-i\alpha x} dx = \frac{1}{2\pi} \left[\int_{-\infty}^{-a} + \int_{-a}^a + \int_a^{\infty} \right]$. Since $f(x) = 0$ in $(-\infty, -a)$ and (a, ∞) , we have

$$F(\alpha) = \frac{1}{2\pi} \int_{-a}^a (a^2 - x^2) e^{-i\alpha x} dx = \frac{1}{2\pi} [I_1 - I_2]$$

where

$$I_1 = \int_{-a}^a a^2 e^{-i\alpha x} dx = a^2 \left(\frac{e^{-i\alpha x}}{-i\alpha} \right) \Big|_{-a}^a = \frac{a^2}{i\alpha} [e^{i\alpha a} - e^{-i\alpha a}]$$

and integrating by parts.

$$\begin{aligned} I_2 &= \int_{-a}^a x^2 e^{-i\alpha x} dx \\ &= \left(x^2 \frac{e^{-i\alpha x}}{-i\alpha} - 2x \frac{e^{-i\alpha x}}{i^2 \alpha^2} + 2 \frac{e^{-i\alpha x}}{-i^3 \alpha^3} \right) \Big|_{-a}^a \\ &= \frac{a^2}{i\alpha} [e^{i\alpha a} - e^{-i\alpha a}] + \frac{2a}{\alpha^2} [e^{i\alpha a} + e^{-i\alpha a}] + \frac{2}{i\alpha^3} [e^{-i\alpha a} - e^{i\alpha a}] \end{aligned}$$

So

$$F(\alpha) = \frac{1}{2\pi} [I_1 - I_2] = \frac{1}{2\pi} \left[\frac{-2a}{\alpha^2} (2 \cos \alpha a) + \frac{2}{\alpha^3} 2 \cdot \sin \alpha a \right]$$

$$F(\alpha) = + \frac{2}{\pi \alpha^3} [\sin \alpha a - \alpha a \cos \alpha a]$$

Marc Antoine Parseval (1755–1836) French mathematician.

20.18 — HIGHER ENGINEERING MATHEMATICS—V

Apply Parseval's identity for $f(x)$ and $F(\alpha)$.

$$\begin{aligned}
 \int_{-\infty}^{\infty} |F(\alpha)|^2 d\alpha &= \int_{-\infty}^{\infty} \frac{4}{\pi^2} \left(\frac{\sin \alpha a - \alpha \cos \alpha a}{\alpha^3} \right)^2 d\alpha \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} |f(x)|^2 dx \\
 &= \frac{1}{2\pi} \int_{-a}^a (|a^2 - x^2|)^2 dx \\
 &= \frac{1}{2\pi} \int_{-a}^a (a^4 + x^4 - 2a^2 x^2) dx \\
 &= \frac{1}{2\pi} \left[a^4 x + \frac{x^5}{5} - 2a^2 \frac{x^3}{3} \right]_{-a}^a \\
 &= \frac{1}{2\pi} \cdot 2a^2 \left(1 + \frac{1}{5} - \frac{2}{3} \right) \\
 &= \frac{16a^5}{15} \cdot \frac{1}{2\pi} = \frac{8}{15} \frac{a^5}{\pi}
 \end{aligned}$$

Thus

$$2 \int_0^{\infty} \frac{4}{\pi^2} \left(\frac{ax \cos ax - \sin ax}{x^3} \right)^2 dx = \frac{8}{15} \frac{a^5}{\pi}$$

or
$$\int_0^{\infty} \frac{(ax \cos ax - \sin ax)^2}{x^6} dx = \frac{\pi a^5}{15}$$

For $a = 1$, we get the required result.

Example 2: Evaluate $\int_0^{\infty} \frac{x^2}{(a^2+x^2)(b^2+x^2)} dx$ and hence find $\int_0^{\infty} \left(\frac{x}{x^2+1} \right)^2 dx$.

Solution: We know that if $f(x)=e^{-ax}$ then Fourier sine transform of $f(x)=F_s\{f(x)\}=F_s(\alpha)=\frac{\alpha}{a^2+\alpha^2}$. Similarly for $g(x)=e^{-bx}$ then $G_s\{g(x)\}=\frac{\alpha}{b^2+\alpha^2}$. Recall Parseval's identity for sine transform

$$\begin{aligned}
 \frac{2}{\pi} \int_0^{\infty} F_s(\alpha) G_s(\alpha) d\alpha &= \int_0^{\infty} f(x) g(x) dx \\
 \int_0^{\infty} \left(\frac{\alpha}{a^2+\alpha^2} \right) \left(\frac{\alpha}{b^2+\alpha^2} \right) d\alpha &= \int_0^{\infty} e^{-ax} \cdot e^{-bx} dx = \frac{2}{\pi} \int_0^{\infty} e^{-(a+b)x} dx \\
 &= \frac{\pi}{2} \frac{e^{-(a+b)x}}{-(a+b)} \Bigg|_{x=0}^{\infty} = \frac{1}{(a+b)} \frac{\pi}{2}
 \end{aligned}$$

Thus

$$\int_0^{\infty} \frac{x^2}{(a^2+x^2)(b^2+x^2)} dx = \frac{\pi}{2(a+b)}$$

For $a = b = 1$, $\int_0^{\infty} \left(\frac{x}{x^2+1} \right)^2 dx = \frac{\pi}{4}$.

EXERCISE

Solve the following problems using Parseval's identity for Fourier transforms.

1. Show that $\int_0^{\infty} \frac{\sin^2 ax}{x^2} dx = \frac{\pi a}{2}$

Hint: Consider $f(x) = 1, |x| < a$ and $f(x) = 0$ for $|x| > a$. Then $F\{f(x)\} = F(\alpha) = \frac{2 \sin a\alpha}{\alpha}$, apply P.I. then $\int_{-a}^a (1)^2 dx = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{4 \sin^2 a\alpha}{\alpha^2} d\alpha$

2. Evaluate (a) $\int_0^{\infty} \frac{dx}{(a^2+x^2)(b^2+x^2)}$ and hence find (b) $\int_0^{\infty} \frac{dx}{(x^2+1)^2}$.

Hint: $F_c\{e^{-ax}\} = \frac{a}{a^2+\alpha^2}$, $F_c\{e^{-bx}\} = \frac{b}{b^2+\alpha^2}$, use P.I.

Ans. (a) $\frac{\pi}{2ab(a+b)}$ (b) For $a = b = 1$, $\frac{\pi}{4}$.

3. Prove that $\int_0^{\infty} \left(\frac{\sin x}{x} \right)^4 dx = \frac{\pi}{3}$

Hint: Take $f(x) = 1 - |x|$, for $|x| < 1, 0$, otherwise, $F\{f(x)\} = \sqrt{\frac{2}{\pi}} \left(\frac{1-\cos \alpha}{\alpha^2} \right)$, use P.I.

4. Evaluate (a) $\int_0^{\infty} \left(\frac{1-\cos x}{x} \right)^2 dx$ (b) $\int_0^{\infty} \frac{\sin^4 x}{x^2} dx$

Hint: Take $f(x) = 1$, for $0 \leq x < 1, 0$ otherwise, then $F_c\{f(x)\} = \frac{1-\cos \alpha}{\alpha}$, $F_s\{f(x)\} = \frac{\sin \alpha}{\alpha}$, use P.I.

Ans. (a) $\frac{\pi}{2}$ (b) $\frac{\pi}{2}$

5. Evaluate $\int_0^{\infty} \frac{\sin ax}{x(a^2+x^2)} dx$

Hint: $F_c\{e^{-ax}\} = \frac{a}{a^2+\alpha^2}$, $F_c\{g(x)\} = \frac{\sin a\alpha}{\alpha}$ where $g(x) = 1, 0 < x < a$, zero for $x > a$. use (a) in cor. 2.

Ans. $\frac{\pi}{2} \left(\frac{1-e^{-a^2}}{a^2} \right)$

Chapter 21

Linear Difference Equations and Z-Transforms

INTRODUCTION

Difference Equations

Difference equations model processes in which we know relationships between changes or differences rather than rates of changes which lead to differential equations. Thus a difference equation is an equation relating various terms of a sequence $a_0, a_1, a_2, \dots$. A string loaded with a finite number of beads at equally spaced points leads to a difference equation. Recurrence relations obtained in the solution of DE by power series or Frobenius method are also difference equations. Numerical solution of DE also leads to difference equations.

Z-transforms

Solution of a discrete system, expressed as a difference equation is obtained using z -transform. Discrete analysis played important role in the development of communication engineering.

21.1 LINEAR DIFFERENCE EQUATIONS

Difference equations are functional equations that define sequences just as differential equations define functions. They arise in several situations as follows.

Finance: Compound Interest

Let P_0 be the amount of money deposited (invested) in a bank earning interest periodically say monthly or

quarterly or annually. The conversion period r is the time period between interest payment. Let P_n denote the value of the deposit at the end of the n th conversion period, after n interest payments have accrued.

Then in case of simple interest,

$$P_{n+1} = P_n + rP_0$$

which is a first order difference equation

$$P_{n+1} - P_n = rP_0$$

with solution $P_n = P_0(1 + nr)$

In case of compound interest

$$P_{n+1} = P_n + rP_n$$

which is a homogeneous difference equation

$$P_{n+1} - (1 + r)P_n = 0$$

with solution $P_n = P_0(1 + r)^n$. In this discrete process P is a function of an integer n rather than a continuous variable.

Fibonacci Relation:

Suppose there is only one pair of rabbits male and female just born. Further suppose that every month each pair of rabbits that are one month old produce a new pair of offspring of opposite sexes. Then F_n the number of rabbits after n months is given by the recurrence relation.

$$F_n = F_{n-1} + F_{n-2} \text{ for } n \geq 2$$

with the initial conditions $F_0 = F_1 = 1$. This gives rise to a second order homogeneous difference equation.

tion

$$F_n - F_{n-1} + F_{n-2} = 0$$

By repeated application of the recurrence relation the equation can be solved recursively. Then we get $F_2 = 2, F_3 = 3, F_4 = 5, F_5 = 8, F_6 = 13, F_7 = 21, F_8 = 34$ etc. The disadvantage here is that F_n is calculated upto certain value of n and these values are also dependent on the initial conditions. Instead the general solution

$$F_n = c_1 \left(\frac{1 + \sqrt{5}}{2} \right)^n + c_2 \left(\frac{1 - \sqrt{5}}{2} \right)^n$$

is function of n and is independent of the initial conditions.

Differential Equations

In the numerical solution of ordinary differential equations, the derivatives are discretized by replacing them by the finite (forward) differences. This gives rise to difference equations of the higher order. Thus a continuous process described by a differential equation is approximated by a discrete process described by its counterpart a difference equation. (see Chapter on Numerical Analysis 33). For example, in a third order ordinary differential equation

$$a_3 y''' + a_2 y'' + a_1 y' + a_0 y = F(x)$$

the derivatives can be replaced by $y' = \frac{y_{n+1} - y_n}{h}$,

$$y'' = \frac{y_{n+2} - 2y_{n+1} + y_n}{h^2}$$

$$y''' = \frac{y_{n+3} - 3y_{n+2} + 3y_{n+1} - y_n}{h^3}, \text{ which results}$$

in a third order differences equation of the form

$$b_3 y_{n+3} + b_2 y_{n+2} + b_1 y_{n+1} + b_0 y_n = F(x)$$

Recall that a sequence is a numerical valued function whose domain of definition is the set of integers. It is denoted by $\{a_n\}$ or a_n or $a(n)$.

A k th order linear difference equation in the sequence y_n is of the form

$$a_k y_{n+k} + a_{k-1} y_{n+k-1} + \dots + a_1 y_{n+1} + a_0 y_n = f(n) \quad (1)$$

where $n = 0, 1, 2, 3, \dots$. Thus (1) represents not just a single equation but an infinite system of equations one equation for every n . Here the coefficients $a_0, a_1, \dots, a_k$ are all constants and do not depend on

n . Here $f(n)$ depends only on n . When a_k is chosen as one, (1) is said to be in the standard form. If $f_n \neq 0$ for all n , then (1) is said to be non-homogeneous. Otherwise it is said to be homogeneous if $f_n = 0$ for all n . The *order* of the difference equation (1) is the positive integer k which is the greatest difference in the index of non-zero values of y . Equation (1) is linear because each term in (1) is of first degree (linear) in y_n . Thus (1) is a non-homogeneous k th order linear difference equation with constant coefficients.

Difference equation is also referred to as recurrence relation since it expresses y_{n+k} in terms of one or more of the previous terms (of the sequence) namely $y_{n+k-1}, \dots, y_{n+1}, y_n$. In this case (1) can be written as $y_{n+k} = -a_{k-1} y_{n+k-1} \dots - a_1 y_{n+1} - a_0 y_n + f(n)$. The difference equation (1) models a physical system. So f_n is known as system input (system excitation or forcing sequence or driving sequence) while y_n is referred to as system output (system response). The structure of the system is defined by the values of the coefficients and order of the equation. Thus any system output depends on the system input and the structure of the system. The general solution of (1) determines the output y_n which depends only on n (but no longer on the prior terms of the sequence) and describes the complete sequence y_n in the closed form. Thus any sequence y_n that satisfies the difference equation (1) is a solution of (1). The solution of (1) can be obtained by (a) classical approach similar to those used for solving linear non-homogeneous differential equations with constant coefficients (b) Laplace transform method (c) z -transform method (d) recursive method (which is a numerical solution yielding a finite number of terms of the sequence and is disadvantageous because it is influenced by the change of initial conditions). Here we consider only the classical approach since theory of difference equations is analogous to that of differential equations (which is considered in chapter 9).

Homogeneous Equations

First order homogeneous difference equation

Consider a first order linear homogeneous difference equation $y_{n+1} - b y_n = 0$ for $n \geq 0$ and b is a

constant. Assume the solution of the form $y_n = cr^n$ where $c \neq 0$, $r \neq 0$. Then $y_{n+1} = cr^{n+1}$. Substituting in the given difference equation, we have

$$cr^{n+1} - bcr^n = cr^n(r - b) = 0 \Rightarrow r - b = 0$$

or $b = r$. Thus the general solution of the difference equation $y_{n+1} - by_n = 0$ is given by $y_n = cb^n$. In addition, if a boundary condition $y_0 = d$ then $d = y_0 = cb^0 \therefore c = d$. Then the particular solution is $y_n = db^n$. The solution y_n defines a discrete function whose domain is the set N of all non-negative integers.

Second-order linear homogeneous difference equation with constant coefficients

Consider $a_2y_{n+2} + a_1y_{n+1} + a_0y_n = 0$ (2)

Assume $y_n = cr^n$ (with $c \neq 0$, $r \neq 0$) (3)

as a solution of (2). Then substituting (3) in (2), we get

$$a_2cr^{n+2} + a_1cr^{n+1} + a_0cr^n = 0$$

or $cr^n(a_2r^2 + a_1r + a_0) = 0$

Thus (3) is solution of (2) if

$$a_2r^2 + a_1r + a_0 = 0 \quad (4)$$

since $c \neq 0$ and $r \neq 0$. The equation (4) which is a quadratic in r is known as the *characteristic or auxiliary equation* of (2). Three cases arise.

Case 1: When the roots of the characteristic equation are *real and distinct* given by r_1 and r_2 then r_1^n and r_2^n are two linearly independent solutions. Thus the general solution of (2) is

$$y_n = c_1r_1^n + c_2r_2^n \quad (5)$$

where c_1, c_2 are two arbitrary constants.

Case 2: If the roots are *real and equal*, say r , then the general solution of (2) is

$$y_n = c_1r^n + c_2 \cdot n \cdot r^n = (c_1 + n \cdot c_2)r^n \quad (6)$$

Case 3: Suppose the roots of (4) are *complex conjugate* given by $a \pm bi$. Then the general solution of (2) is

$$y_n = r^n(c_1 \cos n\theta + c_2 \sin n\theta) \quad (7)$$

where $r = \sqrt{a^2 + b^2}$, $\tan \theta = \frac{b}{a}$.

This analysis can easily be extended to k th order difference equation by considering the nature of the k roots of the auxiliary equation which is a k th degree polynomial. (see Chapter 9).

Note 1: The forward-difference or advancing-difference operator Δ is defined by $\Delta f_k = f_{k+1} - f_k$

Note 2: The shift operator E is defined as the operator that increases the argument of a function by one tabular interval. Thus

$$Ef_k = Ef(x_k) = f(x_k + h) = f(x_{k+1}) = f_{k+1}$$

Note 3: Δ and E are related by $E = 1 + \Delta$.

Note 4: The difference equation

$$a_ky_{n+k} + a_{k-1}y_{n+k-1} + \dots + a_1y_{n+1} + a_0y_n = f(n) \quad (1)$$

can be written in terms of E as follows

$$(a_kE^k + a_{k-1}E^{k-1} + \dots + a_1E + a_0)y_n = f(n) \quad (8)$$

Non-homogeneous Equations

The general solution of a non-homogeneous linear difference equation with constant coefficients (1) is the sum of the complementary function and any particular solution. Here the complementary function (C.F.) of (1) is the general solution of the corresponding homogeneous equation (2). Particular solution, more often known as particular integral of (1) can be obtained by (a) method of undetermined coefficients (b) short cut inverse operator methods.

(a) In the method of undetermined coefficients

The particular integral is assumed in a particular form depending on the form of the RHS function f_n .

(b) Inverse operator methods

The non-homogeneous equation (8) can be written as

$$F(E)y_n = f(n) \quad (9)$$

21.4 — HIGHER ENGINEERING MATHEMATICS—V

where $F(E) = (a_k E^k + a_{k-1} E^{k-1} + \dots + a_1 E + a_0)$ (10)

is a function of the operator E .

Then the particular integral is

$$\text{P.I.} = \frac{1}{F(E)} f(n)$$

Case 1: If $f(n) = a^n$ then

$$\text{P.I.} = \frac{1}{F(E)} a^n = \frac{1}{F(a)} a^n, \text{ provided } F(a) \neq 0.$$

Case 2: Failure case: If $F(a) = 0$, then

$$\text{P.I.} = \frac{1}{(E-a)^3} a^n = \frac{n(n-1)(n-2)}{3!} a^{n-3}$$

Case 3: If $f(n) = \sin \alpha n$ then

$$\begin{aligned} \text{P.I.} &= \frac{1}{F(E)} \sin \alpha n = \frac{1}{F(E)} \left(\frac{e^{i\alpha n} - e^{-i\alpha n}}{2i} \right) \\ &= \frac{1}{2i} \left[\frac{1}{F(E)} a^n - \frac{1}{F(E)} b^n \right] \end{aligned}$$

where $a = e^{i\alpha n}$ and $b = e^{-i\alpha n}$.

Similarly if $f(n) = \cos \alpha n$, replace

$$\cos \alpha n = \frac{1}{2}(e^{i\alpha n} + e^{-i\alpha n}) = \frac{1}{2}(a^n + b^n)$$

Case 4: If $f(n) = n^m$ or polynomial in n . Replace E by $1 + \Delta$ and expand $1/F(1 + \Delta)$ in binomial series in ascending powers of Δ upto Δ^m . Express $f(n)$ in factorials and use $\Delta[x]^n = n[x]^{n-1}$

Case 5: If $f(n) = a^n V(n)$ where $V(n)$ is a polynomial in n . Then

$$\text{P.I.} = \frac{1}{F(E)} \{a^n V(n)\} = a^n \frac{1}{F(aE)} V(n)$$

A. Homogeneous difference equations

WORKED OUT EXAMPLES

First-order difference equation

Example 1: Find the general solution of the first order difference equation $2a_n - 3a_{n-1} = 0$, $n \geq 1$, $a_4 = 81$.

Solution: The general solution of $a_n - \frac{3}{2}a_{n-1} = 0$ or $a_{n+1} - \frac{3}{2}a_n = 0$ for $n \geq 0$ is $a_n = A d^n = A \left(\frac{3}{2}\right)^n$. Since $81 = a_4 = A \left(\frac{3}{2}\right)^4$
 $\therefore A = 16$. Thus the unique solution is $a_n = 16 \left(\frac{3}{2}\right)^n$ for $n \geq 0$.

Finance: Compound interest

Example 2: If Raju invests Rs 1000 at 6% interest compounded quarterly, how many month must he wait for his money to double (Note that Raju can *not* withdraw the money before the quarter is up). How many months it trebles.

Solution: Annual interest rate is 6% so the quarterly rate is $\frac{6\%}{4} = \frac{3}{2}\% = \frac{3}{200} = 0.015$. For $0 \leq n \leq 4$, P_n denotes the value of Raju's deposit at the end of n quarters.

Then $P_{n+1} = P_n + 0.015 P_n$ where $0.015 P_n$ is the interest earned on P_n during $(n+1)$ th quarter. Here $P_0 = 1000$. The solution of the difference equation $P_{n+1} - 1.015 P_n = 0$ is $P_n = P_0(1.015)^n = 1000(1.015)^n$. If the money doubles then $P_n = 2P_0 = 2000$. Then $2000 = 1000(1.015)^n$ or $\frac{\ln 2}{\ln(1.015)} = n$
 or $n = 46.56 \approx 47$ quarters. So money doubles in $47 \times 3 = 141$ months.

If money trebles then $3000 = 1000(1.015)^n$ so

$$n = \frac{\ln 3}{\ln(1.015)} = 73.80 \approx 74,$$

i.e. in $74 \times 3 = 222$. Thus money trebles in 222 months.

Formation of difference equation

Example 3: Form the differences equation corresponding to the family of curves by eliminating the two arbitrary constants.

$$(a) y_n = A3^n + B5^n \quad (b) y(x) = ax + b2^x$$

Solution: (a) From $y_n = A3^n + B5^n$ with $n = n+1$ and $n+2$ we get $y_{n+1} = A3^{n+1} + B5^{n+1} = 3A3^n + 5B5^n$ and $y_{n+2} = A3^{n+2} + B5^{n+2} =$

$9A3^n + 25B5^n$. Eliminating A and B , we get

$$\begin{vmatrix} y_n & 1 & 1 \\ y_{n+1} & 3 & 5 \\ y_{n+2} & 9 & 25 \end{vmatrix} = 0.$$

Expanding the determinant

$$y_n(75 - 45) - 1(25y_{n+1} - 5y_{n+2}) + 1(9y_{n+1} - 3y_{n+2}) = 0$$

or the required differences equation is

$$30y_n - 16y_{n+1} - 2y_{n+2} = 0$$

(b) Rewriting $y_n = a_n + b2^n$, we get

$$\Delta y_n = y_{n+1} - y_n = [a(n+1) + b2^{n+1}] - [an + b2^n]$$

$$\Delta y_n = a + b2^n(2 - 1) = a + b2^n$$

Now $\Delta^2 y_n = \Delta y_{n+1} - \Delta y_n$

$$= (a + b2^{n+1}) - (a + b2^n)$$

$$= b2^n(2 - 1) = b2^n$$

Thus $b = \frac{\Delta^2 y_n}{2^n}$.

Substituting b , we get

$$\Delta y_n = a + b2^n = a + \Delta^2 y_n$$

$$\text{or } a = \Delta y_n - \Delta^2 y_n$$

Now eliminating a and b

$$y_n = a_n + b2^n = (\Delta y_n - \Delta^2 y_n)n + \Delta^2 y_n$$

$$y_n = \Delta y_n + (1 - n)\Delta^2 y_n$$

since $\Delta^2 y_n = \Delta y_{n+1} - \Delta y_n =$

$$(y_{n+2} - y_{n+1}) - (y_{n+1} - y_n)$$

$$= y_{n+2} - 2y_{n+1} + y_n$$

We get

$$y_n = (y_{n+1} - y_n) + (1 - n)(y_{n+2} - 2y_{n+1} + y_n)$$

$$\text{or } (1 - n)y_{n+2} + y_{n+1}(1 - 2 + 2n) + y_n(-2 + 1 - n)$$

Thus the difference equation is

$$(1 - x)y_{x+2} + (2x - 1)y_{x+1} - (x + 1)y_x = 0$$

Real, distinct roots

Example 4: Solve $y_{n+2} - 3y_{n+1} - 10y_n = 0$

Solution: The auxiliary equation (A.E.) is obtained by assuming $y_n = cr^n$ and substituting in the given difference equation. Thus $y_{n+1} = cr^{n+1}$, $y_{n+2} = cr^{n+2}$ so

$$cr^{n+2} - 3cr^{n+1} - 10cr^n = 0$$

$$\text{or } r^2 - 3r - 10 = 0$$

is the characteristic equation with distinct real roots $r_1 = 5$ and $r_2 = -2$ (since $r^2 - 3r - 10 = (r - 5)(r + 2) = 0$). Symbolically the A.E. is obtained by replacing y_n by 1, y_{n+1} by r , y_{n+2} by r^2 (or equivalently E by r and E^2 by r^2).

Then $y_n = 5^n$ and $y_n = (-2)^n$ are two linearly independent solutions because one is *not* a multiple of the other. Thus the general solution of the given difference equation is

$$y_n = c_1 5^n + c_2 (-2)^n$$

Equal roots

Example 5: Solve $a_n - 6a_{n-1} + 9a_{n-2} = 0$, $n \geq 2$, $a_0 = 5$, $a_1 = 12$.

Solution: The auxiliary equation is $r^2 - 6r + 9 = 0$ or $(r - 3)^2 = 0$. So the roots are $r = 3, 3$, real equal. The general solution is

$$a_n = c_1 3^n + c_2 \cdot n 3^n$$

$$\text{Since } 5 = a_0 = c_1 \cdot 1 + c_2 \cdot 0 \cdot 1 \quad \therefore c_1 = 5$$

$$\text{Since } 12 = a_1 = 5 \cdot 3 + c_2 \cdot 1 \cdot 3 \quad \therefore c_2 = -1$$

The required (particular) solution satisfying the given two conditions is

$$a_n = 53^n - n3^n = (5 - n)3^n$$

Complex conjugate roots

Example 6: Solve $(E^3 - E^2 + E - 1)y = 0$ with $y_0 = 1$, $y_1 = 0$ and $y_2 = 2$.

Solution: Here E is the shift operator. So the given equation is $y_{n+3} - y_{n+2} + y_{n+1} - y_n = 0$.

Its auxiliary equation is $m^3 - m^2 + m - 1 = 0$ or $(m - 1)(m^2 + 1) = 0$. So $m = 1$ and $m = \pm i$ are the

21.6 — HIGHER ENGINEERING MATHEMATICS—V

three roots. For the complex conjugate roots $a = 0$, $b = 1$, so in the polar form $i = 1 \cdot e^{j\frac{\pi}{2}}$. Here $r = \sqrt{a^2 + b^2} = 1$, $\theta = \tan^{-1} \frac{b}{a} = \infty \therefore \theta = \pi/2$. Then the general solution is

$$y_n = c_1 1^n + r^n (c_2 \cos n\theta + c_3 \sin n\theta)$$

$$y_n = c_1 + 1^n \left(c_2 \cos n \frac{\pi}{2} + c_3 \sin n \frac{\pi}{2} \right)$$

Since $1 = y_0 = c_1 + c_2 + c_3 \cdot 0 \therefore c_1 + c_2 = 1$
 Since $0 = y_1 = c_1 + c_2 \cdot 0 + c_3 \therefore c_1 + c_3 = 0$
 Since $2 = y_2 = c_1 - c_2 + c_3 \cdot 0 \therefore c_1 - c_2 = 2$
 Solving $c_1 = \frac{3}{2}$, $c_2 = -\frac{1}{2}$, $c_3 = -\frac{3}{2}$.

Thus the particular solution is

$$y_n = \frac{3}{2} - \frac{1}{2} \cos \frac{n\pi}{2} - \frac{3}{2} \sin \frac{n\pi}{2}$$

Simultaneous equations

Example 7: Solve $x_{n+1} - 7x_n - 10y_n = 0$ and $y_{n+1} - x_n - 4y_n = 0$, with $x_0 = 3$ and $y_0 = 2$.

Solution: Introducing the shift operator E notation, the given two equations can be written as

$$(E - 7)x_n - 10y_n = 0 \quad (1)$$

$$-x_n + (E - 4)y_n = 0 \quad (2)$$

Multiplying (1) by (E-4) and (2) by 10 and adding, we get

$$(E - 7)(E - 4)x_n - 10x_n = 0$$

$$\text{or} \quad (E^2 - 11E + 28 - 10)x_n$$

$$= (E^2 - 11E + 18)x_n = 0.$$

Its auxiliary equation is $r^2 - 11r + 18 = 0$ with two real distinct roots 2 and 9. Then

$$x_n = c_1 2^n + c_2 9^n \quad (3)$$

Using $3 = x_0 = c_1 \cdot 1 + c_2 \cdot 1$, we get $c_1 + c_2 = 3$ (4)
 Substituting (3) in (1) we have

$$(c_1 2^{n+1} + c_2 9^{n+1}) - 7(c_1 2^n + c_2 9^n) - 10y_n = 0$$

$$\text{So } y_n = \frac{1}{10}[-5c_1 2^n + 2c_2 9^n]$$

Using $2 = y_0 = \frac{1}{10}[-5 \cdot c_1 \cdot 1 + 2c_2 \cdot 1]$, we get

$$-5c_1 + 2c_2 = 20 \quad (5)$$

Solving (4) and (5) we have $c_1 = -2$, $c_2 = 5$. Thus the required solution is

$$x_n = -2 \cdot 2^n + 5 \cdot 9^n$$

and $y_n = \frac{1}{10}[102^n + 109^n] = 2^n + 9^n$

Determinant

Example 8: Express the following n th order determinant D_n as an explicit function of n . When $a > 2$, show that $D_n = \frac{\sinh(n+1)\mu}{\sinh \mu}$ where $\cosh \mu = \frac{a}{2}$. What is the value of D_n when (i) $a = 2$ (ii) $a = -2$ where

$$D_n = \begin{vmatrix} a & 1 & 0 & \dots & 0 & 0 \\ 1 & a & 1 & \dots & 0 & 0 \\ 0 & 1 & a & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & a & 1 \\ 0 & 0 & 0 & \dots & 1 & a \end{vmatrix}$$

Solution: Expanding D_n in terms of the elements in the first row (or column), we get

$$D_n = a \cdot \begin{vmatrix} a & 1 & 0 & \dots & 0 & 0 \\ 1 & a & 1 & \dots & 0 & 0 \\ 0 & 1 & a & \dots & \dots & \dots \\ \dots & \dots & 0 & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & a & 1 \\ 0 & 0 & 0 & \dots & 1 & a \end{vmatrix} -$$

$$-1 \cdot \begin{vmatrix} 1 & 1 & \dots & \dots & 0 & 0 \\ 0 & a & 1 & \dots & 0 & 0 \\ 0 & 1 & a & 1 \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & a & 1 \\ 0 & 0 & 0 & \dots & 1 & a \end{vmatrix}$$

The first determinant in RHS is identical in structure to D_n except that it contains only $n - 1$ rows and $n - 1$ columns. Thus the first determinant in RHS is D_{n-1} . The second determinant in RHS does not have the form of D_n . But expanding the second determi-

nant by the first row, we get

$$D_n = a \cdot D_{n-1} - 1 \cdot 1 \begin{vmatrix} a & 1 & 0 & \dots & 0 & 0 \\ 1 & a & 1 & \dots & 0 & 0 \\ 0 & 1 & a & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & 0 & 0 \\ 0 & 0 & 0 & \dots & a & 1 \\ 0 & 0 & 0 & \dots & 1 & a \end{vmatrix}$$

Now the second determinant in RHS has the same structure as D_n but is of $(n-2)$ order. Thus

$$D_n = aD_{n-1} - D_{n-2}$$

$$\text{or } D_{n+2} - aD_{n+1} + D_n = 0$$

i.e., $(E^2 - aE + 1)D_n = 0$ (1)
The auxiliary equation is

$$m^2 - am + 1 = 0$$

Its roots are given by

$$m = \frac{a \pm \sqrt{a^2 - 4}}{2} = \frac{a \pm b}{2} \text{ where } b = \sqrt{a^2 - 4} \quad (2)$$

If $a > 2$ then $b > 0$ so the roots are real, distinct given by

$$m_1 = \frac{a+b}{2}, \quad m_2 = \frac{a-b}{2} \quad (3)$$

Then the general solution of the difference equation (1) is

$$D_n = c_1 m_1^n + c_2 m_2^n$$

$$D_n = c_1 \left(\frac{a+b}{2} \right)^n + c_2 \left(\frac{a-b}{2} \right)^n \quad (4)$$

Thus (4) expresses the n th order determinant D_n as an explicit function of n (in terms of the parameter ' a ').

Put $\cosh \mu = \frac{a}{2}$ then $b = a^2 - 4 = \sqrt{4 \cosh^2 \mu - 4}$
so ' b ' = $2 \sinh \mu$. Then $m_1 = \frac{a+b}{2} = \frac{2 \cosh \mu + 2 \sinh \mu}{2} = e^\mu$

Similarly $m_2 = \frac{a-b}{2} = \cosh \mu - \sinh \mu = e^{-\mu}$,
then the general solution (4) takes the form

$$D_n = c_1 (e^\mu)^n + c_2 (e^{-\mu})^n$$

$$= c_1 (\cosh \mu n + \sinh \mu n) + c_2 (\cosh \mu n - \sinh \mu n)$$

$$D_n = A \cosh \mu n + B \sinh \mu n$$

where $A = c_1 + c_2$ and $B = c_1 - c_2$. Choosing $A = 1$ and $B = \coth \mu$, we get

$$D_n = \cosh \mu n + \coth \mu \cdot \sinh \mu n = \frac{\sinh(n+1)\mu}{\sinh \mu}$$

Now for $n = 1$, $D_1 = a$ and $n = 2$, $D_2 = \begin{vmatrix} a & 1 \\ 1 & a \end{vmatrix} = a^2 - 1$. Thus $D_1 = a = 2 \cosh \mu$, $D_2 = 4 \cosh^2 \mu - 1 = 2 \cosh 2\mu$. Using $2 \cosh \mu = a = D_1 = A \cosh \mu + B \sinh \mu$. So $A = 2$ and $B = 0$. Using $2 \cosh 2\mu = D_2 = 2 \cdot \cosh 2\mu + 0 \cdot \sinh 2\mu = 2 \cosh 2\mu$ which is true.

Case 1: For $a = 2$, $b = 0$, the roots are real and equal given by $m_1 = m_2 = 1$. Then the general solution is

$$D_n = (c_1 + nc_2) \cdot 1^n = c_1 + nc_2$$

For $n = 1$, $D_1 = a = 2 = c_1 + 1 \cdot c_2$.

For $n = 2$, $D_2 = a^2 - 1 = 4 - 1 = 3 = c_1 + 2c_2$
Solving $c_1 = c_2 = 1$. Thus when $a = 2$, $D_n = 1 + n$.

Case 2: When $a = -2$, the general solution is $D_n = (c_1 + c_2 \cdot n)(-1)^n$

For $n = 1$, $D_1 = a = -2 = (c_1 + c_2)(-1)$

For $n = 2$, $D_2 = a^2 - 1 = 3 = c_1 + 2c_2$

Solving $c_1 = c_2 = 1$. Thus when $a = -2$, we get

$$D_n = (1 + n)(-1)^n$$

Example 9: A seed of a particular plant produces 8-fold when one year old and produces 18-fold when two or more years old. If a_n denotes the number of seeds produced at the end of the n th year, express a_n in term of n .

Solution: At the end of $(n+1)$ th year, the a_n seeds which are one year old produces 8-fold. The a_{n-1} seeds which are two years old produces 18-fold. Similarly the a_{n-2} , a_{n-3} , $\dots$, a_2 , a_1 which are more than two years old also produces 18 fold. Thus the recurrence relation is

$$a_{n+1} = 8(a_n) + 18(a_{n-1} + a_{n-2} + \dots + a_2 + a_1)$$

Similarly

$$a_{n+2} = 8(a_{n+1}) + 18(a_n + a_{n-1} + \dots + a_3 + a_2 + a_1)$$

21.8 — HIGHER ENGINEERING MATHEMATICS—V

Subtracting

$$a_{n+2} - a_{n+1} = 8a_{n+1} + 18a_n - 8a_n$$

or the difference equation is

$$a_{n+2} - 9a_{n+1} - 10a_n = 0.$$

Its characteristic equation is

$$m^2 - 9m - 10 = (m - 10)(m + 1) = 0$$

with real distinct roots $m_1 = 10, m_2 = -1$. The general solution is

$$a_n = c_1(10)^n + c_2(-1)^n$$

Non-homogeneous difference equations

WORKED OUT EXAMPLES

Method of undetermined coefficients

Example 1: Determine a formula for the sum of the first n cubes of natural numbers.

Solution: Let S_n be the partial sum of the cubes of the first n natural numbers. Then

$$S_n = 1^3 + 2^3 + 3^3 + \dots + n^3 = \sum_{i=1}^n i^3$$

$$\begin{aligned} \text{Now } S_{n+1} &= 1^3 + 2^3 + 3^3 + \dots + n^3 + (n+1)^3 \\ &= \sum_{i=1}^{n+1} i^3 \end{aligned}$$

Subtracting

$$S_{n+1} - S_n = (n+1)^3 \quad (1)$$

This is a first order non-homogeneous difference equation with auxiliary equation $m - 1 = 0$. So the complementary function is

$$S_c = c \cdot 1^n = c \quad (2)$$

where c is an arbitrary constant. To determine the particular integral, use the method of undetermined coefficients. Since the RHS is a function of the type

$$(n+1)^3 = n^3 + 3n^2 + 3n + 1$$

We assume the particular integral of the form

$$S_n = An^4 + Bn^3 + Cn^2 + Dn \quad (3)$$

(Even if we take an additional constant E , it will become redundant). Substituting (3) in (1), we get

$$S_{n+1} - S_n = [A(n+1)^4 + B(n+1)^3 + C(n+1)^2$$

$$+ D(n+1)] - [An^4 + Bn^3 + Cn^2 + Dn] = (n+1)^3 \quad (5)$$

The unknown coefficients A, B, C, D will be determined by equating the coefficients of like powers of n on both sides of (5).

$$\begin{aligned} &A(n^4 + 4n^3 + 6n^2 + 4n + 1) + B(n^3 + 3n^2 + 3n + 1) \\ &+ C(n^2 + 2n + 1) - (An^4 + Bn^3 + Cn^2 + Dn) \\ &= n^3 + 3n^2 + 3n + 1 \end{aligned}$$

$$\begin{aligned} \text{or } (4A)n^3 + (6A + 3B)n^2 + (4A + 3B + 2C)n \\ + (A + B + C + D) &= n^3 + 3n^2 + 3n + 1 \end{aligned}$$

Then $4A = 1, 6A + 3B = 3, 4A + 3B + 2C = 3$, and $A + B + C + D = 1$

Solving $A = \frac{1}{4}, B = \frac{1}{2}, C = \frac{1}{4}, D = 0$. Thus the particular integral is $\frac{1}{4}n^4 + \frac{1}{2}n^3 + \frac{1}{4}n^2$. Then the general solution of the difference equation (1) is given by

$$S_n = \text{C.F.} + \text{P.I.} = c + \frac{1}{4}n^4 + \frac{1}{2}n^3 + \frac{1}{4}n^2 \quad (6)$$

For $n = 1$, we know that $S_1 = 1^3 = 1$. Using this in (6), we get

$$1 = S_1 = c + \frac{1}{4} + \frac{1}{2} + \frac{1}{4} \quad \therefore c = 0$$

Thus the formula expressing the sum of cubes of the first n natural numbers is

$$S_n = \sum_{i=1}^n i^3 = 0 + \frac{1}{4}n^4 + \frac{1}{2}n^3 + \frac{1}{4}n^2$$

$$S_n = \frac{n^2(n+1)^2}{4}$$

Short cut inverse operator methods

Power function

Example 2: Solve $a_{n+2} - 6a_{n+1} + 5a_n = 2^n$ with $a_0 = 0, a_1 = 0$.

Solution: The auxiliary equation is $m^2 - 6m + 5 = 0$ with real distinct roots $m_1 = 1, m_2 = 5$. So the complementary function is $c_1 \cdot 1^n + c_2 5^n$. The particular integral is obtained by inverse operator method. The given difference equation is rewritten in

terms of the shift operator E as $(E^2 - 6E + 5)a_n = 2^n$. Then the particular integral is

$$\begin{aligned} \text{P.I.} &= \frac{1}{E^2 - 6E + 5} \cdot 2^n = \frac{1}{2^2 - 6 \cdot 2 + 5} \cdot 2^n \\ &= -\frac{1}{3} 2^n \end{aligned}$$

Here E is replaced by 2. Thus the general solution is

$$a_n = \text{C.F.} + \text{P.I.} = c_1 + c_2 5^n - \frac{1}{3} 2^n$$

Since $0 = a_0 = c_1 + c_2 - \frac{1}{3} \therefore c_1 + c_2 = \frac{1}{3}$

Since $0 = a_1 = c_1 + 5c_2 - \frac{2}{3} \therefore c_1 + 5c_2 = \frac{2}{3}$

Solving $c_1 = \frac{1}{4}, c_2 = \frac{1}{12}$. Then

$$a_n = \frac{1}{4} + \frac{1}{12} 5^n - \frac{1}{3} 2^n$$

Failure case

Example 3: Solve $y_{n+3} - 12y_{n+2} + 48y_{n+1} - 64y_n = 5 \cdot 4^n$.

Solution: A.E. is $m^3 - 12m^2 + 48m - 64 = 0$ or $(m - 4)^3 = 0$. The roots are real, equal repeated thrice $m = 4, 4, 4$. So the

$$\text{C.F.} = c_1 4^n + c_2 \cdot n \cdot 4^n + c_3 n^2 4^n$$

$$\begin{aligned} \text{Now P.I.} &= \frac{1}{E^3 - 12E^2 + 48E - 64} 5 \cdot 4^n \\ &= \frac{5}{(E - 4)^3} \cdot 4^n \end{aligned}$$

Here E can not be replaced by 4. Then by result (case 2 on page 21.4) we have

$$\text{P.I.} = 5 \cdot \frac{n(n-1)(n-2)}{3!} 4^{n-3}$$

Thus the general solution is

$$y_n = \text{C.F.} + \text{P.I.} = (c_1 + c_2 \cdot n + c_3 \cdot n^2) 4^n +$$

$$+ \frac{5n(n-1)(n-2)}{3!} 4^{n-3}$$

Trigonometric function

Example 4: Find the general solution of $(E^2 + 4)y_n = \cos \alpha n$.

Solution: A.E. is $m^2 + 4 = 0$ with conjugate complex roots $\pm 2i$. So $a = 0, b = 2$, then $r = \sqrt{a^2 + b^2} = 2$, and $\tan \theta = \frac{2}{0} = \infty \therefore \theta = \frac{\pi}{2}$. Thus

$$\text{C.F.} = r^n (c_1 \cos n\theta + c_2 \sin n\theta)$$

$$\text{C.F.} = 2^n \left(c_1 \cos \frac{n\pi}{2} + c_2 \sin \frac{n\pi}{2} \right)$$

Now P.I. = $\frac{1}{E^2 + 4} \cos \alpha n = \frac{1}{(E + 2i)(E - 2i)} \cos \alpha n$.

But $\cos \alpha n = \frac{1}{2}(e^{i\alpha n} + e^{-i\alpha n})$. So

$$\begin{aligned} \text{P.I.} &= \frac{1}{(E + 2i)(E - 2i)} \left\{ \frac{1}{2}(e^{i\alpha n} + e^{-i\alpha n}) \right\} \\ &= \frac{1}{(E + 2i)(E - 2i)} \frac{1}{2}(a^n + b^n) \end{aligned}$$

where $a = e^{i\alpha}, b = e^{-i\alpha}$

$$\begin{aligned} &= \frac{1}{2} \frac{1}{(a + 2i)(a - 2i)} a^n + \frac{1}{2} \frac{1}{(b + 2i)(b - 2i)} b^n \\ &= \frac{1}{2} \cdot \frac{1}{a^2 + 4} a^n + \frac{1}{2} \frac{1}{(b^2 + 4)} b^n \\ &= \frac{1}{2} \left[\frac{1}{e^{2i\alpha} + 4} e^{i\alpha n} + \frac{1}{e^{-2i\alpha} + 4} e^{-i\alpha n} \right] \\ &= \frac{1}{2} \left[\frac{(e^{-2i\alpha} + 4)e^{i\alpha n} + (e^{2i\alpha} + 4)e^{-i\alpha n}}{(e^{2i\alpha} + 4)(e^{-2i\alpha} + 4)} \right] \\ &= \frac{4 \cos \alpha n + \frac{1}{2}\{e^{i\alpha(n-2)} + e^{i\alpha(n-2)}\}}{1 + 4(e^{2i\alpha} + e^{-2i\alpha}) + 16} \\ &= \frac{4 \cos \alpha n + \cos \alpha(n-2)}{17 + 8 \cos 2\alpha} \end{aligned}$$

Thus the general solution is

$$\begin{aligned} y_n &= 2^n \left(c_1 \cos \frac{n\pi}{2} + c_2 \sin \frac{n\pi}{2} \right) + \\ &+ \left(\frac{4 \cos \alpha n + \cos \alpha(n-2)}{17 + 8 \cos 2\alpha} \right) \end{aligned}$$

Polynomial

Example 5: Solve $a_{n+2} - 5a_{n+1} + 6a_n = 2n^2 - 6n - 1$.

21.10 — HIGHER ENGINEERING MATHEMATICS—V

Solution: A.E. is $m^2 - 5m + 6 = 0$ with real distinct roots 2 and 3. So C.F. = $c_1 2^n + c_2 3^n$. The given difference equation in shift operator E is

$$(E^2 - 5E + 6)a_n = 2n^2 - 6n - 1$$

$$\text{So P.I.} = \frac{1}{E^2 - 5E + 6}(2n^2 - 6n - 1)$$

Replace E by $1 + \Delta$ then

$$E^2 - 5E + 6 = (1 + \Delta)^2 - 5(1 + \Delta) + 6$$

$$= 1 + \Delta^2 + 2\Delta - 5 - 5\Delta + 6 = \Delta^2 - 3\Delta + 2$$

Then

$$\begin{aligned} \text{P.I.} &= \frac{1}{\Delta^2 - 3\Delta + 2}(2n^2 - 6n - 1) \\ &= \frac{1}{2} \frac{1}{1 + \left(\frac{\Delta^2 - 3\Delta}{2}\right)}(2n^2 - 6n - 1) \end{aligned}$$

Expanding in binomial series

$$\begin{aligned} &= \frac{1}{2} \left[1 - \left(\frac{\Delta^2 - 3\Delta}{2}\right) + \left(\frac{\Delta^2 - 3\Delta}{2}\right)^2 + \dots \right] \times \\ &\quad \times (2n^2 - 6n - 1) \end{aligned}$$

Neglecting powers of Δ more than 2, we get

$$\begin{aligned} \text{P.I.} &= \frac{1}{2} \left[1 + \frac{3}{2}\Delta + \frac{7}{4}\Delta^2 \right] [2n^2 - 6n - 1] \\ &= \frac{1}{2} \left[1 + \frac{3}{2}\Delta + \frac{7}{4}\Delta^2 \right] \{2[n]^2 - 4[n] - 1\} \end{aligned}$$

where $[n]^2 = n(n-1)$. Then

$$\begin{aligned} \text{P.I.} &= \frac{1}{2} \left[\{2[n]^2 - 4[n] - 1\} + \frac{3}{2} \{4[n] - 4\} + \frac{7}{4} \{4\} \right] \\ &= \frac{1}{2} [\{2n^2 - 6n - 1\} + 6\{(n-1)\} + 7] = n^2 \end{aligned}$$

Therefore the general solution is

$$a_n = c_1 2^n + c_2 3^n + n^2$$

Exponential shift

Example 6: Solve $(E^2 + E - 56)a_n = 2^n(n^2 - 3)$

Solution: A.E. is $m^2 + m - 56 = (m+8)(m-7) = 0$ with distinct real roots $-8, 7$. So C.F. = $c_1(-8)^n + c_2(7)^n$.

Since the R.H.S. is of the form $a^n F(n)$, apply shift result for obtaining particular integral. So replace E by $2E$, we get

$$\text{P.I.} = \frac{1}{E^2 + E - 56} \{2^n(n^2 - 3)\}$$

$$= \frac{2^n}{(2E)^2 + 2E - 56} \{(n^2 - 3)\}$$

$$= \frac{2^n}{2(2E^2 + E - 28)} (n^2 - 3)$$

$$= \frac{2^n}{2[2(1 + \Delta)^2 + (1 + \Delta) - 28]} (n^2 - 3)$$

where E is replaced by $1 + \Delta$.

$$\text{P.I.} = \frac{2^n}{2[2\Delta^2 + 5\Delta - 25]} (n^2 - 3)$$

$$= -\frac{2^n}{50} \left[1 - \left(\frac{5\Delta + 2\Delta^2}{25}\right) \right]^{-1} (n^2 - 3)$$

Expanding in binomial series we get

$$\begin{aligned} \text{P.I.} &= -\frac{2^n}{50} \left[1 + \frac{5\Delta + 2\Delta^2}{25} + \left(\frac{5\Delta + 2\Delta^2}{25}\right)^2 + \dots \right] \times \\ &\quad \times (n^2 - 3). \end{aligned}$$

Neglecting powers of Δ more than 2 we have

$$\text{P.I.} = -\frac{2^n}{50} \left[1 + \frac{5}{25}\Delta + \frac{3}{25}\Delta^2 \right] \{[n]^2 + [n] - 3\}$$

where $n^2 - 3 = n^2 - n + n - 3 = n(n-1) + n - 3 = [n]^2 + [n] - 3$.

$$\text{P.I.} = -\frac{2^n}{50} \{[n]^2 + [n] - 3\} + \frac{5}{25} \{2[n] + 1\} + \frac{3}{25} \{2\}$$

$$\text{P.I.} = -\frac{2^n}{50} \left[n^2 + \frac{2}{5}n - \frac{64}{25} \right]$$

Therefore the general solution is

$$a_n = c_1(-8)^n + c_2(7)^n - \frac{2^{n-1}}{25} \left(n^2 + \frac{2}{5}n - \frac{64}{25} \right)$$

Homogeneous difference equations

EXERCISE

First order

Solve the difference equation

1. $a_n - 7a_{n-1} = 0$ when $n \geq 1$ and $a_2 = 98$

Ans. $a_n = 2(7)^n$ for $n \geq 0$

2. $a_{n+1}^2 - 5a_n^2 = 0$ when $a_n > 0$ for $n \geq 0$ and $a_0 = 2$. Also find a_{12} .

Ans. $a_n = 2(\sqrt{5})^n$, $a_{12} = 2(\sqrt{5})^{12} = 31, 250$

Hint: $a_n^2 = b_n$ and solve for b_n .

3. How much will be the deposit of Rs 1000 a year later, if the bank pays 6% annual interest, compounding the interest monthly.

Ans. Rs 1061.68

Hint: $P_{n+1} = P_n + 0.005P_n$, $P_n = P_0(1.005)^n$, $P_0 = 1000$, $n = 12$

4. How much will be Rs 10,000 after 30 years in a bank yielding 11% per year interest compounded annually.

Ans. Rs 228,922.97

Hint: $P_{n+1} = P_n + 0.11P_n$, $P_n = P_0(1.11)^n$, $P_0 = 10,000$, $n = 30$

5. Solve the following difference equations

(a) $a_n - 3a_{n-1} = 0$, $a_0 = 2$

Ans. $a_n = 2 \cdot 3^n$

(b) $a_n - 2a_{n-1} + 1 = 0$, $a_0 = 1$

Ans. $a_n = 1$

(c) $a_n - 2na_{n-1} = 0$, $a_0 = 1$,

Ans. $a_n = 2^n \cdot n!$

Second and higher order

Solve the following difference equations

6. $y_{n+2} + y_{n+1} - 6y_n = 0$ with $a_0 = -1$, $a_1 = 8$

Ans. $y_n = 2^n - 2(-3)^n$

7. $F_{n+2} - F_{n+1} - F_n = 0$ for $n \geq 0$, with $F_0 = 0$, $F_1 = 1$.

Ans. $F_n = \frac{1}{a} \left[\left(\frac{1+a}{2} \right)^n - \left(\frac{1-a}{2} \right)^n \right]$, $n \geq 0$, $a = \sqrt{5}$

8. $a_n - a_{n-1} + 2a_{n-2} = 0$, $a_0 = 2$, $a_1 = 7$

Ans. $a_n = 3 \cdot 2^n - (-1)^n$

9. $a_n - 6a_{n-1} + 9a_{n-2} = 0$, $a_0 = 1$, $a_1 = 6$

Ans. $a_n = (1+n)3^n$

10. $y_{n+3} - 6y_{n+2} + 11y_{n+1} - 6y_n = 0$ with initial conditions $y_0 = 2$, $y_1 = 5$, $y_2 = 15$.

Ans. $y_n = 1 - 2^n + 2 \cdot 3^n$

11. $y_{n+3} + 3y_{n+2} + 3y_{n+1} + y_n = 0$ with $y_0 = 1$, $y_1 = -2$ and $y_2 = -1$.

Ans. $y_n = (1 + 3n - 2n^2)(-1)^n$.

12. $y_{n+3} - 2y_{n+2} - y_{n+1} + 2y_n = 0$ with $y_0 = 0$, $y_1 = 1$, $y_2 = 1$. Also find y_{10} .

Ans. $y_n = \frac{1}{3} \{ 2^n - (-1)^n \}$, $y_{10} = 341$

13. $y_{n+2} - 2y_{n+1} + 2y_n = 0$, with $y_0 = 0$, $y_1 = 1$

Ans. $y_n = \frac{(1+i)^n - (1-i)^n}{2i}$

14. $y_{n+3} - 2y_{n+2} - 5y_{n+1} + 6y_n = 0$

Ans. $y_n = c_1 \cdot 1^n + c_2(-2)^n + c_33^n$

15. $y_{n+1} - 2y_n \cos \alpha + y_{n-1} = 0$

Ans. $y_n = c_1 \cos n\alpha + c_2 \sin n\alpha$

16. $a_{m+4} + 16a_m = 0$

Ans. $a_m = 2^m \left[c_1 \cos \frac{m\pi}{4} + c_2 \sin \frac{m\pi}{4} + c_3 \cos \frac{3m\pi}{4} + c_4 \sin \frac{3m\pi}{4} \right]$

17. $(E^2 + 2E + 4)y_n = 0$

Ans. $y_n = 2^n \left(c_1 \cos \frac{2n\pi}{3} + c_2 \sin \frac{2n\pi}{3} \right)$

18. Determine D_n as a function of n where

$$D_n = \begin{vmatrix} 2 & 2 & 0 & 0 & \dots & 0 & 0 \\ 1 & 2 & 2 & 0 & \dots & 0 & 0 \\ 0 & 1 & 2 & 2 & \dots & 0 & 0 \\ 0 & 0 & 1 & 2 & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & 0 & \dots & 2 & 2 \\ 0 & 0 & 0 & 0 & \dots & 1 & 2 \end{vmatrix}$$

Ans. $D_n = 2^{n/2} \left(\cos \frac{n\pi}{4} + \sin \frac{n\pi}{4} \right)$

Hint Solve $D_n - 2D_{n-1} + 2D_{n-2} = 0$.

Non-homogeneous difference equations

EXERCISE

Solve

1. Determine a formula for the sum of the squares of the first n natural numbers.

Ans. $S_n = n(n+1)(2n+1)/6$

Hint: Solve $S_{n+1} - S_n = (n+1)^2$, use $S_1 = 1$.

2. $y_n - y_{n-1} = 3n^2$, $n \geq 1$, $y_0 = 7$

Ans. $y_n = 7 + \frac{1}{2}n(n+1)(2n+1)$

3. $y_{n+1} - 3y_n = 357^n$, $y_0 = 2$

Ans. $y_n = \frac{5}{4}7^{n+1} - \frac{1}{4}3^{n+3}$

4. Tower of Hanoi: $a_{n+1} - 2a_n = 1$, $a_0 = 0$, find a_{64} .

Ans. $a_n = 2^n - 1$,
 $a_{64} = 18, 446, 744, 073, 709, 551, 615$

5. A car loan of S rupees is to be paid back in T periods of time. Determine the equi (constant) payment P at the end of each period if r is the interest rate per period for the loan.

Ans. $P = (S \cdot r) / [1 - (1+r)^{-T}]$

Hint: Solve $a_{n+1} - a_n(1+r) = P$, $a_0 = S$, $a_T = 0$ and $0 \leq n \leq T-1$

6. $(E^2 + 2E - 8)a_n = 5n + 3(2^n)$

Ans. $a_n = c_1 2^n + c_2 (-4)^n - n - \frac{4}{5} + n 2^{n-2}$

7. $a_{n+2} + 2a_{n+1} + a_n = n + 2$, $a_0 = 0$, $a_1 = 0$

Ans. $a_n = \frac{1}{4}(3n-1)(-1)^n + \frac{1}{4}(n+1)$

8. $a_{n+2} - 5a_{n+1} + 6a_n = 2n + 1$, $a_0 = 0$, $a_1 = 1$

Ans. $a_n = \frac{5}{2}3^n - 5 \cdot 2^n + n + \frac{5}{2}$

9. $a_{n+2} + 4a_{n+1} - 5a_n = 24n - 8$, $a_0 = 3$, $a_1 = -5$

Ans. $a_n = 2n^2 - 4n + 2 + (-5)^n$

10. $a_{n+2} - 4a_{n+1} + 3a_n = 5^n$

Ans. $a_n = c_1 + c_2 \cdot 3^n + \frac{1}{8}5^n$

11. $(E^2 - 4E + 4)a_n = 2^n$

Ans. $a_n = (c_1 + c_2 \cdot n)2^n + n(n-1)2^{n-3}$

12. $(E^2 - 2\cos \alpha E + 1)a_n = \cos \alpha n$

Ans. $a_n = c_1 \cos \alpha n + c_2 \sin \alpha n + n \cdot \frac{\sin(n-1)\alpha}{2 \sin \alpha}$

13. $(E^2 - 4)a_n = n^2 + n - 1$

Ans. $a_n = c_1 2^n + c_2 (-2)^n - \frac{n^2}{3} - \frac{7n}{9} - \frac{17}{27}$

14. $(E^2 - 2E + 1)a_n = 2^n \cdot n^2$

Ans. $a_n = c_1 + c_2 \cdot n + 2^n(n^2 - 8n + 20)$

15. $a_n - 7a_{n-1} + 10a_{n-2} = 7 \cdot 3^n$ for $n \geq 2$

Ans. $a_n = c_1 2^n + c_2 5^n + \left(\frac{-63}{2}\right) 3^n$

16. $a_n - 6a_{n-1} + 8a_{n-2} = n \cdot 4^n$ with $a_0 = 8$,
 $a_1 = 22$

Ans. $a_n = 3 \cdot 4^n + 5 \cdot 2^n + n(n-1)4^n$

Simultaneous equations

Solve

17. $x_{n+1} - y_n = 1$; $y_{n+1} - x_n = 1$; $x_0 = 0$, $y_0 = -1$

18. $x_{n+1} + y_n - 3x_n = n$, $3x_n + y_{n+1} - 5y_n = 4^n$ with $x_1 = 2$, $y_1 = 0$

Ans. $x_n = (1.33)2^n - (0.0167)6^n - 0.8n - 0.76 + 4^{n-1}$,
 $y_n = (1.33)2^n - (0.05)6^n - 0.6n - 1.36 - 4^{n-1}$

19. $x_{n+1} - 3x_n - 2y_n = -n$,
 $-x_n + y_{n+1} - 2y_n = n$, $x_0 = 0$, $y_0 = 3$

Ans. $x_n = 2 \cdot 4^n - 2 - \frac{1}{2}n(n-1)$,
 $y_n = 4^n + 2 + \frac{1}{2}n(n+1)$

20. $x_{n+1} - y_n - 1 = 0$, $y_{n+1} + x_n = 0$, $x_0 = 0$,
 $y_0 = -1$.

21.2 Z-TRANSFORMS

Introduction

Z-transform is useful in solving difference equations which represent a discrete system. Z-transform operates on a sequence u_n of discrete integer-valued arguments $n = 0, \pm 1, \pm 2, \dots$ unlike the Laplace transform which operates on continuous functions.

Thus Z-transform is the discrete analogue of Laplace transform. Therefore for every operational rule and application of Laplace transform, there corresponds an operational rule and application of Z-transform.

Definition

The Z-transform of a sequence u_n defined for discrete values $n = 0, 1, 2, \dots$ (and $u_n = 0$ for $n < 0$) is denoted by $Z(u_n)$ and is defined as

$$Z(u_n) = \sum_{n=0}^{\infty} u_n z^{-n} = U(z) \quad (1)$$

where U is a function of z .

Z-transforms exist only when the infinite series in (1) is convergent.

Inverse Z-transform

is denoted by $Z^{-1}(U(z)) = u_n$ determines the sequence u_n which generates the given Z-transform.

Results

Z-transform of some standard sequences

1. $U_n = \{a^n\} = \{1, a, a^2, a^3, \dots, a^n, \dots\}$

By definition,

$$\begin{aligned} Z(u_n) &= Z(a^n) = \sum_{n=0}^{\infty} u_n z^{-n} = \sum_{n=0}^{\infty} a^n z^{-n} \\ &= 1 + \frac{a}{z} + \frac{a}{z^2} + \frac{a}{z^3} + \dots + \frac{a^n}{z^n} + \dots = \frac{1}{1 - \frac{a}{z}} \\ Z(a^n) &= \frac{z}{z - a}. \end{aligned}$$

Recurrence formula

2. $u_n = \{n^p\} = \{0, 1^p, 2^p, 3^p, \dots, n^p, \dots\}$ where p is a positive integer

By definition

$$Z(n^p) = \sum_{n=0}^{\infty} n^p z^{-n} \quad (i)$$

Replacing p by $p - 1$

$$Z(n^{p-1}) = \sum_{n=0}^{\infty} n^{p-1} z^{-n} \quad (ii)$$

Differentiating (ii) w.r.t. z , we get

$$\begin{aligned} \frac{d}{dz} [Z(n^{p-1})] &= \frac{d}{dz} \left[\sum_{n=0}^{\infty} n^{p-1} z^{-n} \right] \\ &= \sum_{n=0}^{\infty} n^{p-1} \cdot (-n) z^{-n-1} \\ &= -z^{-1} \sum_{n=0}^{\infty} n^p \cdot z^{-n} \\ &= -z^{-1} Z(n^p), \text{ using (i)} \end{aligned}$$

$$\text{Thus } Z(n^p) = -z \frac{d}{dz} [Z(n^{p-1})]$$

Special cases of result 1.

3. $Z(1) = \frac{z}{z-1}$
obtained by putting $a = 1$ in result 1.

4. $Z(k) = \frac{kz}{z-1}$ (where k is a constant)
since $z(k) = \sum k z^{-n} = k \frac{1}{1 - \frac{1}{z}} = k \frac{z}{z-1}$

5. $Z[(-1)^n] = \frac{z}{z+1}$
obtained by taking $a = -1$ in result 1.

Special cases of result 2.

6. $Z(n) = \frac{z}{(z-1)^2}$
since with $p = 1$, $Z(n) = -z \cdot \frac{d}{dz} [Z(1)] = -z \frac{d}{dz} \left(\frac{z}{z-1} \right) = -z \cdot \left[\frac{(z-1) \cdot 1 - z \cdot 1}{(z-1)^2} \right] = \frac{z}{(z-1)^2}$

7. $Z(n^2) = \frac{z^2+z}{(z-1)^3}$ by taking $p = 2$ in result 2.

8. $Z(n^3) = \frac{z^3+4z^2+z}{(z-1)^4}$

9. $Z(n^4) = \frac{z^4+11z^3+11z^2+z}{(z-1)^5}$

10. $Z\left(\frac{1}{n!}\right) = \sum_{n=0}^{\infty} \frac{1}{n!} z^{-n} = 1 + \frac{1}{z} + \frac{1}{2!} \frac{1}{z^2} + \frac{1}{3!} \frac{1}{z^3} + \dots + \frac{1}{n!} \frac{1}{z^n} + \dots = e^{\left(\frac{1}{z}\right)}$

11. Unit step sequence $u(n) = \begin{cases} 0, & \text{for } n < 0 \\ 1, & \text{for } n \geq 0 \end{cases}$

$$\begin{aligned} Z(u(n)) &= \sum_{n=0}^{\infty} u(n) z^{-n} = \sum_{n=0}^{\infty} 1 \cdot z^{-n} \\ &= 1 + \frac{1}{z} + \frac{1}{z^2} + \dots + \frac{1}{z^n} + \dots \\ Z[u(n)] &= \frac{1}{1 - \frac{1}{z}} = \frac{z}{z-1} \end{aligned}$$

12. Unit impulse sequence $\delta(n) = \begin{cases} 1, & \text{for } n = 0 \\ 0, & \text{for } n \neq 0 \end{cases}$

$$Z[\delta(n)] = \sum_{n=0}^{\infty} \delta(n)z^{-n} = 1 + 0 + 0 + 0 \cdots = 1.$$

Properties

I. Linearity

$$Z(au_n + bv_n) = aZ(u_n) + bZ(v_n)$$

$$\begin{aligned} \text{since } Z(au_n + bv_n) &= \sum (au_n + bv_n)z^{-n} \\ &= a \sum u_n z^{-n} + b \sum v_n z^{-n}. \end{aligned}$$

II. Change of scale (or damping rule)

If $Z(u_n) = U(z)$ then $Z(a^{-n}u_n) = U(az)$
since

$$Z(a^{-n}u_n) = \sum_{n=0}^{\infty} a^{-n}u_n z^{-n} = \sum_{n=0}^{\infty} u_n (az)^{-n} = U(az)$$

Similarly,

$$Z(a^n u_n) = U(z/a)$$

Results from application of damping rule:

$$13. Z(na^n) = \frac{az}{(z-a)^2}$$

because $Z(n) = \frac{z}{(z-1)^2}$ then $Z(na^n)$ is obtained by replacing z by z/a . So $Z(na^n) = \frac{z/a}{(z/a-1)^2} = \frac{az}{(z-a)^2}$

$$14. Z(n^2 a^n) = \frac{az^2 + a^2 z}{(z-a)^3}$$

since $Z(n^2) = \frac{z^2 + z}{(z-1)^3}$ by damping rule. $Z(n^2 a^n)$ is obtained by replacing z by z/a

$$\text{i.e., } Z(n^2 a^n) = \frac{(z/a)^2 + (z/a)}{[(z/a) - 1]^3} = \frac{a(z^2 + az)}{(z-a)^3}$$

$$15. Z(\cos n\theta) = \frac{z(z - \cos \theta)}{z^2 - 2z \cos \theta + 1}$$

Solution:

$$Z(e^{-in\theta}) = Z[(e^{-i\theta})^n] = Z[(e^{-i\theta})^n \cdot 1]$$

since $Z(1) = \frac{z}{z-1}$, apply damping rule and replace z

by z/a where $a = e^{-i\theta}$ i.e., z by $z/e^{-i\theta}$ or $ze^{i\theta}$. Thus

$$\begin{aligned} Z[(e^{-i\theta})^n \cdot 1] &= \frac{z}{z-1} \Big|_{ze^{i\theta}} = \frac{ze^{i\theta}}{ze^{i\theta}-1} \\ &= \frac{z}{z-e^{-i\theta}} = \frac{z(z-e^{i\theta})}{(z-e^{-i\theta})(z-e^{i\theta})} \\ &= \frac{z[z - \cos \theta - i \sin \theta]}{z^2 - z(e^{i\theta} + e^{-i\theta}) + 1} \end{aligned}$$

Thus

$$\begin{aligned} Z(e^{-in\theta}) &= Z(\cos n\theta - i \sin n\theta) \\ &= \frac{z(z - \cos \theta) - iz \sin \theta}{z^2 - 2z \cos \theta + 1} \end{aligned}$$

$$\text{Since } \cos \theta = (e^{i\theta} + e^{-i\theta})/2$$

Applying linearity property and comparing the real parts on both sides, we get

$$Z(\cos n\theta) = \frac{z(z - \cos \theta)}{z^2 - 2z \cos \theta + 1}$$

Similarly, comparing the imaginary parts

$$16. Z(\sin n\theta) = \frac{z \sin \theta}{z^2 - 2z \cos \theta + 1}$$

17. $Z(a^n \cos n\theta) = \frac{z(z - a \cos \theta)}{z^2 - 2az \cos \theta + a^2}$ obtained by replacing z by z/a in (15) by damping rule.

Similarly,

$$18. Z(a^n \sin n\theta) = \frac{az \sin \theta}{z^2 - 2az \cos \theta + a^2}$$

III. Shifting property

a. Shifting u_n to the right

If $Z(u_n) = U(z)$ then $Z(u_{n-k}) = z^{-k}U(z)$ for $k > 0$

This follows from the definition

$$\begin{aligned} Z(u_{n-k}) &= \sum_{n=0}^{\infty} u_{n-k} z^{-n} \\ &= u_0 z^{-k} + u_1 z^{-(k+1)} + u_2 z^{-(k+2)} + \dots \end{aligned}$$

since $u_n = 0$ for $n < 0$ (so $u_{-k}, u_{1-k}, u_{2-k}, \dots$ are all 0)

$$\begin{aligned} &= z^{-k} \sum_{n=0}^{\infty} u_n z^{-n} = z^{-k} U(z) \end{aligned}$$

b. Shifting to the left

If $Z(u_n) = U(z)$ then

$$Z(u_{n+k}) = z^k \left[U(z) - u_0 - \frac{u_1}{z} - \frac{u_2}{z^2} \cdots \frac{u_{k-1}}{z^{k-1}} \right]$$

Proof:

$$\begin{aligned} Z(u_{n+k}) &= \sum_{n=0}^{\infty} u_{n+k} z^{-n} = z^k \sum_{n=0}^{\infty} u_{n+k} z^{-(n+k)} \\ &= z^k \left[u_k z^{-k} + u_{1+k} z^{-(1+k)} + u_{2+k} z^{-(2+k)} + \cdots \right] \\ &= z^k \left[(u_0 + u_1 z^{-1} + u_2 z^{-2} + \cdots + u_{k-1} z^{-(k-1)}) + \right. \\ &\quad \left. + u_k z^{-k} + u_{k+1} z^{-(k+1)} + \cdots \right] - \\ &\quad - z^k \left[u_0 + u_1 z^{-1} + u_2 z^{-2} + \cdots + u_{k-1} z^{-(k-1)} \right] \\ Z(u_{n+k}) &= z^k \left[\sum_{n=0}^{\infty} u_n z^{-n} - \sum_{n=0}^{k-1} u_n z^{-n} \right] \\ Z(u_{n+k}) &= z^k \left[U(z) - u_0 - u_1 z^{-1} - u_2 z^{-2} \cdots \right. \\ &\quad \left. - u_{k-1} z^{-(k-1)} \right] \end{aligned}$$

In particular for $k = 1, 2, 3$

$$19. Z(u_{n+1}) = z[U(z) - u_0]$$

$$20. Z(u_{n+2}) = z^2[U(z) - u_0 - u_1 z^{-1}]$$

$$21. Z(u_{n+3}) = z^3[U(z) - u_0 - u_1 z^{-1} - u_2 z^{-2}].$$

IV. Multiplication by n

If $Z(u_n) = U(z)$ then $Z(nu_n) = -z \frac{dU}{dz}(z)$.

Proof:

$$\begin{aligned} Z(nu_n) &= \sum_{n=0}^{\infty} n \cdot u_n z^{-n} = -z \sum_{n=0}^{\infty} u_n (-n) z^{-n-1} \\ &= -z \sum_{n=0}^{\infty} u_n \frac{d}{dz} (z^{-n}) = -z \sum_{n=0}^{\infty} \frac{d}{dz} (u_n z^{-n}) \\ &= -z \frac{d}{dz} \left(\sum_{n=0}^{\infty} u_n z^{-n} \right) = -z \cdot \frac{d}{dz} U(z) \end{aligned}$$

In general (by mathematical induction)

$$Z(n^p u_n) = (-z)^p \frac{d^p U(z)}{dz^p}$$

Initial value and final value theorems determine the values of u_n for $n = 0$ and for $n \rightarrow \infty$ without the complete knowledge of u_n .

V. Initial value theorem

Theorem: If $Z(u_n) = U(z)$ then $u_0 = \lim_{z \rightarrow \infty} U(z)$

Proof: By definition

$$U(z) = Z(u_n) = u_0 + \frac{u_1}{z} + \frac{u_2}{z^2} + \cdots + \frac{u_n}{z^n} + \cdots$$

Taking the limit as $z \rightarrow \infty$

$$22. \lim_{z \rightarrow \infty} U(z) = u_0 + 0 + 0 \cdots = u_0$$

$$23. \lim_{z \rightarrow \infty} z[U(z) - u_0] = \lim_{z \rightarrow \infty} \left[u_1 + \frac{u_2}{z} + \frac{u_3}{z^2} + \cdots \right] = u_1$$

$$24. \lim_{z \rightarrow \infty} z^2 \left[U(z) - u_0 - \frac{u_1}{z} \right] = \lim_{z \rightarrow \infty} \left[u_2 + \frac{u_3}{z} + \frac{u_4}{z^2} + \cdots \right] = u_2.$$

VI. Final value theorem

Theorem: If $Z(u_n) = U(z)$ then

$$\lim_{n \rightarrow \infty} u_n = \lim_{z \rightarrow 1} \{(z-1)U(z)\}$$

Proof: Consider

$$\begin{aligned} Z(u_{n+1} - u_n) &= Z(u_{n+1}) - Z(u_n) \\ &= z[U(z) - u_0] - U(z) \quad \text{using (19)} \\ &= U(z) \cdot (z-1) - u_0 z \end{aligned}$$

From definition and the above result, we have

$$(z-1)U(z) - u_0 z = Z(u_{n+1} - u_n) = \sum_{n=0}^{\infty} (u_{n+1} - u_n) z^{-n}$$

As $z \rightarrow 1$, we have

$$\begin{aligned} &\lim_{z \rightarrow 1} [(z-1)U(z)] - u_0 \\ &= \lim_{z \rightarrow 1} \sum_{n=0}^{\infty} (u_{n+1} - u_n) z^{-n} = \sum_{n=0}^{\infty} (u_{n+1} - u_n) \\ &= \lim_{n \rightarrow \infty} [(u_1 - u_0) + (u_2 - u_1) + \cdots + (u_{n+1} - u_n)] \\ &= \lim_{n \rightarrow \infty} [u_{n+1} - u_0] = \lim_{n \rightarrow \infty} u_{n+1} - u_0 \end{aligned}$$

Thus

$$\lim_{n \rightarrow \infty} u_n = \lim_{z \rightarrow 1} [(z-1)U(z)].$$

VII. Convolution theorem

Theorem: If $Z^{-1}[U(z)] = u_n$ and $Z^{-1}[V(z)] = v_n$ then

$$Z^{-1}[U(z) \cdot V(z)] = u_n * v_n = \text{convolution of } u_n \text{ and } v_n$$

$$= \sum_{m=0}^n u_m v_{n-m}$$

Proof:

$$U(z) \cdot V(z) = \left[\sum_{n=0}^{\infty} u_n z^{-n} \right] \left[\sum_{n=0}^{\infty} v_n z^{-n} \right]$$

$$= \left[u_0 + \frac{u_1}{z} + \frac{u_2}{z^2} + \cdots + \frac{u_n}{z^n} + \cdots \right] \times$$

$$\times \left[v_0 + \frac{v_1}{z} + \frac{v_2}{z^2} + \cdots + \frac{v_n}{z^n} + \cdots \right]$$

Collecting the coefficients of z^{-n}

$$= \sum_{n=0}^{\infty} (u_0 v_n + u_1 v_{n-1} + u_2 v_{n-2} + \cdots + u_n v_0) z^{-n}$$

$$= Z(u_0 v_n + u_1 v_{n-1} + \cdots + u_n v_0) \quad \text{by definition}$$

$$= Z \left(\sum_{m=0}^n u_m v_{n-m} \right)$$

Taking inverse Z-transform the result follows.

VIII. Region of convergence (R.O.C.)

The region of convergence of Z-transform is the region in the z -plane where the infinite series convergence absolutely.

Thus the region of convergence of a one-sided Z-transform of a right-sided sequence i.e.,

$$U(z) = \sum_{n=0}^{\infty} u_n z^{-n}$$

is $|z| > a$ i.e., the exterior of the circle with centre at origin and of radius a .

Similarly the R.O.C. of

$$U(z) = \sum_{n=-\infty}^0 u_n z^{-n}$$

is $|z| < a$. Finally the R.O.C. of two-sided Z-transform defined by

$$U(z) = \sum_{n=-\infty}^{\infty} u_n z^{-n}$$

is the annulus region $a < |z| < b$.

IX. Solution of difference equations

Step 1. Take Z-transform on both sides of the given difference equation.

Step 2. Use given conditions and solve for $U(z)$.

Step 3. Apply partial fractions method.

Step 4. Take inverse Z-transform on both sides which results in the given sequence.

Note: A list of standard Z-transforms is presented on page 21.30.

WORKED OUT EXAMPLES

Linearity property

Example 1: Find the Z-transform of $2n + 5 \sin \frac{n\pi}{4} - 3a^4$.

Solution: By linearity property

$$Z \left(2n + 5 \sin \frac{n\pi}{4} - 3a^4 \right)$$

$$= 2Z(n) + 5Z \left(\sin \frac{n\pi}{4} \right) - 3a^4 Z(1)$$

$$= \frac{2 \cdot z}{(z-1)^2} + \frac{5 \cdot z \cdot \sin \frac{\pi}{4}}{z^2 - 2z \cdot \cos \frac{\pi}{4} + 1} - 3a^4 \frac{z}{z-1}$$

$$= \frac{2z}{(z-1)^2} + \frac{5(z/\sqrt{2})}{z^2 - \sqrt{2}z + 1} - 3a^4 \frac{z}{z-1}.$$

Example 2: Find $Z(\cos \theta + i \sin \theta)^n$.

Solution: We know that $(\cos \theta + i \sin \theta) = e^{i\theta}$

$$Z(\cos \theta + i \sin \theta)^n = Z \left[(e^{i\theta})^n \right] = \frac{z}{z - e^{i\theta}}$$

since $Z(a^n) = \frac{z}{z - a}.$

Example 3: Find $Z[(n+1)^2]$.

Solution:

$$Z(n+1)^2 = Z(n^2 + 2n + 1) = Z(n^2) + 2Z(n) + Z(1)$$

$$= \frac{z^2 + z}{(z-1)^3} + \frac{2 \cdot z}{(z-1)^2} + \frac{z}{z-1}$$

$$= \frac{(z^2 + z) + 2z(z-1) + z(z-1)^2}{(z-1)^3} = \frac{z^3 + z^2}{(z-1)^3}$$

Damping rule

Example 4: Find $Z(e^{-an} \cdot \sin n\theta)$.

Solution: We know that $Z(\sin n\theta) = \frac{z \sin \theta}{z^2 - 2z \cos \theta + 1}$

Now $Z(e^{-an} \cdot \sin n\theta) = Z[(e^a)^{-n} \sin n\theta]$

Applying damping rule $Z[a^{-n} u_n] = U(az)$

Replace z by az i.e., $e^a z$ then

$$\begin{aligned} z[e^{-an} \sin n\theta] &= \frac{z \sin \theta}{z^2 - 2z \cos \theta + 1} \Big|_{z=e^a z} \\ &= \frac{e^a z \cdot \sin \theta}{e^{2a} z^2 - 2e^a z \cos \theta + 1}. \end{aligned}$$

Multiplication by n

Example 5: Find $Z(n \cos n\theta)$.

Solution: We know that $Z(nu_n) = -z \frac{d}{dz}(U(z))$

Here $u_n = \cos n\theta$

and $Z(u_n) = U(z) = \frac{z(z - \cos \theta)}{z^2 - 2z \cos \theta + 1}$

so $Z(n \cos n\theta) = -z \cdot \frac{d}{dz} \left\{ \frac{z(z - \cos \theta)}{z^2 - 2z \cos \theta + 1} \right\}$

$$\begin{aligned} Z(n \cos n\theta) &= -z \cdot \frac{[-z^2 \cos \theta + 2z - \cos \theta]}{(z^2 - 2z \cos \theta + 1)^2} \\ &= \frac{z^3 \cos \theta - 2z^2 + z \cos \theta}{(z^2 - 2z \cos \theta + 1)^2}. \end{aligned}$$

Shift and initial value theorems

Example 6: Find $Z(u_{n+2})$ if $Z(u_n) = \frac{z}{z-1} + \frac{z}{z^2+1}$.

Solution:

Here $Z(u_n) = U(z) = \frac{z}{z-1} + \frac{z}{z^2+1}$

To find u_0, u_1 by initial value theorem

$$u_0 = \lim_{z \rightarrow \infty} U(z) = \lim_{z \rightarrow \infty} \left[\frac{z}{z-1} + \frac{z}{z^2+1} \right] = 1$$

$$\begin{aligned} u_1 &= \lim_{z \rightarrow \infty} \{z[U(z) - u_0]\} \\ &= \lim_{z \rightarrow \infty} z \cdot \frac{2z^2 - z + 1}{(z-1)(z^2+1)} = 2 \end{aligned}$$

From shift to left we know that

$$\begin{aligned} Z(u_{n+2}) &= z^2 \left[U(z) - u_0 - u_1 z^{-1} \right] \\ Z(u_{n+2}) &= z^2 \left[\frac{z}{z-1} + \frac{z}{z^2+1} - 1 - \frac{2}{z} \right] \\ &= z^3 \left[\frac{1}{z-1} + \frac{1}{z^2+1} - \frac{(z+2)}{z^2} \right] \\ Z(u_{n+2}) &= \frac{z(z^2 - z + 2)}{(z-1)(z^2+1)}. \end{aligned}$$

Inverse transform by partial fractions

Example 7: Find the inverse Z -transform of $\frac{4z^2-2z}{z^3-5z^2+8z-4}$.

Solution: Consider

$$\frac{4z^2 - 2z}{z^3 - 5z^2 + 8z - 4} = \frac{2z(2z - 1)}{(z - 1)(z - 2)^2}$$

By partial fractions

$$\frac{2z - 1}{(z - 1)(z - 2)^2} = \frac{A}{z - 1} + \frac{B}{z - 2} + \frac{C}{(z - 2)^2}$$

$$(2z - 1) = A(z - 2)^2 + B(z - 1)(z - 2) + C(z - 1)$$

when $z = 2, 3 = C$; when $z = 1, A = 1$ and when $z = 0$

$$-1 = 4A + 2B - C \quad \therefore B = -1$$

Thus

$$\begin{aligned} Z^{-1} \left[\frac{4z^2 - 2z}{(z - 1)(z - 2)^2} \right] &= Z^{-1} \left[2z \cdot \frac{1}{z - 1} \right] + Z^{-1} \left[2z \cdot \frac{-1}{z - 2} \right] \\ &\quad + Z^{-1} \left[2z \cdot \frac{3}{(z - 2)^2} \right] \\ &= 2 \cdot 1 - 2 \cdot 2^n + 3z^{-1} \left[\frac{2z}{(z - 2)^2} \right] \\ &= 2 - 2^{n+1} + 3n \cdot 2^n \end{aligned}$$

$$\text{since } Z(na^n) = \frac{az}{(z - a)^2}$$

Region of convergence

Example 8: Find $Z^{-1} \{(z-5)^{-3}\}$ when $|z| > 5$. Determine the region of convergence.

Solution: Consider

$$(z-5)^{-3} = \frac{1}{(z-5)^3} = \frac{1}{z^3} \frac{1}{\left(1 - \frac{5}{z}\right)^3}$$

Expanding by Binomial series which is valid when $|\frac{5}{z}| < 1$ or $|z| > 5$, we have

$$\begin{aligned} \frac{1}{(z-5)^3} &= \frac{1}{z^3} \left[1 + 3\left(\frac{5}{z}\right) + \frac{3 \cdot 4}{1 \cdot 2} \cdot \left(\frac{5}{z}\right)^2 \right. \\ &\quad \left. + \frac{3 \cdot 4 \cdot 5}{1 \cdot 2 \cdot 3} \cdot \left(\frac{5}{z}\right)^3 + \frac{3 \cdot 4 \cdot 5 \cdot 6}{1 \cdot 2 \cdot 3 \cdot 4} \left(\frac{5}{z}\right)^4 + \dots \right] \\ \frac{1}{(z-5)^3} &= \frac{1}{2} \cdot \frac{1}{z^3} \left[1 \cdot 2 \left(\frac{5}{z}\right)^0 + 2 \cdot 3 \left(\frac{5}{z}\right)^1 + 3 \cdot 4 \left(\frac{5}{z}\right)^2 \right. \\ &\quad \left. + 4 \cdot 5 \left(\frac{5}{z}\right)^3 + 5 \cdot 6 \left(\frac{5}{z}\right)^4 + \dots \right] \\ &= \frac{1}{2} \sum_{m=0}^{\infty} (m+1)(m+2)5^m \cdot z^{-m-3}; \text{ put } m+3=n \end{aligned}$$

$$\begin{aligned} U(z) = (z-5)^{-3} &= \frac{1}{2} \sum_{n=3}^{\infty} (n-1)(n-2)5^{n-3} z^{-n} \\ &= \sum_{n=0}^{\infty} u_n z^{-n} \end{aligned}$$

Taking inverse Z-transform

$$\begin{aligned} Z^{-1}[U(z)] &= Z^{-1}[(z-5)^{-3}] = u_n \\ &= \frac{1}{2}(n-1)(n-2)5^{n-3} \\ &\quad \text{for } n \geq 3 \\ &= 0 \quad \text{for } n < 3 \end{aligned}$$

Fig. 21.1

The region of convergence is the exterior of the circle $|z| = 5$ i.e., with centre at origin and of radius 5 (Fig. 21.1).

Convolution

Example 9: Using convolution theorem, find the inverse Z-transform of $\left(\frac{z}{z-a}\right)^3$. Deduce for $\left(\frac{z}{z-1}\right)^3$.

Solution: We know that

$$Z^{-1} \left\{ \frac{z}{z-a} \right\} = a^n, \quad Z^{-1} \left\{ \frac{z}{z-a} \right\} = a^n$$

So

$$\begin{aligned} Z^{-1} \left\{ \frac{z^2}{(z-a)^2} \right\} \\ &= Z^{-1} \left\{ \frac{z}{z-a} \cdot \frac{z}{z-a} \right\} = a^n * a^n \\ &\quad \text{by convolution theorem} \\ &= \sum_{m=0}^n a^m a^{n-m} = a^n \sum_{m=0}^n a^m \cdot a^{-m} = a^n \sum_{m=0}^n 1 \\ &= a^n \cdot [1 + 1 + 1 + \dots + 1] = a^n(n+1). \end{aligned}$$

Applying convolution theorem again

$$\begin{aligned} Z^{-1} \left\{ \frac{z^3}{(z-a)^3} \right\} &= Z^{-1} \left\{ \frac{z^2}{(z-a)^2} \cdot \frac{z}{z-a} \right\} \\ &= [a^n \cdot (n+1)] * a^n \\ &= \sum_{m=0}^n a^m \cdot (m+1) \cdot a^{n-m} \\ &= a^n \sum_{m=0}^n (m+1) \\ Z^{-1} \left[\left(\frac{z}{z-a} \right)^3 \right] &= a^n \cdot [1 + 2 + 3 + \dots + (n+1)] \\ &= a^n \cdot \frac{1}{2} \cdot (n+1)(n+2) \end{aligned}$$

Put $a = 1$, then

$$Z^{-1} \left\{ \frac{z}{(z-1)^3} \right\} = \frac{1}{2}(n+1)(n+2).$$

Solution of difference equations

Example 10: Using Z-transform, solve the difference equation $u_{n+2} - 4u_{n+1} + 3u_n = 5^n$.

Solution: Take Z-transform on both sides of the difference equation

$$Z(u_{n+2}) - 4Z(u_{n+1}) + 3Z(u_n) = Z(5^n)$$

Denote $Z(u_n) = U(z)$, then

$$Z(u_{n+2}) = z^2 [U(z) - u_0 - u_1 z^{-1}]$$

$$Z(u_{n+1}) = z[U(z) - u_0]$$

Substituting these values

$$z^2 [U(z) - u_0 - u_1 z^{-1}] - 4z [U(z) - u_0] + 3U(z) = \frac{z}{z-5}$$

$$U(z) [z^2 - 4z + 3] - u_0 [z^2 - 4z] - u_1 z = \frac{z}{z-5}$$

Solving

$$\frac{U(z)}{z} = \frac{1}{(z-5)(z-1)(z-3)} + \frac{u_0(z-4) + u_1}{(z-1)(z-3)}$$

By partial fractions

$$\frac{U(z)}{z} = \left[\frac{A}{(z-1)} + \frac{B}{(z-3)} + \frac{C}{(z-5)} \right]$$

$$+ \left[\frac{D}{(z-1)} + \frac{E}{z-3} \right]$$

$$U(z) = \left[\frac{1}{8} \frac{z}{z-1} - \frac{1}{4} \frac{z}{z-3} + \frac{1}{8} \frac{z}{z-5} \right] + \left[\frac{(u_1 - 3u_0)z}{2(z-1)} + \frac{3z(u_0 - u_1)}{2(z-3)} \right]$$

Taking inverse Z-transform on both sides

$$u_n = Z^{-1}[U(z)] = \frac{1}{8} \cdot 1 - \frac{1}{4} 3^n + \frac{1}{8} 5^n + \left(\frac{u_1 - 3u_0}{2} \right) 1 + \frac{3(u_0 - u_1)}{2} 3^n$$

$$u_n = C_1 + C_2 3^n + \frac{1}{8} 5^n \quad \text{is the solution}$$

Here $C_1 = \frac{1}{8} + \frac{u_1 - 3u_0}{2}, C_2 = \frac{3(u_0 - u_1)}{2} - \frac{1}{4}.$

Example 11: Solve $u_{n+2} + 2u_{n+1} + u_n = n$ with $u_0 = u_1 = 0$

Solution: Taking Z-transform on both sides

$$Z(u_{n+2}) + 2Z(u_{n+1}) + Z(u_n) = Z(n)$$

$$z^2 [U(z) - u_0 - u_1 z^{-1}] + 2z [U(z) - u_0] + U(z) = \frac{z}{(z-1)^2}$$

Putting $u_0 = u_1 = 0$ and solving

$$U(z) = \frac{z}{(z-1)^2(z+1)^2}$$

By partial fractions

$$\frac{1}{(z-1)^2(z+1)^2} = \frac{A}{(z-1)} + \frac{B}{(z-1)^2} + \frac{C}{(z+1)} + \frac{D}{(z+1)^2}$$

we get $A = -\frac{1}{4}, B = C = D = \frac{1}{4}$ so

$$U(z) = \frac{1}{4} \left[-\frac{z}{z-1} + \frac{z}{(z-1)^2} + \frac{z}{z+1} + \frac{z}{(z+1)^2} \right]$$

Taking inverse Z-transform on either side

$$u_n = \frac{1}{4} [-1^n + n + (-1)^n - n(-1)^n]$$

$$u_n = \left(\frac{n-1}{4} \right) [1 - (-1)^n].$$

EXERCISE

Find the Z-transform:

1. $\frac{1}{(n+2)!}$ Ans. $z^2(e^{\frac{1}{z}} - 1 - z^{-1})$

2. $\cosh n\theta$ Ans. $\frac{z(z - \cosh \theta)}{z^2 - 2z \cosh \theta + 1}$

3. $a^n \cdot \sinh n\theta$

Hint: Use damping rule for $z(\sinh n\theta) = \frac{z \sinh \theta}{z^2 - 2z \cosh \theta + 1}$

Ans. $\frac{az \cdot \sinh \theta}{z^2 - 2az \cdot \cosh \theta + a^2}$

4. $a^n e^{-a}/n!$ Ans. $e^{a(z^{-1}-1)}$

5. $\sin(n+1)\theta$ Ans. $\frac{z^2 \sin \theta}{z^2 - 2z \cos \theta + 1}$

6. $\frac{1}{n+1}$ Ans. $z \ln \left(\frac{z}{z+1} \right)$

7. Find u_2, u_3 if $U(z) = (2z^2 + 5z + 14)/(z-1)^4$.

Ans. $u_0 = 0, u_1 = 0, u_2 = 2, u_3 = 13$

8. Find u_2, u_3 when $U(z) = (5z^2 + 3z + 12)/(z-1)^4$.

Ans. $u_0 = 0, u_1 = 0, u_2 = 5, u_3 = 23$

9. Determine u_2 where $U(z) = (2z^2 + 3z + 4)/(z-3)^3$

21.20 — HIGHER ENGINEERING MATHEMATICS—V

Ans. $u_0 = 0, u_1 = 2, u_2 = 21$

10. Use convolution theorem to find the inverse Z-transform of $z^2 / [(z-a)(z-b)]$.

Ans. $(a^{n+1} - b^{n+1}) / (a - b)$

11. By convolution, evaluate $Z^{-1}[z^2 / (z-a)^2]$

Ans. $(n+1)a^n$

Find the inverse Z-transform of

12. $\frac{2z^2+3z}{(z+2)(z-4)}$

Ans. $\frac{1}{6}(-2)^n + \frac{11}{6}4^n$

13. $\frac{z^3-20z}{(z-2)^3(z-4)}$

Ans. $\frac{1}{2}(2^n + 2 \cdot n2^n) - 4^n$

14. $\frac{z}{z^2+11z+24}$

Ans. $\frac{1}{5}[(-3)^n - (-8)^n]$

15. $\frac{z}{z^3-z^2+z-1}$

Ans. $\frac{1}{2}\left[1 - \cos\left(\frac{n\pi}{2}\right) - \sin\left(\frac{n\pi}{2}\right)\right]$

16. $\frac{z}{(z+3)^2(z-2)}$

Ans. $-\frac{1}{25}(-3)^n - \frac{1}{5}n(-3)^n + \frac{1}{25}2^n$

17. $\frac{2(z^2-5z+6.5)}{(z-2)(z-3)^2}$

for $2 < |z| < 3$

Ans. $u_n = 2^{n-1}$, for $n \geq 1$

$u_n = -(n+2)3^{n-2}$, for $n \leq 0$

18. $\frac{1}{(z-2)(z-3)}$ for

i. $|z| < 2$

ii. $2 < |z| < 3$

iii. $|z| > 3$

Ans. i. $-\left(\frac{1}{3} + \frac{z}{3^2} + \frac{z^2}{3^3} + \frac{z^3}{3^4} + \dots\right)$
 $+\left(\frac{1}{2} + \frac{z}{2^2} + \frac{z^2}{2^3} + \frac{z^3}{2^4} + \dots\right)$

ii. (-2^{n-1}) for $n > 0$

iii. $3^{n-1} - 2^{n-1}$, $n \geq 1, 0$ for $n < 0$

Using Z-transform solve the difference equation:

19. $u_{n+2} + 4u_{n+1} + 3u_n = 3^n$ with $u_0 = 0, u_1 = 1$

Ans. $u_n = \frac{3}{8}(-1)^n + \frac{1}{24}3^n - \frac{5}{12}(-3)^n$

20. $u_{n+2} + 6u_{n+1} + 9u_n = 2^n$ with $u_0 = u_1 = 0$

Ans. $u_n = \frac{1}{25}\left[2^n - (-3)^n + \frac{5}{3}n(-3)^n\right]$

21. $u_{n+2} - 5u_{n+1} + 6u_n = y_n$ with $u_0 = 0, u_1 = 1$ where $y(n) = 1$ for $n = 0, 1, 2, 3, \dots$

Ans. $u_n = \frac{1}{2} - 2(2)^n + \frac{3}{2}(3)^n$

22. $u_n + \frac{1}{4}u_{n-1} = y_n + \frac{1}{3}y_{n-1}$ where y_n is a unit step sequence.

Ans. $\frac{1}{12}\left(-\frac{1}{4}\right)^{n-1}$

23. $u_{n+2} - 2u_{n+1} + u_n = 3n + 5$

Ans. $\frac{1}{2}n(n-1)(n+3) + C_0 + C_1n$ where $C_0 = u_0, C_1 = u_1 - u_0$

24. $4u_n - u_{n+2} = 0$ with $u_0 = 0, u_1 = 2$

Ans. $u_n = (-2)^{n-1} + 2^{n-1}$

25. $u_{n+2} - 2u_{n+1} + u_n = 2^n$ with $u_0 = 2, u_1 = 1$

Ans. $u_n = 2^n + 1 - 2n$.

21.3 STANDARD Z-TRANSFORMS

	Sequence u_n (for $n \geq 0$)	$U(z)$: Z-transform
1.	n	$z/(z-1)^2$
2.	n^2	$(z^2+z)/(z-1)^3$
3.	n^p	$-z \frac{d}{dz} [Z(n^{p-1})]$ (p is positive integer)
4.	a^n	$z/(z-a)$
5.	nu_n	$-z \frac{d}{dz} [U(z)]$
6.	$a^n u_n$	$U(z/a)$
7.	u_{n+1}	$z[U(z) - u_0]$
8.	u_{n+2}	$z^2[U(z) - u_0 - u_1 z^{-1}]$
9.	u_{n+3}	$z^3[U(z) - u_0 - u_1 z^{-1} - u_2 z^{-2}]$
10.	u_{n-k}	$z^{-k}U(z)$
11.	u_0	$\lim_{z \rightarrow \infty} U(z)$
12.	$\lim_{n \rightarrow \infty} u_n$	$\lim_{z \rightarrow 1} [(z-1)U(z)]$
13.	$\sin n\theta$	$\frac{z \sin \theta}{z^2 - 2z \cos \theta + 1}$
14.	$\cos n\theta$	$\frac{z(z - \cos \theta)}{z^2 - 2z \cos \theta + 1}$

Chapter 22

Complex Function Theory

INTRODUCTION

Complex-valued functions or simply complex functions are functions which produce complex numbers from complex numbers. Complex analysis or complex function theory is the study of complex analytic functions. It is an elegant and powerful method useful in the study of heat flow, fluid dynamics and electrostatics. Two-dimensional potential problem can be solved using analytic functions since the real and imaginary part of an analytic function are solutions of two-dimensional Laplace's equation.

22.1 COMPLEX FUNCTION

Basic Definitions

Circle

$|z - z_0| = \rho$ represents a circle with centre at the point z_0 and of radius ρ .

Neighbourhood

Neighbourhood of a point z_0 is the set of all points z for which $|z - z_0| < \delta$ where δ is a positive constant (Fig. 22.1).

Fig. 22.1

Deleted neighbourhood of z_0 is $0 < |z - z_0| < \delta$.
Annulus of z_0 is : $\rho_1 < |z - z_0| < \rho_2$.

Interior point z_0 of a set S

If there exists some neighbourhood of z_0 which contains only points of S .

Boundary point z_0 of S

If every neighbourhood of z_0 contains both points in S and points not in S .

Connected set

If any two points of the set S are joined by a polygonal line, all the points of which lie in S .

Domain

A set S is said to be a domain if every point of S is an interior point and connected.

Boundary of a domain is the collection of all boundary points of S .

Region

is a domain together with some of its boundary points.

Closed region

is a region together with the boundary (all boundary points included).

22.2 — HIGHER ENGINEERING MATHEMATICS—VI

Bounded region

is bounded if it can be enclosed in a circle of finite radius.

Examples:

1. $|z| \leq 1$ is closed bounded region.
2. $\text{Im}(z^2) > 0$ i.e., $xy > 0$ is open unbounded, unconnected region.

Complex variable is denoted by $z = x + iy$ where x and y are real variables.

Complex Function of a Complex Variable z

If for every z in a set S , a unique value w is associated, then w is said to be a function of z and is denoted by

$$w = f(z)$$

S is known as the domain of definition of f . Range of f is the totality (set of) all values of $f(z)$ corresponding to z in S .

Since w is complex, it is written as

$$w = f(z) = u(x, y) + iv(x, y)$$

Here $u(x, y)$ and $v(x, y)$, real valued functions of x and y , are known as the real and imaginary parts of the functions w (or $f(z)$).

Example:

$$\begin{aligned} f(z) &= 2z^2 - 3iz = 2(x + iy)^2 - 3i(x + iy) \\ &= 2(x^2 - y^2) + 4ixy - 3ix + 3y \end{aligned}$$

$$\text{So } u(x, y) = 2x^2 - 2y^2 + 3y, \quad v = 4xy - 3x$$

Multi-valued function f is one in which for every z more than one value of w is associated. **We consider only single-valued functions.**

Polynomial in z of degree n (zero or positive integer) is the function

$$f(z) = P_n(z) = a_0 + a_1z + \dots + a_nz^n$$

where $a_0, a_1, \dots, a_n$ are complex constants. Rational fractional function is the quotient of polynomials $P(z)/Q(z)$ defined for all z except those for which $Q(z) = 0$.

Limit: L is said to be the limit of $f(z)$ as z approaches z_0 and is denoted by

$$\lim_{z \rightarrow z_0} f(z) = L$$

if for every $\epsilon > 0$, there exists $\delta > 0$ such that $|f(z) - L| < \epsilon$ whenever $|z - z_0| < \delta$.

Here z may approach z_0 from any direction.

22.2 CONTINUITY

A function $f(z)$ is said to be continuous at a point z_0 if $f(z_0)$ exists, $\lim_{z \rightarrow z_0} f(z)$ exists and

$$\lim_{z \rightarrow z_0} f(z) = f(z_0)$$

i.e., limiting value of $f(z)$ as z approaches z_0 coincides with the value $f(z_0)$.

A function is said to be continuous in a domain if it is continuous at every point of the domain.

A function which is not continuous at z_0 ($f(z_0)$ does not exist, or $\lim_{z \rightarrow z_0} f(z)$ does not exist or $\lim_{z \rightarrow z_0} f(z) \neq f(z_0)$) is known as discontinuous at z_0 .

Result 1: If $f(z)$ and $g(z)$ are continuous functions in D , then their sum $f + g$, difference $f - g$, product fg , quotient f/g are all continuous in D . Continuous function of a continuous function is continuous.

Result 2: $f = u + iv$ is continuous if both u and v are continuous.

22.3 DIFFERENTIABILITY

A function $f(z)$ is said to be differentiable at a point z_0 if the limit

$$\begin{aligned} f'(z_0) &= \lim_{\Delta z \rightarrow 0} \frac{f(z_0 + \Delta z) - f(z_0)}{\Delta z} \\ &= \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} \quad (\text{with } z = z_0 + \Delta z) \end{aligned}$$

exists. The limit $f'(z_0)$ is known as the derivative of $f(z)$ at z_0 . The above limit should be the same along any path from z to z_0 . Thus differentiability of a complex function is a severe requirement.

Differentiation rules

of real calculus are valid in complex differentiation also.

$$1. \frac{dc}{dz} = 0, \quad \text{where } c = \text{complex constant}$$

$$2. \frac{d}{dz}[f \pm g] = \frac{df}{dz} \pm \frac{dg}{dz}$$

$$3. \frac{d}{dz}[cf(z)] = c \frac{df}{dz}$$

$$4. \frac{d}{dz}[f \cdot g] = f \frac{dg}{dz} + \frac{df}{dz} \cdot g$$

$$5. \frac{d}{dz}\left[\frac{f}{g}\right] = \frac{g \frac{df}{dz} - f \frac{dg}{dz}}{g^2}$$

$$6. \text{ a. } \frac{d}{dz}[f(z)]^n = n[f(z)]^{n-1} \frac{df}{dz}$$

$$\text{ b. } \frac{d}{dz}z^n = nz^{n-1}$$

$$7. \text{ Chain rule } \frac{dw}{dz} = \frac{dw}{d\zeta} \cdot \frac{d\zeta}{dz} \text{ if } w = f(\zeta), \text{ and } \zeta = g(z).$$

22.4 ANALYTICITY

A function $f(z)$ is said to be **analytic** at a point z_0 if f is differentiable not only at z_0 but at every point of some neighbourhood of z_0 .

A function $f(z)$ is analytic in a domain if it is analytic at every point of the domain.

An analytic function is also known as “holomorphic”, “regular”, “monogenic”.

Entire Function

A function which is analytic everywhere (for all z in the complex plane) is known as entire function (refer Fig. 22.2).

Example: Polynomials, rational functions are entire.

Example: $|z|^2$ is differentiable only at $z = 0$. So it is nowhere analytic.

Thus analyticity is a very stringent condition.

Fig. 22.2

22.5 CAUCHY-RIEMANN (C-R) EQUATIONS: IN CARTESIAN COORDINATES

Cauchy-Riemann equations (or conditions) are used to determine whether a complex function is analytic or not.

Theorem: If $f(z) = u(x, y) + iv(x, y)$ is differentiable at z then at this point the first order partial derivatives of u and v exist and satisfy the Cauchy-Riemann equations

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \text{ and } \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x} \quad (1)$$

Proof: By hypothesis, f is differentiable, so f' exists i.e.,

$$f'(z) = \lim_{\Delta z \rightarrow 0} \frac{f(z + \Delta z) - f(z)}{\Delta z} \quad (2)$$

Since the limit in (2) exists, the limit value along any two paths must be equal, which results in the Cauchy-Riemann Equations (1) (see Fig. 22.3).

Consider path I: $\Delta y \rightarrow 0$ and $\Delta x \rightarrow 0$

$$\begin{aligned} f'(z) &= \lim_{\substack{\Delta y \rightarrow 0 \\ \Delta x \rightarrow 0}} \frac{u(x+\Delta x, y+\Delta y) + iv(x+\Delta x, y+\Delta y) - u(x, y) - iv(x, y)}{\Delta x + i\Delta y} \\ &= \lim_{\Delta x \rightarrow 0} \frac{u(x+\Delta x, y) - u(x, y)}{\Delta x} + \\ &\quad + i \lim_{\Delta x \rightarrow 0} \frac{v(x+\Delta x, y) - v(x, y)}{\Delta x} = u_x + iv_x \end{aligned} \quad (3)$$

Fig. 22.3

Consider path II: $\Delta x \rightarrow 0$ and $\Delta y \rightarrow 0$

$$\begin{aligned} f'(z) &= \lim_{\substack{\Delta x \rightarrow 0 \\ \Delta y \rightarrow 0}} \frac{u(x+\Delta x, y+\Delta y) + iv(x+\Delta x, y+\Delta y) - u(x, y) - iv(x, y)}{\Delta x + i\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{u(x, y+\Delta y) - u(x, y)}{i\Delta y} + \\ &\quad + \lim_{\Delta y \rightarrow 0} \frac{v(x, y+\Delta y) - v(x, y)}{\Delta y} \\ f' &= \frac{1}{i}u_y + v_y = -iu_y + v_y \quad \because \frac{1}{i} = -i \end{aligned} \quad (4)$$

Equating the limit values (3) and (4) of f' along path I and II, we get

$$u_x + iv_x = f' = -iu_y + v_y$$

Thus $u_x = v_y$ and $u_y = -v_x$.

Corollary 1: If f is analytic in a domain D , then u, v satisfy C-R conditions at all points in D .

Corollary 2: Derivative f' can be calculated using (3) or (4).

Corollary 3: C-R conditions are necessary but not sufficient.

Corollary 4: C-R conditions are sufficient if the partial derivatives are continuous i.e., if $u(x, y), v(x, y)$ have continuous first partial derivatives and satisfy C-R conditions then $f = u + iv$ is analytic.

$$\begin{aligned} f \text{ analytic} &\Rightarrow \text{C-R conditions} \\ &+ \\ \text{analyticity} &\Leftarrow \text{Continuous P.D.} \end{aligned}$$

Properties of analytic functions

1. If $f(z)$ and $g(z)$ are analytic, then $f \pm g, fg, f/g$ are analytic if $g(z) \neq 0$.
2. Analytic function of an analytic function is analytic.

3. An entire function of an entire function is entire.

4. If f is analytic, then it is continuous (analyticity $\Rightarrow$ differentiability $\Rightarrow$ continuity).

5. Derivative of an analytic function is itself analytic. ($f' = u_x + iv_x = U + iV$. f analytic, so $u_x = v_y, u_y = -v_x$, differentiating w.r.t x and $y, u_{xx} = v_{yx}, u_{yy} = -v_{xy}$ or $U_x = V_y$ and $U_y = -V_x$ i.e., U, V satisfy C-R conditions. Hence f' is analytic).

6. If $f = u + iv$ is analytic, then the family of curves $u(x, y) = c_1$ and $v(x, y) = c_2$ are mutually orthogonal i.e., $u = c_1$ are orthogonal trajectories of $v = c_2$ and vice versa.

(By implicit differentiation of $u = c_1$, we get

$$\frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} \cdot \frac{dy}{dx} = 0 \quad \text{or} \quad \frac{dy}{dx} = \frac{-u_x}{u_y}$$

$$\text{Similarly } v_x + v_y \frac{dy}{dx} = 0 \quad \text{or} \quad \frac{dy}{dx} = \frac{-v_x}{v_y}$$

Product of slopes = $\frac{-u_x}{u_y} \cdot \left(\frac{-v_x}{v_y}\right) = -1$ by C-R conditions.)

22.6 HARMONIC AND CONJUGATE HARMONIC FUNCTIONS

Harmonic Function

A function $A(x, y)$ is said to be a harmonic function if it satisfies the Laplace's equation i.e., $\nabla^2 A = 0$.

Theorem: The real and imaginary parts of an analytic function are harmonic.

Proof: Let $f(z) = u(x, y) + iv(x, y)$ be analytic. So C-R conditions $u_x = v_y, u_y = -v_x$ are satisfied. Differentiating partially w.r.t., x and y , we get

$$u_{xx} = v_{yx}$$

$$u_{yy} = -v_{xy}$$

$$\text{Adding } \nabla^2 u = u_{xx} + u_{yy} = v_{yx} - v_{xy} = 0$$

Thus u is a solution of Laplace's equation. Hence u is a harmonic function.

Similarly, differentiating w.r.t., y and x

$$u_{xy} = v_{yy}$$

$$-u_{yx} = v_{xx}$$

Adding $\nabla^2 v = v_{xx} + v_{yy} = u_{xy} - u_{yx} = 0$.

so v is harmonic.

Complex form of Laplace's equation $\frac{\partial^2 u}{\partial z \partial \bar{z}} = 0$

Laplacian operator $\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = 4 \frac{\partial^2}{\partial z \partial \bar{z}}$.

Conjugate Harmonic Function

The real part u of an analytic function $f = u + iv$ is known as the conjugate harmonic function of v and vice versa (i.e., v is the conjugate harmonic of u). Conjugate of a given harmonic function is uniquely determined upto an arbitrarily real additive constant.

Note: Adjective conjugate here is not to be confused with conjugate $\bar{z} = x - iy$.

22.7 CAUCHY-RIEMANN EQUATIONS: IN POLAR COORDINATES

Let $x = r \cos \theta$, $y = r \sin \theta$. Then

$$z = x + iy = r \cos \theta + ir \sin \theta = r e^{i\theta}.$$

$$\text{So } u + iv = f(z) = f(r e^{i\theta})$$

Differentiating partially w.r.t., r and θ ,

$$\begin{aligned} \frac{\partial u}{\partial r} + i \frac{\partial u}{\partial \theta} &= f'(r e^{i\theta}) \cdot e^{i\theta} \\ \frac{\partial u}{\partial \theta} + i \frac{\partial v}{\partial \theta} &= f'(r e^{i\theta}) \cdot i r e^{i\theta} \\ &= i r \left(\frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} \right) \end{aligned}$$

Equating the real and imaginary parts

$$\frac{\partial u}{\partial r} = \frac{1}{r} \frac{\partial v}{\partial \theta} \quad \text{and} \quad \frac{\partial v}{\partial r} = -\frac{1}{r} \frac{\partial u}{\partial \theta}$$

The derivative f' can be calculated using

$$f' = e^{-i\theta} (u_r + i v_r)$$

or

$$f' = \frac{-i}{r e^{i\theta}} (u_\theta + i v_\theta)$$

Milne Thompson Method

I. If u is given, take $f' = u_x - i u_y$

If v is given, take $f' = v_y + i v_x$

II. Replace x by z and y by 0 in f' .

III. Integrate f' w.r.t., z .

WORKED OUT EXAMPLES

Limit: Stringent Condition

Example 1: Show that $\lim_{z \rightarrow 0} \frac{x^2 y}{x^4 + y^2}$ does not exist even though this function approaches the same limit along every straight line through the origin.

Solution:

Path I.

$$\lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x^2 y}{x^4 + y^2} = \lim_{y \rightarrow 0} 0 = 0$$

Path II.

$$\lim_{\substack{y \rightarrow 0 \\ x \rightarrow 0}} \frac{x^2 y}{x^4 + y^2} = \lim_{x \rightarrow 0} 0 = 0$$

Path III. along any straight line through origin.

Let $y = mx$.

$$\lim_{\substack{y=mx \\ x \rightarrow 0}} \frac{x^2 y}{x^4 + y^2} = \lim_{x \rightarrow 0} \frac{mx^3}{x^4 + m^2 x^2} = \lim_{x \rightarrow 0} \frac{mx}{x^2 + m^2} = 0$$

choose **path IV** as $y = mx^2$, then

$$\begin{aligned} \lim_{\substack{y=mx^2 \\ x \rightarrow 0}} \frac{x^2 y}{x^4 + y^2} &= \lim_{x \rightarrow 0} \frac{m \cdot x^4}{x^4 + m^2 x^4} \\ &= \lim_{x \rightarrow 0} \frac{m}{1 + m^2} = \frac{m}{1 + m^2} \neq 0 \end{aligned}$$

and different for different values of m . Therefore the limit does not exist.

Continuity

Example 2: Determine where the given function is continuous (a) $\frac{1}{1+z^2}$ (b) $\frac{1}{z-1}$ inside a unit circle. How about in the complex plane.

Solution: $\frac{1}{1+z^2}$ is continuous everywhere except where $1 + z^2 = 0$ i.e., at $z = \pm i$. When unit circle is considered, $|z| < 1$, $z = \pm i$ are excluded. Thus $\frac{1}{1+z^2}$ is continuous inside $|z| = 1$.

Similarly, $\frac{1}{z-1}$ is also continuous inside $|z| = 1$. If the entire complex plane is considered, both $\frac{1}{1+z^2}$ and $\frac{1}{z-1}$ are discontinuous, at $z = \pm i$ and $z = 1$ respectively.

22.6 — HIGHER ENGINEERING MATHEMATICS—VI

Example 3: Is $f(z) = z/|z|$ continuous at origin (defined for $z \neq 0$ and $f(0) = 0$).

Solution: $\lim_{z \rightarrow 0} f(z) = \lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x+iy}{\sqrt{x^2+y^2}}$

Path I.

$$\lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x+iy}{\sqrt{x^2+y^2}} = i$$

Path II.

$$\lim_{\substack{x \rightarrow 0 \\ y \rightarrow 0}} \frac{x+iy}{\sqrt{x^2+y^2}} = 1$$

since limit does not exist, f is discontinuous at $z_0 = 0$.

Example 4: Determine where the function

$$f(z) = \begin{cases} \frac{z^2+3iz-2}{z+i}, & \text{for } z \neq -i \\ 5, & \text{for } z = -i. \end{cases}$$

is continuous? Can the function be refined to make it continuous at $z = -i$?

Solution: $f(z) = \frac{g(z)}{h(z)}$ is continuous when $g(z)$ and $h(z)$ are continuous except at $h(z) = 0$. So $f(z)$ is continuous everywhere except at $z = -i$, since $g(z), h(z)$ are continuous.

$$\begin{aligned} \lim_{z \rightarrow -i} f(z) &= \lim_{\substack{x \rightarrow 0 \\ y \rightarrow -1}} \frac{(x+iy)^2 + 3i(x+iy) - 2}{x+iy+i} \\ &= \lim_{y \rightarrow -1} \frac{-y^2 - 3y - 2}{i(y+1)} \\ &= \lim_{y \rightarrow -1} \frac{-2y-3}{i} = -\frac{1}{i} = i \end{aligned}$$

$$\text{Also } \lim_{z \rightarrow -i} f(z) = \lim_{\substack{y \rightarrow -1 \\ x \rightarrow 0}} = \lim_{x \rightarrow 0} \frac{2(x-i)+3i}{1} = i$$

$$\text{Thus } \lim_{z \rightarrow -i} f(z) = i \neq 5 = f(-i)$$

Hence f is not continuous at $z = -i$. Suppose we redefine $f(z)$ as follows:

i.e., $f(-i) = i$ (instead of 5).

Then $f(z)$ is continuous at $z = i$ and is therefore continuous everywhere. $z = i$ is known as **removable discontinuity**.

Differentiability/Derivative

Example 5: Show that $f(z) = \text{Re } z = x$ is continuous but not differentiable.

Solution: Continuity: For any point z ,

$$\lim_{z \rightarrow z_0} f(z) = \lim_{z \rightarrow z_0} x = \lim_{\substack{x \rightarrow x_0 \\ y \rightarrow y_0}} x = x_0 = f(z_0)$$

Not differentiable: For any point z ,

$$\begin{aligned} f'(z) &= \lim_{\Delta z \rightarrow 0} \frac{f(z + \Delta z) - f(z)}{\Delta z} \\ &= \lim_{\Delta z \rightarrow 0} \frac{x + \Delta x - x}{\Delta x + i \Delta y} \\ &= \lim_{\substack{\Delta x \rightarrow 0 \\ \Delta y \rightarrow 0}} \frac{\Delta x}{\Delta x + i \Delta y} = 0 \end{aligned}$$

while

$$= \lim_{\substack{\Delta y \rightarrow 0 \\ \Delta x \rightarrow 0}} \frac{\Delta x}{\Delta x + i \Delta y} = 1.$$

So limit does not exist i.e., f is not differentiable.

Example 6: Find the derivative from (a) definition (b) differentiation rules of $f(z) = 3z^2 + 4iz - 5 + i$ at $z = 2$.

Solution:

a. From definition:

$$\begin{aligned} f'(z) &= \lim_{\Delta z \rightarrow 0} \frac{3(z+\Delta z)^2 + 4i(z+\Delta z) - 5 + i - 3z^2 - 4iz - 5 + i}{\Delta z} \\ &= \lim_{\Delta z \rightarrow 0} \frac{3\Delta z^2 + 6z\Delta z + 4i\Delta z}{\Delta z} \\ &= \lim_{\Delta z \rightarrow 0} (3\Delta z + 6z + 4i) \\ &= 6z + 4i = 12 + 4i \text{ at } z = 2. \end{aligned}$$

b. From rules of differentiation:

$$\begin{aligned} \frac{df}{dz} &= \frac{d}{dz} (3z^2 + 4iz - 5 + i) \\ &= 3 \cdot 2z + 4i \cdot 1 + 0 \Big|_{\text{at } z=2} = 12 + 4i. \end{aligned}$$

C-R Equation/condition: Cartesian coordinates

Example 7: Prove that $\frac{d}{dz}(z^2\bar{z})$ does not exist anywhere.

Solution:

a. From definition, for any z :

$$\begin{aligned} \frac{d}{dz}(z^2\bar{z}) &= \lim_{\Delta z \rightarrow 0} \frac{(z + \Delta z)^2 \overline{(z + \Delta z)} - z^2 \bar{z}}{\Delta z} \\ &= \lim_{\Delta z \rightarrow 0} \frac{\bar{z}\Delta z^2 + 2z\bar{z}\Delta z + z^2\Delta\bar{z} + \Delta z^2\overline{\Delta z} + 2z\Delta z\overline{\Delta z}}{\Delta z} \\ &= \lim_{\Delta z \rightarrow 0} \left[0 + 2z\bar{z} + z^2 \frac{\overline{\Delta z}}{\Delta z} + 0 + 0 \right] \\ &= \lim_{\substack{\Delta x \rightarrow 0 \\ \Delta y \rightarrow 0}} \left[2z\bar{z} + z^2 \frac{\overline{\Delta z}}{\Delta z} \right] = 2z\bar{z} + iz^2 \\ &= \lim_{\substack{\Delta y \rightarrow 0 \\ \Delta x \rightarrow 0}} \left[2z\bar{z} + z^2 \frac{\overline{\Delta z}}{\Delta z} \right] = 2z\bar{z} + z^2 \end{aligned}$$

So limit does not exist. Nowhere differentiable.

b. From Cauchy-Riemann conditions:

$$\begin{aligned} z^2\bar{z} &= (x + iy)^2(x - iy) = \left[x(x^2 - y^2) + 2xy^2 \right] \\ &\quad + i \left[2x^2y + y(y^2 - x^2) \right] \end{aligned}$$

$$\text{So } u = x(x^2 - y^2) + 2xy^2, v = 2x^2y + y(y^2 - x^2)$$

$$u_x = 3x^2 - y^2 + 2y^2, u_y = -2xy + 4xy$$

$$v_x = 4xy - 2xy, v_y = 2x^2 + 3y^2 - x^2$$

C-R conditions are not satisfied for any x, y so $f' = u_x + iv_x = v_y - iu_y$ does not exist for any x, y i.e., for any z .

Example 8: Show that every differentiable function is continuous (converse is not true i.e., a function may be continuous but not differentiable).

Solution: Let $f(z)$ be differentiable at z_0 . Then

$$f'(z_0) = \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} \text{ exists.}$$

Therefore $f(z_0)$ is well defined.

Consider

$$\begin{aligned} \lim_{z \rightarrow z_0} f(z) - f(z_0) &= \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} \cdot z - z_0 \\ &= \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} \lim_{z \rightarrow z_0} (z - z_0) \end{aligned}$$

$$= f'(z_0) \cdot \lim_{z \rightarrow z_0} (z - z_0) = 0$$

$$\text{Thus } \lim_{z \rightarrow z_0} f(z) = \lim_{z \rightarrow z_0} f(z_0) = f(z_0).$$

Therefore $f(z)$ is continuous at z_0 .

Counter Example: (a) $f(z) = \bar{z}$, (b) $f(z) = |z|^2$, (c) $f(z) = \text{Im } z$ are continuous but not differentiable at (a) any point (b) at zero (c) any point.

Analyticity

Example 9: Determine where the Cauchy-Riemann equations are satisfied for the given functions. Determine the region of analyticity.

a. $f(z) = e^z = e^x(\cos y + i \sin y)$

Solution:

$$u(x, y) = e^x \cos y, \quad v(x, y) = e^x \sin y$$

$$u_x = e^x \cos y, \quad u_y = -e^x \sin y,$$

$$v_x = e^x \sin y, \quad v_y = e^x \cos y.$$

So

$$u_x = v_y \quad \text{and} \quad u_y = -v_x$$

i.e., C-R conditions are satisfied for all x and y . Therefore given function e^z is analytic everywhere. Thus e^z is an entire function.

b. $f(z) = (x - y)^2 + 2i(x + y)$

Solution:

$$u = (x - y)^2, \quad v = 2(x + y)$$

$$u_x = 2(x - y), u_y = -2(x - y), v_x = 2, v_y = 2$$

$$\text{So } u_x = 2(x - y) = v_y = 2 \text{ if } (x - y) = 1.$$

$$\text{Also } u_y = -2(x - y) = -v_x = -2 \text{ if } (x - y) = 1.$$

Thus C-R equations are satisfied only along the straight line $x - y = 1$. So

$$f'(z) = u_x + iv_x = 2(x - y) + i2 = 2.1 + i2 = 2 + 2i$$

exists only along the line $x - y = 1$, not through any region (neighbourhood) R . Hence $f(z)$ is nowhere analytic.

c. $f(z) = e^{i\bar{z}} = e^y(\cos x + i \sin x).$

22.8 — HIGHER ENGINEERING MATHEMATICS—VI

Solution:

$$u = e^y \cos x, \quad v = e^y \sin x,$$

$$\text{So } u_x = -e^y \sin x, \quad u_y = e^y \cos x,$$

$$v_x = e^y \cos x, \quad v_y = e^y \sin x$$

Thus $u_x \neq v_y$ and $u_y \neq -v_x$ for any x and y . C-R conditions are not satisfied for any z . Hence $f(z) = e^{iz}$ is nowhere analytic.

d. $f(z) = \cos x(\cosh y + a \sinh y) + i \sin x(\cosh y + b \sinh y)$ where a and b are constants.

Solution:

$$u = \cos x(\cosh y + a \sinh y)$$

$$v = \sin x(\cosh y + b \sinh y)$$

$$u_x = -\sin x(\cosh y + a \sinh y)$$

$$v_y = \sin x(\sinh y + b \cosh y)$$

$$u_y = \cos x(\sinh y + a \cosh y)$$

$$v_x = \cos x(\cosh y + b \sinh y)$$

So $u_x = v_y$ and $u_y = -v_x$ if $a = b = -1$.
 f is analytic when $a = b = -1$.

$$\text{e. } f(z) = \frac{(z+3i)^5}{(z^2-2z+5)^2}.$$

Solution: $f(z) = \frac{g(z)}{h(z)}$ where $g(z) = (z+3i)^5$ (polynomial) is analytic everywhere and $h(z) = (z^2 - 2z + 5)^2$ (polynomial) is analytic everywhere. The quotient $f(z) = \frac{g(z)}{h(z)}$ is analytic everywhere except when $h(z) = (z^2 - 2z + 5)^2 = 0$. Thus $f(z)$ is analytic everywhere except at $z^2 - 2z + 5 = 0$ i.e., at $z = 1 \pm 2i$.

Example 10: If $f(z)$ is analytic, show that

$$\left[\frac{\partial}{\partial x} |f| \right]^2 + \left[\frac{\partial}{\partial y} |f| \right]^2 = |f'|^2$$

Solution: $|f(z)| = |u(x, y) + i v(x, y)| = \sqrt{u^2 + v^2}$
partially differentiating w.r.t., x and y

$$\frac{\partial}{\partial x} |f| = \frac{1}{2}(u^2 + v^2)^{-\frac{1}{2}} [2uu_x + 2vv_x] = \frac{uu_x + vv_x}{|f|}$$

Similarly,

$$\frac{\partial}{\partial y} |f| = \frac{uu_y + vv_y}{|f|}.$$

Squaring and adding, we get

$$\begin{aligned} \left[\frac{\partial}{\partial x} |f| \right]^2 + \left[\frac{\partial}{\partial y} |f| \right]^2 &= \frac{(uu_x + vv_x)^2 + (uu_y + vv_y)^2}{|f|^2} \\ &= \left[(u^2 u_x^2 + v^2 v_x^2 + 2uv u_x v_x) \right. \\ &\quad \left. + (u^2 u_y^2 + v^2 v_y^2 + 2uv u_y v_y) \right] / |f|^2 \end{aligned}$$

Since f is analytic, C-R conditions are satisfied. So $u_x = v_y, u_y = -v_x$. Then $2uv u_x v_x = -2uv u_y v_y$

$$= \frac{(u^2 + v^2)(u_x^2 + v_x^2)}{|f|^2} = u_x^2 + v_x^2 = |f'|^2$$

since $f' = u_x + i v_x$ and $|f'| = \sqrt{u_x^2 + v_x^2}$.

Example 11: Is the function $u(x, y) = 2xy + 3xy^2 - 2y^3$ harmonic (i.e., solution of Laplace's equation)?

Solution: $u_x = 2y + 3y^2, u_{xx} = 0, u_y = 2x + 6xy - 6y^2, u_{yy} = 6x - 12y$. So $u_{xx} + u_{yy} \neq 0$. Therefore u is not harmonic.

Harmonic and conjugate harmonic functions

Example 12: Show that $v(x, y) = -\sin x \sinh y$ is harmonic. Find the conjugate harmonic of v (or find an analytic function $f = u + i v$).

Solution: Differentiating v partially w.r.t., x and y , we get

$$v_x = -\cos x \sinh y, \quad v_{xx} = \sin x \sinh y$$

$$v_y = -\sin x \cdot \cosh y, \quad v_{yy} = -\sin x \cdot \sinh y.$$

Then $v_{xx} + v_{yy} = \sin x \sinh y + (-\sin x \sinh y) = 0$.
Therefore v is harmonic.

To find conjugate harmonic u of v :

From C-R conditions $u_x = v_y$ and $u_y = -v_x$.

$$\text{So } u_x = v_y = -\sin x \cdot \cosh y \quad (1)$$

Integrating (1) partially w.r.t. x , we get

$$u(x, y) = \cos x \cdot \cosh y + c(y) \quad (2)$$

Differentiating (2) partially w.r.t., y and using second C-R condition, ($u_y = -v_x$), we have

$$\cos x \cdot \sinh y + \frac{dc}{dy} = \frac{\partial u}{\partial y} = -v_x = \cos x \cdot \sinh y$$

So $\frac{dc}{dy} = 0$ or $c = \text{constant}$.

Hence the conjugate harmonic u of v is

$$u(x, y) = \cos x \cdot \cosh y + c$$

The required analytic function is

$$f(z) = \cos x \cosh y + c + i(-\sin x \cdot \sinh y).$$

Milne-Thompson method

Example 13: Find the analytic function $f(z) = u + iv$ where $u = e^x(x \cos y - y \sin y) + 2 \sin x \cdot \sinh y + x^3 - 3xy^2 + y$.

Solution: Differentiating partially w.r.t., x and y

$$u_x = e^x(x \cos y - y \sin y) + e^x(\cos y) + 2 \cos x \sinh y + 3x^2 - 3y^2$$

$$u_y = e^x(-x \sin y - \sin y - y \cos y) + 2 \sin x \cosh y - 6xy + 1.$$

We know that $f'(z) = u_x + iv_x = u_x - iu_y$
Replace x by z and $y = 0$, then

$$f'(z) = e^z(z \cdot 1 - 0) + e^z(1) + 0 + 3z^2 - 0 - 2i \sin z - i$$

Integrating w.r.t. ' z ', we get

$$f(z) = \int (ze^z + e^z + 3z^2 - 2i \sin z - i) dz$$

$$f(z) = ze^z - e^z + e^z + z^3 + 2i \cos z - iz + c.$$

Example 14: Determine the analytic function $f(z)$ such that $\text{Re}(f'(z)) = 3x^2 - 4y - 3y^2$ and $f(1+i) = 0$.

Solution: $f'(z)$ is analytic since f is analytic. Let $f' = U + iV$.

Then $U = \text{Re}(f'(z)) = 3x^2 - 4y - 3y^2$. $U_x = 6x$, $U_y = -4 - 6y$. Since U, V , satisfy C-R conditions, $U_x = 6x = V_y$.

Integrating w.r.t. y , we get

$$V = 6xy + c_1(x)$$

Differentiating V w.r.t. x and using second C-R condition ($V_x = -U_y$), we have

$$6y + \frac{dc_1}{dx} = V_x = -U_y = 4 + 6y$$

$$c_1(x) = 4x + c_2$$

$$\text{Thus } V(x, y) = 6xy + 4x + c_2$$

where c_2 is an arbitrary constant. Then

$$f'(z) = U + iV$$

$$= (3x^2 - 4y - 3y^2) + i(6xy + 4x + c_2)$$

Applying Milne-Thompson method, replace x by z and y by 0 , we have

$$f'(z) = 3z^2 + 4iz + c_2$$

Integrating w.r.t. z , we get

$$f(z) = z^3 + 2iz^2 + c_2z + c_3$$

where c_3 is an arbitrary constant. Since $f(1+i) = 0$, we get

$$0 = f(1+i) = (1+i)^3 + 2i(1+i)^2 + c_2(1+i) + c_3$$

$$c_3 = -c_2(1+i) - 6 + 2i$$

Thus

$$f(z) = z^3 + 2iz^2 + c_2z - c_2(1+i) - 6 + 2i.$$

C-R Equations not sufficient

Example 15: Show that for

$$f(z) = \frac{2xy(x+iy)}{x^2+y^2} \quad \text{if } z \neq 0$$

$$= 0 \quad \text{if } z = 0$$

The C-R are satisfied at origin but derivative of $f(z)$ at origin does not exist. (i.e., C-R conditions are not sufficient conditions for analyticity).

Solution: C-R conditions at origin:

$$f(z) = \frac{2xy(x+iy)}{x^2+y^2}, \text{ so } u = \frac{2x^2y}{x^2+y^2}, v = \frac{2xy^2}{x^2+y^2}$$

$$\frac{\partial u}{\partial x} = \lim_{x \rightarrow 0} \frac{u(x, 0) - u(0, 0)}{x} = \lim_{x \rightarrow 0} \frac{0 - 0}{x} = 0$$

$$\frac{\partial u}{\partial y} = \lim_{y \rightarrow 0} \frac{u(0, y) - u(0, 0)}{y} = \lim_{y \rightarrow 0} \frac{0 - 0}{y} = 0$$

$$\frac{\partial v}{\partial x} = \lim_{x \rightarrow 0} \frac{v(x, 0) - v(0, 0)}{x} = \lim_{x \rightarrow 0} \frac{0 - 0}{x} = 0$$

$$\frac{\partial v}{\partial y} = \lim_{y \rightarrow 0} \frac{v(0, y) - v(0, 0)}{y} = \lim_{y \rightarrow 0} \frac{0 - 0}{y} = 0.$$

22.10 — HIGHER ENGINEERING MATHEMATICS—VI

So C-R conditions are satisfied at $z = 0$.

Derivative at $z = 0$:

$$\begin{aligned} f'(0) &= \lim_{z \rightarrow 0} \frac{f(z) - f(0)}{z - 0} = \lim_{z \rightarrow 0} \frac{\frac{2xy(x+iy)}{x^2+y^2} - 0}{x + iy} \\ &= \lim_{z \rightarrow 0} \frac{2xy}{x^2 + y^2} = 0 \quad \text{as } \begin{matrix} x \rightarrow 0 & y \rightarrow 0 \\ y \rightarrow 0, & x \rightarrow 0 \end{matrix} \quad \text{and} \\ &= \lim_{\substack{y \rightarrow mx \\ x \rightarrow 0}} \frac{2xy}{x^2 + y^2} = \lim_{x \rightarrow 0} \frac{2mx^2}{x^2 + m^2x^2} = \lim_{x \rightarrow 0} \frac{2m}{1 + m^2} \\ &= \frac{2m}{1 + m^2} \neq 0 \end{aligned}$$

Thus derivative of $f(z)$ does not exist at $z = 0$.

Orthogonal trajectories

Example 16: Find the orthogonal trajectories of the family of curves $x^3y - xy^3 = c = \text{constant}$.

Solution: Take $u(x, y) = x^3y - xy^3$. Then the $v = \text{constant}$ family of curves will be the required orthogonal trajectories if $f(z) = u + iv$ is analytic. So

$$u_x = 3x^2y - y^3, \quad u_y = x^3 - 3xy^2.$$

$$\text{Then } v_y = u_x = 3x^2y - y^3,$$

$$\text{Integrating } v = \frac{3x^2y^2}{2} - \frac{y^4}{4} + c(x)$$

Differentiating

$$3xy^2 - 0 + \frac{dc}{dx} = v_x = -u_y = -x^3 + 3xy^2$$

$$c(x) = -\frac{x^4}{4} + c$$

where c is an arbitrary constant. Thus

$$v(x, y) = \frac{3x^2y^2}{2} - \frac{y^4}{4} - \frac{x^4}{4} + c$$

The required orthogonal trajectories

$$v = \text{constant}$$

$$\text{or } x^4 + y^4 - 6x^2y^2 = \text{constant}.$$

C-R Equations: in polar coordinates

Example 17: Find the derivative of $f(z) = \frac{1}{z^n}$ for $n \neq -1$.

Solution: Introducing polar coordinates

$$f(z) = \frac{1}{(r \cos \theta + ir \sin \theta)^n} = \frac{1}{r^n} (\cos n\theta - i \sin n\theta)$$

$$\text{so } u = r^{-n} \cos n\theta, \quad v = -r^{-n} \sin n\theta$$

$$\begin{aligned} f'(z) &= e^{-i\theta} (u_r + iv_r) \\ &= e^{-i\theta} \left(-nr^{-n-1} \cdot \cos n\theta \right. \\ &\quad \left. + i(-1)(-n)r^{-n-1} \cdot \sin n\theta \right) \end{aligned}$$

$$= \frac{-n}{r^{n+1}} \cdot e^{-i\theta} (\cos n\theta - i \sin n\theta)$$

$$= \frac{-n}{r^{n+1}} \cdot e^{-i\theta} \cdot e^{-in\theta} = \frac{n}{r^{n+1}} e^{-i(n+1)\theta}$$

$$f'(z) = \frac{-n}{r^{n+1}} \cdot \frac{1}{e^{i(n+1)\theta}} = \frac{-n}{z^{n+1}}, \quad n \neq -1.$$

Example 18: If $v(r, \theta) = (r - \frac{1}{r}) \sin \theta$, $r \neq 0$, then find an analytic function $f(z) = u + iv$.

Solution: C-R conditions in polar coordinates are $u_r = \frac{1}{r} v_\theta$ and $u_\theta = -rv_r$.

Differentiating

$$u_\theta = -rv_r = -r \cdot \left(1 + \frac{1}{r^2} \right) \sin \theta = -\left(r + \frac{1}{r} \right) \sin \theta$$

Integrating w.r.t. θ , we get

$$u(r, \theta) = \left(r + \frac{1}{r} \right) \cos \theta + c_1(r)$$

Differentiating w.r.t. r and using $u_r = \frac{1}{r} v_\theta$, we get

$$\left(1 - \frac{1}{r^2} \right) \cos \theta + \frac{dc_1}{dr} = u_r = \frac{1}{r} v_\theta = \frac{1}{r} \left(r - \frac{1}{r} \right) \cos \theta$$

$$\therefore \frac{dc_1}{dr} = 0 \quad \text{or} \quad c_1 = \text{constant}$$

$$\text{Hence } u(r, \theta) = \left(r + \frac{1}{r} \right) \cos \theta + c_1$$

$$\begin{aligned} \text{Thus } f(z) &= u + iv = \left(r + \frac{1}{r} \right) \cos \theta \\ &\quad + i \left(r - \frac{1}{r} \right) \sin \theta + c \end{aligned}$$

Example 19: If f is analytic show that

$$f' = (\cos \theta - i \sin \theta) \frac{\partial f}{\partial r}.$$

Solution: $x = r \cos \theta$, $y = r \sin \theta$, $r = \sqrt{x^2 + y^2}$,
 $\theta = \tan^{-1} \frac{y}{x}$.

$$r_x = \frac{1}{2} \frac{2x}{\sqrt{x^2 + y^2}} = \frac{x}{r} = \cos \theta, r_y = \sin \theta,$$

$$\theta_x = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \left(\frac{-y}{x^2}\right) = \frac{-y}{x^2 + y^2} = \frac{-y}{r^2}$$

$$\theta_x = \frac{-\sin \theta}{r}, \quad \theta_y = \frac{\cos \theta}{r}.$$

We know that $f' = u_x + i v_x = u_x - i u_y$

$$f' = (u_r \cdot r_x + u_\theta \cdot \theta_x) - i(u_r r_y + u_\theta \theta_y).$$

since u is function of r, θ which are functions of x, y .

$$f' = \left(\cos \theta u_r - \frac{\sin \theta}{r} u_\theta \right) - i \left(u_r \cdot \sin \theta + \frac{\cos \theta}{r} \cdot u_\theta \right)$$

since f is analytic, C-R conditions are satisfied (in polar coordinates) $u_r = \frac{v_\theta}{r}$, $u_\theta = -r v_r$

$$\begin{aligned} f' &= \left(\cos \theta \cdot u_r + \frac{\sin \theta}{r} \cdot r v_r \right) \\ &\quad - i(u_r \sin \theta - v_r \cos \theta) \\ &= (\cos \theta - i \sin \theta) u_r + i(\cos \theta - i \sin \theta) v_r \\ &= (\cos \theta - i \sin \theta)(u_r + i v_r) \end{aligned}$$

$$f' = (\cos \theta - i \sin \theta) \frac{\partial f}{\partial r}$$

$$\text{since } \frac{\partial f}{\partial r} = \frac{\partial}{\partial r}(u + i v) = u_r + i v_r.$$

Example 20: Find the orthogonal trajectories of the family of curves $r^2 \cos 2\theta = c_1$.

Solution: Take $u(r, \theta) = r^2 \cos 2\theta$,
 so $u_r = 2r \cos 2\theta$, $u_\theta = -2r^2 \sin 2\theta$.

From C-R conditions $v_\theta = r u_r$

$$v_\theta = 2r^2 \cos 2\theta \quad \text{or} \quad v(r, \theta) = r^2 \sin 2\theta + c(r).$$

Differentiating w.r.t. r ,

$$\begin{aligned} 2r \sin 2\theta + \frac{dc}{dr} &= v_r = -\frac{1}{r} u_\theta \\ &= -\frac{1}{r} (-2r^2 \sin 2\theta) \end{aligned}$$

$$\therefore \frac{dc}{dr} = 0 \quad \therefore c = \text{constant}.$$

Orthogonal trajectories : $v = r^2 \sin 2\theta$.

EXERCISE

Complex function

1. Classify the following regions:

- $0 < |z| < 1$
- $0 < |z| \leq 1$
- $1 < |z| < 2$
- $|z| < 1$ and $|z| > 2$
- $|\operatorname{Re} z| < 2$
- $|z - 4| > 3$
- $|z - 1 + 3i| \leq 1$

Ans. a. Open region.

b. Region.

c. Connected open region.

d. Unconnected.

e. Open unbounded region.

f. Open unbounded region.

g. Closed bounded region.

2. Determine the domains of definition of $f(z)$.

a. $\frac{y}{x} + \frac{1}{1-y} i$

b. $z^4 + 3z^2 + iz$

c. $\frac{1}{(z^2+4)(z^2-9)}$

d. $y \int_0^\infty e^{-xt} dt + i \sum_{n=0}^\infty y^n$

Ans. a. Entire complex plane except $x = 0, y = 1$.

b. For all z .

c. For all z except $z = \pm 2i, \pm 3$.

d. $x > 0$ and $-1 < y < 1$.

3. Find the real and imaginary parts u, v of $f = u + i v$ where $f(z)$ is

a. $z + \frac{1}{z}$

b. $\frac{(1-z)}{(1+z)}$

c. $z^{\frac{1}{2}}$

Ans. a. $u = x + \frac{x}{(x^2+y^2)}, v = y - \frac{y}{(x^2+y^2)}$

b. $\frac{(1-x^2-y^2)}{[(1+x)^2+y^2]}, \frac{-2y}{[(1+x)^2+y^2]}$

c. $u = \sqrt{r} \cos \frac{\theta}{2}, v = \sqrt{2} \sin \frac{\theta}{2}$

where $x = r \cos \theta, y = r \sin \theta$.

22.12 — HIGHER ENGINEERING MATHEMATICS—VI

Continuity

Determine whether the function $f(z)$ is continuous at origin. Give reason.

$$4. f(z) = \frac{(x+y)^2}{(x^2+y^2)}, \quad z \neq 0 \\ = 0, \quad z = 0$$

Ans. Not continuous. $\lim f$ along $y = mx$ has $\frac{(1+m)^2}{(1+m^2)}$ different values.

$$5. f(z) = \frac{z \operatorname{Re} z}{|z|}, \quad \text{for } z \neq 0 \\ = 2, \quad \text{for } z = 0$$

Ans. Discontinuous at origin. But by redefining $f(0) = 0$, the function can be made continuous at origin.

6. Is the function $f(z) = (x + y^2) + ixy$ continuous?

Ans. Continuous everywhere.

7. Determine whether $f(z)$ is continuous. Redefine if necessary to make it continuous

$$f(z) = \begin{cases} z^2 + iz + 2, & z \neq i \\ i, & z = i \end{cases}$$

Ans. $f(z)$ is continuous everywhere except at $z = i$, since $\lim_{z \rightarrow i} f = 0 \neq f(i) = i$. By redefining $f(i) = 0$, f becomes continuous at $z = i$ also.

8. Show that $f(z) = P_n(z) = a_0 + a_1z + a_2z^2 + \dots + a_nz^n$ is continuous everywhere.

9. Prove that

$$f(z) = \begin{cases} z^3, & z \neq z_0 \\ 2, & z = z_0 \end{cases} \quad \text{where } z_0 \neq 2^{\frac{1}{3}}$$

is discontinuous at z_0 .

10. Is the function

$$f(z) = \frac{3z^4 - 2z^3 + 8z^2 - 2z + 5}{z - i}$$

continuous at $z = i$?

Ans. $f(i)$ is undefined. Discontinuous at $z = i$. Redefine $f(i) = \lim_{z \rightarrow i} f(z) = 4 + 4i$. Then f becomes continuous at $z = i$. It is known as removable discontinuity.

11. Determine for what values of z the given functions are continuous

$$\text{a. } f(z) = \frac{z}{(z^2+1)} \\ \text{b. } \operatorname{csc} z = \frac{1}{\sin z}$$

Ans. a. Continuous everywhere except where the denominator $z^2 + 1 = 0$ i.e., at $z = \pm i$.

b. Continuous everywhere except where $\sin z = 0$ i.e., at $z = \pm n\pi, n = 0, 1, 2, 3, \dots$

Differentiability

12. Find derivative of $f(z) = \frac{1+z}{1-z}$

a. From definition.

b. From differentiation rules at $z = 2$.

$$\text{Ans. a. } f' = \lim_{\Delta z \rightarrow 0} \left[\frac{1 + (z + \Delta z)}{1 - (z + \Delta z)} - \frac{1 + z}{1 - z} \right] \frac{1}{\Delta z} \\ = \frac{2}{(1-z)^2}$$

b. By Quotient rule at $z = 2, f' = 2$

13. Show that the following functions are continuous but not differentiable:

$$(a) \bar{z} \quad (b) |z|^2 \quad (c) \operatorname{Im} z \quad (d) |z| \quad (e) \frac{1}{z}$$

Hint:

a. Not differentiable anywhere.

b. Differentiable only at origin.

c. Nowhere differentiable.

d. Nowhere differentiable.

e. Not differentiable at 0.

14. Find the derivative at indicated points:

$$\text{a. } \frac{2z-i}{z+zi} \text{ at } z = -i$$

$$\text{b. } 3z^{-2}, z = 1 + i$$

$$\text{Ans. a. } -5i \quad \text{b. } \frac{3}{2}(1 + i).$$

Analyticity

Determine where C-R conditions are satisfied for the given function $f(z)$:

$$15. f(z) = \frac{1}{2} \ln(x^2 + y^2) + i \tan^{-1} \frac{y}{x}$$

Ans. For all z , everywhere (entire)

$$16. f(z) = x + ay + i(bx + cy)$$

$$\text{Ans. } a = -b, c = 1$$

$$17. f(z) = xy + iy$$

Ans. Nowhere (analytic).

18. $f(z) = |x^2 - y^2| + 2i|xy|$

Ans. a. For $f(z) = z^2$, $0 < \theta < \frac{\pi}{4}$, $\pi < \theta < \frac{5\pi}{4}$

b. For $f(z) = -z^2$, $\frac{\pi}{2} < \theta < \frac{3\pi}{4}$, $\frac{3\pi}{2} < \theta < \frac{7\pi}{4}$

19. $f(z) = z\bar{z}$

Ans. Only at origin.

20. $f(z) = \sin x \cosh y + i \cos x \sinh y$

Ans. Everywhere.

21. Show that $f = x^2 + iy^3$ is nowhere analytic.

Hint: C-R conditions satisfied only at origin.

22. If $f(z) = xy^2 + ix^2y$, determine where

a. C-R conditions satisfied

b. f' exist

c. f is analytic

Ans. a. C-R satisfied only at origin

b. f' exist only at origin

c. f is nowhere analytic.

Show that the given function satisfies C-R conditions at origin but does not have a derivative at origin:

23. $f(z) = \begin{cases} \frac{\bar{z}^2}{z}, & z \neq 0 \\ 0, & z = 0 \end{cases}$

24. $f(z) = \sqrt{|xy|}$

25. $f(z) = \begin{cases} \frac{(x^3 - y^3) + i(x^3 + y^3)}{x^2 + y^2}, & \text{if } z \neq 0 \\ 0, & \text{if } z = 0. \end{cases}$

Harmonic and conjugate harmonic functions

Verify that the given function is harmonic and find its conjugate harmonic function. Express $u + iv$ as an analytic function $f(z)$:

26. $u = x^2 - y^2 - y$

Ans. $v = 2xy + x + c$, $f(z) = z^2 + iz + c$

27. $v = x^2 - y^2 + \frac{x}{x^2 + y^2}$

Ans. $u = -2xy + \frac{y}{x^2 + y^2} + c$, $w = i(z^2 + \frac{1}{z}) + c$

28. $u = \frac{\sin 2x}{(\cosh 2y - \cos 2x)}$

Ans. $v = \frac{-\sinh 2y}{(\cosh 2y - \cos 2x)}$, $f = \cot z + c$

29. $u = 3xy^2 - x^3$

Ans. $v = y^3 - 3x^2y + c$, $f = -z^3 + ic$

30. $v = y^2 - x^2$

Ans. $u = 2xy + c$, $f = -iz^2 + c$

31. $u = e^{-x}(x \sin y - y \cos y)$

Ans. $v = e^{-x}(y \sin y + x \cos y) + c$

$$f(z) = iz e^{-z}$$

32. $u = \frac{x^2 - y^2}{(x^2 + y^2)^2}$

Ans. $v = \frac{-2xy}{(x^2 + y^2)^2}$, $f(z) = \frac{1}{z^2} + c$

33. $u = \frac{1}{2} \ln(x^2 + y^2)$

Ans. $v = \arg z + c$, $f = \ln z + c$

34. $u = 3x^3y + 2x^2 - y^3 - 2y^2$

Ans. Not harmonic.

35. $u = e^{-2xy} \sin(x^2 - y^2)$

Ans. $v = -e^{-2xy} \cos(x^2 - y^2) + c$

$$f(z) = -ie^{iz^2} + ci$$

36. If $\operatorname{Im}\{f'(z)\} = 6x(2y - 1)$ and $f(0) = 3 - 2i$, $f(1) = 6 - 5i$ find $(1 + i)$.

Hint: f' is analytic. Determine $\operatorname{Re}\{f'\}$. Use Milne-Thompson method.

Ans. $6 + 3i$

37. If $u - v = \frac{\cos x + \sin x - e^{-y}}{2(\cos x - \cosh y)}$ and $f(\frac{\pi}{2}) = 0$

determine the analytic function $f(z) = u + iv$

Hint: Differentiating w.r.t., x , y , use C-R, find u_x , v_x , use Milne-Thompson method.

38. Determine constant 'b' such that $u = e^{bx} \cos 5y$ is harmonic. Find its conjugate harmonic.

Ans. $b = \pm 5$, $v = \pm e^{\pm 5x} \sin 5y + c$

39. If $f(z)$ is analytic in a domain D and $|f(z)| = k = \text{constant}$ in D , then show that $f(z)$ is constant in D .

40. If $f(z)$ is a regular function, show that

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) |f(z)|^2 = 4|f'(z)|^2.$$

22.14 — HIGHER ENGINEERING MATHEMATICS—VI

41. If $f'(z) = 0$ then show that $f(z)$ is constant.
42. If both $f(z)$ and $\overline{f(z)}$ are analytic show that $f(z)$ is constant.
43. If $f = u + iv$ is analytic show that $g = -v + iu$ is also analytic. Also show that u and $-v$ are conjugate harmonic.
- Hint:** f analytic, $u_x = v_y$, $u_y = -v_x$, so g satisfies C-R $-v_x = u_y$ and $-v_y = -u_x$. g analytic, $-v, u$, C.H.F.

44. If $f(z)$ is an analytic function, show that

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) |\text{Res } f(z)|^2 = 2|f'(z)|^2$$

Hint: For 40, 44, $\nabla^2 = \frac{\partial^2}{\partial z \partial \bar{z}}$, write $|f(z)|^2 = f(z)\overline{f(z)}$ and $\text{Res } f(z) = \frac{(f(z) + \overline{f(z)})}{2}$.

45. If $f(z)$ is analytic, prove that

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) |f(z)|^n = n^2 |f(z)|^{n-2} \cdot |f'(z)|^2$$

46. Show that (a) $\nabla^2 \ln |f(z)| = 0$ (b) $\nabla^2 \arg f(z) = 0$ if f is analytic.
47. Show that $U(x, y) = e^u \cos v$, $V(x, y) = e^u \sin v$ are conjugate harmonic of each other if $f = u + iv$ is analytic.

Orthogonal trajectories, polar coordinates

Find the orthogonal trajectories of the family of curves:

48. $e^{-x}(x \sin y - y \cos y) = c_1$

Ans. $e^{-x}(y \sin y + x \cos y) = c_2$

49. $e^{-x} \cos y + xy = c_1$

Ans. $2e^{-x} \sin y + x^2 - y^2 = c_2$

50. $x^4 - 6x^2y^2 + y^4 = c_1$

Ans. $x^3y - xy^3 = c_2$

51. $x^3 - 3xy^2 = c_1$

Ans. $3x^2y - y^3 = c_2$

52. $(r^2 + 1) \cos \theta = c_1 r$

Ans. $(r^2 - 1) \sin \theta = c_2 r$

53. If $f(z)$ is analytic, show that

$$f' = \frac{-\sin \theta + i \cos \theta}{r} \cdot \frac{\partial f}{\partial \theta}$$

54. Show that $u(r, \theta) = e^{-\theta} \cos(\ln r)$ is harmonic. Find its conjugate harmonic function.

Hint: u is harmonic if it satisfies the Laplace's equation in polar coordinates.

$$r^2 u_{rr} + r u_r + u_{\theta\theta} = 0$$

Ans. $v(r, \theta) = e^{-\theta} \sin(\ln r) + c$

55. Find the conjugate harmonic function of $v(r, \theta) = r^2 \cos 2\theta - r \cos \theta + 2$. Show that v is harmonic.

Ans. $u(r, \theta) = -r^2 \sin 2\theta + r \sin \theta + c$

56. Find the conjugate harmonic function of $u(r, \theta) = -r^3 \sin 3\theta$. Show that u is harmonic.

Ans. $v = r^3 \cos 3\theta + c$

22.8 ELEMENTARY FUNCTIONS

Algebraic function of z is a function $w = f(z)$ which is a solution of the polynomial equation

$$P_0(z) \cdot w^n + P_1(z)w^{n-1} + \dots + P_{n-1}(z)w + P_n(z) = 0$$

where $P_0 \neq 0$, $P_1(z)$, $P_2(z)$, $\dots$, $P_n(z)$ are polynomials in z and n is a positive integer.

Polynomials and rational functions are special cases of algebraic functions. Transcendental functions are those which cannot be expressed as an algebraic function.

Logarithmic, trigonometric, hyperbolic and their corresponding inverses are transcendental (non-algebraic) functions. Elementary functions consist of algebraic functions and transcendental functions and functions derived from them by a finite number of algebraic operations of addition, subtraction, multiplication, division and root taking.

Exponential Function: e^z

For $z = x + iy$, exponential function e^z also written as $\exp z$ is defined as

$$e^z = e^{x+iy} = e^x (\cos y + i \sin y)$$

e^z may also be defined by a power series as

$$e^z = \sum_{n=0}^{\infty} \frac{z^n}{n!} = 1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \cdots$$

which converges for all z .

Properties

1. e^z is an entire function

$$f(z) = u + iv = e^z = e^x(\cos y + i \sin y)$$

$$\text{so } u = e^x \cos y, v = e^x \sin y.$$

$$\text{Now } u_x = e^x \cos y, u_y = -e^x \sin y,$$

$$v_x = e^x \sin y, v_y = e^x \cos y.$$

Thus C-R conditions are satisfied for all z .

$$\begin{aligned} 2. \frac{d}{dz} e^z &= u_x + i v_x = e^x \cos y + i e^x \sin y \\ &= e^x(\cos y + i \sin y) = e^{x+iy} = e^z. \end{aligned}$$

3. e^z has no zeros i.e., $e^z \neq 0$ for any z .

$$e^z = R e^{i\phi} \quad \text{so } R = e^x > 0, y = \phi, |e^{iy}| = 1$$

$$\text{so } |e^z| = e^x \neq 0.$$

$$4. e^{2n\pi i} = \cos(2n\pi) + i \sin(2n\pi) = 1$$

$$\text{Thus } e^{\pm 2n\pi i} = 1, e^{\pm \pi i} = -1$$

$$e^{\frac{\pi i}{2}} = i, e^{-\frac{i\pi}{2}} = -i$$

5. Periodic function

$$e^{z \pm 2n\pi i} = e^z \cdot e^{\pm 2n\pi i} = e^z$$

e^z is a periodic function of imaginary period $2\pi i$.

6. From definition

$$a. e^{z_1} \cdot e^{z_2} = e^{z_1+z_2}$$

$$b. \frac{e^{z_1}}{e^{z_2}} = e^{z_1-z_2}$$

$$c. (e^z)^n = e^{nz}$$

$$7. \overline{e^z} = \overline{e^z}$$

$$\overline{e^z} = e^{x-iy} = e^x(\cos y - i \sin y)$$

$$= \overline{e^x(\cos y + i \sin y)} = \overline{e^z}.$$

8. Polar form of z in terms of exponential,

$$z = x + iy = r \cos \theta + i r \sin \theta = r e^{i\theta}.$$

WORKED OUT EXAMPLES

Exponential function

Example 1: Separate into real and imaginary:

$$(a) e^{2 \pm 3\pi i} \quad (b) e^{5 + \frac{i\pi}{2}} \quad (c) e^{(5+3i)^2}.$$

Solution:

$$a. e^{2 \pm 3\pi i} = e^2 \cdot e^{\pm 3\pi i} = e^2 \cdot (-1) = -e^2$$

$$b. e^{5 + \frac{i\pi}{2}} = e^5 \cdot e^{\frac{i\pi}{2}} = e^5 \cdot i = i e^5$$

$$c. e^{(5+3i)^2} = e^{(25-9+30i)} = e^{16} \cdot e^{30i} = e^{16} \operatorname{cis} 30$$

Example 2: Show that $\frac{d}{dz}(e^{iz}) = i e^{iz}$.

Solution:

$$e^{iz} = e^{i(x+iy)} = e^{-y+ix} = e^{-y}(\cos x + i \sin x)$$

$$\frac{d}{dz}(e^{iz}) = \frac{\partial}{\partial x}[e^{-y} \cos x] + i \frac{\partial}{\partial x}[e^{-y} \sin x]$$

$$\text{since } f' = u_x + i v_x$$

$$= -e^{-y} \cdot \sin x + i e^{-y} \cos x$$

$$= i(e^{-y} \cos x + i e^{-y} \sin x) = i e^{iz}$$

Example 3: Find all values of z such that $e^z = -2$.

Solution: Express -2 in polar form: $x = -2$, $y = 0$

$$r = \sqrt{2^2 + 0^2} = 2, \cos \theta = -1, \sin \theta = 0, \therefore \theta = \pm \pi$$

$$e^z = -2 = 2 \cdot e^{\pm \pi i \pm 2n\pi i} = e^{\ln 2 \pm (2n+1)\pi i}$$

$$\therefore z = \ln 2 \pm (2n+1)\pi i, n = 0, 1, 2, \dots$$

Example 4: Show that $\overline{e^z}$ is nowhere analytic.

$$\begin{aligned} \text{Solution: } f(z) = u + iv &= \overline{e^z} = e^{x-iy} \\ &= e^x(\cos y - i \sin y) \end{aligned}$$

$$\text{so } u = e^x \cos y, v = -e^x \sin y.$$

$$\text{Differentiating, } u_x = e^x \cos y, u_y = -e^x \sin y,$$

$$v_x = -e^x \sin y, v_y = -e^x \cos y.$$

$\overline{e^z}$ is nowhere analytic since C-R conditions are not satisfied for any z .

Example 5: Show in two ways that e^{z^2} is entire. Find its derivative in two ways.

22.16 — HIGHER ENGINEERING MATHEMATICS—VI

Solution:

- a. z^2 is entire, e^w is entire, entire function of an entire function is entire. Therefore e^{z^2} is entire.

By chain rule differentiation

$$\frac{d}{dz} e^{z^2} = e^{z^2} \cdot \frac{d}{dz} (z^2) = 2ze^{z^2}$$

- b. $f(z) = u + iv = e^{z^2} = e^{x^2 - y^2 + i2xy}$ so

$$u = e^{x^2 - y^2} \cos 2xy, v = e^{x^2 - y^2} \sin 2xy$$

$$u_x = 2xe^{x^2 - y^2} \cos 2xy - 2ye^{x^2 - y^2} \sin 2xy$$

$$u_y = 2xu - 2yv$$

Similarly, $u_y = -2yu - 2xv$

$$v_x = 2xv + 2yu, v_y = -2yv + 2xu$$

Thus C-R conditions are satisfied for all x, y .
Hence e^{z^2} is an entire function.

$$f' = u_x + iv_x = (2xu - 2yv) + i(2xv + 2yu)$$

By Milne-Thompson method, replace x by z , y by 0

$$f'(z) = (2ze^{z^2} - 0) + i(0 + 0) = 2ze^{z^2}.$$

Hint: $\ln 5 = 1.609$, $\sin y = 0.8$, $y = 0.927$

Ans. $z = 1.609 + 0.927i \pm 2n\pi i, n = 0, 1, 2, \dots$

$$5. e^{3z} = 1$$

Ans. $z = \frac{2k\pi i}{3}, k = 0, \pm 1, \pm 2$

$$6. e^{4z} = i$$

Ans. $z = \left(\frac{1}{8}\pi + \frac{k\pi}{2}\right)i, k = 0, \pm 1, \pm 2$

$$7. e^{2z-1} = 1 + i$$

Ans. $z = \frac{1}{2} + \frac{1}{4} \ln 2 + i \left(n\pi + \frac{\pi}{8}\right),$
 $n = 0, \pm 1, \pm 2, \pm 3, \dots$

8. Show that e^z and $e^{\bar{z}}$ are conjugate.

9. Prove that $\frac{e^{z_1}}{e^{z_2}} = e^{z_1 - z_2}$.

Trigonometric Functions

$\cos z$ and $\sin z$ are defined in terms of e^z as

$$\cos z = \frac{1}{2}(e^{iz} + e^{-iz})$$

$$\sin z = \frac{1}{2i}(e^{iz} - e^{-iz})$$

From these definitions, it follows that

$$e^{iz} = \cos z + i \sin z$$

which shows that Euler's formula is valid for complex z .

The other trigonometric functions are defined

$$\tan z = \frac{\sin z}{\cos z}, \cot z = \frac{\cos z}{\sin z}, \sec z = \frac{1}{\cos z}, \operatorname{cosec} z = \frac{1}{\sin z}.$$

Properties

1. $\sin z, \cos z$ are entire functions since e^z is entire.

2. $\tan z, \sec z$ and $\cot z, \operatorname{cosec} z$ are analytic everywhere except where $\cos z$ is zero and $\sin z$ is zero respectively.

3. Since $\frac{d}{dz} e^z = e^z$ and $\frac{d}{dz} e^{iz} = ie^{iz}$, it follows that $\frac{d}{dz}(\sin z) = \cos z, \frac{d}{dz}(\cos z) = -\sin z, \frac{d}{dz}(\tan z) = \sec^2 z$ etc.

4. Even and odd functions. $\sin z, \tan z, \operatorname{cosec} z$ are odd functions, $\cos z, \sec z$ are even functions.

$$\begin{aligned} \sin(-z) &= \frac{1}{2i}[e^{i(-z)} - e^{-i(-z)}] = -\frac{1}{2i}[-e^{-iz} + e^{iz}] \\ &= -\sin z \end{aligned}$$

EXERCISE

Exponential function

1. Find e^z (in the form $u + iv$) and $|e^z|$ if z equals

- (a) $3 - 5\pi i$ (b) $4\pi(2 + i)$ (c) $6 - \frac{\pi i}{2}$
(d) $1.4 - 0.6i$.

Ans. (a) $-e^3, e^3$ (b) $e^{8\pi}, e^{8\pi}$ (c) $-ie^6, e^6$
(d) $3.347 - 2.290i, 4.055$

2. Represent each of the following in the exponential form $re^{i\theta}$ (a) $3 + 4i$ (b) $-4i$ (c) -2 .

Ans. (a) $5 \cdot \exp\left(i \arctan \frac{4}{3}\right)$ (b) $4 \cdot e^{-\frac{i\pi}{2}}$
(c) $2e^{\pm 2n\pi i}, n = 0, 1, 2, \dots$

Find all solutions:

$$3. \exp(2z - 1) = 1$$

Ans. $z = \frac{1}{2} \pm n\pi i, n = 0, 1, 2, \dots$

$$4. e^z = 3 + 4i$$

5. Periodic functions $\cos z$, $\sin z$ are periodic functions with real period 2π while $\tan z$, $\cot z$ have period π

$$\begin{aligned}\cos(z + 2\pi) &= \frac{1}{2}[e^{i(z+2\pi)} + e^{-i(z+2\pi)}] \\ &= \frac{1}{2}[e^{iz} + e^{-iz}] = \cos z, \\ \text{since } e^{\pm 2\pi i} &= 1.\end{aligned}$$

6. Real and imaginary parts

$$\begin{aligned}\text{For } \cos z &= \frac{1}{2}(e^{iz} + e^{-iz}) \\ &= \frac{1}{2}[e^{i(x+iy)} + e^{-i(x+iy)}] \\ &= \frac{1}{2}[e^{ix}e^{-y} + e^{-ix} \cdot e^y] \\ &= \frac{1}{2}e^{-y}(\cos x + i \sin x) \\ &\quad + \frac{1}{2}e^y(\cos x - i \sin x) \\ &= \frac{1}{2}(e^{-y} + e^y)\cos x - \frac{1}{2}i(e^y - e^{-y}) \cdot \sin x \\ \cos z &= \cosh y \cdot \cos x - i \sinh y \cdot \sin x\end{aligned}$$

Thus absolute value of $\cos z$ is

$$\begin{aligned}|\cos z| &= \sqrt{\cosh^2 y \cos^2 x + \sinh^2 y \sin^2 x} \\ |\cos z|^2 &= (1 + \sinh^2 y) \cos^2 x + \sinh^2 y \sin^2 x \\ &= \cos^2 x + \sinh^2 y.\end{aligned}$$

Similarly,

$$\begin{aligned}\sin z &= \sin x \cdot \cosh y + i \cos x \cdot \sinh y \\ |\sin z|^2 &= \sin^2 x + \sinh^2 y.\end{aligned}$$

Similarly,

$$\tan z = \frac{\sin 2x + i \sinh 2y}{\cos 2x + \cosh 2y}$$

(See WE 4,5 on pages 22.18, 22.19)

7. Zeros of $\sin z$ and $\cos z$ are given by $z = \pm 2n\pi$, and $z = \pm \frac{1}{2}(2n + 1)\pi$, $n = 0, 1, 2, \dots$ respectively.
8. All the general formulas for the real trigonometric functions are valid for complex trigonometric

functions also.

$$\begin{aligned}\cos^2 z + \sin^2 z &= \left[\frac{1}{2}(e^{iz} + e^{-iz}) \right]^2 + \left[\frac{1}{2} \frac{(e^{iz} - e^{-iz})}{i} \right]^2 \\ &= \left(\frac{e^{2iz} + 2 + e^{-2iz}}{4} \right) - \left(\frac{e^{2iz} - 2 + e^{-2iz}}{4} \right) \\ &= 1.\end{aligned}$$

Similarly,

$$\begin{aligned}\sin(z_1 \pm z_2) &= \sin z_1 \cdot \cos z_2 \pm \cos z_1 \cdot \sin z_2 \\ \cos(z_1 \pm z_2) &= \cos z_1 \cdot \cos z_2 \mp \sin z_1 \cdot \sin z_2\end{aligned}$$

9. Relations between trigonometric and hyperbolic:

$$\cos(iz) = \frac{1}{2}[e^{i(iz)} + e^{i(-iz)}] = \frac{1}{2}[e^{-z} + e^{-z}]$$

a. $\cos(iz) = \cosh z$

$$\begin{aligned}\text{Also } \sin(iz) &= \frac{1}{2i}[e^{i(iz)} - e^{-i(iz)}] \\ &= \frac{1}{2i}(e^{-z} - e^{-z})\end{aligned}$$

b. $\sin(iz) = i \sinh z$

c. $\tan(iz) = i \tanh z$

Hyperbolic Functions

Complex hyperbolic sine and cosine are defined as

$$\begin{aligned}\sinh z &= \frac{1}{2}(e^z - e^{-z}) \\ \cosh z &= \frac{1}{2}(e^z + e^{-z}).\end{aligned}$$

Properties

1. Both $\sinh z$ and $\cosh z$ are entire functions since e^z is entire. Other functions are similarly defined

$$\begin{aligned}\tanh z &= \frac{\sinh z}{\cosh z}, \coth z = \frac{\cosh z}{\sinh z}, \operatorname{sech} z = \frac{1}{\cosh z} \\ \text{and } \operatorname{cosech} z &= \frac{1}{\sinh z}\end{aligned}$$

2. *Derivatives:* $\frac{d}{dz}(\sinh z) = \frac{d}{dz} \left[\frac{1}{2}(e^z - e^{-z}) \right]$
 $= \frac{1}{2}[e^z + e^{-z}] = \cosh z$, etc.

3. *Periodic:* $\sinh z$, $\cosh z$ are periodic functions of imaginary period $2\pi i$ since

$$\begin{aligned}\sinh(z + 2\pi i) &= \frac{1}{2}(e^{z+2\pi i} - e^{-(z+2\pi i)}) \\ &= \frac{1}{2}(e^z - e^{-z}) = \sinh z.\end{aligned}$$

4. Real and imaginary parts

$$\begin{aligned}\sinh z &= \frac{1}{2}(e^z - e^{-z}) = \frac{1}{2}[e^{x+iy} - e^{-(x+iy)}] \\ &= \frac{1}{2}e^x(\cos y + i \sin y) - \frac{1}{2}e^{-x}(\cos y - i \sin y) \\ &= \cos y \cdot \frac{1}{2}(e^x - e^{-x}) + i \sin y \frac{1}{2}(e^x + e^{-x}) \\ \sinh z &= \cos y \cdot \sinh x + i \sin y \cosh x\end{aligned}$$

Similarly,

$$\cosh z = \cosh x \cdot \cos y + i \sinh x \cdot \sin y$$

5. Even and odd: $\cosh z$ is even, $\sinh z$ is odd function

6. Relation between hyperbolic and trigonometric functions:

$$\begin{aligned}\text{a. } \cosh iz &= \frac{1}{2}(e^{iz} + e^{-iz}) = \cos z \\ \sinh iz &= \frac{1}{2}(e^{iz} - e^{-iz}) = \frac{i}{2i}(e^{iz} - e^{-iz}) \\ \text{b. } \sinh iz &= i \sin z \\ \text{c. } \tanh iz &= i \tan z\end{aligned}$$

7. Zeros of $\sinh z$ are $\pm n\pi i$ and zeros of $\cosh z$ are $z = \pm(n + \frac{1}{2})\pi i, n = 0, 1, 2, \dots$ (see Worked Out Example 10 on Page 22.19)

8. General formulas true for real are valid for complex functions also

$$\begin{aligned}\text{a. } \cosh^2 z - \sinh^2 z &= \left(\frac{e^z + e^{-z}}{2}\right)^2 - \left(\frac{e^z - e^{-z}}{2}\right)^2 \\ &= 1 \\ \text{b. } 1 - \tanh^2 z &= \operatorname{sech}^2 z \\ \text{c. } \cosh(z_1 + z_2) &= \cosh z_1 \cdot \cosh z_2 + \sinh z_1 \cdot \sinh z_2 \\ \text{d. } \sinh(z_1 + z_2) &= \sinh z_1 \cdot \cosh z_2 + \cosh z_1 \cdot \sinh z_2\end{aligned}$$

WORKED OUT EXAMPLES

Trigonometric and hyperbolic functions

Example 1: Find all solutions of $\sin z = 3$

$$\begin{aligned}\text{Solution: } \sin z &= \frac{e^{iz} - e^{-iz}}{2i} = 3 \\ (e^{iz})^2 - 6ie^{iz} - 1 &= 0\end{aligned}$$

$$e^{iz} = \frac{6i \pm \sqrt{-36 + 4}}{2} = (3 \pm \sqrt{8})i = (3 \pm \sqrt{8})e^{i\frac{\pi}{2} \pm 2n\pi i}$$

$$e^{iz} = e^{\ln(3 \pm \sqrt{8}) + i(\frac{\pi}{2} \pm 2n\pi)}, n = 0, 1, 2, 3, \dots$$

$$z = (-\frac{\pi}{2} \pm 2n\pi) + i \ln(3 \pm \sqrt{8}), n = 0, 1, 2, 3, \dots$$

$$(3 + \sqrt{8} = 5.828, 3 - \sqrt{8} = 0.1715).$$

Example 2: Find all solutions of $\cosh z = -2$.

$$\text{Solution: } \cosh z = \cosh x \cdot \cos y + i \sinh x \cdot \sin y = -2.$$

Since R.H.S. is real, $\sinh x \cdot \sin y = 0$, which is possible when $x = 0$ or $y = \pm n\pi, n = 0, 1, 2, 3, \dots$
Now $\cosh x \cdot \cos y = -2$.

Since $\cosh x \geq 1$ for any x , we must take $y = \pm n\pi$. So $\cosh x \cdot \cos(\pm n\pi) = -2, n$ odd.

Or $\cosh x = 2$ or $x = \cosh^{-1} 2$.

So all solutions to the given equation are

$$z = x + iy = \cosh^{-1} 2 + (2m + 1)\pi i, m = 0, 1, 2, 3, \dots$$

Example 3: Find all roots of the equation:

$$\tanh z + 2 = 0.$$

$$\text{Solution: } \tanh z + 2 = \frac{\sinh z}{\cosh z} + 2 = 0$$

$$\begin{aligned}\frac{e^z - e^{-z}}{e^z + e^{-z}} + 2 &= 0 \quad \text{or} \quad e^z - e^{-z} + 2(e^z + e^{-z}) = 0 \\ 3e^z + e^{-z} &= 0 \quad \text{or} \quad 3(e^z)^2 = -1\end{aligned}$$

$$\text{so } e^z = \left(-\frac{1}{3}\right)^{\frac{1}{2}} = \frac{1}{\sqrt{3}}i = \frac{1}{\sqrt{3}}e^{i(\frac{\pi}{2} \pm 2n\pi)}$$

$$e^z = e^{-\frac{1}{2} \ln 3 + i(\frac{\pi}{2} \pm 2n\pi)}, n = 0, 1, 2, \dots$$

$$\therefore z = -\frac{1}{2} \ln 3 + i\pi \left(2n + \frac{1}{2}\right), n = 0, \pm 1, \pm 2, \dots$$

Example 4: Find the real and imaginary parts of $\cot z$.

$$\text{Solution: } \cot z = \frac{\cos z}{\sin z} = \frac{\cos(x+iy)}{\sin(x+iy)}$$

$$\begin{aligned}&= \frac{\cos x \cdot \cosh y - i \sin x \cdot \sinh y}{\sin x \cdot \cosh y + i \cos x \cdot \sinh y}, \quad \text{rationalizing} \\ &= \frac{(\cos x \cosh y - i \sin x \sinh y)(\sin x \cosh y - i \cos x \sinh y)}{\sin^2 x \cosh^2 y + \cos^2 x \sinh^2 y} \\ &= \frac{\cos x \sin x (\cosh^2 y - \sinh^2 y) - i \sinh y \cosh y (\sin^2 x + \cos^2 x)}{\left(\frac{1 - \cos 2x}{2}\right) \left(\frac{1 + \cosh 2y}{2}\right) + \left(\frac{1 + \cos 2x}{2}\right) \left(\frac{\cosh 2y - 1}{2}\right)} \\ &= \frac{\frac{1}{2}(\sin 2x - i \sinh 2y)}{\frac{1}{2}(\cosh 2y - \cos 2x)} = \frac{\sin 2x - i \sinh 2y}{\cosh 2y - \cos 2x}\end{aligned}$$

$$\begin{aligned}\text{Thus } \operatorname{Re}(\cot z) &= \frac{\sin 2x}{\cosh 2y - \cos 2x} \quad \text{and} \\ \operatorname{Im}(\cot z) &= \frac{-\sinh 2y}{\cosh 2y - \cos 2x}.\end{aligned}$$

Example 5: Find the real and imaginary parts of $\operatorname{sech} z$.

Solution: $\operatorname{sech} z = \frac{1}{\cosh z} = \frac{1}{\cosh x \cdot \cosh y + i \sinh x \sin y}$
rationalizing, we get

$$\begin{aligned}\operatorname{sech} z &= \frac{\cosh x \cdot \cosh y - i \sinh x \cdot \sin y}{\cosh^2 x \cdot \cosh^2 y + \sinh^2 x \cdot \sin^2 y} \\ &= \frac{\cosh x \cdot \cosh y - i \sinh x \cdot \sin y}{\left(\frac{1+\cosh 2x}{2}\right)\left(\frac{1+\cosh 2y}{2}\right) + \left(\frac{\cosh 2x-1}{2}\right)\left(\frac{1-\cos 2y}{2}\right)} \\ &= \frac{\cosh x \cdot \cosh y - i \sinh x \cdot \sin y}{\frac{1}{4}(2 \cosh 2x + 2 \cos 2y)}\end{aligned}$$

$$\operatorname{Re}(\operatorname{sech} z) = \frac{2 \cosh x \cdot \cosh y}{\cosh 2x + \cos 2y}$$

$$\operatorname{Im}(\operatorname{sech} z) = \frac{-2 \sinh x \cdot \sin y}{\cosh 2x + \cos 2y}.$$

Example 6: Prove that (a) $\overline{\sin z} = \sin \bar{z}$ (b) $\overline{\cos z} = \cos \bar{z}$ (c) $\overline{\tan z} = \tan \bar{z}$.

$$\begin{aligned}\text{Solution: (a) } \overline{\sin z} &= \overline{\sin(x - iy)} \\ &= \sin x \cdot \cos(-iy) + \sin(-iy) \cos x \\ &= \sin x \cdot \cos iy - \sin(iy) \cos x \\ \sin \bar{z} &= \sin x \cdot \cosh y - i \sinh y \cdot \cos x \quad (1)\end{aligned}$$

$$\text{since } \cos iy = \cosh y, \sin iy = i \sinh y$$

By definition

$$\begin{aligned}\sin z &= \sin x \cosh y + i \cos x \cdot \sinh y \\ \text{so } \overline{\sin z} &= \sin x \cosh y - i \sinh y \cos x \quad (2)\end{aligned}$$

Hence from (1) and (2), $\overline{\sin z} = \sin \bar{z}$

$$\begin{aligned}\text{(b) } \overline{\cos z} &= \overline{\cos(x - iy)} \\ \cos(x - iy) &= \cos x \cos(-iy) - \sin x \cdot \sin(-iy) \\ &= \cos x \cdot \cos(iy) + \sin x \cdot \sin iy \\ &= \cos x \cosh y + i \sinh y \cdot \sin x \quad (3)\end{aligned}$$

$$\text{But } \cos z = \cos x \cdot \cosh y - i \sin x \sinh y$$

$$\text{so } \overline{\cos z} = \cos x \cosh y + i \sin x \sinh y \quad (4)$$

Hence from (3) and (4), $\overline{\cos z} = \cos \bar{z}$

$$\text{(c) } \overline{\tan z} = \overline{\left\{ \frac{\sin z}{\cos z} \right\}} = \frac{\overline{\sin z}}{\overline{\cos z}} = \frac{\sin \bar{z}}{\cos \bar{z}} = \tan \bar{z}$$

Example 7: Find derivative of $\cos z$.

$$\text{Solution: } \frac{d}{dz}(\cos z) = \frac{d}{dz} \left(\frac{e^{iz} + e^{-iz}}{2} \right)$$

But since $\frac{d}{dz}e^{iz} = ie^{iz}$, we have

$$\begin{aligned}\frac{d}{dz}(\cos z) &= \frac{1}{2}i(e^{iz} - e^{-iz}) = \frac{i^2(e^{iz} - e^{-iz})}{2i} \\ &= - \left(\frac{e^{iz} - e^{-iz}}{2i} \right) = -\sin z.\end{aligned}$$

Example 8: Find the derivative of $\tanh z$.

$$\begin{aligned}\text{Solution: } \frac{d}{dz}(\tanh z) &= \frac{d}{dz} \left(\frac{\sinh z}{\cosh z} \right) \\ &= \frac{\cosh z \cdot \cosh z - \sinh z \cdot \sinh z}{\cosh^2 z} = \frac{1}{\cosh^2 z} = \sec^2 hz.\end{aligned}$$

Example 9: Find all zeros of (a) $\sin z$ (b) $\cos z$.

Solution:

a. $\sin z = \sin x \cdot \cosh y + i \cos x \sinh y = 0$ so,
 $\sin x \cosh y = 0$ and $\cos x \cdot \sinh y = 0$.

Since $\cosh y \geq 1$, $\sin x = 0$ or $x = \pm n\pi, n = 0, 1, 2, \dots$. Then $\cos x = \cos(n\pi) = -1 \neq 0$ so $\sinh y = 0$ or $y = 0$.

Thus the zeros of $\sin z$ are $z = x + iy = \pm n\pi, n = 0, 1, 2$

b. $\cos z = \cos x \cdot \cosh y - i \sin x \cdot \sinh y = 0$ so,
 $\cos x \cdot \cosh y = 0$ and $\sin x \cdot \sinh y = 0$.

Since $\cosh y \geq 1$, $\cos x = 0$ or $x = \pm(2n - 1)\frac{\pi}{2}, n = 1, 2, 3, \dots$. Then $\sin x = \sin(2n - 1)\frac{\pi}{2} \neq 0$ so $\sinh y = 0$ or $y = 0$.

Thus the zeros of $\cos z$ are $z = x + iy = \pm(2n - 1)\frac{\pi}{2}, n = 1, 2, \dots$

Example 10: Find all zeros of (a) $\sinh z$ (b) $\cosh z$.

Solution:

$$\text{a. } \sinh z = \frac{1}{2}(e^z - e^{-z}) = 0 \text{ or } (e^z)^2 - 1 = 0$$

$$\begin{aligned}\text{so } e^z &= \pm 1 = e^{\pm 2n\pi i}, n = 0, 1, 2, \dots \\ &= e^{\pm n\pi i} \text{ for } n \text{ odd}\end{aligned}$$

Thus zeros of $\sinh z$ are

$$\begin{aligned}z &= \pm 2n\pi i, n = 0, 1, 2, 3, \dots \\ &= \pm n\pi i, n \text{ odd}\end{aligned}$$

$$\text{b. } \cosh z = \frac{e^z + e^{-z}}{2} = 0 \text{ or } (e^z)^2 + 1 = 0$$

$$\begin{aligned}\text{so } e^z &= \pm i = 1 \cdot e^{\pm i\frac{\pi}{2} \pm 2n\pi i}, n = 0, 1, 2, \dots \\ \text{zeros are } z &= \pm(2n + \frac{1}{2})\pi i, n = 0, 1, 2, \dots\end{aligned}$$

22.20 — HIGHER ENGINEERING MATHEMATICS—VI

Example 11: If $|z| = 1$ prove that $\frac{z^2-1}{z^2+1} = i \tan \theta$

Solution: Since $|z| = 1$, $z = e^{i\theta}$.

Substituting

$$\begin{aligned}\frac{z^2-1}{z^2+1} &= \frac{e^{i2\theta}-1}{e^{i2\theta}+1} = \frac{e^{i\theta}-e^{-i\theta}}{e^{i\theta}+e^{-i\theta}} = i \frac{\left(\frac{e^{i\theta}-e^{-i\theta}}{2i}\right)}{\left(\frac{e^{i\theta}+e^{-i\theta}}{2}\right)} \\ &= i \frac{\sin \theta}{\cos \theta} = i \tan \theta.\end{aligned}$$

Example 12: If $\tan(x+iy) = A+iB$ show that $A^2+B^2+2A \cot 2x = 1$.

Solution: We know that

$$A = \operatorname{Re}(\tan(x+iy)) = \frac{\sin 2x}{\cos 2x + \cosh 2y} \text{ and}$$

$$B = \operatorname{Im}(\tan(x+iy)) = \frac{\sinh 2y}{\cos 2x + \cosh 2y}$$

Now $A^2+B^2+2A \cot 2x$

$$\begin{aligned}&= \frac{\sin^2 2x}{(\cos 2x + \cosh 2y)^2} + \frac{\sinh^2 2y}{(\cos 2x + \cosh 2y)^2} \\ &+ 2 \cdot \frac{\sin 2x}{(\cos 2x + \cosh 2y)} \cdot \cot 2x \\ &= \frac{[\sin^2 2x + \sinh^2 2y + 2 \cos 2x \cdot (\cos 2x + \cosh 2y)]}{(\cos 2x + \cosh 2y)^2} \\ &= \frac{1 + \sinh^2 2y + 2 \cos 2x \cdot \cosh 2y + \cos^2 2x}{(\cos 2x + \cosh 2y)^2} \\ &= \frac{(\cos 2x + \cosh 2y)^2}{(\cos 2x + \cosh 2y)^2} = 1.\end{aligned}$$

EXERCISE

Trigonometric and hyperbolic functions

- Find the real and imaginary parts of (a) $\tan z$ (b) $\sec z$ (c) $\operatorname{cosec} z$ (d) $\tanh z$

Ans.

- $\frac{\sin 2x}{\cos 2x + \cosh 2y}, \frac{\sinh 2y}{\cos 2x + \cosh 2y}$
- $\frac{2 \cos x \cdot \cosh y}{\cos 2x + \cosh 2y}, \frac{2 \sin x \cdot \sinh y}{\cos 2x + \cosh 2y}$
- $\frac{2 \sin x \cdot \cosh y}{\cosh 2y - \cos 2x}, \frac{-2 \cos x \cdot \sinh y}{\cosh 2y - \cos 2x}$
- $\frac{\sinh 2x}{\cosh 2x + \cos 2y}, \frac{\sin 2y}{\cosh 2x + \cos 2y}$

- Find all zeros of (a) $\tan z$ (b) $\cot z$ (c) $\tanh z$ (d) $\coth z$.

Ans. Zeros are the zeros of the numerator

- $z = \pm n\pi$,
- $z = \pm(2n-1)\frac{\pi}{2}$
- $\pm 2n\pi i$, $n = 0, 1, 2, 3$ and $\pm n\pi i$, n odd
- $\pm(2n+\frac{1}{2})\pi i$, $n = 0, 1, 2, \dots$

- If $\cosh(x+iy) = A+iB$, show that $\frac{A^2}{\cosh^2 x} + \frac{B^2}{\sinh^2 x} = 1$ and $\frac{A^2}{\cos^2 y} - \frac{B^2}{\sin^2 y} = 1$

- If $\tan(x+iy) = A+iB$ show that
 - $A^2+B^2-2B \cot 2y+1=0$
 - $A \sinh 2y = B \sin 2x$

Find all the solutions of the equation

$$5. \cos z = 5$$

Ans. $\pm 2n\pi \pm 2.292i$, $n = 0, 1, 2, \dots$

$$6. \cos(2iz+13) = 0$$

Ans. $[(2n-1)\pi+26]i/4$, $n = 0, \pm 1, \pm 2, \dots$

$$7. \cosh z = \frac{1}{2}$$

Ans. $(\pm \frac{1}{3} \pm 2n)\pi i$, $n = 0, 1, 2, \dots$

$$8. \sin z = 2$$

Ans. $2n\pi + \frac{\pi}{2} - i \ln(2+\sqrt{3})$, $n = 0, 1, 2, \dots$

$$9. \sinh z = i$$

Ans. $i(2n+\frac{1}{2})\pi$, $n = 0, 1, 2, \dots$

$$10. \sin z = \cosh 4$$

Ans. $n\pi + (-1)^n(\frac{\pi}{2} - 4i)$, $n = 0, 1, 2, \dots$

- Show that $\tan z = z$ has only real roots.

Hint: From $\frac{\sin 2x}{\cos 2x + \cosh 2y} = x$, $\frac{\sinh 2y}{\cos 2x + \cosh 2y} = y$, we have $\frac{\sin 2x}{x} = \frac{\sinh 2y}{y}$, $\tan x = x$ has solutions but $\tanh y = y$ has no solutions.

- If $\cos(\alpha+i\beta) = re^{i\theta}$, prove that

$$e^{2\beta} = \frac{\sin(\alpha-\theta)}{\sin(\alpha+\theta)}.$$

- Show that $\cos z$, $\cosh z$ are even functions while $\sin z$, $\tan z$, $\sinh z$, $\tanh z$ are odd functions.

Hint: $\cos(-z) = \frac{e^{-z}+e^{-(-z)}}{2} = \frac{e^{-z}+e^z}{2} = \cos z$, etc.

Logarithm

For $z = x + iy \neq 0$, the exponential function $z = e^w \neq 0$ for any w . The natural logarithm of z , denoted by $\ln z$ is defined as the inverse of the exponential function $e^w = z$.

Let $w = u + iv$ and $z = x + iy = re^{i\theta}$.

Then $e^w = e^{u+iv} = e^u e^{iv} = z = re^{i\theta}$ so $e^u = r$ or $u = \ln r$, $v = \theta$.

Thus $\ln z = w = u + iv = \ln r + i(\theta + 2k\pi)$ where $k = 0, 1, 2, 3, \dots$

Here $\theta = \arg z$ can assume infinitely many values which differ by 2π . Hence the complex natural logarithm $\ln z$ is infinitely many valued (unlike the real $\ln$ which is single valued).

$\text{Ln } z$: principal value of $\ln z$ is denoted by $\text{Ln } z$ is the value of $\ln z$ for the principal value of $\arg z$, Θ which lies in $-\pi < \Theta \leq \pi$. Thus

$$\text{Ln } z = \ln r + i\Theta, \quad (r > 0, -\pi < \Theta \leq \pi).$$

$\text{Ln } z$ is single valued since Θ is unique. In general, $\ln z$ can be expressed in terms of $\text{Ln } z$ as

$$\ln z = \text{Ln } z \pm 2n\pi i, \quad n = 1, 2, 3, \dots$$

$\text{Ln } z$ becomes the real natural logarithm when z is positive real ($\because \arg z = 0$).

Analytic

$\ln z$ is analytic everywhere except on the negative real axis ($x = -\pi$).

Derivative

In cartesian form

$$w = \ln z = \ln(x + iy) = \ln r + i\theta$$

$$\ln z = \ln \sqrt{x^2 + y^2} + i \tan^{-1} \left(\frac{y}{x} \right)$$

$$\text{so } u = \ln \sqrt{x^2 + y^2}, \quad v = \tan^{-1} \frac{y}{x}$$

Differentiating partially w.r.t. x

$$u_x = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \frac{1}{\sqrt{x^2 + y^2}} \cdot 2x = \frac{x}{x^2 + y^2}$$

$$v_x = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \left(\frac{-y}{x^2}\right) = -\frac{y}{x^2 + y^2}$$

Then

$$\begin{aligned} \frac{d}{dz}(\ln z) &= u_x + i v_x \\ &= \frac{x}{x^2 + y^2} + i \frac{(-y)}{x^2 + y^2} = \frac{x - iy}{x^2 + y^2} = \frac{\bar{z}}{z\bar{z}} = \frac{1}{z} \end{aligned}$$

Standard results

For any two complex numbers z_1 and z_2 ,

$$\text{a. } \ln(z_1 z_2) = \ln z_1 + \ln z_2 \text{ with } z_1 = r_1 e^{i\theta_1}, \quad z_2 = r_2 e^{i\theta_2}$$

$$\begin{aligned} \ln(z_1 z_2) &= \ln(r_1 r_2 e^{i\theta_1} e^{i\theta_2}) = \ln(r_1 r_2 e^{i(\theta_1 + \theta_2)}) \\ &= \ln(r_1 r_2) + i(\theta_1 + \theta_2) \\ &= (\ln r_1 + \ln r_2) + i\theta_1 + i\theta_2 = \ln z_1 + \ln z_2 \end{aligned}$$

$$\text{b. } \ln(z_1 / z_2) = \ln z_1 - \ln z_2$$

$$\text{c. } \ln z^{m/n} = \frac{m}{n} \ln z.$$

WORKED OUT EXAMPLES

Example 1: Determine all values and the principal value of (a) $\ln(-4)$ (b) $\ln(3i)$ (c) $\ln(\sqrt{3} - i)$.

Solution:

$$\text{a. } z = x + iy = -4, \quad x = -4, \quad y = 0,$$

$$r = x^2 + y^2 = \sqrt{(-4)^2 + 0} = 4,$$

$$-4 = x = r \cos \theta = 4 \cos \theta,$$

$$\cos \theta = -1, \quad \sin \theta = 0 \quad \therefore \theta = \pi.$$

$$\ln z = \ln(-4) = \ln r + i(\theta \pm 2k\pi) =$$

$$\ln 4 + i(\pi \pm 2k\pi)$$

$$\text{principal value: } \text{Ln } z = \ln 4 + i\pi$$

$$\text{b. } \ln 3i = \ln 3 + i\left(\frac{\pi}{2} \pm 2k\pi\right), \quad k = 0, 1, 2, \dots$$

$$\text{principal value: } \ln 3 + i\pi/2$$

$$\text{c. } \ln(\sqrt{3} - i); \quad z = \sqrt{3} - i, \quad x = \sqrt{3}, \quad y = -1;$$

$$r = \sqrt{(\sqrt{3})^2 + (-1)^2} = \sqrt{4} = 2,$$

$$\sqrt{3} = x = r \cos \theta = 2 \cos \theta.$$

$$\cos \theta = \frac{\sqrt{3}}{2}, \quad \sin \theta = -\frac{1}{2} \text{ so } \theta = 2\pi - \frac{\pi}{6} = \frac{11\pi}{6}.$$

$$\ln(\sqrt{3} - i) = \ln 2 + i\left(\frac{11\pi}{6} \pm 2k\pi\right),$$

$$k = 0, 1, 2, \dots$$

$$\text{principal value } \text{Ln } (\sqrt{3} - i) = \ln 2 + i\frac{11\pi}{6}.$$

22.22 — HIGHER ENGINEERING MATHEMATICS—VI

Example 2: Find the modulus and argument of $(i)^{\sqrt{i}}$

Solution: $(i)^{\sqrt{i}} = e^{i \ln \sqrt{i}} = e^{\frac{1}{2} i \ln i}$

$$= e^{\frac{1}{2} i \left\{ \ln 1 \pm \left(i \frac{\pi}{2} \pm 2n\pi \right) \right\}}$$

$$(i)^{\sqrt{i}} = e^{-\frac{1}{2} \left(2n + \frac{1}{2} \right) \pi}$$

modulus is $e^{-(2n+\frac{1}{2})\pi}$, argument 0.

Example 3: Find the real and imaginary parts of $\ln \cos(x + iy)$.

Solution: Let $\ln(Re^{i\phi}) = \ln(R \cos \phi + Ri \sin \phi)$

$$= \ln \cos(x + iy)$$

$$= \ln(\cos x \cdot \cosh y - i \sin x \cdot \sinh y).$$

Thus $R \cos \phi = \cos x \cdot \cosh y$,

$R \sin \phi = -\sin x \sinh y$

Then squaring and adding

$$\begin{aligned} R^2 &= \cos^2 x \cosh^2 y + \sin^2 x \cdot \sinh^2 y \\ &= \left(\frac{1 + \cos 2x}{2} \right) \left(\frac{1 + \cosh 2y}{2} \right) \\ &\quad + \left(\frac{1 - \cos 2x}{2} \right) \left(\frac{\cosh 2y - 1}{2} \right) \\ &= \frac{1}{2} (\cos 2x + \cosh 2y) \end{aligned}$$

Now

$$\frac{R \sin \phi}{R \cos \phi} = \tan \phi = \frac{-\sin x \sinh y}{\cos x \cosh y} = -\tan x \cdot \tanh y$$

Hence

$$\begin{aligned} \ln \cos(x + iy) &= \ln(Re^{i\phi}) = \ln R + i\phi \\ &= \ln \left\{ \frac{1}{\sqrt{2}} \sqrt{\cos 2x + \cosh 2y} \right\} - \\ &\quad - i \tan^{-1}(\tan x \tanh y) \end{aligned}$$

Example 4: If $\tan \ln(x + iy) = a + ib$ such that $a^2 + b^2 \neq 1$, show that

$$\tan \ln(x^2 + y^2) = \frac{2a}{1 - a^2 - b^2}.$$

Solution: Let $\tan \ln(x + iy) = \tan \ln(re^{i\theta})$

$$= \tan\{\ln r + i\theta\} = \tan(A + iB) = a + ib$$

We know that

$$a = \operatorname{Re} \tan(A + iB) = \frac{\sin 2A}{\cos 2A + \cosh 2B} \text{ and}$$

$$b = \operatorname{Im} \tan(A + iB) = \frac{\sinh 2B}{\cos 2A + \cosh 2B}$$

Consider $1 - a^2 - b^2$

$$\begin{aligned} &= 1 - \frac{(\sin^2 2A + \sinh^2 2B)}{(\cos 2A + \cosh 2B)^2} \\ &= \frac{\cos^2 2A + \cosh^2 2B + 2 \cos 2A \cdot \cosh 2B - \sin^2 2A - \sinh^2 2B}{(\cos 2A + \cosh 2B)^2} \\ &= \frac{\cos^2 2A + 1 - \sin^2 2A + 2 \cos 2A \cdot \cosh 2B}{(\cos 2A + \cosh 2B)^2} \\ &= \frac{2 \cos^2 2A + 2 \cos 2A \cdot \cosh 2B}{(\cos 2A + \cosh 2B)^2} = \frac{2 \cos 2A}{(\cos 2A + \cosh 2B)} \end{aligned}$$

So

$$\begin{aligned} \frac{2a}{1 - a^2 - b^2} &= \frac{2 \cdot \sin 2A}{\cos 2A + \cosh 2B} \cdot \frac{\cos 2A + \cosh 2B}{2 \cos 2A} = \tan 2A \\ &= \tan(2 \ln r) = \tan(2 \ln \sqrt{x^2 + y^2}) \\ \frac{2a}{1 - a^2 - b^2} &= \tan(\ln(x^2 + y^2)). \end{aligned}$$

EXERCISE

Find all values and the principal value of:

1. $\ln 1$

Ans. $0, \pm 2n\pi i, n = 0, 1, 2, \dots, \ln 1 = 0$

2. $\ln 4$

Ans. $1.386294 \pm 2n\pi i, \ln 4 = 1.386294$

3. $\ln(-1)$

Ans. $\pm n\pi i, n \text{ odd}, \ln(-1) = \pi i$

4. $\ln(-4)$

Ans. $1.386294 \pm (2n + 1)\pi i,$
 $\ln(-4) = 1.386 + \pi i$

5. $\ln i$

Ans. $\frac{\pi i}{2}, \frac{-3\pi i}{2}, \frac{5\pi i}{2}, \dots, \ln i = \frac{\pi i}{2}$

6. $\ln(-4i)$

Ans. $1.386 - \frac{\pi}{2}i \pm 2n\pi i, \ln(-4i) = 1.386 - \frac{\pi}{2}i$

7. $\ln(3 - 4i)$

Ans. $\ln 5 + i \arg(3 - 4i)$

$$= 1.609 - 0.927i \pm 2n\pi i$$

$$\ln(3 - 4i) = 1.609 - 0.927i$$

$$8. \ln i$$

$$\text{Ans. } e^{-(4n+1)\frac{\pi}{2}}$$

$$9. \ln(1 - i)$$

$$\text{Ans. } \ln \sqrt{2} + \frac{7\pi i}{4} + 2k\pi i$$

$$\text{principal value: } \frac{1}{2} \ln 2 + \frac{7\pi i}{4}$$

$$10. \text{ Find the modulus and argument of } i^{\ln(1+i)}$$

$$\text{Ans. } e^{-\pi^2/8}, \frac{\pi}{4} \ln e^2$$

$$11. \text{ Determine the real and imaginary parts of } \ln \sin(x + iy).$$

$$\text{Ans. } \frac{1}{2} \ln \left[\frac{1}{2} (\cosh 2y - \cos 2x) \right];$$

$$\tan^{-1}(\cot x \cdot \tanh y)$$

$$12. \text{ Show that } \ln \left(\frac{a+ib}{a-ib} \right) = i2 \tan^{-1} \left(\frac{b}{a} \right).$$

$$\text{Hence prove that } \cos \left[i \ln \left(\frac{a+ib}{a-ib} \right) \right] = \frac{a^2 - b^2}{a^2 + b^2}$$

General Powers: $w = z^c$

The general power of a complex number $z = x + iy$ with respect to a complex exponent c is defined by

$$z^c = e^{c \ln z} \quad \text{with } z \neq 0$$

z^c is multivalued since $\ln z$ is infinitely many-valued. The principal value of z^c written as

$$\text{principal value: } \text{of } z^c = e^{c \text{Ln} z}$$

where $\text{Ln} z$ is principal value of $\ln z$.

For any complex number c

$$c^z = e^{z \text{Ln} c}$$

Results

For c, d any complex numbers, $z \neq 0$,

$$1. z^{-c} = \frac{1}{z^c}$$

$$2. z^c z^d = z^{c+d}$$

$$3. z^c / z^d = z^{c-d}$$

$$4. (z^c)^n = z^{cn} \text{ for any integer } n.$$

$$5. \frac{d}{dz} z^c = \frac{d}{dz} e^{c \ln z} = e^{c \ln z} \cdot c \cdot \frac{1}{z} = c \frac{e^{c \ln z}}{e^{\ln z}} =$$

$$c e^{(c-1) \ln z} = c z^{c-1}$$

$$6. \text{ Real and imaginary parts of } (\alpha + i\beta)^{x+iy} :$$

$$(\alpha + i\beta)^{x+iy} = e^{(x+iy) \ln(\alpha + i\beta)} = e^{(x+iy)(\ln r + i(\theta \pm 2n\pi))} :$$

where $r = |\alpha + i\beta|$, $\theta = \arg(\alpha + i\beta)$.

$$(\alpha + i\beta)^{x+iy} = e^{A+iB} = e^A (\cos B + i \sin B)$$

where $B = y \ln r + x(2n\pi + \theta)$.

WORKED OUT EXAMPLES

Example 1: Determine all values of $(1 + i)^i$.

$$\text{Solution: } (1 + i)^i = e^{i \ln(1+i)}$$

Express $1 + i$ in polar form: $x = 1$, $y = 1$, $r = \sqrt{2}$, $\cos \theta = \frac{1}{\sqrt{2}}$, $\sin \theta = \frac{1}{\sqrt{2}}$. Thus $\theta = \frac{\pi}{4} \pm 2n\pi$,

$$1 + i = \sqrt{2} e^{i(\frac{\pi}{4} \pm 2n\pi)}, n = 0, 1, 2, 3, \dots$$

Thus

$$(1 + i)^i = e^{i \ln(1+i)} = e^{i [\ln \sqrt{2} + i(\frac{\pi}{4} \pm 2n\pi)]}$$

since

$$\ln(z) = \ln |z| + i \arg z.$$

$$= e^{i \ln \sqrt{2}} e^{-(\frac{\pi}{4} \pm 2n\pi)}$$

$$= e^{-\frac{\pi}{4} \pm 2k\pi} (\cos \ln \sqrt{2} + i \sin \ln \sqrt{2})$$

where $k = 0, 1, 2, 3, \dots$

Example 2: Find the principal value of $\sqrt{2i}$.

$$\text{Solution: } \sqrt{2i} = (2i)^{\frac{1}{2}} = e^{\frac{1}{2} \ln 2i}$$

$$\text{Now } 2i = 2 \cdot i = 2 \cdot e^{i \frac{\pi}{2} \pm 2n\pi i}$$

$$\ln 2i = \ln 2 + i \left(\frac{\pi}{2} \pm 2n\pi \right), n = 0, 1, 2, 3, \dots$$

$$\text{Ln } 2i = \ln 2 + i \frac{\pi}{2} \quad \text{since } -\pi < \frac{\pi}{2} \leq \pi$$

$$\text{Principal value of } \sqrt{2i} = e^{\frac{1}{2} \text{Ln } 2i}$$

$$= e^{\frac{1}{2} [\ln 2 + i \frac{\pi}{2}]}$$

$$= e^{\frac{1}{2} \ln 2} \cdot e^{i \frac{\pi}{4}} = \sqrt{2} \cdot \left(\cos \frac{\pi}{4} + i \sin \frac{\pi}{4} \right)$$

$$= \sqrt{2} \left(\frac{1}{\sqrt{2}} + i \frac{1}{\sqrt{2}} \right) = 1 + i.$$

Example 3: Find the principal value of

$$\left\{ \frac{1}{2} [e(-1 - i\sqrt{3})] \right\}^{3\pi i}.$$

$$\text{Solution: } \left\{ \frac{1}{2} [e(-1 - i\sqrt{3})] \right\}^{3\pi i}$$

$$= \exp \left[3\pi i \left\{ \ln \left[\frac{1}{2} e(-1 - i\sqrt{3}) \right] \right\} \right]$$

22.24 — HIGHER ENGINEERING MATHEMATICS—VI

$$= \exp \left[3\pi i \left\{ \ln e + \ln \left(-\frac{1}{2} - i \frac{\sqrt{3}}{2} \right) \right\} \right]$$

Consider

$$-\frac{1}{2} - i \frac{\sqrt{3}}{2} = x + iy, \text{ so } x = -\frac{1}{2}, y = -\frac{\sqrt{3}}{2}$$

$$r = \sqrt{\frac{1}{4} + \frac{3}{4}} = 1, \cos \theta = -\frac{1}{2}, \sin \theta = -\frac{\sqrt{3}}{2},$$

$$\theta = \pi + \frac{\pi}{3},$$

Thus

$$-\frac{1}{2} - i \frac{\sqrt{3}}{2} = 1 \cdot e^{i\frac{4\pi}{3}}$$

$$\ln \left(-\frac{1}{2} - i \frac{\sqrt{3}}{2} \right) = \ln 1 + i \left(\frac{4\pi}{3} \pm 2n\pi \right), n = 0, 1, 2.$$

Principal argument which lies in $-\pi < \theta \leq \pi$ is $\frac{4\pi}{3} - 2\pi = -\frac{2\pi}{3}$. Then

$$\text{Ln} \left(-\frac{1}{2} - i \frac{\sqrt{3}}{2} \right) = \ln 1 - i \frac{2\pi}{3} = -\frac{i2\pi}{3}$$

$$\text{principal value of } \left\{ \frac{1}{2} [e(-1 - i\sqrt{3})] \right\}^{3\pi i}$$

$$= \exp \left[3\pi i \left\{ \ln e - \frac{i2\pi}{3} \right\} \right]$$

$$= \exp \left[3\pi i \left\{ 1 - \frac{2\pi i}{3} \right\} \right] = e^{3\pi i} \cdot e^{2\pi^2} = -e^{2\pi^2}.$$

EXERCISE

1. Determine all values of $1^{\sqrt{2}}$.

$$\text{Ans. } \cos 2\sqrt{2}k\pi + i \sin 2\sqrt{2}k\pi, k = 0, 1, 2, 3, \dots$$

2. Find $\text{Re} \{(1 - i)^{1+i}\}$

$$\text{Ans. } e^{\ln \sqrt{2} - 7\pi/4 - 2k\pi} \cdot \cos(7\pi/4 + \ln \sqrt{2}).$$

3. Determine the modulus of $(-i)^{-i}$

$$\text{Ans. } e^{\frac{3\pi}{2} + 2k\pi}, k = 0, 1, 2, 3, \dots$$

Find the principal value of:

4. i^i

$$\text{Ans. } e^{-\pi/2 \pm 2n\pi},$$

$$n = 0, \text{ principal value: } e^{-\pi/2}$$

5. $(1 + i)^{2-i}$

$$\text{Ans. } 2e^{\pi/4 \pm 2n\pi} [\sin \ln \sqrt{2} + i \cos \ln \sqrt{2}]$$

$$n = 0, \text{ principal value: } 2e^{\pi/4} [\sin \ln \sqrt{2} + i \cos \ln \sqrt{2}]$$

$$= 1.490 + 4.126i$$

6. 1^i

$$\text{Ans. } e^{-2k\pi}, k = 0, \text{ principal value: } 1$$

Find all values of:

7. i^{-2i}

$$\text{Ans. } \exp[(4n + 1)\pi], n = 0, \pm 1, \pm 2, \pm 3, \dots$$

$$\text{principal value: } e^\pi$$

8. $(1 - i)^{1+i}$

$$\text{Ans. } \sqrt{2}(1 - i)e^{(2n + \frac{1}{4})\pi} e^{i \ln \sqrt{2}}$$

$$n = 0, \pm 1, \pm 2, \dots,$$

$$\text{principal value: } (1 - i)e^{\pi/4} e^{i \ln \sqrt{2}}$$

9. $\ln i^i$

$$\text{Ans. } -(2n + \frac{1}{2}\pi), n = 0, \pm 1, \pm 2, \dots$$

Find the real part of the principal value of:

10. $i^{\ln(1+i)}$

$$\text{Ans. } e^{-\pi^2/8} \cdot \cos(\frac{\pi}{4} \ln 2)$$

11. $1^{\sqrt{2}}$

$$\text{Ans. } \cos 2k\sqrt{2\pi} + i \sin 2k\sqrt{2\pi}, k = 0, 1, 2, 3, \dots$$

Chapter 23

Complex Integration

INTRODUCTION

The advantage of complex integration is that certain complicated real integrals can be evaluated and properties of analytical functions can be established. In this chapter we consider Cauchy's integral theorem which is one of the fundamental theorems of complex function theory. It gives sufficient conditions for a line integral around a simple closed curve to be zero. An important consequence of this theorem is the Cauchy's integral formula in which the value $f(z_0)$ of an analytic function at z_0 is completely determined by an integral of $f(z)$ on any simple closed curve enclosing z_0 . It is powerful tool in evaluating certain integrals. The complex Taylor series is a direct generalization of the Taylor series of real function. However Laurent series is different from any series in real calculus and is useful in evaluation of both real and complex integrals and in summation of series.

23.1 LINE INTEGRAL IN COMPLEX PLANE

Introduction

Continuous arc: The set of points (x, y) defined by $x = \phi(t)$, $y = \psi(t)$, with parameter t in the interval (a, b) , define a continuous arc provided ϕ and ψ are continuous functions.

Smooth arc If ϕ and ψ are differentiable, arc is said to be smooth.

Simple curve is a curve having no self intersections i.e., no two distinct values of t correspond to the same point (x, y) .

Closed curve is one in which end points coincide i.e., $\phi(a) = \phi(b)$ and $\psi(a) = \psi(b)$.

Simple closed curve is a curve having no self intersections and with coincident end points.

Contour is a continuous chain of a finite number of smooth arcs.

Closed contour is a piecewise smooth closed curve without points of self intersection.

Examples: Boundaries of circle, ellipse, rectangle, triangle.

Positive sense

of traversing a contour is the direction such that the interior domain bounded by the given closed contour remains on the left of the direction of motion.

Line Integral

Definite integral or complex line integral or simply line integral of a complex function $f(z)$ from z_1 to z_2 along a curve c is defined as

$$\begin{aligned}\int_c f(z)dz &= \int_c (u + iv)(dx + idy) \\ &= \int_c (udx - vdy) + i \int_c (vdx + udy) \\ &= \int_{z_1}^{z_2} (u\dot{x} - v\dot{y})dt + i \int_{z_1}^{z_2} (v\dot{x} + u\dot{y})dt\end{aligned}$$

where dot $(\dot{})$ denotes differentiation w.r.t. ' t '.

Here c is known as the path of integration. If it is a closed curve, the line integral is denoted by $\oint_c$

23.2 — HIGHER ENGINEERING MATHEMATICS—VI

(with zero or circle on the integral sign). When the direction is positive sense, it is indicated as $\int_{c+}$ or simply $\int_c$ while negative direction by $\int_{c-}$. Contour integral is an integral along a closed contour.

Basic Properties of Line Integrals

1. Linearity:

$$\int_c \left(k_1 f(z) + k_2 g(z) \right) dz = k_1 \int_c f(z) dz + k_2 \int_c g(z) dz$$

2. Sense reversal:

$$\int_A^B f(z) dz = - \int_B^A f(z) dz$$

3. Partitioning of path:

$$\int_c f(z) dz = \int_{c_1} f(z) dz + \int_{c_2} f(z) dz$$

where curve c consists of the curves c_1 and c_2

Fig. 23.1

4. ML-inequality:

$$\left| \int_c f(z) dz \right| \leq ML$$

where $|f(z)| \leq M$ everywhere on c and L is the length of the curve c .

Note: Although real definite integrals are interpreted as area, no such interpretation is possible for complex definite integrals.

Simply connected domain D is a domain such that every simple closed path in D contains only points of D .

Example 1: Interior of circle, rectangle, triangle, ellipse.

Multiply connected domain is one that is not simply connected (Fig. 23.2).

Example 2: Annulus region, regions with holes.

Fig. 23.2

Evaluation of Complex Line Integral

I. By indefinite integration (of analytic functions):
If $f(z)$ is analytic in a simply connected domain D then

$$\int_{z_1}^{z_2} f(z) dz = F(z_2) - F(z_1)$$

where $F'(z) = \frac{dF}{dz} = f(z)$ in D . (See "Independence of path" on page 23.7.)

II. By use of the path:

If curve c is represented by $z = z(t)$, $a \leq t \leq b$
Then

$$\int_c f(z) dz = \int_a^b f(z(t)) \frac{dz}{dt} dt$$

i.e., the line integral is converted to an ordinary integral in t by making use of the property (nature) of the curve c .

WORKED OUT EXAMPLES

Example 1: Evaluate $\oint_c |z|^2 dz$ around the square with vertices at $(0, 0)$, $(1, 0)$, $(1, 1)$, $(0, 1)$ (refer Fig. 23.3).

Fig. 23.3

Solution: Square c consists of four curves (lines)
 $c_1 : AB$, $c_2 : BC$, $c_3 : CD$, $c_4 : DA$.

$$\begin{aligned} I &= \oint_c |z|^2 dz = \int_{c_1+c_2+c_3+c_4} (x^2 + y^2)(dx + i dy) \\ &= \int_{c_1} + \int_{c_2} + \int_{c_3} + \int_{c_4} \\ &= I_1 + I_2 + I_3 + I_4 \end{aligned}$$

Along $c_1 : AB : y = 0, 0 \leq x \leq 1$.

$$\begin{aligned} I_1 &= \int_{c_1} (x^2 + y^2)(dx + i dy) \\ &= \int_0^1 (x^2 + 0)dx = \frac{x^3}{3} \Big|_0^1 = \frac{1}{3} \end{aligned}$$

Along $c_2 : BC : x = 1, 0 \leq y \leq 1$

$$\begin{aligned} I_2 &= \int_{c_2} (x^2 + y^2)(dx + i dy) \\ &= \int_0^1 (1 + y^2)i dy = i \left(y + \frac{y^3}{3} \right) \Big|_0^1 = \frac{4}{3}i \end{aligned}$$

Along $c_3 : y = 1$ and x varies from 1 to 0

$$\begin{aligned} I_3 &= \int_{c_3} (x^2 + y^2)(dx + i dy) \\ &= \int_1^0 (x^2 + 1)dx = \left(\frac{x^3}{3} + x \right) \Big|_1^0 = -\frac{4}{3} \end{aligned}$$

Along $c_4 : x = 0, y$ varies from 1 to 0

$$\begin{aligned} I_4 &= \int_{c_4} (x^2 + y^2)(dx + i dy) \\ &= \int_1^0 y^2 i dy = i \frac{y^3}{3} \Big|_1^0 = -\frac{i}{3} \\ I &= I_1 + I_2 + I_3 + I_4 \\ &= \frac{1}{3} + \frac{4}{3}i - \frac{4}{3} - \frac{i}{3} = -1 + i \end{aligned}$$

Example 2: Evaluate $\int_c (z - z^2)dz$ where c is the upper half of the circle $|z - 2| = 3$ (Fig. 23.4). What is the value of the integral if c is the lower half of the above circle?

Solution: Equation of the circle is $z - 2 = 3e^{i\theta}$ or

$$z = 2 + 3e^{i\theta}, z^2 = (2 + 3e^{i\theta})^2$$

$$z - z^2 = (2 + 3e^{i\theta}) - (2 + 3e^{i\theta})^2 = -2 - 9e^{i\theta} - 9e^{i2\theta}$$

$$dz = 3ie^{i\theta} d\theta.$$

$$\begin{aligned} \int_c (z - z^2)dz &= - \int_0^\pi (2 + 9e^{i\theta} + 9e^{i2\theta})(i3e^{i\theta})d\theta \\ &= -3i \left[\frac{2e^{i\theta}}{i} + \frac{9e^{i2\theta}}{2i} + \frac{9e^{i3\theta}}{3i} \right]_0^\pi \\ &= -3[-4 + 0 - 6] = 30 \end{aligned}$$

Fig. 23.4

For the lower semicircle

$$\begin{aligned} \int_c (z - z^2)dz &= - \int_\pi^{2\pi} (2 + 9e^{i\theta} + 9e^{i2\theta})(3ie^{i\theta})d\theta \\ &= -3 \left[2e^{i\theta} + 9e^{i2\theta} + 3e^{i3\theta} \right]_\pi^{2\pi} = -30 \end{aligned}$$

Example 3: Evaluate $\int_c f(z)dz$, where

$$f(z) = \begin{cases} 4y & \text{when } y > 0 \\ 1 & \text{when } y < 0 \end{cases} \quad \text{and } c \text{ is the arc}$$

from $z = -1 - i$ to $z = 1 + i$ of the cubical curve $y = x^3$ (see Fig. 23.5).

Solution:

$$\int_c f(z)dz = \int_{BOA} = \int_{BO} + \int_{OA} = \int_{c_1} + \int_{c_2}$$

Fig. 23.5

Along $BO : c_2 : (y < 0), f(z) = 1, y = x^3$

$$dz = dx + i dy = dx + i3x^2 dx$$

x : varies from -1 to 0

$$\int_{c_2} f(z)dz = \int_{-1}^0 1 \cdot (1 + 3x^2 i)dx$$

23.4 — HIGHER ENGINEERING MATHEMATICS—VI

$$= x + x^3 i \Big|_{-1}^0 = 1 + i$$

Along $c_1 : (y > 0), f(z) = 4y, y = x^3, x : \text{varies from } 0 \text{ to } 1$

$$\begin{aligned} \int_{c_1} f(z) dz &= \int_0^1 4y(dx + i dy) \\ &= \int_0^1 4y \left(\frac{1}{3} y^{-\frac{2}{3}} + i \right) dy \end{aligned}$$

since $x = y^{\frac{1}{3}}, dx = \frac{1}{3} y^{-\frac{2}{3}} dy$.

$$= y^{\frac{4}{3}} + 2y^2 i \Big|_0^1 = 1 + 2i$$

Thus

$$\int_c f(z) dz = \int_{c_1} + \int_{c_2} = (1 + i) + (1 + 2i) = 2 + 3i.$$

Example 4: Find an upper bound for the absolute value of the integral $\int_c (e^z - \bar{z}) dz$ where c denotes the boundary of the triangle with vertices at the points $z = 0, -4, 3i$ (refer Fig. 23.6).

Solution: From the ML-inequality

$$\begin{aligned} \left| \oint_c f(z) dz \right| &\leq ML \\ \left| \oint_c (e^z - \bar{z}) dz \right| &= \left| \oint_c e^z dz - \oint_c \bar{z} dz \right| \\ &\leq \left| \oint_c e^z dz \right| + \left| \oint_c \bar{z} dz \right| \end{aligned}$$

But $\oint_c e^z dz = 0$ since e^z is analytic everywhere, (see Page 23.6) so $\left| \oint_c \bar{z} dz \right| \leq (\text{Max} \cdot |\bar{z}| \text{ on } c) \cdot (\text{Length of } c).$

Fig. 23.6

Length of $c = AB + BC + CA = 4 + 3 + 5 = 12$
For straight line maximum occurs at the end points.

$$|\bar{z}| = \sqrt{x^2 + y^2}$$

Along $AB : y = 0, |\bar{z}| = 4$

Along $BC : x = 0, |\bar{z}| = 3$

Along $CA : \text{Max} |\bar{z}| = \text{Max}[C \text{ or } A] = \text{Max}[4, 3] = 4$

Thus maximum value of $\bar{z}$ on c is 4.

$$\text{Hence } \left| \oint_c (e^z - \bar{z}) dz \right| \leq \left| \oint_c \bar{z} dz \right| \leq (4)(12) = 48$$

Example 5: Evaluate $\int_c \text{Re } z dz$ where c is (a) shortest path from $1 + i$ to $3 + 2i$ (b) along the straight line from $(1, 1)$ to $(3, 1)$ and then from $(3, 1)$ to $(3, 2)$ (c) Are the two integrals in (a), (b) equal. If not give reason (see Fig. 23.7).

Solution:

a. The shortest path from A to B is the straight line $y = \frac{x+1}{2}$. So

$$\begin{aligned} \int_c \text{Re } z dz &= \int_{AB} x(dx + i dy) \\ &= \int_1^3 x \left(dx + i \frac{1}{2} dx \right) \\ &= \frac{x^2}{2} + \frac{x^2}{4} i \Big|_1^3 = 4 + 2i \end{aligned}$$

Fig. 23.7

b. $\int_c \text{Re } z dz = \int_{AD+DB} = \int_{AD} + \int_{DB} = I_1 + I_2$
Along $AD : y = 1, x : \text{varies from } 1 \text{ to } 3, dy = 0$

$$I_1 = \int_{AD} \text{Re } z dz = \int_1^3 x dx = \frac{x^2}{2} \Big|_1^3 = 4$$

Along $DB : x = 3, y : \text{varies from } 1 \text{ to } 2, dx = 0$

$$I_2 = \int_{DB} \text{Re } z dz = \int_1^2 3 \cdot i dy = 3iy \Big|_1^2 = 3i$$

$$\int_c \operatorname{Re} z \, dz = I_1 + I_2 = 4 + 3i$$

- c. Integral values along path AB is not equal to integral value along ADB since the integrand $f(z) = \operatorname{Re} z = x$ is not analytic (see Page 609).

Example 6: Evaluate

a. $\int_i^1 (z+1)^2 dz = \int_i^1 (z+1)^2 d(z+1) = \left. \frac{(z+1)^3}{3} \right|_i^1$

$$= \frac{8}{3} - \frac{(i+1)^3}{3} = \frac{10-2i}{3}$$

b. $\int_0^i z e^{z^2} dz = \frac{1}{2} \int e^t dt$ where $t = z^2$
 $= \frac{1}{2} e^t = \left. \frac{1}{2} e^{z^2} \right|_0^i = \frac{1}{2} [e^{-1} - 1]$

c. $\int_0^{\pi i} \cos z \, dz = \sin z \Big|_0^{\pi i} = \sin(i\pi) = i \sinh \pi$

d. $\int_{-\pi i}^{\pi i} \sin^2 z \, dz = \int_{-\pi i}^{\pi i} \frac{1 - \cos 2z}{2} dz = \left. \frac{1}{2} z - \frac{\sin 2z}{4} \right|_{-\pi i}^{\pi i}$
 $= \frac{1}{2}(\pi i + \pi i) - \frac{1}{4}[\sin(2\pi i) - \sin(-2\pi i)]$
 $= \pi i - \frac{1}{2}i \sinh 2\pi$

e. $\int_0^{2i} \sinh z \, dz = \cosh z \Big|_0^{2i} = \cosh 2i - 1 = \cos 2 - 1.$

EXERCISE

Integrate the given function along the given curve c :

1. z^2 ,

a. c_1 : straight line segment $z = 0$ to $z = 2 + i$

b. c_2 : straight line from $(0, 0)$ to $(2, 0)$ and then from $(2, 0)$ to $(2, 1)$

Ans. (a) $\frac{2}{3} + \frac{11}{3}i$ (b) $\frac{2}{3} + \frac{11}{3}i$

2. $\operatorname{Re} z$,

a. c_1 : straight line segment from $z = 0$ to $z = 1 + 2i$

b. c_2 : from $(0, 0)$ to $(1, 0)$ along real axis and then from $(1, 0)$ to $(1, 2)$ vertically.

Ans. (a) $\frac{1}{2} + i$ (b) $\frac{1}{2} + 2i$

3. $(\bar{z})^2$ from 0 to $2 + i$

a. along the line $2y = x$

b. from $(0, 0)$ to $(2, 0)$ along real axis and then from $(2, 0)$ to $(2, 1)$ vertically

Ans. (a) $\frac{5(2-i)}{3}$ (b) $\frac{(14+11i)}{3}$

4. $12z^2 - 4iz : c : y = x^3 - 3x^2 + 4x - 1$ joining $(1, 1)$ and $(2, 3)$

5. $z^2, c : x = 4 - y^2$ from $y = 2$ to -2 ,

Ans. $\frac{16i}{3}$

6. $|z|\bar{z}, c$: consisting of upper semicircle $|z| = 1$ and the line segment $-1 \leq x \leq 1$.

Ans. πi

7. $\bar{z}, c$: (a) circle $|z - 2| = 3$, (b) Square with vertices at $z = 0, 2, 2i, 2 + 2i$, (c) Ellipse $|z - 3| + |z + 3| = 10$.

Ans. (a) $18\pi i$ (b) $8i$ (c) $40\pi i$

8. $\frac{z+2}{z} c$:

a. Circle of radius 2, centre origin.

b. Upper semi-circle.

c. Lower semi-circle.

Hint: Take $z = 2e^{i\theta}$, θ varies from

(a) $-\pi$ to π (b) 0 to π (c) 0 to $-\pi$.

Ans. (a) $4\pi i$ (b) $-4 + 2\pi i$ (c) $-4 - 2\pi i$

9. $8\bar{z} + 3z, c : x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}}$

Ans. $6\pi i a^2$

10. $\pi e^{\pi \bar{z}}, c$: square with vertices $0, 1, 1 + i, i$

Ans. $4(e^\pi - 1).$

Indefinite integration

Evaluate:

1. $\int_0^{1+i} z^2 dz$ Ans. $-\frac{2}{3} + \frac{2}{3}i$

2. $\int_{-\pi i}^{\pi i} \cos z \, dz$ Ans. $2i \sinh \pi$

3. $\int_{8+\pi i}^{8-\pi i} e^{\frac{z}{2}} dz$ Ans. 0

4. $\int_{-i}^i \frac{dz}{z}$ Ans. $i\pi$

5. $\int_{3i}^{1-i} 4z \, dz$ Ans. $18 - 4i$

6. $\int_0^1 z e^{2z} dz$ Ans. $\frac{1}{4}(e^2 + 1)$

7. $\int_0^{2\pi} z^2 \sin 4z \, dz$ Ans. $-\pi^2$

8. $\int_{2i}^3 \sin z \, dz$ Ans. $\cosh 2 - \cos 3$

9. $\int_3^{-3} z^{\frac{1}{2}} dz$ Ans. $-2\sqrt{3}(1 + i)$

23.6 — HIGHER ENGINEERING MATHEMATICS—VI

$$10. \int_{-1}^1 z^i dz \quad \text{Ans. } \frac{1+e^{-\pi}}{2}(1-i)$$

$$11. \int_{-i}^i z \cosh z^2 dz \quad \text{Ans. } 0$$

$$12. \int_1^{1+\pi i} e^z dz \quad \text{Ans. } -2e$$

$$13. \int_0^{1+i\pi} (z^2 + \cosh 2z) dz$$

$$\text{Ans. } \frac{1}{3} - \pi^2 + \frac{\sinh 2}{2} + \frac{i\pi}{3}(3 - \pi^2).$$

ML-inequality

Find an upper bound for the absolute value of the integral, without actually evaluating the integral

$$1. \int_c z^2 dz, c: \text{straight line from } 0 \text{ to } 1+i$$

$$\text{Ans. } 2\sqrt{2}, M = 2, L = \sqrt{2}$$

$$2. \int_c \sin z dz, c: \text{straight line from } 3 \text{ to } 2i.$$

$$\text{Ans. } \sqrt{13}\sqrt{\cosh 4}, M = \sqrt{\cosh^2 2 + \sinh^2 2}, L = \sqrt{13}$$

$$3. \int_c \frac{dz}{z(z-2)^3}, c: |z| = 5.$$

$$\text{Ans. } \frac{2\pi}{27}, L = 2\pi 5, M = \frac{1}{(5)(27)}$$

$$4. \int_c \frac{(z^2+3)e^{iz} \ln z}{z^2-2} dz, c: z = 2e^{i\theta}, 0 \leq \theta \leq \frac{\pi}{3}$$

$$\text{Ans. } ML = \left[7(3 \ln 2 + \pi) \frac{\pi}{9} \right] \left[\frac{2\pi}{3} \right]$$

$$5. \int_c \frac{dz}{z^2+1}, c: |z| = 2 \text{ in 1st quadrant.}$$

$$\text{Ans. } ML = \left(\frac{1}{3} \right) \cdot (\pi)$$

$$6. \int_c \frac{dz}{z^4}, c: \text{Line segment from } i \text{ to } 1.$$

$$\text{Hint: } y = 1 - x, |z^4| = \left[2 \left(x - \frac{1}{2} \right)^2 + \frac{1}{2} \right]^2 \geq \frac{1}{4}$$

$$\text{Ans. } ML = 4 \cdot (\sqrt{2}).$$

$$7. \text{ Show that } \left| \int_c z^2 dz \right| \leq 10, c: \text{Line from } i \text{ to } 2+i. \text{ Compare with exact value.}$$

$$\text{Ans. } ML = (5)(2), \text{ Exact value} = \sqrt{\frac{148}{9}} = 4.055.$$

23.2 CAUCHY'S INTEGRAL THEOREM

If $f(z)$ is analytic in a simply connected domain D then

$$\oint_c f(z) dz = 0$$

for any simple closed curve c lying entirely within D (Fig. 23.8).

Fig. 23.8

Proof: Consider

$$\begin{aligned} \oint_c f(z) dz &= \oint_c \left(u(x, y) + i v(x, y) \right) [dx + i dy] \\ &= \oint_c (u dx - v dy) + i \oint_c (u dy + v dx) \\ &= I_1 + I_2 \end{aligned}$$

u and v have continuous partial derivative in D because $f(z)$ is analytic and f' is assumed to be continuous. Applying Green's theorem in plane for I_1 ,

$$I_1 = \oint_c u dx - v dy = \int \int_R \left(-\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) dx dy = 0$$

since from Cauchy-Riemann equations $u_y = -v_x$. Here R is the region bounded by c .

Similarly,

$$I_2 = \oint_c u dy - v dx = \int \int_R \left(\frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right) dx dy = 0$$

since $u_x = v_y$. Thus

$$\oint f(z) dz = I_1 + I_2 = 0 + 0 = 0.$$

Thus Cauchy's theorem establishes one of the basic properties of an analytic function that the integral of an analytic function around any simple closed curve lying entirely in the simply connected domain of its analyticity is zero.

Note 1: Cauchy's integral theorem is also known as Cauchy's theorem.

Note 2: Cauchy's theorem without the assumption that f' is continuous is known as Cauchy's-Goursat theorem.

Note 3: Simply connectedness is essential.

Example: $\int_c \frac{dz}{z-1}, c: 1 < |z-1| < 2$. Although $\frac{1}{(z-1)}$ is analytic in the annulus, integral is not zero, since annulus is not simply connected.

Independence of Path

Let $f(z)$ be analytic in a simply connected domain D . Let c_1 and c_2 be any two paths in D joining any two points Z_1 and Z_2 in D and having no further points in common (Fig. 23.9). Then

$$\int_{c_1} f(z)dz = \int_{c_2} f(z)dz$$

Fig. 23.9

both c_1 and c_2 traversed in the same direction i.e., the integral of $f(z)$ from z_1 to z_2 is independent of the path joining them (however it depends on the points z_1 and z_2).

Proof: The two curves c_1, c_2 together form a simple closed curve c in D . By Cauchy's theorem

$$\oint_c f(z)dz = \int_{c_1} f(z)dz + \int_{c_2} f(z)dz = 0$$

or $\int_{c_1} f(z)dz = - \int_{c_2} f(z)dz = \int_{c_2} f(z)dz$

where now c_1 and c_2 are both traversed in the same direction.

Principal of Deformation of Path

From independence of path, it appears as if the path c_2 is obtained by continuous deformation of path c_1 .

Cauchy's Theorem for Multiply Connected Domains

Fig. 23.10

A multiply connected domain can be cut such that the resulting domain is simply connected. For example by one cut c^* the doubly connected domain spreads into a simply connected domain (without any holes) (refer Fig. 23.10). Applying Cauchy's

theorem along the oriented boundary B consisting of c_1, c^*, c_2, c^* , we have

$$\oint_B f(z)dz = \int_{c_1+c^*+c_2+c^*} f(z)dz = 0$$

or $\oint_{c_1} + \int_{c^*} + \oint_{c_2} - \int_{c^*} = 0.$

Thus $\oint_{c_1} f(z)dz = \oint_{c_2} f(z)dz$

where c_1 and c_2 are both traversed in the same direction. Similar result can be obtained for triply connected domain by introducing two cuts c_1^* and c_2^* , resulting

$$\int_{c_1} f(z)dz = \oint_{c_2} f(z)dz + \oint_{c_3} f(z)dz$$

where c_1, c_2, c_3 are all traversed in the same direction (see Fig. 23.11).

Fig. 23.11

Evaluation of line integrals by indefinite integration: If $f(z)$ is analytic in simply connected domain D , there exists $F(z)$ such that $F'(z) = f(z)$ and

$$\int_{z_1}^{z_2} f(z)dz = F(z_2) - F(z_1)$$

along any path joining z_1 to z_2 . (See WE 6 on page 23.5)

Integral of Integer Powers

Book Work: Prove that

$$I = \oint_c (z-a)^n dz = \begin{cases} 0 & \text{if } n \neq -1, \quad a \text{ inside } c \\ 2\pi i & \text{if } n = -1, \quad a \text{ inside } c \\ 0 & \text{if } n = -1, \quad a \text{ outside } c \end{cases}$$

Here n is any integer (positive, negative or zero) a is a complex number. Curve c is oriented counter-clockwise and is

- Circle with centre at a and of radius R .
- Any arbitrary simple closed (piecewise smooth) curve (refer Fig. 23.12).

Fig. 23.12

Proof:

a. c : circle $z - a = Re^{i\theta}$, i.e., a is inside c .

$$I = \int_0^{2\pi} (Re^{i\theta})^n \cdot (iRe^{i\theta})d\theta$$

$$I = iR^{n+1} \int_0^{2\pi} e^{i(n+1)\theta} d\theta$$

Suppose $n \neq -1$,

$$I = iR^{n+1} \cdot \left. \frac{e^{i(n+1)\theta}}{i(n+1)} \right|_0^{2\pi}$$

$$I = \frac{iR^{n+1}}{(n+1)} \cdot [\cos(n+1)2\pi - \cos 0] = 0$$

Suppose $n = -1$, $I = i \int_0^{2\pi} d\theta = 2\pi i$

Suppose $n = -1$ and a is outside circle c .

$I = \int_c \frac{dz}{z-a} = 0$ by Cauchy's theorem since $\frac{1}{z-a}$ is analytic inside c .

b. c : any simple closed curve enclosing a circle c^* : $z - a = Re^{i\theta}$ i.e., c^* is circle with centre at a and of radius R (Fig. 23.13).

Fig. 23.13

Suppose a is inside c . Then $(z - a)^n$ for any n is analytic on and between c and c^* . By Cauchy's theorem for multiply connected domains.

$$\oint_c (z - a)^n dz = \int_{c^*} (z - a)^n dz = \begin{cases} 0, & n \neq -1 \\ 2\pi i, & n = -1. \end{cases}$$

Suppose a is outside c . Then by Cauchy's theorem

$$\int_c (z - a)^n dz = 0$$

Result: $\oint_c \frac{dz}{z} = 2\pi i$, where c : unit circle $|z| = 1$.

Example: Evaluate $I = \oint_c \frac{dz}{z-2}$ around

a. Circle $|z - 2| = 4$

b. Circle $|z - 1| = 5$

c. Rectangle with vertices at $3 \pm 2i$, $-2 \pm 2i$

d. Triangle with vertices at $(0, 0)$, $(1, 0)$, $(0, 1)$.

Solution:

a. $2 \in c$, by above book work with $n = -1$, $I = 2\pi i$ (Fig. 23.14).

Fig. 23.14

b. $2 \in c$: $n = -1$, $I = 2\pi i$ (Fig. 23.15).

Fig. 23.15

c. $2 \in c$, $n = -1$, $I = 2\pi i$ (Fig. 23.16)

Fig. 23.16

- d. $2 \notin \text{triangle}$. $\frac{1}{z-2}$ is analytic in c . By Cauchy's theorem $I = 0$ (Fig. 23.17).

Fig. 23.17

Example: Evaluate $\int_c \frac{1}{z^3} dz$, $c: |z| = 1$

Integral is zero by above book work. Thus f is analytic is a sufficient condition but not necessary.

WORKED OUT EXAMPLES

Example 1: Evaluate $\oint_c (5z^4 - z^3 + 2) dz$ around

- Unit circle $|z| = 1$
- Square with vertices at $(0, 0)$, $(1, 0)$, $(1, 1)$, $(0, 1)$
- Curve consisting of the parabola $y = x^2$ from $(0, 0)$ to $(1, 1)$ and $y^2 = x$ from $(1, 1)$ to $(0, 0)$.

Solution: $f(z) = 5z^4 - z^3 + 2$ is analytic everywhere. So by Cauchy's integral theorem, $\oint_c f(z) dz$ equals to zero for any simple closed curve. The curves in (a), (b) and (c) are all simple closed (piecewise smooth) curves. Therefore

$$\oint_c (5z^4 - z^3 + 2) dz = 0$$

for c in (a), (b) and (c) i.e., in all cases.

Example 2: Verify Cauchy's integral theorem for $f(z) = z^2$ taken over the boundary of a square with vertices at $\pm 1 \pm i$ in counter-clockwise direction (Fig. 23.18).

Solution:

- By Cauchy's theorem, $\oint_c z^2 dz = 0$ since z^2 is analytic everywhere and c the boundary of the square is a closed piecewise-smooth simple curve
- By direct evaluation,

Fig. 23.18

The boundary of square c consists of four curves (lines) c_1, c_2, c_3, c_4 . So

$$\begin{aligned} I &= \oint_c z^2 dz = \int_{c_1} + \int_{c_2} + \int_{c_3} + \int_{c_4} \\ &= I_1 + I_2 + I_3 + I_4. \end{aligned}$$

Along c_1 : $EA: x = 1, -1 \leq y \leq 1, dz = idy$

$$\begin{aligned} I_1 &= \int_{c_1} z^2 dz = \int_{-1}^1 (1 + iy)^2 idy \\ &= \int_{-1}^1 (1 - y^2 + 2iy) idy = \frac{4}{3} \end{aligned}$$

Along c_2 : $AB, y = 1, -1 \leq x \leq 1, dz = dx$

$$\begin{aligned} I_2 &= \int_{c_2} z^2 dz = \int_1^{-1} (x + i)^2 dx \\ &= \int_1^{-1} (x^2 - 1 + 2ix) dx = -\frac{4}{3} \end{aligned}$$

Along c_3 : $BD, x = -1, -1 \leq y \leq 1, dz = idy$

$$\begin{aligned} I_3 &= \int_{c_3} z^2 dz = \int_1^{-1} (-1 + iy)^2 idy \\ &= \int_1^{-1} (1 - y^2 - 2iy) idy = -\frac{4}{3} \end{aligned}$$

Along c_4 : $DE: y = -1, -1 \leq x \leq 1, dz = dx$

$$\begin{aligned} I_4 &= \int_{c_4} z^2 dz = \int_{-1}^1 (x - i)^2 dx \\ &= \int_{-1}^1 (x^2 - 1 - 2ix) dx = -\frac{4}{3} \end{aligned}$$

$$\begin{aligned} \text{So } \oint_c z^2 dz &= I_1 + I_2 + I_3 + I_4 \\ &= \frac{4}{3} - \frac{4}{3} + \frac{4}{3} - \frac{4}{3} = 0. \end{aligned}$$

23.10 — HIGHER ENGINEERING MATHEMATICS—VI

Example 3: Evaluate $\int_c (z^2 + 3z)dz$ along:

- Circle $|z| = 2$ from $(2, 0)$ to $(0, 2)$ in counter-clockwise direction.
- The straight line from $(2, 0)$ to $(0, 2)$.
- The straight lines from $(2, 0)$ to $(2, 2)$ and then from $(2, 2)$ to $(0, 2)$. Is the integral independent of path? Why?

Solution:

- a. $c_1 : |z| = 2$ or $z = 2e^{i\theta}$ (Fig. 23.19).

$$\begin{aligned} \int_{c_1} (z^2 + 3z)dz &= \int_0^{\frac{\pi}{2}} [4e^{i2\theta} + 6e^{i\theta}] 2ie^{i\theta} d\theta = 4i \left[\frac{2e^{i3\theta}}{3i} + \frac{3e^{i2\theta}}{2i} \right]_0^{\frac{\pi}{2}} \\ &= -\frac{8}{3}(i+1) - 12 = -\frac{44}{3} - \frac{8}{3}i \end{aligned}$$

Fig. 23.19

- b. $c_2 : x + y = 2; y = 2 - x, dz = (1 - i)dx$, (Fig. 23.19)

$$\begin{aligned} \int_2^0 \left\{ [x + i(2-x)]^2 + 3[x + i(2-x)] \right\} (1-i)dx \\ = \int_2^0 [x^2 - (2-x)^2 + 2ix(2-x) + 3x + 3i(2-x)] (1-i)dx = -\frac{44}{3} - \frac{8}{3}i \end{aligned}$$

Fig. 23.20

- c. $c : c_1 + c_2$ Along $c_1 : x = 2, 0 \leq y \leq 2, dz = idy$ (Fig. 23.21)

$$\int_{c_1} = \int_0^2 [(2+iy)^2 + 3(2+iy)] idy$$

$$= -14 + \frac{52}{3}i$$

Fig. 23.21

Along $c_2 : y = 2, 0 \leq x \leq 2, dz = dx$

$$\begin{aligned} \int_{c_2} &= \int_2^0 [(x+2i)^2 + 3(x+2i)] dx = -\left[\frac{2}{3} + 20i \right] \\ \int_c &= \int_{c_1} + \int_{c_2} = -14 + \frac{52}{3}i - \frac{2}{3} - 20i = -\frac{44}{3} - \frac{8}{3}i \end{aligned}$$

Yes. The integral is independent of path because the integrand $f(z) = z^2 + 3z$ is analytic, everywhere.

Example 4: Evaluate $\oint_c \frac{2z^3 + z^2 + 4}{z^4 + 4z^2} dz$ where c is the circle $|z - 2| = 4$, clockwise.

Solution: Integrand has 3 singular points at $z = 0, \pm 2i$, all of which lie inside the circle c . By partial fractions (see Fig. 23.22).

$$\frac{2z^3 + z^2 + 4}{z^4 + 4z^2} = \frac{Az + B}{z^2} + \frac{D}{z + 2i} + \frac{E}{z - 2i}$$

Fig. 23.22

$$A = 0, B = D = E = 1.$$

$$\begin{aligned} I &= \oint_c \frac{2z^3 + z^2 + 4}{z^4 + 4z^2} dz \\ &= \oint_c \frac{dz}{z^2} + \oint_c \frac{dz}{z + 2i} + \oint_c \frac{dz}{z - 2i} \end{aligned}$$

By principle of deformation of path

$$= \oint_{c_1} \frac{dz}{(z-0)^2} + \oint_{c_2} \frac{dz}{z - (-2i)} + \oint_{c_3} \frac{dz}{z - 2i}$$

where c_1, c_2, c_3 are circles with centres at $0, -2i, 2i$ and such that they are non-overlapping inside c .
By applying the book work

$$\int_c (z-a)^n dz = \begin{cases} 0, & n \neq -1 \\ 2\pi i, & n = -1 \end{cases}$$

$$I = 0 - 2\pi i - 2\pi i = -4\pi i$$

The minus sign is because curve is traced in the clockwise direction.

Example 5: If n is a positive integer, show that

$$\int_0^{2\pi} e^{\sin n\theta} \cos(\theta - \cos n\theta) d\theta$$

$$= \int_0^{2\pi} e^{\sin n\theta} \cdot \sin(\theta - \cos n\theta) d\theta = 0$$

Solution: Consider $\int_c e^{z^n} dz$ where $c : |z| = 1$. So

$$z = x + iy = \sin \theta + i \cos \theta, z^n = \sin n\theta + i \cos n\theta,$$

$$dz = (\cos \theta - i \sin \theta) d\theta, \theta : \text{varies from } 0 \text{ to } 2\pi.$$

Thus

$$\int_c e^{z^n} dz = \int_0^{2\pi} e^{(\sin \theta + i \cos \theta)^n} \cdot (\cos \theta - i \sin \theta) d\theta$$

$$= \int_0^{2\pi} e^{\sin n\theta + i \cos n\theta} \cdot (\cos \theta - i \sin \theta) d\theta$$

$$= \int_0^{2\pi} e^{\sin n\theta} \cdot \left[\cos(\cos n\theta) + i \sin(\cos n\theta) \right] \times$$

$$[\cos \theta - i \sin \theta] d\theta$$

$$= \int_0^{2\pi} \left[e^{\sin n\theta} \cdot \cos(\theta - \cos n\theta) \right.$$

$$\left. - i \sin(\theta - \cos n\theta) \right] d\theta$$

Since e^{z^n} is analytic, by Cauchy's theorem $\int_c = 0$.
Hence the results follows.

EXERCISE

Using Cauchy's integral theorem evaluate the $\oint_c f(z) dz$ where $f(z)$ and c are:

1. a. e^z
- b. $\sin z$
- c. $\cos z$

d. $z^n, n = 0, 1, 2, 3, \dots$

c is any simple closed path.

Ans. (a), (b), (c) and (d) are all zero.

2. (a) $\sec z$, (b) $\frac{1}{z^2+4}; c : |z| = 1$

Ans. a. 0 since all singularities $z = \pm \frac{\pi}{2}, \pm \frac{3\pi}{2}, \dots \notin c$

b. 0 since $z = \pm 2i \notin c$

3. $\frac{(z^2-z+1)}{(z-2)}, c : |z-1| = \frac{1}{2}$

Ans. 0, since $z = 2$ singularity $\notin c$.

4. $f(z) = \frac{1}{(z^2(z-2)(z-4))}$

Hint: By partial fractions $\frac{3}{32} \frac{1}{z} + \frac{1}{8} \frac{1}{z^2} - \frac{1}{8} \frac{1}{z-2} + \frac{1}{32} \frac{1}{z-4}$ use book work and Cauchy's theorem.

Ans. $-\frac{\pi i}{16}$

5. $\frac{1}{(z^2(z^2+9))}, c : 1 < |z| < 2$

Hint: Apply theorem for doubly connected domain.

Ans. 0

6. Verify Cauchy's theorem for

a. c is the square with vertices at $\pm 1 \pm i$ and $f(z) = 3z^2 + iz - 4, 5 \sin 2x, 3 \cosh(z+2)$.

Ans. 0

b. $f(z) = z^3 - iz^2 - 5z + 2i$.

i. c is the circle $|z| = 1$

ii. circle $|z-1| = 2$

iii. ellipse $|z-3i| + |z+3i| = 20$

Ans. 0

c. z^3 taken over the boundary of the rectangle with vertices at $-1, 1, 1+i, -1+i$.

Ans. 0

7. Show that $\int_0^{2\pi} e^{\cos \theta} \cdot \cos(\theta + \sin \theta) d\theta = \int_0^{2\pi} e^{\cos \theta} \sin(\theta + \sin \theta) d\theta = 0$.

Hint: $\int e^z dz = 0$ by theorem, $c : |z| = 1, z = \cos \theta + i \sin \theta$.

23.3 CAUCHY'S INTEGRAL FORMULA

Let $f(z)$ be analytic in a simply connected domain D . Let c be any simple closed curve in D enclosing any point z_0 in D . Then

$$\oint_c \frac{f(z)}{z - z_0} dz = 2\pi i f(z_0)$$

where c is traversed in counter clockwise direction.

Proof: Consider

$$\begin{aligned} \oint_c \frac{f(z)}{z - z_0} dz &= \oint_c \frac{f(z_0) + [f(z) - f(z_0)]}{z - z_0} dz \\ &= f(z_0) \oint_c \frac{dz}{z - z_0} + \oint_c \frac{f(z) - f(z_0)}{z - z_0} dz \\ &= I_1 + I_2 \\ &= 2\pi i \cdot f(z_0) + I_2 \end{aligned}$$

since the integral value in I_1 is $2\pi i$ by book work. Now by showing I_2 is zero, the proof is complete. Construct a circle c_1 with z_0 as centre and of radius R_1 such that c_1 is non-overlapping with c and lies completely inside c (Fig. 23.23).

Fig. 23.23

Then by Cauchy's theorem for multiply connected domain

$$I_2 = \oint_c \frac{f(z) - f(z_0)}{z - z_0} dz = \oint_{c_1} \frac{f(z) - f(z_0)}{z - z_0} dz,$$

since $\frac{f(z) - f(z_0)}{z - z_0}$ is analytic in between c and c_1 . Since f is analytic, it is continuous. For $\epsilon > 0$ there exists $\delta > 0$ such that

$$|f(z) - f(z_0)| < \epsilon \quad \text{whenever } |z - z_0| < \delta$$

choose $R_1 < \delta$. Then

$$\left| \frac{f(z) - f(z_0)}{z - z_0} \right| < \frac{\epsilon}{R_1}$$

Using ML-inequality

$$|I_2| = \left| \oint_{c_1} \frac{f(z) - f(z_0)}{z - z_0} dz \right| \leq \frac{\epsilon}{R_1} \cdot 2\pi R_1 = 2\pi \epsilon$$

since length of the circle c_1 is $2\pi R_1$.

As $\epsilon \rightarrow 0$, $I_2 \rightarrow 0$. Hence the result.

Note 1: The Cauchy's integral formula is an important consequence of Cauchy's theorem which establishes relation between value of analytic function at interior point z_0 and boundary value of the function.

Note 2: Cauchy's integral formula also known as Cauchy's formula is useful in evaluating integrals, in obtaining Taylor series, etc.

WORKED OUT EXAMPLES

Example 1: Determine $F(2)$, $F(4)$, $F(-3i)$, $F'(i)$, $F''(-2i)$ if $F(\alpha) = \oint_c \frac{5z^2 - 4z + 3}{z - \alpha} dz$ where c is the ellipse $16x^2 + 9y^2 = 144$ (Fig. 23.24).

Solution: Curve c is

$$\left(\frac{x}{3}\right)^2 + \left(\frac{y}{4}\right)^2 = 1$$

Fig. 23.24

use Cauchy's integral formula, with $f(z) = 5z^2 - 4z + 3$ and $z_0 = \alpha$.

a. $z_0 = 2$ lies inside c . So by Cauchy's integral formula

$$F(2) = \oint_c \frac{5z^2 - 4z + 3}{z - 2} dz = 2\pi i f(z) \Big|_{z=2}$$

$$F(2) = 2\pi i \cdot (5z^2 - 4z + 3) \Big|_{\text{at } z=2} = 30\pi i$$

b. $z_0 = 4$ lies outside c . So by Cauchy's theorem $f(4) = 0$ since $\frac{5z^2 - 4z + 3}{(z - 4)}$ is analytic inside c .

- c. $z_0 = -3i$, lies inside c , by Cauchy's integral formula

$$\begin{aligned} F(-3i) &= 2\pi i \cdot (5z^2 - 4z + 3) \Big|_{\text{at } z=-3i} \\ &= -\pi(6 + 90i) \end{aligned}$$

- d. For any α , by Cauchy's integral formula

$$\begin{aligned} F(\alpha) &= \oint_c \frac{5z^2 - 4z + 3}{z - \alpha} dz \\ &= 2\pi i(5\alpha^2 - 4\alpha + 3) \Big|_{\text{at } z=\alpha} \end{aligned}$$

$$F(\alpha) = 2\pi i(5\alpha^2 - 4\alpha + 3)$$

$$\text{So } F'(\alpha) = 2\pi i(10\alpha - 4)$$

$$\text{and } F''(\alpha) = 20\pi i.$$

$$\text{Thus } F'(i) = 2\pi i(10i - 4) = -4\pi(5 + 2i)$$

$$F''(-2i) = 20\pi i.$$

Example 2: Evaluate $\oint_c \frac{dz}{z^2 + 9}$ where c is
(a) $|z - 3i| = 4$ (b) $|z + 3i| = 2$ (c) $|z| = 5$

Solution: The integrand $f(z) = \frac{1}{z^2 + 9}$ has two singular points at $z = \pm 3i$

- a. $c_1 : |z - 3i| = 4$. The singular point

$z_0 = 3i$ lies inside c_1 and the singular point

$z = -3i$ lies outside c_1 (Fig. 23.25).

Fig. 23.25

By Integral formula

$$\begin{aligned} I_1 &= \oint_{c_1} \frac{dz}{z^2 + 9} = \oint_{c_1} \frac{dz}{(z + 3i)(z - 3i)} \\ &= \oint_{c_1} \left(\frac{1}{z + 3i} \right) \cdot \frac{dz}{z - 3i} \end{aligned}$$

where $f(z) = \frac{1}{z - 3i}$ and $z_0 = 3i$

$$I = 2\pi i \cdot f(3i) = 2\pi i \cdot \frac{1}{3i + 3i} = \frac{\pi}{3}.$$

- b. $c_2 : |z + 3i| = 2$ contains $z = -3i$ but $z = 3i$ lies outside c_2 (Fig. 23.26).

So by integral formula

$$I_2 = \oint_{c_2} \left(\frac{1}{z - 3i} \right) \cdot \frac{dz}{z - (-3i)} = 2\pi i \frac{1}{z - 3i} \Big|_{z=-3i}$$

$$I_2 = 2\pi i \cdot \frac{1}{-3i - 3i} = -\frac{\pi}{3}$$

Fig. 23.26

- c. $c : |z| = 5$, contains both the singular points $z = \pm 3i$. Construct two circles c_1 and c_2 with these points as centres such that c_1, c_2 do not overlap and lie completely inside c . Then $f(z) = \frac{1}{z^2 + 9}$ is analytic in the multiply connected domain in between c, c_1 and c_2 (Fig. 23.27).

Fig. 23.27

So by Cauchy's theorem

$$\begin{aligned} \oint_c \frac{1}{z^2 + 9} dz &= \oint_{c_1} \frac{dz}{z^2 + 9} + \oint_{c_2} \frac{dz}{z^2 + 9} \\ &= \frac{\pi}{3} - \frac{\pi}{3} = 0 \end{aligned}$$

using (a) and (b) above.

EXERCISE

Integrate the given function around the given contour c :

1. $\frac{e^z}{(z^2+1)}$, (a) $c : |z - i| = 1$ (b) $|z + i| = 1$

Ans. (a) $\pi(\cos 1 + i \sin 1)$ (b) $-\pi(\cos 1 - i \sin 1)$

2. $\frac{(z^3-6)}{(z^2-i)}$, $c : |z| = 1$

Ans. $\frac{\pi}{8} - 6\pi i$

3. $\frac{(z^2+1)}{(z^2-1)}$, (a) $c_1 : |z - 1| = 1$, (b) $c_2 : |z + 1| = 1$,
(c) $c_3 : |z - i| = 1$

Ans. (a) $2\pi i$ (b) $-2\pi i$ (c) 0 (by Cauchy's theorem)

4. $\frac{\tan z}{(z^2-1)}$, $c : |z| = \frac{3}{2}$ (counter clockwise)

Ans. $2\pi i \tan 1$, use partial fractions: $\frac{1}{z^2-1} = \frac{1}{z-1} - \frac{1}{z+1}$

5. $\frac{(z^2-z+1)}{(z-1)}$, (a) $c : |z| = 1$, (b) $|z| = \frac{1}{2}$

Ans. (a) $2\pi i$ (b) 0 (by Cauchy's theorem)

6. $\frac{e^{2z}}{(z-1)(z-2)}$, $c : |z| = 3$

Ans. $2\pi i(e^4 - e^2)$

7. $\frac{\cos \pi z}{(z^2-1)}$, c : rectangle with vertices $\pm 2 \pm i$

Ans. 0 (use partial fractions $\frac{1}{z^2-1} = \frac{1}{z-1} - \frac{1}{z+1}$)

8. $\frac{\cos(2\pi z)}{(2z-1)(z-3)}$, $c : |z| = 1$

Ans. $\frac{2\pi i}{5}$

9. $\frac{\sin z}{(z^2-iz+2)}$ (a) $c_1 : |z + 2| = 2$ (b) c_2 : rectangle with vertices at (1, 0), (1, 3), (-1, 3), (-1, 0)
(c) c_3 : rectangle with vertices at (2, 0), (2, 3)(-2, 3), (-2, -3).

Ans. (a) 0 (by Cauchy's theorem)

(b) $i \frac{2\pi}{3} \cdot \sinh 2$ (c) $i \frac{2\pi}{3} (\sinh 2 + \sinh 1)$

10. $\frac{(z+4)}{(z^2+2z+5)}$, $c : |z + 1 - i| = 2$

Ans. $\frac{\pi}{2}(3 + 2i)$

11. $\frac{(\sin \pi z^2 + \cos \pi z^2)}{(z-1)(z-2)}$, $c : |z| = 3$

Ans. $4\pi i$

12. Determine $F(4)$, $F(+i)$, $F'(-1)$, $F''(-i)$ if

$$F(\alpha) = \int_c \frac{4z^2 + z + 5}{z - \alpha} dz,$$

$$c : \text{ellipse } \left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^2 = 1$$

Ans. 0, $2\pi(i - 1)$, $-14\pi i$, $16\pi i$.

23.4 DERIVATIVE OF ANALYTIC FUNCTIONS

Formally differentiating the Cauchy's formula under the integral sign w.r.t. z_0

$$\oint_c \frac{(-1) \cdot f(z)}{(z - z_0)^2} \cdot (-1) dz = \oint_c \frac{f(z)}{(z - z_0)^2} dz = 2\pi i f'(z_0).$$

Similarly differentiating once more w.r.t., z_0

$$2\pi i f''(z_0) = \oint_c \frac{f(z)}{(z - z_0)^3} \cdot 2! dz$$

In general, after n differentiations w.r.t., z_0 , we get **the generalized Cauchy's integral formula**

$$\oint_c \frac{f(z)}{(z - z_0)^{n+1}} dz = \frac{2\pi i}{n!} f^{(n)}(z_0)$$

or

$$f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_c \frac{f(z)}{(z - z_0)^{n+1}} dz, \quad n = 1, 2, \dots$$

Thus the values of the derivatives of an analytic function $f(z)$ at a point z_0 are given by the above formula. Hence for an analytic function $f(z)$ the derivatives of all orders exist and are themselves analytic. In contrast, from the knowledge of the first derivative of a real function, no information is obtained about the second and higher order derivatives.

Note: In Cauchy's integral formula for multiply connected domains, c is replaced by the oriented boundary B of the multiply connected domain.

WORKED OUT EXAMPLES

Example 1: Evaluate $\oint_c \frac{e^{3z} dz}{(z - \ln 2)^4}$ where c is the square with vertices at $\pm 1 \pm i$ (Fig. 23.28).

Solution: Here $z_0 = \ln 2 = 0.69315$ lies inside the square c . Using generalized Cauchy's integral formula

$$\begin{aligned} I &= \oint_c e^{3z} \cdot \frac{dz}{(z - \ln 2)^{3+1}} = \frac{2\pi i}{3!} \cdot \frac{d^3}{dz^3} (e^{3z}) \Big|_{\text{at } z=\ln 2} \\ &= \frac{\pi i}{3} 27e^{3z} \Big|_{z=\ln 2} = 9\pi i e^{3\ln 2} = 72\pi i \end{aligned}$$

Fig. 23.28

Example 2: Evaluate $\oint_c \frac{e^z dz}{z(1-z)^3}$ where c is
 (a) $|z| = \frac{1}{2}$ (b) $|z - 1| = \frac{1}{2}$ (c) $|z| = 2$
 (Fig. 23.29).

Solution: $z = 0, 1$ are the singular points

a. $c_1 : |z| = \frac{1}{2}$ contains 0 but does not contain $z = 1$.

Fig. 23.29

Using integral formula

$$\begin{aligned} I_1 &= \oint_{c_1} \frac{e^z}{(1-z)^3} \cdot \frac{dz}{z-0} = 2\pi i \cdot \left[\frac{e^z}{(1-z)^3} \right]_{\text{at } z=0} \\ &= 2\pi i \end{aligned}$$

since $\frac{e^z}{(1-z)^3}$ is analytic inside c_1 .

b. $c_2 : |z - 1| = \frac{1}{2}$ contains 1 but not 0.

Rewriting

$$I_2 = \oint_{c_2} \frac{e^z}{z} \cdot \frac{dz}{(1-z)^{2+1}}.$$

Fig. 23.30

Since $\frac{e^z}{z}$ is analytic inside c_2 (Fig. 23.30), applying generalized formula with $n = 2$,

$$\begin{aligned} I_2 &= \oint_{c_2} -\frac{e^z}{z} \frac{dz}{(z-1)^{2+1}} = -\frac{2\pi i}{2!} \frac{d^2}{dz^2} \left(\frac{e^z}{z} \right) \Big|_{\text{at } z=1} \\ I_2 &= -\pi i \left(\frac{ze^z - e^z}{z^2} - \frac{z^2 e^z - 2ze^z}{z^4} \right) \Big|_{\text{at } z=1} = -\pi e i \end{aligned}$$

c. $c : |z| = 2$ contains both the singular points $z = 0, 1$. Construct two circles c_1 , and c_2 with centres at 0 and 1 such that they do not overlap and lie completely inside c (Fig. 23.31). Then $f(z) = \frac{e^z}{z(1-z)^3}$ is analytic in the region between c , c_1 , and c_2 . By Cauchy's theorem for multiply connected domain

$$\begin{aligned} \oint_c \frac{e^z}{z(1-z)^3} dz &= \oint_{c_1} \frac{e^z}{z(1-z)^3} dz + \oint_{c_2} \frac{e^z}{z(1-z)^3} dz \\ &= 2\pi i - \pi e i = \pi i(2 - e) \end{aligned}$$

where results (a) and (b) above are used.

Fig. 23.31

Example 3: Show that $\int_c \frac{f'(z) dz}{z - z_0} = \int_c \frac{f(z) dz}{(z - z_0)^2}$ if f is analytic within and on a simple closed curve c and z_0 is not on c .

Solution:

i. If z_0 is outside c then $\frac{f'}{(z - z_0)}$ and $\frac{f}{(z - z_0)^2}$ are both analytic in c and by Cauchy's theorem both the integrals are zero.

23.16 — HIGHER ENGINEERING MATHEMATICS—VI

- ii. If z_0 is interior of c , then by generalized Cauchy's integral formula and Cauchy's integral formula

$$\int_c \frac{f(z)}{(z-z_0)^2} dz = \frac{2\pi i}{1!} f'(z_0) = \int_c \frac{f'(z)}{z-z_0} dz$$

EXERCISE

Integrate the given function around the given curve traversed in counter-clockwise direction:

1. $\frac{\cos z}{(z-\pi i)^2}, c : |z| = 5$

Ans. $2\pi \sinh \pi$

2. $\frac{(z^4-3z^2+6)}{(z+i)^3}, c : |z| = 2$

Ans. $-18\pi i$

3. $\frac{e^z}{(z-1)^2(z^2+4)}, c : |z-1| = \frac{1}{2}$

Ans. $\frac{6e\pi}{25}$

4. $\frac{\sin^2 z}{(z-\frac{\pi}{6})^3}, c : |z| = 1$

Ans. πi

5. $\frac{e^{2z}}{(z+1)^4}, c : |z| = 3$

Ans. $\frac{8\pi i e^{-2}}{3}$

6. $\frac{e^z}{(z^2+\pi^2)^2}, c : |z| = 4$

Ans. $\frac{i}{\pi}$

7. $\frac{(z^3-z)}{(z-2)^3}, c_1 : |z| = 3, c_2 : |z-2| = 1, c_3 : |z| = 1$

Ans. $12\pi i, 12\pi i, 0$

8. $\frac{e^z}{z^3}, c : |z| = 1$

Ans. πi

9. $\frac{\sin 2z}{(z+3)(z+1)^2}, c : \text{rectangle with vertices at } 3+i, -2+i, -2-i, 3-i$

Ans. $\frac{\pi i (4 \cos 2 + \sin 2)}{2}$

10. $z^{-2n-1} \cos z, c : |z| = 1$

Hint: $2n$ th derivative of $\cos z$ is $(-1)^n \cos z$

Ans. $(-1)^n \frac{2\pi i}{(2n)!}$

11. $\frac{e^{zt}}{(z^2+1)^2}, c : |z| = 3, t > 0$

Ans. $\pi i (\sin t - t \cos t)$

12. $\frac{\tan(\frac{\pi}{2})}{(z-1-i)^2}, c : \text{rectangle with vertices at } \pm 2 \pm 2i$

Ans. $\pi i \sec^2\left(\frac{(1+i)}{2}\right)$

13. $\frac{\cosh z}{z^4}, c : |z| = \frac{1}{2}$

Ans. 0

14. Show that $\int_0^\pi e^{k \cos \theta} \cdot \cos(k \sin \theta) d\theta = \pi$ and $\int_0^\pi e^{k \cos \theta} \cdot \sin(k \sin \theta) d\theta = 0$.

Hint: By Cauchy's integral formulae $\int_c \frac{e^{kz}}{z} dz = 2\pi i, c : |z| = 1$. Equate real and imaginary parts.

23.5 COMPLEX SEQUENCE, SERIES AND POWER SERIES

Sequence and Series

A **sequence** of complex numbers $z_1, z_2, z_3, \dots, z_n, \dots$ is an assignment to each positive integer n a complex number z_n called the term of the sequence. A sequence denoted by $\{z_n\}$ is said to be convergent if $\lim_{n \rightarrow \infty} z_n = c$ (finite quantity) otherwise it is said to be divergent.

An **infinite complex series or infinite series or simply series** is the sum of the terms of a given sequence of complex numbers $z_1, z_2, \dots, z_n, \dots$ denoted by

$$\sum_{n=1}^{\infty} z_n = z_1 + z_2 + z_3 + \dots + z_n + \dots$$

$z_1, z_2, \dots, z_n, \dots$ are known as 1st, 2nd, $\dots$, n th $\dots$ term of series. The n th partial sum of a series is the sum of the first n terms of the series, denoted by

$$S_n = z_1 + z_2 + \dots + z_n = \sum_{m=1}^n z_m$$

A series is said to be convergent to a sum S if $\lim_{n \rightarrow \infty} S_n = S$ i.e., if sequence of partial sums converges. Otherwise the series is said to be divergent.

Power Series

A **power series** in powers of $(z - z_0)$ is a series of the form

$$\sum_{n=0}^{\infty} a_n (z - z_0)^n = a_0 + a_1 (z - z_0) + a_2 (z - z_0)^2 + \dots \quad (1)$$

Here $a_0, a_1, a_2 \dots$ are complex (or real) constants known as coefficients of the series, (1) z is a complex variable and z_0 is called the centre of the series. (1) is also known as power series about the point z_0 .

Power series in powers of z is

$$\sum_{n=0}^{\infty} a_n z^n = a_0 + a_1 z + a_2 z^2 + \dots \quad (2)$$

obtained as a particular case with $z_0 = 0$ in (1).

Region of convergence

of a series is the set of all points z for which the series converges.

Power series converges in a disk

Three distinct possibilities exist regarding the region of convergence of a power series (1).

- i. The series converges only at the point $z = z_0$.
- ii. The series converges for all z (i.e., in the whole plane).
- iii. The series converges everywhere inside a circular disk $|z - z_0| < R$ and diverges everywhere outside the disk $|z - z_0| > R$. Here R is known as the radius of convergence and the circle $|z - z_0| = R$ as the circle of convergence.

Note: Series may converge or diverge at the points on the circle of convergence.

Examples:

1. Geometric series: $\sum_{m=0}^{\infty} z^m = 1 + z + z^2 + \dots$ converges absolutely when $|z| < 1$ and diverges when $|z| > 1$ i.e., $R = 1$.
2. Power series: $\sum_{n=0}^{\infty} \frac{z^n}{n!}$ converges for all z i.e., $R = \infty$
3. $\sum_{n=0}^{\infty} n^n z^n$ diverges for all z except $z_0 = 0$ i.e., $R = 0$.

Termwise integration of power series:

$$\int_c \sum_{n=0}^{\infty} c_n (z - z_0)^n dz = \sum_{n=0}^{\infty} c_n \int_c (z - z_0)^n dz$$

Power series represent analytic functions. Conversely every analytic function can be represented as a power series known as the Taylor series.

A function $f(z)$ can be expanded about a singular point z_0 as a Laurent series containing both positive and negative integer powers of $(z - z_0)$.

23.6 TAYLOR'S SERIES (THEOREM)

A function $f(z)$ which is analytic at all points within a circle c_2 with centre at z_0 and of radius R_2 can be represented uniquely as a convergent power series in c_2 known as the **Taylor's series** given by

$$f(z) = \sum_{n=0}^{\infty} a_n (z - z_0)^n \quad (1)$$

where $a_n = \frac{f^{(n)}(z_0)}{n!}$.

Proof: Let z be any arbitrary point inside a circle c_1 with centre at z_0 and of radius $R_1 < R_2$. (see Fig. 23.32).

Fig. 23.32

By Cauchy's integral formula, we have

$$f(z) = \frac{1}{2\pi i} \int_{c_1} \frac{f(\alpha)}{\alpha - z} d\alpha \quad (2)$$

The integrand of (2) can be written using binomial series as

$$\begin{aligned} \frac{1}{\alpha - z} &= \frac{1}{\alpha - z_0 + z_0 - z} = \frac{1}{\alpha - z_0} \cdot \frac{1}{1 - \frac{z - z_0}{\alpha - z_0}} \\ &= \frac{1}{\alpha - z_0} \sum_{n=0}^{\infty} \left(\frac{z - z_0}{\alpha - z_0} \right)^n \end{aligned}$$

$$= \sum_{n=0}^{\infty} \frac{(z - z_0)^n}{(\alpha - z_0)^{n+1}} \quad (3)$$

because $\left| \frac{z - z_0}{\alpha - z_0} \right| < 1$ (i.e., $|z - z_0| < |\alpha - z_0|$)

Putting (3) in (2) and integrating termwise

$$f(z) = \frac{1}{2\pi i} \int_{c_1} f(\alpha) \left(\sum_{n=0}^{\infty} \frac{(z - z_0)^n}{(\alpha - z_0)^{n+1}} \right) d\alpha$$

$$= \sum_{n=0}^{\infty} \frac{1}{2\pi i} \left[\int_{c_1} \frac{f(\alpha) \cdot d\alpha}{(\alpha - z_0)^{n+1}} \right] (z - z_0)^n \quad (4)$$

$$f(z) = \sum_{n=0}^{\infty} a_n (z - z_0)^n \quad (5)$$

where $a_n = \frac{1}{2\pi i} \int_{c_1} \frac{f(\alpha) d\alpha}{(\alpha - z_0)^{n+1}}$

$$= \frac{1}{2\pi i} \int_c \frac{f(\alpha) d\alpha}{(\alpha - z_0)^{n+1}} \quad (6)$$

Since $f(z)$ is analytic within c_2 , by Cauchy's theorem the circle c_1 in (4) can be replaced by any closed contour c completely lying inside c_2 . By Cauchy's integral formula for derivatives

$$a_n = \frac{1}{2\pi i} \int_c \frac{f(\alpha) d\alpha}{(\alpha - z_0)^{n+1}} = \frac{f^{(n)}(z_0)}{n!} \quad (7)$$

Substituting (7) in (5), we get the Taylor's series expansion of $f(z)$ with centre at z_0 (or about z_0) as

$$f(z) = \sum_{n=0}^{\infty} \frac{f^{(n)}(z_0)}{n!} (z - z_0)^n \quad (8)$$

Corollary: **Maclaurin's series** is a Taylor's series about $z_0 = 0$ (i.e., the centre is origin), given by

$$f(z) = \sum_{n=0}^{\infty} \frac{f^{(n)}(0)}{n!} z^n \quad (9)$$

Standard Maclaurin's Series

$$1. e^z = \sum_{n=0}^{\infty} \frac{z^n}{n!} \quad \text{for } |z| < \infty$$

since $f^{(n)}(z) = \frac{d^n}{dz^n} e^z = e^z$, $f^{(n)}(0) = e^0 = 1$, for any n .

$$2. \sin z = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n+1}}{(2n+1)!} \quad \text{for } |z| < \infty.$$

$$3. \cos z = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n}}{(2n)!} \quad \text{for } |z| < \infty.$$

$$4. \sinh z = \sum_{n=0}^{\infty} \frac{z^{2n+1}}{(2n+1)!} \quad \text{for } |z| < \infty.$$

$$5. \cosh z = \sum_{n=0}^{\infty} \frac{z^{2n}}{(2n)!} \quad \text{for } |z| < \infty.$$

$$6. \frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad \text{for } |z| < 1$$

(known as **geometric series**).

$$7. \ln(1+z) = z - \frac{z^2}{2} + \frac{z^3}{3!} + \dots \quad \text{for } |z| < 1$$

Hint: n th derivative $= (-1)^{n-1} \cdot (n-1)! (1+z)^{-n}$.

$$8. \frac{1}{(1-z)^m} = \sum_{n=0}^{\infty} \frac{(m+n-1)!}{(m-1)! n!} z^n \quad \text{for } |z| < 1$$

$$= 1 + mz + \frac{m(m+1)}{2!} z^2 + \frac{m(m+1)(m+2)}{3!} z^3 + \dots$$

(known as **binomial series** for any positive integer m).

$$9. \frac{1}{(1+z)^m} = \sum_{n=0}^{\infty} \binom{-m}{n} z^n = 1 - mz + \frac{m(m+1)}{2!} z^2 - \frac{m(m+1)(m+2)}{3!} z^3 + \dots$$

WORKED OUT EXAMPLES

Find the Taylor's series expansion of $f(z)$ about the indicated point. Determine the region of convergence:

Example 1: e^z about $z = a$

Solution: *Direct method:*
Taylor's series of $f(z)$ is

$$f(z) = \sum_{n=0}^{\infty} \frac{f^{(n)}(a)}{n!} (z - a)^n$$

Here $f(z) = e^z$, $f^{(n)}(z) = e^z$, $f^{(n)}(a) = e^a$
So

$$e^z = \sum_{n=0}^{\infty} \frac{e^a}{n!} (z - a)^n = e^a \sum_{n=0}^{\infty} \frac{(z - a)^n}{n!}$$

Indirect method:

$$e^z = e^{z-a+a} = e^a \cdot e^{z-a}$$

$$= e^a \cdot \sum_{n=0}^{\infty} \frac{(z - a)^n}{n!}, \quad |z - a| < \infty.$$

Example 2: $f(z) = \frac{a}{bz+c}$ about z_0

Solution:

$$\begin{aligned} f(z) &= \frac{a}{bz+c} = \frac{a}{bz-bz_0+bz_0+c} \\ &= \frac{1}{(bz_0+c)} \left[\frac{a}{1 + \frac{b(z-z_0)}{bz_0+c}} \right] \\ &\quad \text{put } bz_0+c=d, \frac{b}{d}=e \\ &= \frac{a}{d} \left[\frac{1}{1+e(z-z_0)} \right] \end{aligned}$$

Expanding by binomial series

$$\begin{aligned} &= \frac{a}{d} \left[\sum_{n=0}^{\infty} (-1)^n e^n (z-z_0)^n \right] \quad \text{if } |e(z-z_0)| < 1 \\ f(z) &= \frac{a}{bz_0+c} \sum_{n=0}^{\infty} (-1)^n \left(\frac{b}{bz_0+c} \right)^n (z-z_0)^n \\ &\quad \text{if } |z-z_0| < \frac{1}{e} = \frac{d}{b}. \end{aligned}$$

Example 3: $f(z) = \frac{1}{4-3z}$, $z_0 = 1+i$

Solution: In the previous problem

$$\begin{aligned} a &= 1, b = -3, c = 4, z_0 = 1+i, d = bz_0+c \\ &= -3(1+i) + 4 = 1-3i \end{aligned}$$

$$f(z) = \frac{1}{1-3i} \sum_{n=0}^{\infty} (-1)^n \left(\frac{-3}{1-3i} \right)^n (z-(1+i))^n.$$

Region of convergence

$$|z-(1+i)| < \frac{bz_0+c}{b} = \left| \frac{1-3i}{-3} \right|$$

$$\text{or} \quad \left| z-(1+i) \right| < \frac{\sqrt{10}}{3}.$$

Example 4: $f(z) = \frac{1}{z^2-z-6}$ about (a) $z = -1$, (b) $z = 1$.

Solution: By partial fractions

$$\begin{aligned} f(z) &= \frac{1}{z^2-z-6} = \frac{1}{(z-3)(z+2)} \\ &= \frac{1}{5} \left[\frac{1}{z-3} - \frac{1}{z+2} \right] \end{aligned}$$

a. About $z = -1$ i.e., in powers of $(z+1)$

$$\begin{aligned} f(z) &= \frac{1}{5} \left[\frac{1}{z-3} - \frac{1}{z+2} \right] \\ &= \frac{1}{5} \left[\frac{1}{z+1-4} - \frac{1}{1+(z+1)} \right] \\ &= \frac{1}{5} \frac{1}{-4 \left[1 - \left(\frac{z+1}{4} \right) \right]} - \frac{1}{5} \frac{1}{1+(z+1)} \end{aligned}$$

Expanding by binomial series

$$\begin{aligned} &= -\frac{1}{20} \sum_{n=0}^{\infty} \left(\frac{z+1}{4} \right)^n - \frac{1}{5} \sum_{n=0}^{\infty} (-1)^n (z+1)^n \\ &= \frac{1}{20} \sum_{n=0}^{\infty} \frac{(-4)^{n+1} - 1}{4^n} (z+1)^n \end{aligned}$$

Valid for $|z+1| < 1$ i.e., region of convergence is the interior of circle with centre at $z = -1$ and radius 1.

b. About $z = 1$ i.e., in powers of $(z-1)$

$$\begin{aligned} f(z) &= \frac{1}{5} \left[\frac{1}{z-3} - \frac{1}{z+2} \right] \\ &= \frac{1}{5} \left[\frac{1}{z-1-2} - \frac{1}{z-1+3} \right] \\ &= \frac{1}{5} \left[\frac{1}{-2 \left(1 - \left(\frac{z-1}{2} \right) \right)} \right] - \frac{1}{5} \cdot \frac{1}{3} \frac{1}{1 + \left(\frac{z-1}{3} \right)} \end{aligned}$$

Expanding by binomial series

$$f(z) = -\frac{1}{10} \sum_{n=0}^{\infty} \left(\frac{z-1}{2} \right)^n - \frac{1}{15} \sum_{n=0}^{\infty} (-1)^n \left(\frac{z-1}{3} \right)^n$$

valid when $\left| \frac{z-1}{2} \right| < 1$ and $\left| \frac{z-1}{3} \right| < 1$
Region of convergence is $|z-1| < 2$
(common region).

Example 5: $f(z) = \frac{1}{(2z+1)^3}$ about (a) $z = 0$ (b) about $z = 2$.

Solution:

a. About $z = 0$

From binomial series

23.20 — HIGHER ENGINEERING MATHEMATICS—VI

$$\frac{1}{(1-z)^m} = \sum_{n=0}^{\infty} \frac{(m+n-1)!}{(m-1)!n!}, \quad |z| < 1$$

with $m = 3$, we get

$$\begin{aligned} \frac{1}{(1+2z)^3} &= \sum_{n=0}^{\infty} \frac{(-1)^n(3+n-1)!}{2!n!} (2z)^n \quad \text{if } |2z| < 1 \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{2} (n+2)(n+1) \cdot 2^n \cdot z^n \\ &\quad \text{if } |z| < \frac{1}{2} \end{aligned}$$

b. About $z = 2$

$$\begin{aligned} \frac{1}{(1+2z)^3} &= \frac{1}{(1+2z-4+4)^3} \\ &= \frac{1}{5^3} \frac{1}{\left[1 + \frac{2}{5}(z-2)\right]^3} \\ &= \frac{1}{125} \sum_{n=0}^{\infty} (-1)^n \cdot \frac{(n+2)(n+1)}{2} \times \\ &\quad \times \left(\frac{2}{5}\right)^n (z-2)^n \end{aligned}$$

with region of convergence $\left|\frac{2}{5}(z-2)\right| < 1$

$$\text{i.e., } |z-2| < \frac{5}{2}.$$

Example 6: $f(z) = \cosh z$ (a) $z_0 = 0$ (b) $z_0 = \pi i$

Solution: a.

$$\begin{aligned} f(z) = \cosh z &= \frac{e^z + e^{-z}}{2} \\ &= \frac{e^{z-z_0+z_0} + e^{-z+z_0-z_0}}{2} \\ &= \frac{1}{2} e^{z_0} \cdot e^{z-z_0} + \frac{e^{-z_0}}{2} \cdot e^{-(z-z_0)} \\ &= \frac{1}{2} e^{z_0} \cdot \sum_{n=0}^{\infty} \frac{(z-z_0)^n}{n!} + \frac{e^{-z_0}}{2} \cdot \sum_{n=0}^{\infty} \frac{(-1)^n (z-z_0)^n}{n!} \end{aligned}$$

b. put $z_0 = \pi i$

$$\begin{aligned} f(z) &= -\frac{1}{2} \sum_{n=0}^{\infty} \frac{(z-\pi i)^n}{n!} - \frac{1}{2} \sum_{n=0}^{\infty} \frac{(z-\pi i)^n \cdot (-1)^n}{n!} \\ f(z) &= -\sum_{n=0}^{\infty} \frac{(z-\pi i)^{2n}}{(2n)!} \quad \text{if } |z-\pi i| < \infty. \end{aligned}$$

Example 7: $f(z) = e^z \sin z$, about $z = 0$

Solution:

$$\begin{aligned} f(z) &= e^z \cdot \sin z = \left[\sum_{n=0}^{\infty} \frac{z^n}{n!} \right] \left[\sum_{n=0}^{\infty} \frac{(-1)^n z^{2n+1}}{(2n+1)!} \right] \\ &= \left[1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \dots \right] \left[z - \frac{z^3}{3!} + \frac{z^5}{5!} + \dots \right] \\ &= z + z^2 + \frac{z^3}{3} - \frac{1}{30} z^5 + \dots \end{aligned}$$

Example 8: Find Maclaurin's series by termwise integrating the integrand: $f(z) = e^{z^2} \int_0^z e^{t^2} dt$.

Solution:

$$\begin{aligned} e^{t^2} &= \sum_{n=0}^{\infty} \frac{(t^2)^n}{n!} = \sum_{n=0}^{\infty} \frac{t^{2n}}{n!} \\ \int_0^z e^{t^2} dt &= \int_0^z \left[1 + t^2 + \frac{t^4}{2!} + \frac{t^6}{3!} + \frac{t^8}{4!} + \dots \right] dt \\ &= z + \frac{z^3}{3} + \frac{1}{2!} \frac{z^5}{5} + \frac{1}{3!} \frac{z^7}{7} + \frac{1}{4!} \frac{z^9}{9} + \dots \end{aligned}$$

Then

$$\begin{aligned} e^{z^2} \int_0^z e^{t^2} dt &= \left[1 + z^2 + \frac{z^4}{2!} + \frac{z^6}{3!} + \frac{z^8}{4!} + \dots \right] \\ &\quad \left[z + \frac{z^3}{3!} + \frac{1}{2!} \frac{z^5}{5} + \frac{1}{3!} \frac{z^7}{7} + \dots \right] \\ &= z + \frac{7}{6} z^3 + \frac{23}{30} z^5 + \dots \end{aligned}$$

EXERCISE

Find the Taylor's series expansion of $f(z)$ about the indicated point z_0 . Determine the region of convergence:

1. $\frac{1}{1+z^2}$, $z_0 = 0$

Ans. $\sum_{n=0}^{\infty} (-1)^n z^{2n}$, $|z| < 1$

2. $\tan^{-1} z$, $z_0 = 0$

Hint: $(\tan^{-1} z)' = \frac{1}{1+z^2}$, integrate series in the above Example 1.

Ans. $z - \frac{z^3}{3} + \frac{z^5}{5} - \dots$, $|z| < 1$

3. $\frac{1}{\alpha-z}, z = z_0$

Ans. $\frac{1}{\alpha-z_0} \sum_{n=0}^{\infty} \left(\frac{z-z_0}{\alpha-z_0} \right)^n, |z-z_0| < |\alpha-z_0|$

4. $\frac{2z^2+9z+5}{z^3+z^2-8z-12}, z_0 = 1$

Hint: By partial fractions $= \frac{1}{(z+2)^2} + \frac{2}{z-3}$, use binomial series $= \frac{1}{[3+(z-1)]^2} - \frac{2}{2-(z-1)}$.

Ans. $\sum_{n=0}^{\infty} \left[\frac{(-1)^n(n+1)}{3^{n+2}} - \frac{1}{2^n} \right] (z-1)^n, |z-1| < 2$

5. $\frac{3}{3z-z^2}, z_0 = 1$

Ans. $\frac{3}{2} - \frac{3}{4}(z-1) + \frac{9}{8}(z-1)^2 + \dots \left[\frac{1}{2^{n+1}} + (-1)^n \right] (z-1)^n + \dots$

6. $\sinh z, z_0 = -i\pi$

Ans. $i \sum_{n=0}^{\infty} \frac{(z+i\pi)^{2n+1}}{(2n+1)!}$

7. $\frac{1}{(3-z)^2}, z_0 = i$

Ans. $\frac{1}{(3-i)^2} \sum_{n=0}^{\infty} (n+1) \left(\frac{z-i}{3-i} \right)^n, |z-i| < |3-i|$

8. $\ln \left(\frac{1+z}{1-z} \right), z_0 = 0$

Ans. $\sum_{n=0}^{\infty} \frac{2z^{2n+1}}{2n+1}, |z| < 1$

9. $\sin z, z_0 = \frac{\pi}{4}$

Ans. $\frac{1}{\sqrt{2}} \left[1 + \left(z - \frac{\pi}{4} \right) - \frac{\left(z - \frac{\pi}{4} \right)^2}{2!} - \frac{\left(z - \frac{\pi}{4} \right)^3}{3!} + \dots, |z| < \infty \right]$

10. $\frac{1}{(z+1)^2}, z_0 = -i$

Ans. $\frac{i}{2} \left[1 + \sum_{n=1}^{\infty} \frac{(-1)^n(n+1)(z+i)^n}{(1-i)^{n+1}} \right]$

11. $\frac{2z^3+1}{z^2+z}, z_0 = i$

Hint: Partial fractions: $(2i-2) + 2(z-i) + \frac{1}{z} + \frac{1}{z+1}$.

Ans. $\left(\frac{i}{2} - \frac{3}{2} \right) + \left(3 + \frac{i}{2} \right) (z-i) + \sum_{n=2}^{\infty} (-1)^n \left\{ \frac{1}{i^{n+1}} + \frac{1}{(1+i)^{n+1}} \right\} (z-i)^n$

12. $\frac{1}{(z-1)(z-2)}, z_0 = 0$

Ans. $\frac{1}{2} + \frac{3}{4}z + \frac{7}{8}z^2 + \frac{15}{16}z^3 + \dots, |z| < 1$

13. $\frac{e^z}{\cos z}, z_0 = 0$

Hint: Method of undetermined coefficients:

Assume $\frac{e^z}{\cos z} = a_0 + a_1z + a_2z^2 + a_3z^3 + \dots$

$$\sum_{n=0}^{\infty} \frac{z^n}{n!} = \left(\sum_{n=0}^{\infty} a_n z^n \right) \left(\sum_{n=0}^{\infty} \frac{(-1)^n z^{2n}}{(2n)!} \right)$$

Equate coefficients of like powers of z .

Ans. $1 + z + z^2 + \frac{2}{3}z^3 + \dots$

14. $\frac{z-1}{z^2}, z_0 = 1$

Ans. $\sum_{n=1}^{\infty} (-1)^{n+1} \cdot n \cdot (z-1)^n$

15. $e^z \cdot \cosh z, z_0 = 0$

Hint: Multiply the series $\left(\sum \frac{z^n}{n!} \right) \cdot \left(\sum \frac{z^{2n}}{2n!} \right)$.

Ans. $1 + z + z^2 + \frac{5}{6}z^3 + \dots$

16. $\frac{e^z}{z(z+1)}, z_0 = 2$

Ans. $\frac{1}{6} - \frac{5}{9}(z-2) + \frac{19}{27}(z-2)^2 + \dots, |z-2| < 1$

17. Evaluate the integral of the series $\sum_{n=0}^{\infty} z^n$ along a straight-line path from $z = 0$ to $z = \frac{1+i}{2}$.

Hint: $\int_c \sum_{n=0}^{\infty} z^n dz = \int_0^{\frac{1+i}{2}} \frac{dz}{1-z}$
 $= -\ln(1-z) \Big|_{z=0}^{\frac{z=(1+i)}{2}}$

Ans. $\left(\frac{1+i}{2} \right) + \frac{1}{2} \left(\frac{1+i}{2} \right)^2 + \frac{1}{3} \left(\frac{1+i}{2} \right)^3 + \dots$

23.7 LAURENT SERIES

Let $f(z)$ be analytic on two concentric circles c_1 and c_2 with centre z_0 and radii R_1 and R_2 and in the annulus region $R_1 < |z-z_0| < R_2$ (Fig. 23.33). Then $f(z)$ is uniquely represented by a convergent **Laurent series** given by

$$f(z) = \sum_{n=0}^{\infty} a_n (z-z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z-z_0)^n} \quad (1)$$

Fig. 23.33

Proof: For any arbitrary point z_0 in the annulus region, applying Cauchy's integral formula for multiply connected domain, we have

$$f(z) = \frac{1}{2\pi i} \int_{c_2} \frac{f(\alpha)}{\alpha - z} d\alpha + \frac{1}{2\pi i} \int_{c_1} \frac{f(\alpha)}{\alpha - z} d\alpha = I_1 + I_2 \quad (2)$$

Since $\left| \frac{z - z_0}{\alpha - z_0} \right| < 1$ for any α on c_2 , the integrand $\frac{1}{\alpha - z}$ of the first integral I_1 can be represented as

$$\begin{aligned} \frac{1}{\alpha - z} &= \frac{1}{\alpha - z_0 - (z - z_0)} = \frac{1}{\alpha - z_0} \frac{1}{1 - \frac{z - z_0}{\alpha - z_0}} \\ &= \frac{1}{\alpha - z_0} \cdot \sum_{n=0}^{\infty} \left(\frac{z - z_0}{\alpha - z_0} \right)^n \end{aligned} \quad (3)$$

Using (3) in I_1 and performing term by term integration, we get

$$\begin{aligned} I_1 &= \frac{1}{2\pi i} \int_{c_2} \frac{f(\alpha)}{\alpha - z} d\alpha \\ &= \sum_{n=0}^{\infty} \left[\frac{1}{2\pi i} \int_{c_2} \frac{f(\alpha)}{(\alpha - z_0)^{n+1}} d\alpha \right] (z - z_0)^n \\ I_1 &= \sum_{n=0}^{\infty} a_n (z - z_0)^n \end{aligned} \quad (4)$$

$$\text{where } a_n = \frac{1}{2\pi i} \int_c \frac{f(\alpha)}{(\alpha - z_0)^{n+1}} d\alpha \quad (5)$$

Here c is any simple closed curve completely lying in the annulus region and traversed in counterclockwise direction.

For any α on c_1 , $\left| \frac{\alpha - z_0}{z - z_0} \right| < 1$. So the integrand of I_2 can be expressed as

$$\begin{aligned} \frac{1}{\alpha - z} &= \frac{1}{\alpha - z_0 - (z - z_0)} = \frac{-1}{(z - z_0)} \frac{1}{1 - \left(\frac{\alpha - z_0}{z - z_0} \right)} \\ &= \frac{-1}{(z - z_0)} \sum_{n=0}^{\infty} \left(\frac{\alpha - z_0}{z - z_0} \right)^n = - \sum_{n=0}^{\infty} \frac{(\alpha - z_0)^n}{(z - z_0)^{n+1}} \\ &= - \sum_{m=1}^{\infty} \frac{(\alpha - z_0)}{(z - z_0)^m} \end{aligned} \quad (6)$$

Using (6) in I_2 and performing integration

$$\begin{aligned} I_2 &= \frac{-1}{2\pi i} \int_{c_1} \frac{f(\alpha)}{\alpha - z} d\alpha \\ &= + \sum_{m=1}^{\infty} \left[\frac{1}{2\pi i} \int_{c_1} f(\alpha) \cdot (\alpha - z_0)^{m-1} d\alpha \right] \frac{1}{(z - z_0)^m} \end{aligned}$$

Here c_1 is traversed in counterclockwise direction, so minus sign is absorbed.

$$I_2 = \sum_{n=1}^{\infty} b_n \cdot \frac{1}{(z - z_0)^n} \quad (7)$$

where

$$b_n = \frac{1}{2\pi i} \int_c \frac{f(\alpha)}{(\alpha - z_0)^{-n+1}} d\alpha \quad (8)$$

with c traversed in the counterclockwise direction.

Thus using (4) and (7) in (2), we get the required Laurent series (1) where a_n, b_n are given by (5) and (8).

Note: Laurent series (1) can also be written as

$$f(z) = \sum_{n=-\infty}^{\infty} c_n (z - z_0)^n \quad (9)$$

$$\text{where } c_n = \frac{1}{2\pi i} \int_c \frac{f(\alpha)}{(\alpha - z_0)^{n+1}} d\alpha \quad (10)$$

Note 1: If $f(z)$ is analytic at all points inside c_1 (i.e., no singular points inside c_2) then by Cauchy's theorem $b_n = 0$ for all $n - 1 \geq 0$.

Hence the Laurent series reduces to Taylor series. Thus Laurent series expansion about an analytic point z_0 is Taylor series about z_0 .

Note 2: The region of convergence (validity) of Laurent series is the annulus region,

$$R_1 < |z - z_0| < R_2$$

Note 3: If z_0 is the only singular point inside c_1 , then series is convergent in the deleted neighbourhood $0 < |z - z_0| < R_1$.

Note 4: In practice, the Laurent series is obtained by rearrangement, manipulation and using the standard series expansions (both Taylor's and Maclaurin's) and not by formulae (5) and (8).

Note 5: If $f(z)$ has more than one singular point, then several (more than one) Laurent series expansions can be obtained about the same singular point by appropriately considering analytic regions about (centered) at z_0 .

WORKED OUT EXAMPLES

Example 1: Find Laurent series of $f(z) = \frac{\sinh 3z}{z^3}$ for $0 < |z| < \infty$.

Solution:

$$\begin{aligned} \frac{\sinh 3z}{z^3} &= \frac{1}{z^3} \cdot \sum_{n=0}^{\infty} \frac{(3z)^{2n+1}}{(2n+1)!} \\ &= \sum_{n=0}^{\infty} \frac{3^{2n+1} \cdot z^{2n-2}}{(2n+1)!} = \frac{3}{z^2} + \frac{9}{2} + \frac{81}{40}z^2 + \dots \end{aligned}$$

Example 2: Find Laurent series of $f(z) = \frac{1}{z^2+1}$ about its singular points. Determine the region of convergence.

Solution: $f(z)$ has two singular points at $z = \pm i$

a. Laurent series about $z = i$

$$\begin{aligned} f(z) &= \frac{1}{z^2+1} = \frac{1}{(z-i)(z+i)} = \frac{1}{(z-i)} \cdot \frac{1}{z-i+2i} \\ &= \frac{1}{(z-i)} \frac{1}{2i} \frac{1}{1 + \left(\frac{z-i}{2i}\right)} \quad \text{provided } \left|\frac{z-i}{2i}\right| < 1 \\ &= \frac{1}{2i} \frac{1}{z-i} \cdot \sum_{n=0}^{\infty} (-1)^n \left(\frac{z-i}{2i}\right)^n \end{aligned}$$

$$\text{if } |z-i| < |2i| = 2$$

$$f(z) = \sum_{n=0}^{\infty} (-1)^n \frac{(z-i)^{n-1}}{(2i)^{n+1}} \quad \text{if } |z-i| < 2$$

Region of convergence is $|z-i| < 2$

b. Laurent series about $z = -i$

$$\begin{aligned} f(z) &= \frac{1}{z^2+1} = \frac{1}{(z+i)(z-i)} \\ &= \frac{1}{(z+i)} \cdot \frac{1}{z+i-2i} \\ &= \frac{1}{z+i} \frac{1}{(-2i) \left(1 - \frac{z+i}{2i}\right)} \\ &= \frac{1}{z+i} \left(\frac{-1}{2i}\right) \cdot \sum_{n=0}^{\infty} \left(\frac{z+i}{2i}\right)^n \quad \text{if } \left|\frac{z+i}{2i}\right| < 1 \\ &= - \sum_{n=0}^{\infty} \frac{(z+i)^{n-1}}{(2i)^{n+1}} \end{aligned}$$

Region of convergence is $|z+i| < 2$.

Example 3: Find Laurent series of $f(z) = \frac{e^z}{z(1-z)}$ about $z = 1$. Find region of convergence.

Solution:

$$\begin{aligned} f(z) &= \frac{e^z}{z(1-z)} = \frac{1}{e} \cdot e^{z-1} \cdot \frac{1}{(z-1+1)} \cdot \frac{1}{(1-z)} \\ &= \frac{1}{e} \frac{1}{1-z} \cdot e^{z-1} \cdot \frac{1}{1+(z-1)} \\ &= \frac{-1}{e(z-1)} \left[\sum_{n=0}^{\infty} \frac{(z-1)^n}{n!} \right] \left[\sum_{n=0}^{\infty} (-1)^n (z-1)^n \right] \\ &\quad \text{if } |z-1| < 1 \\ &= -\frac{1}{e} \frac{1}{(z-1)} \left[1 + (z-1) + \frac{(z-1)^2}{2!} \right. \\ &\quad \left. + \frac{(z-1)^3}{3!} + \dots \right] \times \\ &\quad \times \left[1 - (z-1) + (z-1)^2 - (z-1)^3 + \dots \right] \\ &= -\frac{1}{e} \left[\frac{1}{z-1} \right] \left[1 + \frac{3}{2}(z-1)^2 - \frac{1}{3}(z-1)^3 + \dots \right] \\ f(z) &= \frac{1}{e} \left[-\frac{1}{z-1} - \frac{3}{2}(z-1) + \frac{1}{3}(z-1)^2 + \dots \right] \end{aligned}$$

23.24 — HIGHER ENGINEERING MATHEMATICS—VI

Region of convergence is $|z - 1| < 1$

Example 4: Find all possible Laurent series of $f(z) = \frac{7z^2+9z-18}{z^3-9z}$ about its singular points.

Solution: $f(z)$ has three singular points $z = 0, -3$ and 3 . By partial fractions

$$\begin{aligned} f(z) &= \frac{7z^2+9z-18}{z(z+3)(z-3)} = \frac{A}{z} + \frac{B}{z+3} + \frac{C}{z-3} \\ &= \frac{2}{z} + \frac{1}{z+3} + \frac{4}{z-3} \end{aligned}$$

Case 1: The two analytic regions about $z = 0$ are (a) $0 < |z - 0| < 3$ and (b) $|z - 0| > 3$. So we get two Laurent series of $f(z)$ about the singular point $z = 0$ (Fig. 23.34).

Fig. 23.34

a. For $0 < |z| < 3$

$$\begin{aligned} f(z) &= \frac{2}{z} + \frac{1}{z+3} + \frac{4}{z-3} \\ &= \frac{2}{z} + \frac{1}{3} \frac{1}{1+\frac{z}{3}} - \frac{4}{3} \frac{1}{1-\frac{z}{3}} \\ &= \frac{2}{z} + \frac{1}{3} \sum_{n=0}^{\infty} (-1)^n \left(\frac{z}{3}\right)^n - \frac{4}{3} \sum_{n=0}^{\infty} \left(\frac{z}{3}\right)^n \end{aligned}$$

Fig. 23.35

provided $\left|\frac{z}{3}\right| < 1$ or $0 < |z| < 3$

$$f(z) = \frac{2}{z} + \sum_{n=0}^{\infty} \left[(-1)^n - 4 \right] \frac{z^n}{3^{n+1}},$$

b. For $|z| > 3$

$$\begin{aligned} f(z) &= \frac{2}{z} + \frac{1}{z+3} + \frac{4}{z-3} \\ &= \frac{2}{z} + \frac{1}{z} \frac{1}{1+\frac{3}{z}} + \frac{4}{z} \frac{1}{1-\frac{3}{z}} \\ &= \frac{2}{z} + \frac{1}{z} \sum_{n=0}^{\infty} (-1)^n \left(\frac{3}{z}\right)^n + \frac{4}{z} \sum_{n=0}^{\infty} \left(\frac{3}{z}\right)^n \\ f(z) &= \frac{2}{z} + \sum_{n=0}^{\infty} \left[(-1)^n + 4 \right] \frac{3^n}{z^{n+1}} \end{aligned}$$

Fig. 23.36

Case 2: (refer Fig. 23.37). The three analytic regions of $f(z)$ about $z = 3$ are

- $0 < |z - 3| < 3$, I
- $3 < |z - 3| < 6$, II
- $|z - 3| > 6$, III

Fig. 23.37

So three Laurent series of $f(z)$ about $z = 3$ can be obtained as follows:

a. For $0 < |z - 3| < 3$. (Region I in Fig. 23.37)

$$f(z) = \frac{2}{z} + \frac{1}{z+3} + \frac{4}{z-3}$$

$$\begin{aligned}
 &= \frac{2}{z-3+3} + \frac{1}{z-3+6} + \frac{4}{z-3} \\
 &= \frac{2}{3} \frac{1}{1+\left(\frac{z-3}{3}\right)} + \frac{1}{6} \frac{1}{1+\left(\frac{z-3}{6}\right)} + \frac{4}{z-3} \\
 f(z) &= \frac{2}{3} \sum (-1)^n \left(\frac{z-3}{3}\right)^n + \frac{1}{6} \sum (-1)^n \left(\frac{z-3}{6}\right)^n \\
 &\quad + \frac{4}{z-3}
 \end{aligned}$$

if $\left|\frac{z-3}{3}\right| < 1$ and $\left|\frac{z-3}{6}\right| < 1$
 i.e., $|z-3| < 3$ and $|z-3| < 6$,
 the common region is $0 < |z-3| < 3$.

b. For $3 < |z-3| < 6$ (Region II in Fig. 23.37)

$$\begin{aligned}
 f(z) &= \frac{2}{z-3+3} + \frac{1}{z-3+6} + \frac{4}{z-3} \\
 &= \frac{1}{z-3} \cdot \frac{2}{1+\left(\frac{3}{z-3}\right)} + \frac{1}{6} \frac{1}{1+\left(\frac{z-3}{6}\right)} + \frac{4}{z-3} \\
 &= \frac{1}{z-3} \cdot 2 \sum_{n=0}^{\infty} (-1)^n \left(\frac{3}{z-3}\right)^n \\
 &\quad + \frac{1}{6} \sum_{n=0}^{\infty} (-1)^n \left(\frac{z-3}{6}\right)^n + \frac{4}{z-3}
 \end{aligned}$$

if $\left|\frac{3}{z-3}\right| < 1$ and $\left|\frac{z-3}{6}\right| < 1$ i.e., $3 < |z-3| < 6$

c. For $|z-3| > 6$ (Region III in Fig. 23.37)

$$\begin{aligned}
 f(z) &= \frac{2}{z-3+3} + \frac{1}{z-3+6} + \frac{4}{z-3} \\
 &= \frac{1}{z-3} \frac{2}{1+\left(\frac{3}{z-3}\right)} + \frac{1}{z-3} \frac{1}{1+\left(\frac{6}{z-3}\right)} + \frac{4}{z-3} \\
 &= \frac{2}{z-3} \cdot \sum_{n=0}^{\infty} (-1)^n \left(\frac{3}{z-3}\right)^n + \\
 &\quad + \frac{1}{z-3} \sum_{n=0}^{\infty} (-1)^n \left(\frac{6}{z-3}\right)^n + \frac{4}{z-3}
 \end{aligned}$$

if $\left|\frac{3}{z-3}\right| < 1$ and $\left|\frac{6}{z-3}\right| < 1$ i.e., $|z-3| > 3$
 and $|z-3| > 6$.

The common region is $|z-3| > 6$.

Case 3: Three Laurent series of $f(z)$ can be obtained about $z = -3$ in the regions, I, II, III shown in Fig. 23.38.

Fig. 23.38

a. For $0 < |z+3| < 3$

$$\begin{aligned}
 f(z) &= \frac{2}{z} + \frac{1}{z+3} + \frac{4}{z-3} \\
 &= \frac{2}{z+3-3} + \frac{1}{z+3} + \frac{4}{z+3-6} \\
 &= -\frac{2}{3} \sum_{n=0}^{\infty} \left(\frac{z+3}{3}\right)^n + \frac{1}{z+3} - \frac{4}{6} \sum_{n=0}^{\infty} \left(\frac{z+3}{6}\right)^n
 \end{aligned}$$

b. For $3 < |z+3| < 6$

$$\begin{aligned}
 f(z) &= \frac{2}{z+3} \sum_{n=0}^{\infty} \left(\frac{3}{z+3}\right)^n + \frac{1}{z+3} \\
 &\quad - \frac{4}{6} \sum_{n=0}^{\infty} \left(\frac{z+3}{6}\right)^n
 \end{aligned}$$

c. For $|z+3| > 6$

$$\begin{aligned}
 f(z) &= \frac{2}{z+3} \sum_{n=0}^{\infty} \left(\frac{3}{z+3}\right)^n + \frac{1}{z+3} \\
 &\quad - \frac{4}{(z+3)} \sum_{n=0}^{\infty} \left(\frac{6}{z+3}\right)^n
 \end{aligned}$$

Example 5: Show that $\operatorname{cosec} z = \frac{1}{z} + \frac{1}{3!}z + \frac{7}{360}z^3 + \dots$

Solution: $\operatorname{csc} z = \frac{1}{\sin z}$ has singular points at $z = 0, \pm n\pi, n$ integer. Expand in series in $0 < |z| < \pi$.

$$\operatorname{cosec} z = \frac{1}{\sin z} = \frac{1}{z - \frac{z^3}{3!} + \frac{z^5}{5!} - \frac{z^7}{7!} + \dots}$$

$$\begin{aligned}
 &= \frac{1}{z} \left[\frac{1}{1 - \left(\frac{z^2}{3!} - \frac{z^4}{5!} + \frac{z^6}{7!} + \dots \right)} \right] \\
 &= \frac{1}{z} \left[1 + \left(\frac{z^2}{3!} - \frac{z^4}{5!} + \frac{z^6}{7!} + \dots \right) \right. \\
 &\quad \left. + \left(\frac{z^2}{3!} - \frac{z^4}{5!} + \frac{z^6}{7!} + \dots \right)^2 + \dots \right] \\
 &= \frac{1}{z} \left[1 + \frac{z^2}{3!} - \frac{z^4}{5!} + \frac{z^4}{(3!)^2} + \dots \right] \\
 &= \frac{1}{z} + \frac{1}{3!} z^2 + \left(\frac{1}{3!^2} - \frac{1}{5!} \right) z^3 + \dots
 \end{aligned}$$

Example 6: Prove that for k real, $k^2 < 1$

$$\begin{aligned}
 \sum_{n=0}^{\infty} k^n \sin(n+1)\theta &= \frac{\sin \theta}{(1 - 2k \cos \theta + k^2)} \\
 \sum_{n=0}^{\infty} k^n \cos(n+1)\theta &= \frac{\cos \theta - k}{(1 - 2k \cos \theta + k^2)}
 \end{aligned}$$

Solution: $\frac{1}{z-k} = \frac{1}{z} \frac{1}{1-\frac{k}{z}} = \frac{1}{z} \sum_{n=0}^{\infty} \left(\frac{k}{z}\right)^n = \sum_{n=0}^{\infty} \frac{k^n}{z^{n+1}}; |z| > k$

Put $z = e^{i\theta} = \cos \theta + i \sin \theta$

$$\begin{aligned}
 \frac{1}{z-k} &= \frac{1}{e^{i\theta} - k} = \sum k^n \cdot e^{-(n+1)\theta i} \\
 &= \sum k^n \cos(n+1)\theta - i \sin(n+1)\theta \quad (*)
 \end{aligned}$$

$$\text{But } \frac{1}{e^{i\theta} - k} = \frac{1}{\cos \theta + i \sin \theta - k} = \frac{(\cos \theta - k) - i \sin \theta}{1 - 2k \cos \theta + k^2}$$

Comparing real and imaginary parts of (*), the result is obtained.

EXERCISE

Find the Laurent series of $f(z)$ about the indicated point. State the region of convergence:

1. $z^{-5} \cdot \sin z, z_0 = 0$

Ans. $\sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} z^{2n-4}, |z| > 0$

2. $z^2 e^{1/z}, z_0 = 0$

Ans. $z^2 + z + \frac{1}{2} + \frac{1}{3!} \frac{1}{z} + \frac{1}{4!} \frac{1}{z^2} + \dots, |z| > 0$

3. $\frac{1}{1-z}, z_0 = 0, 1$

Ans. $\sum_{n=0}^{\infty} z^n$ (Taylor's), $-\sum_{n=0}^{\infty} \frac{1}{z^{n+1}}, |z| > 1$ (Laurent)

4. $\frac{-2z+3}{z^3-3z+2}, z_0 = 0$

a. $|z| < 1, \sum_{n=0}^{\infty} \left(1 + \frac{1}{2^{n+1}}\right) z^n$

b. For $1 < |z| < 2, \sum_{n=0}^{\infty} \frac{1}{2^{n+1}} z^n$

c. For $|z| > 2, -\sum_{n=0}^{\infty} (2^n + 1) \frac{1}{z^{n+1}}$

Ans. Three Laurent series

5. $\frac{7z-2}{(z+1)(z)(z-2)}, z_0 = -1$

Ans. Three Laurent series expansions

a. For $0 < |z+1| < 1, \frac{-3}{z+1} - \frac{5}{3} - \frac{11}{9}(z+1) - \frac{29}{27}(z+1)^2 - \frac{83}{81}(z+1)^3 + \dots$

b. For $1 < |z+1| < 3, \dots + \frac{1}{(z+1)^3} + \frac{1}{(z+1)^2} - \frac{2}{z+1} - \frac{2}{3} - \frac{2}{9}(z+1) - \frac{2}{27}(z+1)^2 - \frac{2}{81}(z+1)^3 + \dots$

c. For $|z+1| > 3, \dots + 19 \frac{1}{(z+1)^3} + 7 \frac{1}{(z+1)^2}$

6. $\frac{1}{(1-z)(z-2)}, z_0 = 0$, two Laurent series

a. For $1 < |z| < 2, \sum_{n=0}^{\infty} \frac{1}{z^{n+1}} + \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}}$

b. For $|z| > 2, \sum_{n=0}^{\infty} \frac{1-2^n}{z^{n+1}}$

7. Expand $\frac{1}{(z+1)(z+3)}$ in Laurent series valid for

a. $1 < |z| < 3$

b. $|z| > 3$

c. $0 < |z+1| < 2$

d. $|z| < 1$

Ans. a. $-\frac{1}{2z^4} + \frac{1}{2z^3} - \frac{1}{2z^2} + \frac{1}{2z} - \frac{1}{6} + \frac{z}{18} - \frac{z^2}{54} + \frac{z^3}{162} + \dots$

b. $\frac{1}{z^2} - \frac{4}{z^3} + \frac{13}{z^4} - \frac{40}{z^5} + \dots$

c. $\frac{1}{2(z+1)} - \frac{1}{4} + \frac{1}{8}(z+1) - \frac{1}{16}(z+1)^2 + \dots$

d. $\frac{1}{3} - \frac{4}{9}z + \frac{13}{27}z^2 - \frac{40}{81}z^3 + \dots$ (Taylor's series)

8. Find Laurent series about the indicated singu-

larity:

a. $\frac{e^{2z}}{(z-1)^3}, z = 1$

b. $(z-3)\sin\left(\frac{1}{z+2}\right), z = -2$

c. $\frac{z-\sin z}{z^3}, z = 0$

d. $\frac{z}{(z+1)(z+2)}, z = -2$

e. $\frac{1}{z^2(z-3)^2}, z = 3$

Ans. a. $\frac{e^2}{(z-1)^3} + \frac{2e^2}{(z-1)^2} + \frac{2e^2}{(z-1)} + \frac{4e^2}{3} + \frac{2e^2}{3}(z-1) + \dots$

b. $1 - \frac{5}{z+2} - \frac{1}{6(z+2)^2} + \frac{5}{6(z+2)^3} + \frac{1}{120(z+2)^4} + \dots$

c. $\frac{1}{3!} - \frac{z^2}{5!} + \frac{z^4}{7!} + \dots$

d. $\frac{2}{2+z} + 1 + (z+2) + (z+2)^2 + \dots$

e. $\frac{1}{9(z-3)^2} - \frac{2}{27(z-3)} + \frac{1}{27} - \frac{4(z-3)}{243} + \dots$

9. $\frac{1}{[(z-a)(z-b)]}, 0 < |a| < |b|$, around $z = 0, a, \infty$ and annulus $|a| < |z| < |b|$.

a. $\frac{1}{b-a} \cdot \sum_{n=0}^{\infty} \frac{b^{n+1} - a^{n+1}}{a^{n+1}b^{n+1}} \cdot z^n$ for $|z| < a$

b. $\frac{1}{a-b} \left[\frac{1}{z-a} + \sum_{n=0}^{\infty} \frac{(z-a)^n}{(b-a)^{n+1}} \right]$

for $0 < |z-a| < |b-a|$

c. $\frac{1}{b-a} \sum_{n=2}^{\infty} \frac{b^{n-1} - a^{n-1}}{z^n}$ for $|z| > b$

d. $\frac{1}{a-b} \sum_{n=0}^{\infty} \left(\frac{z^n}{b^{n+1}} + \frac{a^n}{z^{n+1}} \right), |a| < |z| < |b|$

23.8 ZEROS AND POLES

Zeros

A point z_0 is called a zero of an analytic function $f(z)$ if $f(z_0) = 0$.

Zero of k th order (multiplicity k)

z_0 is called a zero of k th order if not only f but also the derivatives $f', f'', \dots, f^{(k-1)}$ are all zero at z_0 and $f^{(k)}(z_0) \neq 0$.

Simple zero is a zero of first order $k = 1$ (i.e., $f(z_0) = 0$, and $f'(z_0) \neq 0$).

By expanding $f(z)$ about z_0 in power series

$$f(z) = \sum_{n=0}^{\infty} a_n(z-z_0)^n$$

it follows that when z_0 is a simple zero, $a_0 = 0$. For a k th order zero, $a_0, a_1, a_2, \dots, a_{k-1}$ are all zero while $a_k \neq 0$.

Poles

A regular point of $f(z)$ is a point where $f(z)$ is analytic.

A singular point or singularity of $f(z)$ is a point z_0 at which $f(z)$ is not analytic. However, every neighbourhood of z_0 contains points at which $f(z)$ is analytic.

Isolated singular point (ISP)

A singular point z_0 is said to be an isolated singular point if there exists a neighbourhood of z_0 which does not contain any other singular point of $f(z)$.

Classification of Isolated Singular Point z_0

Expand $f(z)$ about the singular point z_0 in Laurent series in the annulus region $0 < |z-z_0| < R$, we get

$$f(z) = \sum_{n=0}^{\infty} a_n(z-z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z-z_0)^n}$$

Then, the series of negative integer powers of $(z-z_0)$ namely $\sum_{n=1}^{\infty} \frac{b_n}{(z-z_0)^n}$ is known as the “**principal part**” of the Laurent series expansion of $f(z)$ about z_0 .

Removable singularity (ISP)

If all the coefficients b_n 's are zero, i.e., Laurent series does not contain negative integer powers of $(z-z_0)$ then z_0 is called a removable singularity i.e., $f(z)$ can be made analytic by redefining $f(z_0)$ suitably i.e., if $\lim_{z \rightarrow z_0} f(z)$ exists.

Pole of order m

If the principal part contains a finite number of terms $\leq m$ involving negative power of $(z-z_0)$, then z_0 is called a pole of order m , of $f(z)$ i.e., $b_m \neq 0$, but

$b_n = 0$ for $n > m$. Then $|f| \rightarrow \infty$ as $z \rightarrow z_0$.

Simple pole is a pole of order one.

Essential singularity

If the principal part contains infinite number of terms containing negative powers of $(z - z_0)$ i.e., all b_n 's are non-zero. i.e., $\lim_{z \rightarrow z_0} f(z)$ does not exist.

Analytic (or singular) at infinity: The behaviour of $f(z)$ at ∞ can be investigated by introducing $z = 1/w$. Then $f(z)$ is said to be analytic (or singular) at infinity if $g(w)$ is analytic (or singular) at $w = 0$.

WORKED OUT EXAMPLES

Zeros

Example 1: Find the orders of all zeros of the given functions:

a. $z^2 + 9$

Ans. $z = \pm 3i$ are simple zeros

b. $\frac{z^2+8}{z^4}$

Ans. $z = \pm\sqrt{8}i$ are simple zeros. $z = \infty$ is a zero of second order, put $w = \frac{1}{z}$.

$$\frac{\frac{1}{w^2} + 8}{\frac{1}{w^4}} = \frac{1 + 8w^2}{w^2} \cdot w^4 = w^2(1 + 8w^2)$$

$w = 0$ is a zero of second order, so $z = \infty$ is a zero of second order

c. $f = z \sin z$.

Ans. $z = 0$ is a zero of second order, since $f'(0) = \sin z + z \cos z = 0$, while $f''(0) = 2 \cos z - \sin z = 2 \neq 0$.

Also $z = \pm k\pi, k = 1, 2, 3, \dots$ are zeros of first order.

d. $f = (1 - e^z)(z^2 - 4)^3$

Ans. $z = \pm 2$ are zeros of 3rd order. $z = 2k\pi, k = 0, \pm 1, \pm 2, \pm \dots$ are zeros of first order

e. $e^{\tan z}$

Ans. no zeros since $e^z \neq 0$ for any z

f. $z^4 \sin^2(1/z)$

Ans. $z = \pm \frac{1}{n\pi}$, double zeros for $n = 1, 2, 3, \dots$

g. $\frac{(z^2 - \pi^2) \sin z}{z^7}$

Ans. $z = \pm \pi$ are 3rd order zeros

$z = k\pi, k = 0, \pm 2, \pm 3, \dots$ are first order zeros.

Poles

Example 2: Determine and classify all singularities of the given functions. (See more examples on page 24.2)

1. $\frac{1}{z - z^3}$

Ans. $z = 0, \pm 1$ are poles of first order

$z = \infty$ is a regular point (zero of 3rd order)

2. $\frac{z^4}{1 + z^4}$

Ans. $z = \pm \frac{1 \pm i}{\sqrt{2}}$ are simple poles

$z = \infty$ is a regular point

3. $\frac{z^5}{(z-2)^2(z^2+4)^3(z-5)^4}$

Ans. $z = 2$ double pole,

$z = \pm 2i$ triple pole

$z = 5$ is pole of 4th order

$z = \infty$ is a regular point (zero of 7th order)

4. $\frac{e^z}{1 + z^2}$

Ans. $z = \pm i$ are simple poles

$z = \infty$ is an essential singularity

(put $z = \frac{1}{w}, \frac{e^z}{1 + z^2} = \frac{w^2 e^{\frac{1}{w}}}{w^2 + 1}, w = 0$ is an essential singularity)

5. $\cot \frac{1}{z} - \frac{1}{z}$

Ans. $z = \frac{1}{k\pi}, k = \pm 1, \pm 2, \dots$ are poles of first order, $z = 0$ is a limit point for poles: $z = 0$ is a non-isolated singular point, $z = \infty$ is a pole of first order.

6. $\frac{1 - e^{2z}}{z^4}$

Ans. $z = 0$ a pole of order 3

(since Laurent series $-\sum_{n=1}^{\infty} \frac{2^n}{n!} \cdot z^{n-4}$)

7. $\frac{1-\cos z}{z}$

Ans. $z = 0$, removable singularity

8. $e^{z/(z-2)}$

Ans. $z = 2$ is essential singularity

$z = \infty$ is removable (put $z = \frac{1}{w}$, $e^{\frac{1}{1-2w}}$).

EXERCISE 3

Zeros

Determine the location and order of the zeros of the given functions:

1. $z^2 + 1$

Ans. $z = \pm i$ simple zeros

2. $(1 - z^4)^2$

Ans. $z = \pm 1, \pm i$ are double zeros

3. $1 - \cos z$

Ans. $z = 2k\pi$, ($k = 0, \pm 1, \pm 2, \dots$) are zeros of 2nd order

4. $(1 - \cos z)^2$

Ans. 4th order zeros at $z = 2k\pi$, where $k = 0, \pm 1, \pm 2, \dots$

5. $e^z - e^{2z}$

Ans. $\pm 2n\pi i$, $n = 0, 1, 2, \dots$ simple zeros

6. $\frac{1-\cot z}{z}$

Ans. $z = \frac{\pi}{4} + k\pi$, $k = 0, \pm 1, \pm 2, \dots$ simple

7. $\cos^3 z$

Ans. $z = (2k + 1)\frac{\pi}{2}$, $k = 0, \pm 1, \pm 2, \dots$, 3rd order

8. $\cos z^3$

Ans. $z = ((2k + 1)\frac{\pi}{2})^{\frac{1}{3}}$ and $z = \frac{1}{2}\sqrt{(2k + 1)\frac{\pi}{2}} (1 \pm i\sqrt{3})$ with $k = 0, \pm 1, \pm 2, \dots$ simple zeros.

9. e^z

Ans. no zeros

10. $\frac{\sin^3 z}{z}$

Ans. $z = 0$, 2nd order

$z = k\pi$, $k = \pm 1, \pm 2, \dots$, 3rd order.

Poles

Determine and classify all the singularities of the given functions:

1. $\frac{z^8 + z^4 + 2}{(z-1)^3(3z+2)^2}$

Ans. $z = 1$ pole of order 3

$z = -2/3$ pole of order 2

$z = \infty$ is pole of order 3

2. $\frac{z+1}{z^3(z^2+1)}$

Ans. $z = 0$, pole of order 3,

$z = \pm i$ simple poles

3. $\frac{1}{z(z-2)^5} + \frac{3}{(z-2)^2}$

Ans. $z = 0$ simple pole,

$z = 2$ pole of order 5

4. $\frac{1}{\sin(\frac{\pi}{z})}$

Ans. $z = \pm \frac{1}{n}$, $n = 1, 2, 3, \dots$ are simple poles

$z = 0$ is a non-isolated singular point

5. $\frac{\sinh z}{z^4}$

Ans. $z = 0$ pole of order 3

6. $\cosh \frac{1}{z}$

Ans. $z = 0$ is essential singularity

7. $\cot z$

Ans. $z = 0, \pm n\pi$ ($n = 1, 2, 3, \dots$) simple

8. $\frac{1}{z(e^z - 1)}$

Ans. $z = 0$ second order pole

9. $\frac{z - \sin z}{z^2}$

Ans. $z = 0$ is removable singularity

10. $(z + 1) \sin \frac{1}{z-2}$

Ans. $z = 2$ is an essential singularity

11. $\frac{1}{\cos z - \sin z}$

Ans. $z = \frac{\pi}{4}$ is simple pole

12. $ze^{\frac{1}{z^2}}$

Ans. $z = 0$ essential singularity

23.30 — HIGHER ENGINEERING MATHEMATICS—VI

13. $\frac{z^2-1}{(z-1)^2}$

Ans. $z = 1$ is simple pole

14. $\frac{1}{e^z}$

Ans. no singular points

15. $\frac{1}{1+1/(1+z)}$

Ans. $z = -2$ simple pole

16. $\frac{1}{z^2}$

Ans. analytic at $z = \infty$

2nd order zero at ∞

17. $e^z, \sin z, \cos z$

Ans. essential singularity at $z = \infty$.

Chapter 24

Theory of Residues

INTRODUCTION

Residue theorem is a very powerful and elegant theorem in complex integration. Using the residue theorem many complicated real integrals can be evaluated. It is also used to sum a real convergent series and to find the inverse Laplace transform.

24.1 RESIDUE

Residue of an analytic function $f(z)$ at an isolated singular point $z = z_0$ is the coefficient say b_1 of $(z - a)^{-1}$ in the Laurent series expansion of $f(z)$ about z_0 . Residue of $f(z)$ at z_0 is denoted by $\text{Res}_{z=z_0} f(z)$ or $\text{Res} f(z)$. From Laurent series, we know that the coefficient b_1 is given by

$$b_1 = \frac{1}{2\pi i} \oint_c f(z) dz$$

Thus

$$\text{Residue of } f(z) = \text{Res}_{z=z_0} f(z) = b_1 = \frac{1}{2\pi i} \oint_c f(z) dz$$

where c is any closed contour enclosing z_0 (and such that f is analytic on and within c).

Calculation of Residue at Simple Pole

Formula I. $\text{Res}_{z=z_0} f(z) = b_1 = \lim_{z \rightarrow z_0} [(z - z_0)f(z)]$
The Laurent series of $f(z)$ about z_0 is

$$f(z) = \frac{b_1}{z - z_0} + \sum_{n=0}^{\infty} a_n (z - z_0)^n$$

is multiplied by $(z - z_0)$ which gives

$$(z - z_0)f(z) = b_1 + (z - z_0) \sum_{n=0}^{\infty} a_n (z - z_0)^n$$

$$\text{As } z \rightarrow z_0, \lim_{z \rightarrow z_0} (z - z_0)f(z) = b_1 + 0 = b_1.$$

Formula II. Suppose $f(z) = \frac{P(z)}{Q(z)}$ has a simple pole at z_0 such that $P(z_0) \neq 0$. Then

$$\text{Res}_{z=z_0} f(z) = \text{Res}_{z=z_0} \frac{P(z)}{Q'(z)} = \frac{P(z_0)}{Q'(z_0)}.$$

Calculation of Residue at a Multiple Pole

The Laurent series expansion of $f(z)$ about a pole z_0 of order $m > 1$ is

$$\begin{aligned} f(z) &= \frac{b_m}{(z - z_0)^m} + \frac{b_{m-1}}{(z - z_0)^{m-1}} + \cdots \\ &+ \frac{b_1}{(z - z_0)} + \sum_{n=0}^{\infty} a_n (z - z_0)^n \end{aligned}$$

Multiply both sides by $(z - z_0)^m$

$$\begin{aligned} (z - z_0)^m f(z) &= b_m + b_{m-1}(z - z_0) \cdots \\ &+ b_1(z - z_0)^{m-1} + \sum_{n=0}^{\infty} a_n (z - z_0)^{n+m} \end{aligned}$$

Differentiating both sides $(n - 1)$ times and let $z \rightarrow z_0$

$$\lim_{z \rightarrow z_0} \frac{d^{m-1}}{dz^{m-1}} (z - z_0)^m f(z) = (m - 1)! b_1 + 0 + \cdots$$

24.2 — HIGHER ENGINEERING MATHEMATICS—VI

Thus residue of $f(z)$ at z_0 is

$$b_1 = \frac{1}{(m-1)!} \lim_{z \rightarrow z_0} \left[\frac{d^{m-1}}{dz^{m-1}} \{ (z - z_0)^m \cdot f(z) \} \right]$$

For simple pole ($m = 1$)

$$b_1 = \text{Res}_{z=z_0} f(z) = \lim_{z \rightarrow z_0} [(z - z_0)f(z)]$$

Note: When $z = z_0$ is an essential singularity of $f(z)$ then the above formulae fail. In such cases the residue at an essential singularity is obtained by expanding $f(z)$ about z_0 in Laurent series (and identify b_1 , the coefficient of $(z - z_0)^{-1}$).

24.2 RESIDUE THEOREM

Residue theorem, which is very powerful (but whose proof is very simple) is useful in evaluating contour integrals where the closed contour contains several singularities inside.

Theorem 1: Let $f(z)$ be analytic within and on a simple closed path c except at a finite number of singular points $z_1, z_2, \dots, z_n$ inside c . Then

$$\oint_c f(z) dz = 2\pi i \sum_{i=1}^n \text{Res}_{z=z_i} f(z)$$

where the integral is taken counterclockwise around c . (Fig. 24.1)

Fig. 24.1

Proof: Enclose each of the singular points z_i in a circle c_i of small radius such that all these n circles and curve c are all separated. Then $f(z)$ is analytic in the multiply connected domain D bounded by B consisting of c and $c_1, c_2, \dots, c_n$ and on the entire boundary B of D . Now by Cauchy's integral theorem

(for multiply connected domain), we have

$$\oint_B = \oint_{c+c_1+c_2+\dots+c_n} = \oint_c f(z) dz + \oint_{c_1} f(z) dz + \dots + \oint_{c_n} f(z) dz = 0$$

where the integral along c taken in the counterclockwise direction and along $c_1, c_2, \dots, c_n$ in the clockwise direction. Thus

$$\oint_c f(z) dz = \oint_{c_1} f(z) dz + \dots + \oint_{c_n} f(z) dz$$

Here $c_1, c_2, \dots, c_n$ are also taken along counterclockwise direction (the minus sign reverses the sense of integration from clockwise to counterclockwise).

By definition of residues

$$\oint_{c_i} f(z) dz = 2\pi i \cdot \text{Res}_{z=z_i} f(z),$$

for $i = 1, 2, 3, \dots, n$

Thus

$$\oint_c f(z) dz = 2\pi i \left[\text{Res}_{z=z_1} f(z) + \dots + \text{Res}_{z=z_n} f(z) \right]$$

$$\oint_c f(z) dz = 2\pi i \sum_{i=1}^n \text{Res}_{z=z_i} f(z).$$

WORKED OUT EXAMPLES

Residues

Example 1: Expand each of the following function in a Laurent series about $z = 0$, name the type of singularity in each case. Find the residues at $z = 0$:

(a) $z^2 e^{-z^4}$ (b) $\frac{(1-\cos z)}{z}$ (c) $\frac{e^{z^2}}{z^3}$ (d) $z^{-1} \cosh z^{-1}$.

Solution:

$$\begin{aligned} \text{a. } z^2 e^{-z^4} &= z^2 \sum_{n=0}^{\infty} \frac{(-z^4)^n}{n!} = \sum_{n=0}^{\infty} \frac{(-1)^n z^{4n+2}}{n!} \\ &= z^2 - z^6 + \frac{z^{10}}{2!} - \frac{z^{14}}{3!} + \dots \end{aligned}$$

Laurent series contains only positive powers of z . Thus $z = 0$ is an ordinary point. Residue at $z = 0$ is 0.

$$\begin{aligned}
 \text{b. } \frac{1-\cos z}{z} &= \frac{1}{z} \left[1 - \left(1 - \frac{z^2}{2!} + \frac{z^4}{4!} - \dots \right. \right. \\
 &\quad \left. \left. \frac{(-1)^{n-1} z^{2n-2}}{(2n-2)!} + \dots \right) \right] \\
 &= \frac{1}{z} \left[\frac{z^2}{2!} - \frac{z^4}{4!} + \dots + \frac{(-1)^n z^{2n-2}}{(2n-2)!} + \dots \right] \\
 &= \frac{z}{2!} - \frac{z^3}{4!} + \frac{z^5}{6!} + \dots
 \end{aligned}$$

Although $\frac{1-\cos z}{z}$ is not defined at $z=0$,

$$\lim_{z \rightarrow 0} \frac{1-\cos z}{z} = 0$$

So $z=0$ is a removable singularity. Residue is 0.

$$\begin{aligned}
 \text{c. } \frac{e^{z^2}}{z^3} &= \frac{1}{z^3} \sum_{n=0}^{\infty} \frac{(z^2)^n}{n!} = \frac{1}{z^3} \left[1 + \frac{z^2}{1!} + \frac{z^4}{2!} \right. \\
 &\quad \left. + \frac{z^6}{3!} + \dots \right] \\
 &= \frac{1}{z^3} + \frac{1}{z} + \frac{z}{2!} + \frac{z^3}{3!} + \frac{z^5}{4!} + \frac{z^7}{5!} + \dots
 \end{aligned}$$

So the principal part contains finite number of terms with the highest power $\frac{1}{z^3}$. Thus $z=0$ is a pole of order 3. Residue is 1.

$$\begin{aligned}
 \text{d. } z^{-1} \cosh z^{-1} &= \frac{1}{z} \sum_{n=1}^{\infty} \left(\frac{1}{z} \right)^{2n-2} \cdot \frac{1}{(2n-2)!} \\
 &= \sum_{n=1}^{\infty} \left(\frac{1}{z} \right)^{2n-1} \cdot \frac{1}{(2n-2)!} \\
 &= \frac{1}{z} + \frac{1}{2!} \frac{1}{z^3} + \frac{1}{4!} \frac{1}{z^5} + \frac{1}{6!} \frac{1}{z^7} + \dots
 \end{aligned}$$

Since the principal part contains infinite number of terms, so $z=0$ is an essential singularity. Residue is 1.

Example 2: Determine and classify the singularities (a) $\frac{z}{(e^z-1)}$ (b) $\frac{1}{(2 \sin z-1)^2}$.

Solution:

a. Singularities are the zeros of the denominator i.e., $e^z - 1 = 0$ or $e^z = 1$ or $e^{\pm 2n\pi i} = 1$.

Therefore the singular points are $z = 2m\pi i$, $m = \pm 1, \pm 2, \dots$ which are simple poles. But $z=0$ is removable singularity since

$$\lim_{z \rightarrow 0} \frac{z}{e^z - 1} = \lim_{z \rightarrow 0} \frac{z}{1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \dots - 1}$$

$$= \lim_{z \rightarrow 0} \frac{1}{1 + \frac{z}{2!} + \frac{z^2}{3!} + \dots} = 1$$

$z = \infty$ is an essential singularity: put $w = \frac{1}{z}$,

$$\begin{aligned}
 \frac{z}{e^z - 1} &= \frac{1}{w} \cdot \frac{1}{e^{\frac{1}{w}} - 1} \\
 &= \frac{1}{w} \cdot \frac{1}{\left[1 + \frac{1}{w} + \frac{1}{w^2} \frac{1}{2!} + \frac{1}{w^3} \frac{1}{3!} + \dots - 1 \right]} \\
 &= \frac{1}{w} \cdot \frac{1}{\frac{1}{w} + \frac{1}{w^2} \frac{1}{2!} + \frac{1}{w^2} \frac{1}{3!} + \dots} \\
 &= \frac{1}{w^2} \left[1 + \frac{1}{w} \frac{1}{2!} + \frac{1}{w^2} \frac{1}{w!} + \dots \right]^{-1} \\
 &= \frac{1}{w^2} \left[1 - \left(\frac{1}{w} \frac{1}{2!} + \frac{1}{w^2} \frac{1}{3!} + \dots \right) \right. \\
 &\quad \left. + \left(\frac{1}{w} \frac{1}{2!} + \frac{1}{w^2} \frac{1}{3!} + \dots \right)^2 + \dots \right]
 \end{aligned}$$

So $w=0$ is an essential singularity. Therefore $z = \infty$ is an essential singularity.

b. Zeros of $2 \sin z - 1$ are solutions of $\sin z = \frac{1}{2}$

$$\frac{e^{iz} - e^{-iz}}{2i} = \frac{1}{2}, (e^{iz})^2 - i e^{iz} - 1 = 0,$$

$$e^{iz} = \frac{i \pm \sqrt{3}}{2} = e^{i(2m\pi + \frac{\pi}{6})}$$

$$e^{iz} = e^{\frac{i(\pm\sqrt{3})}{2}} = e^{i(2m + \frac{\pi}{6})},$$

$$e^{iz} = e^{\frac{i\sqrt{3}}{2}} = e^{i((2m+1)\pi - \frac{\pi}{6})}$$

Thus $\frac{\pi}{6} + 2m\pi$, $(2m+1)\pi - \frac{\pi}{6}$, $m = 0, \pm 1, \pm 2, \pm 3, \dots$ are poles of order 2.

Example 3: Determine the residues at the poles:

$$(a) \frac{2z+1}{z^2-z-2} \quad (b) \left(\frac{z+1}{z-1} \right)^3 \quad (c) \frac{z+1}{(z^2-16)(z+2)} \quad (d) \frac{\sin z}{z^2}$$

$$(e) \frac{1-e^{2z}}{z^4} \quad (f) \frac{(\csc z - \operatorname{csch} z)}{z^3} \quad (g) \frac{z^2}{(z^2+3z+2)^2}.$$

Solution:

a. $\frac{2z+1}{z^2-z-2} = \frac{2z+1}{(z+1)(z-2)}$ so $z = -1, 2$ are poles of order 1 (simple poles)

$$\operatorname{Res}_{z=a} f(z) = \lim_{z \rightarrow a} [(z-a)f(z)]$$

$$\begin{aligned}
 \operatorname{Res}_{z=-1} \frac{2z+1}{(z+1)(z-2)} &= \lim_{z \rightarrow -1} \left[(z+1) \cdot \frac{2z+1}{(z+1)(z-2)} \right] \\
 &= \frac{1}{3}
 \end{aligned}$$

24.4 — HIGHER ENGINEERING MATHEMATICS—VI

$$\begin{aligned}\text{Res}_{\text{at } z=2} \frac{2z+1}{(z+1)(z-2)} &= \lim_{z \rightarrow 2} \left[(z-2) \cdot \frac{2z+1}{(z+1)(z-2)} \right] \\ &= \frac{5}{3}.\end{aligned}$$

b. $\left(\frac{z+1}{z-1}\right)^3$: $z = 1$ is pole of order 3

$$\begin{aligned}\text{Rewriting } \left(\frac{z+1}{z-1}\right)^3 &= \left(\frac{z-1+2}{z-1}\right)^3 = \left(1 + \frac{2}{z-1}\right)^3 \\ &= 1 + 3 \cdot 1 \cdot \left(\frac{2}{z-1}\right) + 3 \cdot 1 \cdot \left(\frac{2}{z-1}\right)^2 + \left(\frac{2}{z-1}\right)^3\end{aligned}$$

Residue of pole $z = 1$ is the coefficient of $\frac{1}{z-1}$ i.e., 6.

c. $z = \pm 4, -2$ are simple poles:

$$\text{Res}_{z=z_0} f(z) = \frac{p(z_0)}{q'(z_0)}$$

Here

$$p(z) = z + 1, q(z) = (z^2 - 16)(z + 2)$$

$$q'(z) = 2z(z + 2) + (z^2 - 16)$$

$$= 3z^2 + 4z - 16$$

$$\text{Res}_{\text{at } z=4} f(z) = \frac{p(4)}{q'(4)} = \frac{4+1}{3 \cdot 4^2 + 4 \cdot 4 - 16} = \frac{5}{48}$$

$$\text{Res}_{\text{at } z=-4} f(z) = \frac{p(-4)}{q'(-4)} = \frac{-4+1}{3(-4)^2 + 4(-4) - 16} = \frac{-3}{16}$$

$$\text{Res}_{\text{at } z=-2} f(z) = \frac{p(-2)}{q'(-2)} = \frac{-2+1}{3(-2)^2 + 4(-2) - 16} = \frac{1}{12}.$$

d. $\frac{\sin z}{z^2}$ has a pole of order two at $z = 0$:

Expanding

$$\begin{aligned}\frac{\sin z}{z^2} &= \frac{1}{z^2} \sum_{n=0}^{\infty} \frac{(-1)^n z^{2n+1}}{(2n+1)!} \\ &= \frac{1}{z^2} \left[z - \frac{z^3}{3!} + \frac{z^5}{5!} + \dots \right] \\ &= \frac{1}{z} - \frac{z}{3!} + \frac{z^3}{5!} + \dots\end{aligned}$$

Residue is the coefficient of $\frac{1}{z}$ i.e., 1.

e. $\frac{1-e^{2z}}{z^4}$ has a pole of order 3 (not 4) at $z = 0$:

Expanding

$$\begin{aligned}\frac{1-e^{2z}}{z^4} &= \frac{1 - \left[1 + 2z + \frac{(2z)^2}{2!} + \frac{(2z)^3}{3!} + \dots \right]}{z^4} \\ &= - \left[\frac{2}{z^3} + \frac{2}{z^2} + \frac{8}{6z} + \frac{16}{24} + \dots \right]\end{aligned}$$

Residue is $-\frac{8}{6} = -\frac{4}{3}$ which is the coefficient of $\frac{1}{z}$.

f. Expanding

$$\begin{aligned}\frac{\csc z \cdot \text{csch } z}{z^3} &= \frac{1}{z^3} \cdot \frac{1}{\sin z \cdot \sinh z} \\ &= \frac{1}{z^3} \cdot \frac{1}{\left[z - \frac{z^3}{3!} + \frac{z^5}{5!} + \dots \right] \left[z + \frac{z^3}{3!} + \frac{z^5}{5!} + \dots \right]} \\ &= \frac{1}{z^3} \cdot \frac{1}{\left[z^2 + 0 + \left(\frac{2}{5!} - \frac{1}{(3!)^2} \right) z^6 + \dots \right]} \\ &= \frac{1}{z^5} \left[1 - \frac{1}{90} z^4 + \dots \right]^{-1} \\ &= \frac{1}{z^5} \left[1 - \frac{1}{90} z^4 + \dots \right] = \frac{1}{z^5} - \frac{1}{90} \frac{1}{z} + \dots \\ \text{Residue is } &\frac{-1}{90}.\end{aligned}$$

g. $\frac{z^2}{(z^2+3z+2)^2}$ has poles of order 2 at $z = -1, -2$.
(since $z^2 + 3z + 2 = (z+1)(z+2)$).

$$\text{Res}_{\text{at } z=a} f(z) = \frac{1}{(m-1)!} \lim_{z \rightarrow a} \frac{d^{m-1}}{dz^{m-1}} \left\{ (z-a)^m \cdot f(z) \right\}$$

$$\text{Res}_{z=-1} f(z) = \lim_{z \rightarrow -1} \frac{d}{dz} \left\{ (z+1)^2 \cdot \frac{z^2}{(z+1)^2(z+2)^2} \right\} = -4$$

$$\text{Res}_{z=-2} f(z) = \lim_{z \rightarrow -2} \frac{d}{dz} \left\{ (z+2)^2 \cdot \frac{z^2}{(z+1)^2(z+2)^2} \right\} = 4.$$

Residue theorem

Example 4: Evaluate $I = \oint_c \frac{z^2+4}{z^3+2z^2+2z}$ where c is

(a) $|z| = 1$ (b) $|z+1-i| = 1$

(c) $|z+1+i| = 1$ (d) $|z-1| = 5$

(e) rectangle with vertices at $2+i, 6+i, 2+4i$, and $6+4i$.

Solution: $f(z) = \frac{z^2+4}{z^3+2z^2+2z}$ has simple poles at $z = 0, -1+i, -1-i$ which are the zeros of

$$z^3 + 2z^2 + 2z = z(z^2 + 2z + 2) = z(z - z_1)(z - z_2)$$

where $z_2 = -1+i, z_3 = -1-i$

$$k_1 = \text{Res}_{\text{at } z=0} f(z) = \frac{p(0)}{q'(0)} = \frac{0+4}{0+0+2} = 2$$

Here $p(z) = z^2 + 4$, $q(z) = z^3 + 2z^2 + 2z$, $q'(z) = 3z^2 + 4z + 2$

$$k_2 = \operatorname{Res}_{\text{at } z=z_2=-1+i} f(z) = \frac{(-1+i)^2 + 4}{3(-1+i)^2 + 4(-1+i) + 2}$$

$$k_2 = \frac{4-2i}{-2(i+1)} = \frac{(i-2)}{(i+1)} = \frac{3i-1}{2} = -\frac{1}{2}(1-3i)$$

$$k_3 = \operatorname{Res}_{\text{at } z=z_3=-1-i} f(z) = \frac{(-1-i)^2 + 4}{3(-1-i)^2 + 4(-1-i) + 2} = -\frac{1}{2}(1+3i).$$

- a. $c : |z| = 1$ is unit circle enclosing only one singular point $z = 0$. By residue theorem

$$I = 2\pi i \cdot \operatorname{Res}_{\text{at } z=0} f(z) = 2\pi i \cdot k_1 = 2\pi i \cdot 2 = 4\pi i.$$

- b. $c : |z+1-i| = 1$ is a circle with centre at $-1+i$ and radius 1. So c encloses only one pole $-1+i$

$$I = 2\pi i \cdot \operatorname{Res}_{z=z_2} f(z) = 2\pi i \cdot k_2 = 2\pi i \left(\frac{3i-1}{2} \right)$$

$$I = -\pi(3+i).$$

- c. $c : |z+1+i| = 1$ is circle centered at $-1-i$ and of radius 1. So c encloses only one pole $-1-i$

$$I = 2\pi i \cdot \operatorname{Res}_{z=z_3} f(z) = 2\pi i \cdot k_3 = 2\pi i \frac{(1+3i)}{-2} = \pi(3-i).$$

- d. $c : |z-1| = 5$ is circle with centre at 1 and radius 5. So c enclosed all the three poles $z = 0, -1+i, -1-i$. By residue theorem

$$\begin{aligned} I &= 2\pi i[k_1 + k_2 + k_3] \\ &= 2\pi i \left[2 + \left(\frac{3i-1}{2} \right) - \frac{(3i+1)}{2} \right] \\ I &= 2\pi i. \end{aligned}$$

- e. c : Rectangle does not include any of the three poles. $f(z)$ is analytic within c . By Cauchy's theorem, $I = 0$.

Example 5: $I = \oint_c \frac{dz}{\sinh 2z}$ where $c : |z| = 2$.

Solution: Zeros of $\sinh 2z$ are $z = \pm \frac{n\pi i}{2}$. Thus out of the infinite number of poles of $f(z) = \frac{1}{\sinh 2z}$ only

three poles $z = 0, \pm \frac{\pi i}{2}$ lies inside the circle $|z| = 2$. Now

$$k_1 = \operatorname{Res}_{z=0} f(z) = \lim_{z \rightarrow 0} \frac{z}{\sinh 2z} = \frac{1}{2}$$

$$\begin{aligned} k_2 = \operatorname{Res}_{z=\frac{\pi i}{2}} f(z) &= \lim_{z \rightarrow \frac{\pi i}{2}} \frac{\left(z - \frac{\pi i}{2} \right)}{\sinh 2z} \\ &= \lim_{z \rightarrow \frac{\pi i}{2}} \frac{1}{2 \cdot \cosh 2z} \text{ is } \begin{pmatrix} 0 \\ 0 \end{pmatrix} \text{ form} \\ &= -\frac{1}{2} \quad (\text{using L' Hospital's Rule}) \end{aligned}$$

$$\begin{aligned} k_3 = \operatorname{Res}_{z=-\frac{\pi i}{2}} f(z) &= \lim_{z \rightarrow -\frac{\pi i}{2}} \frac{\left(z + \frac{\pi i}{2} \right)}{\sinh 2z} \\ &= \lim_{z \rightarrow -\frac{\pi i}{2}} \frac{1}{2 \cdot \cosh 2z} = -\frac{1}{2} \end{aligned}$$

By residue theorem,

$$I = 2\pi i \left[\frac{1}{2} - \frac{1}{2} - \frac{1}{2} \right] = -\pi i.$$

Example 6: Evaluate $I = \oint_c e^{-\frac{1}{z}} \cdot \sin\left(\frac{1}{z}\right) dz$ where c is the circle $|z| = 1$.

Solution: $z = 0$ is an essential singularity, which is enclosed in the circle $|z| = 1$.

Expanding

$$\begin{aligned} e^{-\frac{1}{z}} \cdot \sin\left(\frac{1}{z}\right) &= \left[\sum_{n=0}^{\infty} \left(-\frac{1}{z} \right)^n \frac{1}{n!} \right] \\ &\quad \times \left[\sum_{n=1}^{\infty} (-1)^{n-1} \cdot \left(\frac{1}{z} \right)^{2n-1} \frac{1}{(2n-1)!} \right] \\ &= \left[1 - \frac{1}{z} + \frac{1}{z^2} \cdot \frac{1}{2!} - \frac{1}{z^3} \cdot \frac{1}{3!} \cdots \right] \\ &\quad \times \left[\frac{1}{z} - \frac{1}{z^3} \cdot \frac{1}{3!} + \frac{1}{5!} \frac{1}{z^5} + \cdots \right] \\ &= \left[\frac{1}{z} - \frac{1}{z^3} \frac{1}{3!} + \frac{1}{5!} \frac{1}{z^5} + \cdots \right. \\ &\quad \left. - \frac{1}{z^2} + \frac{1}{z^4} \frac{1}{3!} + \cdots \right] \end{aligned}$$

Residue at $z = 0$ is 1.

By residue theorem,

$$I = 2\pi i \cdot 1 = 2\pi i.$$

EXERCISE

Residue theorem

- Find the nature of singularity and find the residue:

- $\frac{e^{2z}}{(z-1)^3}$
- $(z-3) \sin\left(\frac{1}{z+2}\right)$
- $\frac{(z-\sin z)}{z^3}$
- $\frac{1}{(z^2)(z-3)^2}$
- $e^{\frac{z}{(z-2)}}$

- Ans. a. $z = 1$, pole of order 3, Res $2e^2$
b. $z = -2$ is essential singularity, Res -5
c. $z = 0$ is removable singularity, Res 0
d. $z = 0, 3$ are poles of order 2
Res at $z = 0$ is $\frac{2}{27}$, at $z = 3$ is $-\frac{2}{27}$
e. $z = 2$ is essential singularity, Res at $z = 2$ is $2e$
 $z = \infty$ is removable singularity.

- Determine the nature of singularities of $f(z)$:

- $\frac{(z-\sin z)}{z^2}$
- $(z+1) \sin\left(\frac{1}{z-2}\right)$
- $\frac{1}{(\cos z - \sin z)}$
- $\frac{z}{(e^{\frac{1}{z}} - 1)}$
- $\frac{z^4}{(1+z^4)}$
- $\tanh z$

- Ans. a. $z = 0$ is removable singularity
b. $z = 2$ is essential singularity
c. $z = \frac{\pi}{4}$ is simple pole
d. $z = \frac{i}{2m\pi}$, $m = \pm 1, \pm 2, \dots$ simple poles,
 $z = 0$ is essential, $z = \infty$ is pole of order 2
e. $z = \frac{\pm 1 \pm i}{\sqrt{2}}$ are simple poles
f. $z = n\pi i$, $n = 0, \pm 1, \pm 2, \dots$ simple poles.

- Find the residues at all its poles in finite plane:

- $\frac{z^2 - 2z}{(z+1)^2(z^2+4)}$
- $e^z \cdot \csc^2 z$
- $\frac{\cot z \cdot \coth z}{z^3}$

Hint. Expand, $\cot z$, $\coth z$ in powers of z .

- $\frac{z^2}{(z-1)^2(z+2)}$

- $\frac{(9z+i)}{(z(z^2+1))}$
- $\frac{50z}{[(z+4)(z-1)^2]}$
- $\frac{(1+z)}{(1-\cos z)}$

- Ans. a. $z = -1$, double pole, Res $-\frac{14}{25}$
 $z = \pm 2i$, simple, $\frac{7+i}{25}$, $\frac{7-i}{25}$
b. $z = m\pi$, $m = 0, \pm 1, \pm 2, \dots$ double poles
Res $e^{m\pi}$
c. $z = 0$, Res $-\frac{7}{45}$
d. $z = -2$, Res $\frac{4}{9}$
 $z = 1$, double pole, Res $\frac{5}{9}$
e. $z = 0$, Res i
 $z = \pm i$, Res $-5i, 4i$
f. $z = -4$, Res -8
 $z = 1$, double, Res 8
g. $z = 0$, Res 2

Using residue theorem, evaluate:

$$4. \oint_c \frac{\tan z}{(z^2-1)} dz, c : |z| = \frac{3}{2}$$

- Ans. $I = 2\pi i \tan 1$, simple pole $z = \pm 1$, Res $\frac{\tan 1}{2}$, $\frac{\tan 1}{2}$

5. $\oint_c \frac{4-3z}{z^2-z} dz$, c : any simple closed path such that
(a) $0, 1 \in c$ (b) $0 \in c, 1 \notin c$
(c) $1 \in c, 0 \notin c$ (d) $0, 1 \notin c$

- Ans. $z = 0, 1$ are simple poles, Res at $z = 0$, is -4 ,
Res at $z = 1$ is 1

- (a) $2\pi i(-4+1) = -6\pi i$ (b) $-8\pi i$
(c) $2\pi i$ (d) 0

$$6. I = \oint_c \left(\frac{ze^{\pi z}}{z^4-16} + ze^{\frac{\pi}{z}} \right) dz,$$

$$c : \text{ellipse } 9x^2 + y^2 = 9$$

- Ans. $I = I_1 + I_2$, For I_1 , $z = \pm 2i, \pm 2$ are simple poles
 $z = \pm 2i \in c$, $z = \pm 2 \notin c$, Res at $z = 2i$, $-\frac{1}{16}$, at $z = -2i$, $-\frac{1}{16}$

For I_2 , $z = 0$, essential singularity,
Res at $z = 0$ is $\frac{\pi^2}{2}$

$$\text{Ans. } I = 2\pi i \left(-\frac{1}{16} - \frac{1}{16} \right) + 2\pi i \left(\frac{\pi^2}{2} \right)$$

$$= \pi \left(\pi^2 - \frac{1}{4} \right) i$$

7. $\int_c \frac{z-3}{z^2+2z+5} dz$
a. $c : |z| = 1$

b. $|z + 1 - i| = 2$

c. $|z + 1 + i| = 2$

Ans. $z_{1,2} = -1 \pm 2i$ simple poles

a. $z_{1,2} \notin c, I = 0$

b. $z_1 = -1 + 2i \in c, z_2 = -1 - 2i \notin c,$
 $I = 2\pi i \left(i + \frac{1}{2}\right) = \pi(i - 2)$

c. $z_2 = -1 - 2i \in c, z_1 = -1 + 2i \notin c,$
 $I = 2\pi i \left(\frac{1}{2} - i\right) = \pi(2 + i)$

8. $\int_c \tan z \, dz, c : |z| = 2$

Ans. $z = (2n + 1)\frac{\pi}{2}, n = 0, \pm 1, \pm 2, \dots$ simple poles

$z = \pm \frac{\pi}{2}$ only $\in c$, Res $z = \frac{\pi}{2}$ is -1 , Res at $z = -\frac{\pi}{2}$ is -1

$I = 2\pi i(-1 - 1) = -4\pi i$

9. $\int_c \frac{\sin \pi z^2 + \cos \pi z^2}{(z-1)^2(z-2)} dz, c : |z| = 3$

Ans. $z = 1$ double pole, Res $2\pi + 1, z = 2$ is simple pole, Res 1

$I = 2\pi i [(2\pi + 1) + 1] = 4\pi(\pi + 1)i$

10. $\int_c \frac{4-3z}{z(z-1)(z-2)} dz, c : |z| = \frac{3}{2}$

Ans. $z = 0, 1, 2$ simple poles, Res $2, -1,$
 $(z = 2 \notin c)$

$I = 2\pi i (2 + (-1)) = 2\pi i$

11. $\int_c \frac{dz}{(z^2+4)^2}, c : |z - i| = 2$

Ans. $z = \pm 2i$ double poles, $z = 2i \in c$, Res is $-\frac{2}{64i^3}, I = \frac{\pi}{16}$

12. $\int_c \frac{5z-2}{z(z-1)} dz, c : |z| = 2$

Ans. $z = 0, 1$ simple poles, $\in c$; Res 2, 3, $I = 10\pi i$

13. $\int \frac{(3z^2+2)dz}{(z-1)(z^2+9)}, c : (a) |z - 2| = 2$
 (b) $c : |z| = 4$

Ans. $z = 1, \pm 3i$ simple poles,

a. $z = 1 \in c$, Res $\frac{1}{2}, I = \pi i$

b. all $\in c$, Res $\frac{1}{2}, \frac{2 \mp 81i}{6i(3i-1)}, I = 6\pi i$

14. $\int_c \frac{e^{zt}}{z^2(z^2+2z+2)} dz, c : |z| = 3$

Ans. $z = 0$, double pole, Res $\frac{t-1}{2}, z = -1 \pm i$
 simple poles, Res $\frac{e^{(-1 \pm i)t}}{4},$

$I = 2\pi i \left[\frac{t-1}{2} + \frac{1}{2} e^{-t} \cos t \right].$

24.3 EVALUATION OF REAL INTEGRALS

Real integrals of the following types can be evaluated using the residue theorem.

Type I: Evaluation of Real Definite Integral of Rational Function of $\cos \theta$ and $\sin \theta$

By integration around a unit circle

Consider

$$I = \int_0^{2\pi} F(\sin \theta, \cos \theta) d\theta \quad (1)$$

where F is real rational function of $\cos \theta$ and $\sin \theta$ and is finite in the interval $(0, 2\pi)$. Put $z = e^{i\theta}$ so $dz = ie^{i\theta} d\theta = iz d\theta$. Also

$$\cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2} = \frac{z + \frac{1}{z}}{2} \quad \text{and}$$

$$\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i} = \frac{z - \frac{1}{z}}{2i}$$

Note that $|z| = |e^{i\theta}| = 1$ which represents a unit circle c (with centre at origin). Substituting these values (1) takes the form

$$I = \oint_c f(z) \frac{dz}{iz} = \oint_c G(z) dz \quad (2)$$

Here $f(z) = F(\sin \theta, \cos \theta)$. The complex integral (2) is evaluated around the unit circle c (as θ varies from 0 to 2π).

Here $G(z)$ is a rational function of z . Now by residue theorem

$$I = 2\pi i \sum \text{Res } G(z) \quad (3)$$

where the summation is taken for all poles of $G(z)$ which are within the unit circle $c : |z| = 1$.

Type II: Evaluation of Improper Real Integral (of first kind) of Rational Function

By integration around a semi-circle

Consider

$$I = \int_{-\infty}^{\infty} f(x) dx \quad (4)$$

24.8 — HIGHER ENGINEERING MATHEMATICS—VI

where $f(x) = \frac{p(x)}{q(x)}$. Here $p(x)$ and $q(x)$ are polynomials. Integral (4) converges if

- $q(x)$ has no real zeros (i.e., $q(x) \neq 0$, for any x) and
- the degree of q is at least two greater than the degree of p .

Assuming these conditions, (4) can be evaluated by integrating around a semi-circle as follows:

Consider a simple closed curve c consisting of the straight line L along the real axis from $-R$ to R and the semi-circle S of radius R and with centre at origin (Fig. 24.2). By residue theorem

$$\oint_c f(z) dz = 2\pi i \sum \text{Res } f(z) \quad (5)$$

Fig. 24.2

where the summation is for the residues of $f(z)$ at all the singular points (poles) within c . Since $c = L + S$, (5) is rewritten as

$$\begin{aligned} \int_c &= \int_{L+S} = \int_L + \int_S = \int_{-R}^R f(x) dx + \int_S f(z) dz \\ &= 2\pi i \sum \text{Res } f(z) \end{aligned} \quad (6)$$

As $R \rightarrow \infty$, the semi-circle S engulfs and becomes the entire upper half plane ($y > 0$). Then (6) takes the form

$$\begin{aligned} \lim_{R \rightarrow \infty} \int_{-R}^R f(x) dx &= \lim_{R \rightarrow \infty} 2\pi i \sum \text{Res } f(z) \\ &\quad - \lim_{R \rightarrow \infty} \int_S f(z) dz \\ \int_{-\infty}^{\infty} f(x) dx &= 2\pi i \sum \text{Res } f(z) \\ &\quad - \lim_{R \rightarrow \infty} \int_S f(z) dz \end{aligned} \quad (7)$$

In RHS of (7) the summation of residues is for all poles of $f(z)$ in the upper half plane.

By assumption $|f(z)| < \frac{k}{|z|^2}$. So

$$\left| \int_S f(z) dz \right| \leq M \cdot L = \frac{k}{|z|^2} \cdot 2\pi R = \frac{k}{R^2} 2\pi R = \frac{2\pi k}{R}$$

which tends to zero as $R \rightarrow \infty$. Thus (7) reduces to

$$\begin{aligned} \int_{-\infty}^{\infty} f(x) dx &= 2\pi i \times [\text{sum of the residues of } f(z) \text{ at all} \\ &\quad \text{the poles of } f(z) \text{ in the upper half plane}] \\ &= 2\pi i \sum \text{Res } f(z) \end{aligned} \quad (8)$$

Type III: Fourier Integral: Improper Integral Involving Trigonometric Functions

The integrals

$$\int_{-\infty}^{\infty} f(x) \cos mx dx \quad (9)$$

$$\int_{-\infty}^{\infty} f(x) \sin mx dx \quad (10)$$

can be evaluated by integrating

$$f(z)e^{imz}$$

around the contour c discussed in II. By residue theorem and similar analysis as in II

$$\int_{-\infty}^{\infty} f(x)e^{imx} dx = 2\pi i \sum \text{Res} \left(f(z)e^{imz} \right) \quad (11)$$

where the summation extends to all poles of $f(z)e^{imz}$ in the upper half-plane (since $|e^{imz}| = |e^{imx}||e^{-my}| = e^{-my} \leq 1$ for $m > 0, y \geq 0$ and $|f(z)e^{imz}| = |f(z)||e^{imz}| \leq |f(z)|$ it follows that $\int_S \rightarrow 0$ as $R \rightarrow \infty$). Equating the real and imaginary parts of (11), we get

$$\int_{-\infty}^{\infty} f(x) \cos mx dx = -2\pi \sum \text{Im. Res} \left[f(z)e^{imz} \right] \quad (12)$$

$$\int_{-\infty}^{\infty} f(x) \sin mx dx = 2\pi \sum \text{Re. Res} \left[f(z)e^{imz} \right] \quad (13)$$

Type IV: Evaluation of Improper Integral (of the second kind) whose Integrand Becomes Infinite

By indenting the contours having poles on the real axis

Consider

$$\int_A^B f(x) dx$$

where the integrand $f(x)$ become infinite at a point b between A and B . i.e.,

$$\lim_{x \rightarrow b} f(x) = \infty$$

Then the Cauchy's principal value of the integral is denoted by pr. v. and is defined as

$$\text{pr.v.} \int_A^B f(x) dx = \lim_{\epsilon \rightarrow 0} \left[\int_A^{b-\epsilon} f(x) dx + \int_{b+\epsilon}^B f(x) dx \right]$$

Simple poles on real axis

Delete the pole $z = b$ on the real axis by indenting the contour by drawing a semi-circle of radius r and with centre at b .

Result 1: If $f(z)$ has a simple pole at $z = b$ on the real axis, then

$$\lim_{r \rightarrow 0} \int_{c_1} f(z) dz = \pi i \operatorname{Res}_{z=b} f(z) \quad (14)$$

where c_1 is circle of radius r and with centre at $z = b$.

Poles in the upper half plane and simple poles on real axis:

Result 2: If $f(z)$ has several simple poles on the real axis, then

$$\begin{aligned} \text{pr. v.} \int_{-\infty}^{\infty} f(x) dx &= 2\pi i \sum \operatorname{Res} f(z) \\ &+ \pi i \sum \operatorname{Res} f(z) \end{aligned} \quad (15)$$

In the R.H.S. of (15), the first summation extends overall poles of $f(z)$ in the upper half plane and the second summation overall simple poles on the real axis.

Theorems on limiting contours

These theorems are useful in evaluating $\int_{C_R} f(z) dz$ where C_R is an arc of a circle whose radius $R \rightarrow \infty$ or $\rightarrow 0$.

Theorem 1: If $z \cdot f(z) \rightarrow 0$ uniformly as $R \rightarrow \infty$ then

$$\lim_{R \rightarrow \infty} \int_{C_R} f(z) dz \rightarrow 0$$

where C_R is a circular arc of radius R and with centre at the origin.

Theorem 2: (Jordan's Lemma)

If $f(z) \rightarrow 0$ uniformly as $R \rightarrow \infty$ then

$$\lim_{R \rightarrow \infty} \int_{C_R} e^{imz} f(z) dz = 0, \quad (m > 0)$$

where C_R is a circular arc (with radius R and centre at origin) in the first and/or second quadrants.

Theorem 3: If $(z - a)f(z) \rightarrow 0$ uniformly as $r \rightarrow 0$ then

$$\lim_{r \rightarrow 0} \int_{C_r} f(z) dz = 0$$

where C_r is a circular arc with radius r and with centre at $z = a$.

Type V: Result

Let $f(z)$ be analytic everywhere in the z -plane except at a finite number of poles. Assume that $f(z)$ has no poles on the positive half of the real axis. If $z^a f(z) \rightarrow 0$ as $z \rightarrow 0$, then as $z \rightarrow \infty$

$$\begin{aligned} \int_0^\infty x^{a-1} f(x) dx &= \frac{\pi}{\sin a\pi} \times \\ &\times \sum \operatorname{Residues} \text{ of } \{(-z)^{a-1} \cdot f(z)\} \end{aligned}$$

at all its poles.

WORKED OUT EXAMPLES

Type I

Example 1: Evaluate $I = \int_0^{2\pi} \frac{d\theta}{1 - 2p \sin \theta + p^2}$, $|p| < 1$.

24.10 — HIGHER ENGINEERING MATHEMATICS—VI

Solution: Put $z = e^{i\theta}$, $dz = ie^{i\theta} d\theta = iz d\theta$

$$\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i} = \frac{z - \frac{1}{z}}{2i} = \frac{z^2 - 1}{2iz}$$

$|z| = |e^{i\theta}| = 1$. Thus the given integral reduces to

$$I = \oint_c \frac{1}{1 - 2p \frac{(z^2 - 1)}{2iz} + p^2 iz} dz = -\frac{1}{p} \int_c \frac{dz}{z^2 - \frac{i(1+p^2)}{p} z - 1}$$

where $c : |z| = 1$.

The integrand has simple poles at

$$z = \frac{i(1+p^2) \pm i(1-p^2)}{2p} = \frac{i}{p}, ip$$

$z_1 = \frac{i}{p}$ lies outside while $z_1 = ip$ lies inside the unit circle c since $|z_1| = |ip| = |i||p| = |p| < 1$.

$$\begin{aligned} \text{Res } f(z) &= \lim_{z \rightarrow z_2} (z - z_2) \cdot \frac{1}{(z - z_1)(z - z_2)} = \frac{1}{z_2 - z_1} \\ &= \frac{1}{ip - \frac{i}{p}} = \frac{p}{i(p^2 - 1)} = \frac{ip}{1 - p^2} \end{aligned}$$

By residue theorem

$$\begin{aligned} I &= -\frac{1}{p} \int_c \frac{dz}{(z - z_1)(z - z_2)} = -\frac{1}{p} \cdot 2\pi i \text{Res } f(z) \text{ at } z=z_2 \\ &= -\frac{1}{p} \cdot 2\pi i \cdot \left(\frac{ip}{1 - p^2} \right) = \frac{2\pi}{1 - p^2}. \end{aligned}$$

Example 2: Evaluate $I = \int_0^\pi \frac{\cos^2 3\theta d\theta}{5 - 4 \cos 2\theta}$.

Solution: $I = \frac{1}{2} \int_{-\pi}^\pi \frac{\cos^2 3\theta d\theta}{5 - 4 \cos 2\theta}$

Put $z = e^{i\theta}$, $\cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2} = \frac{z + \frac{1}{z}}{2} = \frac{z^2 + 1}{2z}$

Using $\cos^2 3\theta = \frac{1 + \cos 6\theta}{2}$, $\cos 6\theta = \frac{z^6 + \frac{1}{z^6}}{2} = \frac{z^{12} + 1}{2z^6}$

and $\cos 2\theta = \frac{z^2 + \frac{1}{z^2}}{2} = \frac{z^4 + 1}{2z^2}$.

The integral reduces to

$$\begin{aligned} I &= \frac{1}{2} \oint_c \frac{1}{2} \left(1 + \frac{z^{12} + 1}{2z^6} \right) \left[\frac{1}{5 - 4 \cdot \left(\frac{z^4 + 1}{2z^2} \right)} \right] \cdot \frac{dz}{iz} \\ &= -\frac{1}{16i} \oint_c \frac{z^{12} + 2z^6 + 1}{z^5 \left(z^4 - \frac{5}{2}z^2 + 1 \right)} dz = -\frac{1}{16i} \oint_c f(z) dz \end{aligned}$$

The singular points of the integrand are the zeros of the denominator i.e., $z^5 = 0$ and $z^4 - \frac{5}{2}z^2 + 1 = 0$, or $z^2 = 2, \frac{1}{2}$. Thus $z = 0$ is pole of order 5 and

$z = \pm \frac{1}{\sqrt{2}}$ are two simple poles, which lie inside c , while $z = \pm \sqrt{2}$ lies outside c .

Residue by Laurent series:

Expanding $(1 - (\frac{5}{2}z^2 - z^4))$ in series, we get

$$f(z) = \frac{z^{12} + 2z^6 + 1}{z^5} \cdot \left[1 - \left(\frac{5}{2}z^2 - z^4 \right) \right]^{-1}$$

$$\begin{aligned} f(z) &= \frac{z^{12} + 2z^6 + 1}{z^5} \left[1 + \frac{5}{2}z^2 - z^4 \right. \\ &\quad \left. + \frac{25}{4}z^4 + z^8 - 5z^6 + \dots \right] \end{aligned}$$

Residue of $f(z)$ at $z = 0$ is the coefficient of z^{-1} in this Laurent series expansion, i.e.,

$$k_1 = \text{Res } f(z) \text{ at } z=0 = -1 + \frac{25}{4} = \frac{21}{4}$$

$$k_2 = \text{Res } f(z) \text{ at } z=z_1 = \frac{1}{\sqrt{2}} = \lim_{z \rightarrow z_1} \frac{(z^6 + 1)^2(z - z_1)}{z^5(z^2 - 2)(z - z_1)(z - z_2)}$$

$$\begin{aligned} &= \frac{(z_1^6 + 1)^2}{z_1^5(z_1^2 - 2)(z_1 - z_2)} \\ &= \frac{81}{64} \cdot \frac{1}{\frac{1}{4\sqrt{2}} \left(-\frac{3}{2} \right) \left(\frac{2}{\sqrt{2}} \right)} = -\frac{27}{8} \end{aligned}$$

$$k_3 = \text{Res } f(z) \text{ at } z=z_2 = -\frac{1}{\sqrt{2}}$$

$$= \lim_{z \rightarrow z_2} \frac{(z^6 + 1)^2}{z^5(z^2 - 2)(z - z_1)(z - z_2)} \cdot (z - z_2) = -\frac{27}{8}$$

Thus by residue theorem,

$$\begin{aligned} I &= -\frac{1}{16i} \cdot \{2\pi i (\text{Sum of the residues})\} \\ &= -\frac{1}{16i} \cdot 2\pi i \left(\frac{21}{4} - \frac{27}{8} - \frac{27}{8} \right) = -\frac{1}{16i} 2\pi i \left(-\frac{6}{4} \right) \\ I &= \frac{3\pi}{16}. \end{aligned}$$

Type II

Example 3: Evaluate $\int_0^\infty \frac{dx}{(a^2 + x^2)^2}$.

Solution: Consider a curve c consisting of semicircle S and the line L from $-R$ to R along the real axis (refer Fig. 24.3). Consider

$$\int_c \frac{dz}{(a^2 + z^2)^2} = \oint_c f(z) dz \text{ where } f(z) = (a^2 + z^2)^{-2}$$

Fig. 24.3

Rewriting

$$\oint_C f(z) dz = \int_L + \int_S = \int_{-R}^R f(x) dx + \int_S f(z) dz \quad (1)$$

Since $|a^2 + z^2| > |z|^2 - |a|^2$

$$\text{on } S: |a^2 + z^2| > R^2 - a^2$$

$$\text{or } \left| \frac{1}{(a^2 + z^2)^2} \right| < \frac{1}{(R^2 - a^2)^2}$$

$$\text{So } \left| \int_S f(z) dz \right| \leq \frac{1}{(R^2 - a^2)^2} \cdot \pi R \quad (2)$$

As $R \rightarrow \infty$ $\int_S f(z) dz \rightarrow 0$

As $R \rightarrow \infty$ (1) becomes

$$\lim_{R \rightarrow \infty} \oint_C f(z) dz = \lim_{R \rightarrow \infty} \int_{-R}^R f(x) dx + \lim_{R \rightarrow \infty} \int_S f(z) dz$$

$$\therefore \int_{-\infty}^{\infty} \frac{dx}{(a^2 + x^2)^2} = \lim_{R \rightarrow \infty} \oint_C f(z) dz, \text{ using (2)}$$

As $R \rightarrow \infty$, C engulfs the entire upper half plane. Now evaluating the R.H.S. integral by residue theorem, $= 2\pi i \cdot \text{Res } f(z)$ at singular points which are in the upper half plane.

For $f(z) = \frac{1}{(z^2 + a^2)^2}$ has singular points at $z = \pm ai$ which are poles of order 2. But only $z = ai$ lies in the upper half-plane.

$$\begin{aligned} \text{Res } f(z) &= \lim_{z \rightarrow ai} \frac{d}{dz} (z - ai)^2 \cdot \frac{1}{(z - ai)^2 (z + ai)^2} \\ &= \lim_{z \rightarrow ai} -\frac{2}{(z + ai)^3} = -\frac{2}{8a^3 i^3} = -\frac{i}{4a^3} \end{aligned}$$

$$\begin{aligned} \text{Hence } \int_0^{\infty} \frac{dx}{(a^2 + x^2)^2} &= \frac{1}{2} \int_{-\infty}^{\infty} \frac{dx}{(a^2 + x^2)^2} \\ &= \frac{1}{2} \cdot 2\pi i \cdot \left(-\frac{i}{4a^3} \right) = \frac{\pi}{4a^3}. \end{aligned}$$

Example 4: Evaluate $I = \int_{-\infty}^{\infty} \frac{x dx}{(x^2 + 1)(x^2 + 2x + 2)}$

Solution: Let C be a simple closed curve consisting of semicircle S and line L from $-R$ to R (see Fig. 24.4).

Fig. 24.4

$$\text{Let } f(z) = \frac{z}{((z^2 + 1)(z^2 + 2z + 2))}$$

Consider

$$\oint_C f(z) dz = \oint_C \frac{z dz}{(z^2 + 1)(z^2 + 2z + 2)}$$

This integral can be evaluated by residue theorem.

Rewriting

$$\begin{aligned} \oint_C f(z) dz &= \int_L + \int_S \\ &= \int_{-R}^R \frac{x dx}{(x^2 + 1)(x^2 + 2x + 2)} + \int_S f(z) dz \end{aligned}$$

As $R \rightarrow \infty$, the 2nd integral on the right becomes 0. So

$$\lim_{R \rightarrow \infty} \oint_C f(z) dz = \int_{-\infty}^{\infty} \frac{x dx}{(x^2 + 1)(x^2 + 2x + 2)}$$

As $R \rightarrow \infty$, C encloses the entire upper half plane. Thus by applying residue theorem

$$I = \int_{-\infty}^{\infty} \frac{x dx}{(x^2 + 1)(x^2 + 2x + 2)} = 2\pi i \cdot \sum \text{Res } f(z)$$

The singular points of $f(z) = \frac{z}{(z^2 + 1)(z^2 + 2z + 2)}$ are $z = \pm i$ and $z = -1 \pm i$. Out of these only $z = i$ and $z = -1 + i$ lies in the upper half plane.

$$\begin{aligned} \text{Res } f(z) &= \lim_{z \rightarrow i} (z - i) \cdot \frac{z}{(z - i)(z + i)(z^2 + 2z + 2)} \\ &= \frac{i}{2i(-1 + 2i + 2)} = \frac{1}{2(2i + 1)} \end{aligned}$$

$$\begin{aligned} \text{Res } f(z) &= \lim_{z \rightarrow -1+i} (z + 1 - i) \cdot \frac{z}{(z^2 + 1)(z + 1 - i)(z + 1 + i)} \\ &= \frac{(-1 + i)}{[(-1 + i)^2 + 1] [-1 + i + 1 + i]} = \frac{-1 + i}{2i(1 - 2i)} \end{aligned}$$

Thus

$$I = 2\pi i \left[\frac{1}{2(2i + 1)} + \frac{(-1 + i)}{2i(1 - 2i)} \right] = -\frac{\pi}{5}.$$

Type III

Example 5: Evaluate $\int_{-\infty}^{\infty} \frac{\cos mx}{(x^2+a^2)(x^2+b^2)} dx$.

Solution: We know that $\int_{-\infty}^{\infty} \cos mx Q(x) dx = -2\pi \cdot \sum$ imaginary part of residues of $e^{imz} Q(z)$ at its poles in the upper half plane. So consider

$$f(z) = e^{imz} Q(z) = \frac{e^{imz}}{(z^2+a^2)(z^2+b^2)}$$

$f(z)$ has simple poles at $z = \pm ai, z = \pm bi$ out of which $z = ai, bi$ lies in the upper half plane.

$$\begin{aligned} k_1 = \text{Res } f(z) &= \lim_{z \rightarrow ai} \frac{(z - ai) \cdot e^{imz}}{(z - ai)(z + ai)(z^2 + b^2)} \\ &= \frac{e^{-am}}{2ai(b^2 - a^2)} = \frac{-ie^{-am}}{2a(b^2 - a^2)} \end{aligned}$$

Similarly,

$$k_2 = \text{Res } f(z) = \lim_{z \rightarrow bi} \frac{e^{-bm}}{2bi(a^2 - b^2)} = \frac{-ie^{-bm}}{2b(a^2 - b^2)},$$

$$\begin{aligned} \int_{-\infty}^{\infty} \frac{\cos mx}{(x^2+a^2)(x^2+b^2)} dx \\ &= -2\pi \left[-\frac{e^{-am}}{2a(b^2 - a^2)} - \frac{e^{-bm}}{2b(a^2 - b^2)} \right] \\ &= \frac{\pi}{a^2 - b^2} \left[\frac{e^{-bm}}{b} - \frac{e^{-am}}{a} \right]. \end{aligned}$$

Example 6: $\int_{-\infty}^{\infty} \frac{x \sin mx}{1+x^4} dx$.

Solution: We know that $\int_{-\infty}^{\infty} \sin mx Q(x) dx = 2\pi \sum$ real part of residues of $e^{imz} Q(z)$ at its poles in the upper half plane. So consider $f(z) = e^{imz} \cdot \frac{z}{1+z^4}$ which has singular points at $z = (-1)^k = e^{i\left(\frac{\pi+2k\pi}{4}\right)}$ for $k = 0, 1, 2, 3$. Out of these four, only $z_1 = e^{\frac{i\pi}{4}} = \frac{1}{\sqrt{2}}(1+i)$ and $z_2 = e^{\frac{i3\pi}{4}} = \frac{1}{\sqrt{2}}(-1+i)$ lies in the upper half plane.

$$k_1 = \text{Res } f(z) = \lim_{z \rightarrow z_1} (z - z_1) \cdot \frac{z \cdot e^{imz}}{(1+z^4)},$$

which is $\frac{0}{0}$ form. Applying L' Hostpital's rule

$$= \lim_{z \rightarrow z_1} \frac{[(z - z_1) \{e^{imz} + z \cdot im \cdot e^{imz}\} + ze^{imz}]}{4z^3}$$

$$\begin{aligned} &= \frac{z_1 e^{imz_1}}{4z_1^3} = \frac{e^{imz_1}}{4z_1^2} = \frac{e^{im \frac{1}{\sqrt{2}}(1+i)}}{4 \left[\frac{1}{\sqrt{2}}(1+i) \right]^2} \\ &= \frac{e^{im \frac{1}{\sqrt{2}}(1+i)} \left[\frac{1}{\sqrt{2}}(1-i) \right]^2}{4 \left[\frac{1}{\sqrt{2}}(1+i) \right]^2 \left[\frac{1}{\sqrt{2}}(1-i) \right]^2} \\ k_1 &= \frac{e^{-\frac{m}{\sqrt{2}}} \cdot \left(\cos \frac{m}{\sqrt{2}} + i \sin \frac{m}{\sqrt{2}} \right) \cdot \frac{1}{2}(-2i)}{4 \cdot \frac{1}{2}(1+1)} \end{aligned}$$

Real part of $k_1 = \frac{1}{4} e^{-\frac{m}{\sqrt{2}}} \cdot \sin \frac{m}{\sqrt{2}}$

Similarly,

$$\begin{aligned} k_2 = \text{Res } f(z) &= \lim_{z \rightarrow z_2} \frac{e^{im \frac{1}{\sqrt{2}}(-1+i)} \left[\frac{1}{\sqrt{2}}(-1-i) \right]^2}{4 \left[\frac{1}{\sqrt{2}}(-1+i) \right]^2 \left[\frac{1}{\sqrt{2}}(-1-i) \right]^2} \\ k_2 &= \frac{e^{-\frac{m}{\sqrt{2}}} \cdot \left(\cos \frac{m}{\sqrt{2}} - i \sin \frac{m}{\sqrt{2}} \right) \cdot \frac{1}{2}(2i)}{4 \cdot \frac{1}{2}(1+1)} \end{aligned}$$

Real part of $k_2 = \frac{1}{4} e^{-\frac{m}{\sqrt{2}}} \cdot \sin \frac{m}{\sqrt{2}}$.

Then

$$\begin{aligned} \int_{-\infty}^{\infty} \frac{x \sin mx}{1+x^4} dx &= 2\pi [Re(k_1) + Re(k_2)] \\ &= 2\pi \left[e^{-\frac{m}{\sqrt{2}}} \cdot \sin \frac{m}{\sqrt{2}} \left(\frac{1}{4} + \frac{1}{4} \right) \right] \\ &= \pi e^{-\frac{m}{\sqrt{2}}} \cdot \sin \frac{m}{\sqrt{2}}. \end{aligned}$$

Integration around a rectangular contour

Example 7: Evaluate $\int_{-\infty}^{\infty} \frac{\cos mx}{e^x + e^{-x}} dx$.

Solution: Consider $\oint_c \frac{e^{imz}}{e^z + e^{-z}} dz$ where c is the rectangle having vertices at $-R, R, R + \pi i, -R + \pi i$ and consisting of the lines c_1, c_2, c_3, c_4 as shown in Fig. 24.5.

The poles of $\frac{e^{imz}}{e^z + e^{-z}}$ are simple and occur when $e^z + e^{-z} = 0$ i.e., $e^{2z} = -1 = e^{\pm(2n+1)\pi i}$ i.e., $z = (n + \frac{1}{2})\pi i$ with $n = 0, \pm 1, \pm 2, \dots$. Out of these only $z = (\frac{\pi i}{2})$ lies inside the rectangle c .

By residue theorem

$$I = \oint_c \frac{e^{imz}}{e^z + e^{-z}} dz = \frac{1}{2} \oint_c \frac{e^{imz}}{\left(\frac{e^z + e^{-z}}{2} \right)} = \frac{1}{2} \oint_c \frac{e^{imz}}{\cosh z}$$

Fig. 24.5

$$= \frac{1}{2} 2\pi i \left(\text{Res} \frac{e^{imz}}{\cosh z} \text{ at } z = \frac{\pi i}{2} \right) \quad (1)$$

Now

$$\begin{aligned} \text{Res}_{\text{at } z = \frac{\pi i}{2}} \frac{e^{imz}}{\cosh z} &= \lim_{z \rightarrow \frac{\pi i}{2}} \left(z - \frac{\pi i}{2} \right) \cdot \frac{e^{imz}}{\cosh z}, \left(\frac{0}{0} \text{ form} \right) \\ &= \lim_{z \rightarrow \frac{\pi i}{2}} \frac{\left(z - \frac{\pi i}{2} \right) \cdot i m e^{imz} + 1 \cdot e^{imz}}{\sinh z} \\ &= \frac{e^{im \cdot \frac{\pi i}{2}}}{\sinh \left(\frac{\pi i}{2} \right)} = \frac{e^{-\frac{m\pi}{2}}}{i \sin(\pi/2)} = -i e^{-\frac{m\pi}{2}} \quad (2) \end{aligned}$$

Therefore substituting (2) in (1)

$$\begin{aligned} I &= \oint_c \frac{e^{imz}}{e^z + e^{-z}} dz = \frac{1}{2} \cdot 2\pi i \cdot \left(-i e - \frac{m\pi}{2} \right) = \frac{\pi}{e^{\frac{m\pi}{2}}} \\ I &= \oint_c \frac{e^{imz} dz}{2 \cdot \cosh z} = \frac{\pi}{e^{\frac{m\pi}{2}}} \\ \therefore \oint_c \frac{e^{imz}}{\cosh z} &= \frac{2\pi}{e^{\frac{m\pi}{2}}} \quad (3) \end{aligned}$$

Since $c = c_1 + c_2 + c_3 + c_4$, we have

$$\begin{aligned} \oint_c f(z) dz &= \int_{c_1} + \int_{c_2} + \int_{c_3} + \int_{c_4} \text{ where } f(z) = \frac{e^{imz}}{\cosh z} \\ &= \int_{-R}^R f(x) dx + \int_0^\pi f(R + iy) i dy \\ &\quad + \int_R^{-R} f(x + \pi i) dx + \int_\pi^0 f(-R + iy) i dy \\ &= \int_{-R}^R \frac{e^{imx}}{\cosh x} dx + \int_0^\pi \frac{e^{im(R+iy)}}{\cosh(R+iy)} i dy \\ &\quad + \int_R^{-R} \frac{e^{im(x+\pi i)}}{\cosh(x+\pi i)} dx \end{aligned}$$

$$\begin{aligned} &+ \int_\pi^0 \frac{e^{im(-R+iy)}}{\cosh(-R+iy)} i dy \\ &= I_1 + I_2 + I_3 + I_4. \end{aligned} \quad (4)$$

To show that I_2 and $I_4 \rightarrow 0$ as $R \rightarrow \infty$:
Note $|e^{im(R+iy)}| = |e^{imR}| \cdot |e^{-my}| = |e^{-my}| < 1$ for $y > 0$

Since $|\cosh(R+iy)|$

$$\begin{aligned} &= \frac{e^{R+iy} + e^{-R-iy}}{2} \geq \frac{1}{2} \left\{ |e^{R+iy}| - |e^{-R-iy}| \right\} \\ &= \frac{1}{2} (e^R - e^{-R}) \geq \frac{1}{4} e^R \end{aligned}$$

from triangle inequality $|z_1 + z_2| \geq |z_1| - |z_2|$.

$$|I_2| = \left| \int_0^\pi \frac{e^{im(R+iy)}}{\cosh(R+iy)} i dy \right| \leq \int_0^\pi \frac{1}{\frac{e^R}{4}} dy = 4e^{-R} \cdot \pi$$

As $R \rightarrow \infty$, $I_2 \rightarrow 0$.

Similarly as $R \rightarrow \infty$, $I_4 \rightarrow 0$.

Now (4) reduces to

$$\lim_{R \rightarrow \infty} \left[\int_{-R}^R \frac{e^{imx}}{\cosh x} dx + e^{-m\pi} \int_{-R}^R \frac{e^{imx}}{\cosh x} dx \right] = \oint_c \frac{e^{imz}}{\cosh z} dz$$

since $\cosh(x+\pi i) = \cosh x \cdot \cos \pi - 0 = -\cosh x$

$$(1 + e^{-m\pi}) \cdot \int_{-\infty}^{\infty} \frac{e^{imx}}{\cosh x} dx = \oint_c \frac{e^{imz}}{\cosh z} dz = \frac{2\pi}{e^{\frac{m\pi}{2}}} \quad \text{from (3)}$$

$$\int_{-\infty}^{\infty} \frac{e^{imx}}{\cosh x} dx = \frac{2 \cdot \pi}{e^{\frac{m\pi}{2}} (1 + e^{-m\pi})}$$

$$\int_{-\infty}^{\infty} \frac{e^{imx} dx}{(e^x + e^{-x})} = \frac{\pi}{(e^{\frac{m\pi}{2}} + e^{-\frac{m\pi}{2}})}$$

Type IV By Indentation

Example 8: Show that

$$\int_0^\infty \frac{\cos x}{\sqrt{x}} dx = \int_0^\infty \frac{\sin x}{\sqrt{x}} dx = \sqrt{\frac{\pi}{2}}.$$

Solution: Consider the contour c consisting of c_1, c_2, c_3, c_4 where $c_1 : AB$: straight-line from r to R along x -axis, $c_2 : BD$: arc of the circle of radius R in the first quadrant, $c_3 : DE$: straight line from R to r along y -axis, $c_4 : EA$: arc of circle of radius r lying in the first quadrant (Fig. 24.6).

Fig. 24.6

The function $f(z) = \frac{e^{iz}}{\sqrt{z}}$ has a singular point at $z = 0$ which lies on both the x -axis and y -axis. To delete this singular point from the region, indent the contour by drawing a quadrant circle with this singular point $z = 0$ as the centre.

Since the only singular point $z = 0$ of $f(z)$ is deleted $f(z)$ has no singular point within c , therefore by Cauchy's theorem,

$$\oint_c f(z) dz = 0$$

Since $c = c_1 + c_2 + c_3 + c_4$, we have

$$\int_c = \int_{c_1} + \int_{c_2} + \int_{c_3} + \int_{c_4} = I_1 + I_2 + I_3 + I_4 = 0$$

$$\text{or } \int_r^R f(x) dx + \int_{c_2} f(z) dz + \int_R^r f(iy) i dy + \int_{c_4} f(z) dz = 0 \quad (1)$$

As $R \rightarrow \infty, z \rightarrow \infty$ then $f(z) \rightarrow 0$.
By Jordan's Lemma (see page 24.9)

$$I_2 = \int_{c_2} f(z) dz \rightarrow 0 \quad \text{as } R \rightarrow \infty \quad (2)$$

$$(* \lim_{R \rightarrow \infty} \int_{c_R} e^{imz} f(z) dz = 0 \quad \text{when } f(z) \rightarrow 0 \text{ as } R \rightarrow \infty)$$

Also as $r \rightarrow 0, (z - 0) \cdot \frac{e^{iz}}{\sqrt{z}} = \sqrt{z} e^{iz} \rightarrow 0$ then

$$I_4 = \int_{c_4} f(z) dz \rightarrow 0 \quad \text{as } r \rightarrow 0 \quad (3)$$

(If $(z - a)f(z) \rightarrow 0$ as $\rho \rightarrow 0$ then $\lim_{\rho \rightarrow 0} \int_{c_\rho} f(z) dz = 0$ where c_ρ is circular arc of

radius ρ , centre at $z = a$. (see theorem 3 on page 24.9)

Since I_2, I_4 are zero from (2) and (3), as $r \rightarrow 0$ and $R \rightarrow \infty$, (1) reduces to

$$\begin{aligned} \int_0^\infty \frac{e^{ix}}{\sqrt{x}} dx + \int_\infty^0 \frac{e^{i(iy)}}{\sqrt{iy}} i dy &= 0 \\ \int_0^\infty \frac{e^{ix}}{\sqrt{x}} dx &= \int_0^\infty e^{-y} \cdot y^{-\frac{1}{2}} \cdot i^{\frac{1}{2}} dy \\ &= (e^{\frac{i\pi}{2}})^{\frac{1}{2}} \int_0^\infty e^{-y} y^{\frac{1}{2}-1} dy \end{aligned}$$

since $i = e^{\frac{i\pi}{2}}$.

$$\begin{aligned} \int_0^\infty \frac{e^{ix}}{\sqrt{x}} dx &= e^{\frac{i\pi}{4}} \Gamma\left(\frac{1}{2}\right) = \left(\cos \frac{\pi}{4} + i \sin \frac{\pi}{4}\right) \sqrt{\pi} \\ &= \sqrt{\frac{\pi}{2}} (1 + i) \end{aligned}$$

$$\text{since } \int_0^\infty e^{-y} y^{\frac{1}{2}-1} dy = \Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$$

Equating the real and imaginary parts on both sides, we get

$$\int_0^\infty \frac{\cos x}{\sqrt{x}} dx = \int_0^\infty \frac{\sin x}{\sqrt{x}} dx = \sqrt{\frac{\pi}{2}}.$$

Example 9: Find the Cauchy principal value of

$$I = \int_{-\infty}^\infty \frac{dx}{x^2 - ix}.$$

Solution: The function $f(z) = \frac{1}{z^2 - iz} = \frac{1}{z(z-i)}$ has simple poles at $z = 0$ and $z = i$. While $z = i$ lies in the upper half-plane, $z = 0$ lies on the real axis. Then

$$\text{pr. v. } \int_{-\infty}^\infty f(x) dx = 2\pi i \sum \text{Res } f(z) + \pi i \sum \text{Res } f(z)$$

where the first sum extends to poles in upper half-plane, second sum to poles on real axis.

$$\text{Res } f(z) = \lim_{z \rightarrow 0} z \cdot \frac{1}{z(z-i)} = \frac{1}{-i} = i$$

$$\text{Res } f(z) = \lim_{z \rightarrow i} (z-i) \cdot \frac{1}{z(z-i)} = \frac{1}{i} = -i$$

$$\text{pr. v. } \int_{-\infty}^\infty \frac{dx}{x^2 - ix} = 2\pi i(-i) + \pi i(i) = 2\pi - \pi = \pi.$$

Type V

Example 10: Evaluate

$$I = \int_0^\infty \frac{x^{a-1}}{1+x^3} dx, \quad 0 < a < 3.$$

Solution: We know that
$$\int_0^\infty x^{a-1} f(x) dx = \frac{\pi}{\sin a\pi} \sum \text{Res of } (-z)^{a-1} f(z) \text{ at all its poles.}$$

$$f(z) = \frac{1}{1+z^3} \text{ has simple poles at } z_1 = -1 \text{ and}$$

$$z_2 = \frac{1+\sqrt{3}i}{2}, z_3 = \frac{1-\sqrt{3}i}{2} \text{ (where } z_2, z_3 \text{ are roots of } z^2 - z + 1 = 0).$$

$$\begin{aligned} k_1 &= \text{Res at } z = z_1 = \lim_{z \rightarrow -1} \frac{(-z)^{a-1}}{1+z^3} \cdot (z+1) \\ &= \frac{1^{a-1}}{1+1+1} = \frac{1}{3} \end{aligned}$$

$$\begin{aligned} k_2 &= \text{Res at } z = z_2 = \lim_{z \rightarrow z_2} \frac{(-z)^{a-1}}{(z+1)(z-z_2)(z-z_3)} (z-z_2) \\ &= \frac{(-z_2)^{a-1}}{(z_2+1)(z_2-z_3)} \\ &= -\frac{1}{z_2} \cdot \frac{1}{(z_2+1)(z_2-z_3)} \cdot \left(-\frac{1}{2} - \frac{\sqrt{3}}{2}i\right)^a \end{aligned}$$

$$\begin{aligned} k_2 &= \frac{1}{3} \left(e^{\frac{i4\pi}{3}}\right)^a = \frac{1}{3} e^{\frac{i4\pi a}{3}} \\ &\text{since } z_2 \cdot (z_2+1)(z_2-z_3) \\ &= \left(\frac{1+\sqrt{3}i}{2}\right) \left(\frac{3+\sqrt{3}i}{2}\right) (\sqrt{3}i) = 3, \end{aligned}$$

Similarly,

$$\begin{aligned} k_3 &= \text{Res at } z = z_3 = \lim_{z \rightarrow z_3} \frac{(-z)^{a-1}}{(z+1)(z-z_2)(z-z_3)} (z-z_3) \\ &= \frac{(-z_3)^{a-1}}{(z_3+1)(z_3-z_2)} \\ &= -\frac{1}{z_3(z_3+1)(z_3-z_2)} \left(-\frac{1}{2} + \frac{\sqrt{3}}{2}i\right)^a \\ &= \frac{1}{3} \left(e^{\frac{i2\pi}{3}}\right)^a = \frac{1}{3} e^{\frac{i2\pi a}{3}} \end{aligned}$$

$$\text{Then } I = \frac{\pi}{\sin a\pi} \left[\frac{1}{3} + \frac{1}{3} e^{\frac{i4\pi a}{3}} + \frac{1}{3} e^{\frac{i2\pi a}{3}} \right]$$

$$= \frac{\pi}{3 \sin a\pi} \left[1 + 2 \cos \frac{2\pi a}{3} \right].$$

EXERCISE

Type I

Evaluate

$$1. \int_0^{2\pi} \frac{d\theta}{\sqrt{2-\cos \theta}}$$

$$\text{Ans. } 2\pi, z_1 = \sqrt{2} - 1, \text{Res } \frac{1}{2}$$

$$2. \int_0^{2\pi} \frac{\cos 2\theta d\theta}{1-2p \cos \theta + p^2}$$

24.4 ARGUMENT PRINCIPLE

Argument principle determines the number (how many) of zeros or poles of a function in a given region which is useful in the stability criteria of linear systems.

Argument Theorem

Theorem: Let $f(z)$ be analytic on and within a simple closed curve c except for a pole $z = a$ of order

(multiplicity) p inside c . Further suppose that $f(z)$ has only one zero $z = b$ of order (multiplicity) n and no other zeros on c .

Then

$$\frac{1}{2\pi i} \oint_c \frac{f'(z)}{f(z)} dz = n - p \quad (1)$$

Proof: Enclose $z = a$ and $z = b$ by non-overlapping circles c_1 and c_2 respectively (Fig. 24.8).

Then

$$\frac{1}{2\pi i} \oint_c \frac{f'(z)}{f(z)} dz = \frac{1}{2\pi i} \oint_{c_1} \frac{f'(z)}{f(z)} dz + \frac{1}{2\pi i} \oint_{c_2} \frac{f'(z)}{f(z)} dz \quad (2)$$

Since $f(z)$ has a pole of order p at $z = a$, we have

$$f(z) = \frac{F(z)}{(z-a)^p} \quad (3)$$

Fig. 24.8

where $F(z)$ is analytic and non-vanishing on and within c_1 . Taking log of (3) and differentiating w.r.t., z , we get

$$\frac{f'(z)}{f(z)} = \frac{F'(z)}{F(z)} - \frac{p}{z-a} \quad (4)$$

$$\begin{aligned} \text{Thus } \frac{1}{2\pi i} \oint_{c_1} \frac{f'(z)}{f(z)} dz &= \frac{1}{2\pi i} \oint_{c_1} \frac{F'(z)}{F(z)} dz \\ &\quad - \frac{p}{2\pi i} \oint_{c_1} \frac{dz}{z-a} \end{aligned} \quad (5)$$

Since F is analytic, so is F' and therefore $\frac{F'}{F}$ is analytic in c_1 . Therefore by Cauchy's theorem $\oint_{c_1} \frac{F'}{F} dz = 0$. For a circle c_1 with centre at $z = a$, $\oint_{c_1} \frac{dz}{z-a} = 2\pi i$. With these values, (5) reduces to

$$\frac{1}{2\pi i} \oint_{c_1} \frac{f'(z)}{f(z)} dz = 0 - \frac{p}{2\pi i} \cdot 2\pi i = -p \quad (6)$$

Since $f(z)$ has a zero of order n at $z = b$, we have

$$f(z) = (z-b)^n G(z) \quad (7)$$

24.18 — HIGHER ENGINEERING MATHEMATICS—VI

where $G(z)$ is analytic and non-vanishing on and within c_2 . Taking log of (7) and differentiating, we get

$$\frac{f'(z)}{f(z)} = \frac{G'(z)}{G(z)} + \frac{n}{z-b} \quad (8)$$

Thus

$$\begin{aligned} \frac{1}{2\pi i} \oint_{c_2} \frac{f'}{f} dz &= \frac{1}{2\pi i} \oint_{c_2} \frac{G'}{G} dz + \frac{n}{2\pi i} \oint_{c_2} \frac{dz}{z-b} \\ &= 0 + \frac{n}{2\pi i} \cdot 2\pi i = n \end{aligned} \quad (9)$$

Substituting (6) and (9) in (2), we get

$$\frac{1}{2\pi i} \oint_c \frac{f'(z)}{f(z)} dz = n - p$$

Generalization of Argument Theorem

Theorem: Let $f(z)$ be analytic on and within a simple closed curve c except at a finite number of poles $a_1, a_2, \dots, a_j$ with respective multiplicities $p_1, p_2, \dots, p_j$ inside c . Further $f(z)$ has a finite number of zeros inside c at $b_1, b_2, \dots, b_k$ with respective multiplicities $n_1, n_2, \dots, n_k$. Also $f(z) \neq 0$ on c .

Then

$$\frac{1}{2\pi i} \oint_c \frac{f'(z)}{f(z)} dz = N - P$$

where $N = \sum_{r=1}^k n_r$ = total number of zeros of $f(z)$ inside c , counting their multiplicities and $P = \sum_{r=1}^j p_r$ = total number of poles of $f(z)$ inside c , counting multiplicities.

Fig. 24.9

Proof: Enclose $a_1, a_2, \dots, a_j$ and $b_1, b_2, \dots, b_k$ by non-overlapping circles $c_1, c_2, \dots, c_j$ and $\Gamma_1, \Gamma_2, \dots, \Gamma_k$ respectively and use the argument theorem above (Fig. 24.9).

$$\frac{1}{2\pi i} \oint_c \frac{f'}{f} dz = \sum_{r=1}^k \frac{1}{2\pi i} \oint_{\Gamma_r} \frac{f'}{f} dz + \sum_{r=1}^j \frac{1}{2\pi i} \oint_{c_r} \frac{f'}{f} dz$$

$$\frac{1}{2\pi i} \oint_c \frac{f'(z)}{f(z)} dz = \sum_{r=1}^k n_r - \sum_{r=1}^j p_r = N - P.$$

Argument Principle: (or Principle of Argument (Angle))

From Argument theorem

$$\begin{aligned} N - P &= \frac{1}{2\pi i} \oint_c \frac{f'(z)}{f(z)} dz = \frac{1}{2\pi i} \oint_c d[\ln f(z)] \\ &= \frac{1}{2\pi i} [\text{Variation of } \ln f(z) \text{ in going completely (once) around (along) } c] \\ &= \frac{1}{2\pi i} \text{var} [\ln |f(z)| + i \arg f(z)] \end{aligned}$$

Since $\ln |f|$ is same at the beginning and at the end of one full circuit around c , therefore

$$\begin{aligned} N - P &= \frac{i}{2\pi} \text{var of } \arg f = \frac{1}{2\pi} \text{var of } \arg f(z) \\ &= \frac{1}{2\pi} [\text{variation of argument of } f(z) \\ &\quad \text{(i.e., change in the angle } f(z) \text{) as curve } c \\ &\quad \text{is traversed completely once}] \end{aligned}$$

Corollary: If $f(z)$ is analytic everywhere (so $P = 0$) then

$$\begin{aligned} N &= \text{Number of zeros of } f(z) \text{ inside } c \\ &= \frac{1}{2\pi} \cdot \text{net variation of argument of } f(z) \\ &\quad \text{as } z \text{ traverses the closed curve } c. \end{aligned}$$

Geometrically the number of zeros of $f(z)$ is the number of times the locus c^* of $w = f(z)$ encircles the origin.

Note: If $w = 0$, origin $\notin c^*$, then $N = \text{net variation of argument } f(z) \text{ is zero.}$

24.5 ROUCHE'S THEOREM

Introduction

The counting of the total number of zeros of an analytic function in a given domain can be appreciably simplified by Rouché's theorem.

Theorem: Let the functions $f(z)$ and $g(z)$ be analytic within and on a simple closed curve c bounding a region R . Further $|f(z)| > |g(z)|$ on c and f and g are non-vanishing on c . Then the total number of zeros inside c (in region R) of $f(z) + g(z)$ is equal to the total number of zeros of $f(z)$.

Proof: Let $F(z) = f(z) + g(z)$. Then on c $|F(z)| = |f(z) + g(z)| \geq |f(z)| - |g(z)| > 0$. Thus both $f(z)$ and $F(z)$ are analytic in c and non-vanishing on c . Therefore by argument principle, number of zeros $F(z) = \frac{1}{2\pi}$ variation of the argument of $F(z)$ as z traverses along the closed curve c completely once i.e.,

$$N[f(z) + g(z)] = \frac{1}{2\pi} \text{var} [\arg (f + g)]_c$$

Similarly,

$$N[f(z)] = \frac{1}{2\pi} \text{var} [\arg f]_c$$

Taking the difference

$$\begin{aligned} N[f + g] - N[f] &= \frac{1}{2\pi} \text{var} [\arg (f + g) - \arg f]_c \\ &= \frac{1}{2\pi} \text{var} \left[\arg \left(\frac{f + g}{f} \right) \right]_c \\ &= \frac{1}{2\pi} \text{var} \left[\arg \left(1 + \frac{g}{f} \right) \right]_c = \frac{1}{2\pi} \text{var} [\arg w]_c \end{aligned}$$

where

$$w = 1 + \frac{g(z)}{f(z)} = w(z). \text{ Then } |w - 1| = \left| \frac{g}{f} \right| < 1.$$

As the point z traverses c completely in the z -plane the corresponding point w describes a closed curve c^* in the w -plane. Since $|w - 1| < 1$, c^* lies entirely inside some circle $|w - 1| = \rho_0$. So the point $w = 0$ lies outside c^* . Consequently the $\text{var} [\arg w]_{c^*} = 0$.

Hence the total number of zeros inside c of $f + g$ and f are same.

Fig. 24.10

Note: If $w = 0$ origin lies inside c^* , then the variation of argument of w is not zero, but is determined by the number of total circuits about the point $w = 0$ performed by w in its complete motion along the closed contour c^* (Fig. 24.10).

WORKED OUT EXAMPLES

Argument principle

Evaluate $\int_c \frac{f'(z)}{f(z)} dz$ where c is a simple closed curve:

Example 1: $f(z) = z^5 - 3iz^2 + 2z - 1 + i$

Solution: By fundamental theorem of algebra, $f(z)$ has 5 zeros. But $f(z)$ has no poles.

By argument principle

$$\int_c \frac{f'(z)}{f(z)} dz = 2\pi i [N - P] = 2\pi i [5 - 0] = 10\pi i.$$

Example 2: $f(z) = (z^2 + 1)^2 / (z^2 + 2z + 2)^3$, $c : |z| = 4$

Solution: $z = \pm i$ are zeros of $f(z)$ each of order 2 (i.e., multiplicity 2). Poles of $f(z)$ are zeros of $z^2 + 2z + 2$ i.e., $z = -1 \pm i$. Thus $-1 \pm i$ are poles of $f(z)$ each of order 3. By argument principle $\oint_c \frac{f'(z)}{f(z)} dz = 2\pi i [2 \times 2 - 2 \times 3] = -4\pi i$.

Example 3: $f(z) = \tan \pi z$, $c : |z| = \pi$.

Solution: Since $\tan \pi z = \frac{\sin \pi z}{\cos \pi z}$, the zeros of $\tan \pi z$ are zeros of $\sin \pi z$ which are $z = \pm n$, $n = 0, 1, 2, 3, \dots$ of these only $z = 0, \pm 1, \pm 2, \pm 3$ (seven of them) lies in c . Similarly, poles of $\tan \pi z$

24.20 — HIGHER ENGINEERING MATHEMATICS—VI

are zeros of $\cos \pi z$ which are $z = \pm \frac{1}{2}, \pm \frac{3}{2}, \pm \frac{5}{2}, \dots$, etc. Of these 6 lie in c . Thus by argument principle

$$\oint_c \frac{f'(z)}{f(z)} dz = 2\pi i [7 - 6] = 2\pi i.$$

Rouche's theorem

Apply Rouché's theorem to determine the number of roots (zeros) of $p(z)$ that lie within the circle/annulus region:

Example 4: $p(z) = z^9 - 2z^6 + z^2 - 8z - 2$,
 $c : |z| = 1$

Solution: Choose $f(z) = -8z$,
 $g(z) = z^9 - 2z^6 + z^2 - 2$

$$\text{on } c : |z| = 1, |f| = |-8z| = |8||z| = 8$$

$$\begin{aligned} \text{on } c : |z| = 1, |g| &= |z^9 - 2z^6 + z^2 - 2| \\ &\leq |z^9| + |2z^6| + |z^2| + |2| \\ &= 1 + 2 + 1 + 2 = 6 \end{aligned}$$

Thus $|f| = 8 > 6 = |g|$ on c , f, g are analytic on and within c . So by Rouché's theorem f and $p = f + g$ has same number of roots within c . But f has only one zero in c . Hence $p(z)$ has one zero inside $c : |z| = 1$.

Example 5: $p(z) = z^4 - 5z + 1$, annulus region $1 < |z| < 2$.

Solution: $c_1 : |z| = 1$. Take $f(z) = -5z$,
 $g(z) = z^4 + 1$.

Then on c , $|f| = 5 > 2 = |g|$.

So by Rouché's theorem $p = f + g$ has one zero inside c_1 since f has one zero in c_1 .

Take $f = z^4$, $g = -5z + 1$. Then on c_2 , $|z| = 2$,
 $|f| = 2^4 = 16 > 11 = |g|$.

So by Rouché's theorem, $p = f + g$ has 4 zeros within c_2 since f has 4 zeros within c_2 . Hence there are $4 - 1 = 3$ zeros of p in the annulus region $1 < |z| < 2$.

Example 6: $p(z) = e^z - 4z^n + 1$, $c : |z| = 1$

Solution: Take $f = -4z^n$, $g = e^z + 1$

$$\text{on } c : |z| = 1, |f| = 4|z^n| = 4 > |g| = |e^z| + 1 = e + 1$$

Therefore $p = f + g$ has n zeros within c since f has n zeros within c .

EXERCISE

Argument principle

Evaluate $\oint_c \frac{f'(z)}{f(z)} dz$ where c is a simple closed curve:

$$1. f(z) = (z^2 - 1)/(z^2 + z)^2, c : |z| = 2$$

Ans. $-4\pi i$

$$2. f(z) = (z^2 + 2)^3/(z^3 + 2z^2 + 2z)^4, \\ c : |z| = 10$$

Ans. $-12\pi i$

$$3. f(z) = \sin \pi z, c : |z| = \pi$$

Ans. $14\pi i$

$$4. f(z) = \cos \pi z, c : |z| = \pi$$

Ans. $12\pi i$.

Rouché's theorem

Use Rouché's theorem to determine the number roots (zeros) of $f(z)$ within the circle c /annulus region indicated:

$$5. f(z) = 2z^5 - z^3 + 3z^2 - z + 8, c : |z| = 1$$

Ans. No zeros

$$6. f(z) = z^7 - 5z^4 + z^2 - 2, c : |z| = 1$$

Ans. 4 zeros

$$7. f(z) = z^6 - 5z^4 + z^3 - 2z, c : |z| = 1$$

Ans. 4

$$8. f(z) = 2z^4 - 2z^3 + 2z^2 - 2z + 9, c : |z| = 1$$

Ans. 0

$$9. f(z) = z^7 - 4z^3 + z - 1, c : |z| = 1$$

Ans. 3

$$10. f(z) = z^7 - z^3 + 12, \quad \text{annulus region} \\ 1 < |z| < 2$$

Ans. 7

$$11. f(z) = z^4 - 8z + 10, 1 < |z| < 3$$

Ans. 4

$$12. f(z) = 2z^5 - 6z^2 + z + 1, 1 < |z| < 2$$

Ans. 3

$$13. f(z) = az^n - e^z, c : |z| = 1, |a| > e$$

Ans. n

$$14. f(z) = 2z^5 + 8z - 1, c : |z| = 2$$

Ans. 5

$$15. f(z) = z^5 + 15z + 1, \frac{3}{2} < |z| < 2$$

Ans. 4.

24.6 FUNDAMENTAL THEOREM OF ALGEBRA

Theorem 1: Every polynomial of degree n in the complex plane has at least one zero.

Proof: (By Liouville's theorem)

Let $p(z)$ be a polynomial in z of degree $n > 1$ given by

$$p(z) = a_0 + a_1z + a_2z^2 + \cdots + a_nz^n$$

where $a_n \neq 0$

Suppose that $p(z)$ has no zeros, then $p(z) \neq 0$ for any value of z . Now $f(z) = \frac{1}{p(z)}$ is analytic everywhere. Also $|f(z)| \rightarrow 0$ as $|z| \rightarrow \infty$ so that $|f(z)|$ is bounded for all z . Liouville's theorem states that a function $f(z)$ which is analytic everywhere and bounded is constant. This is a contradiction since $p(z)$ is not constant. Hence $p(z)$ is zero for at least one value of z .

Aliter

Every polynomial of degree n in the complex plane has n zeros, counting the multiplicities.

Proof: (By Rouché's theorem)

Let $p(z) = a_0 + a_1z + a_2z^2 + \cdots + a_nz^n$ be the polynomial with $a_n \neq 0$. Choose $f(z) = a_nz^n$ and $g(z) = a_0 + a_1z + \cdots + a_{n-1}z^{n-1}$. Let c be a circle with centre at origin of radius $R (> 1)$. Then on c

$$\begin{aligned} \left| \frac{g(z)}{f(z)} \right| &= \frac{|a_0 + a_1z + \cdots + a_{n-1}z^{n-1}|}{|a_nz^n|} \\ &\leq \frac{|a_0| + |a_1|R + |a_2|R^2 + \cdots + |a_{n-1}|R^{n-1}}{|a_n|R^n} \end{aligned}$$

$$\begin{aligned} &\leq \frac{|a_0|R^{n-1} + |a_1|R^{n-1} + \cdots + |a_{n-1}|R^{n-1}}{|a_n|R^n} \\ &= \frac{|a_0| + |a_1| + \cdots + |a_{n-1}|}{|a_n|R} \end{aligned}$$

For any specified values of the coefficients $a_0, a_1, \cdots, a_n$ we can choose R such that

$$0 < \left| \frac{g(z)}{f(z)} \right|_{\text{on } c} = \left| \frac{g(z)}{f(z)} \right|_{|z|=R} < 1 \text{ i.e., } |g(z)| < |f(z)|$$

By Rouché's theorem, the total number of zeros of the polynomial $p(z) = f(z) + g(z)$ in the circle c is same as the number of zeros of $f(z) = a_nz^n$ in c . But the function $f(z) = a_nz^n$ has $(n\text{-fold zero})$ n zeros all located at $z = 0$. Hence $p(z) = f(z) + g(z)$ has n zeros in c . Since R is arbitrary, this is true for the entire complex plane.

24.7 LIOUVILLE* THEOREM

Theorem: If $f(z)$ is entire and $|f(z)|$ is bounded for all z , then $f(z)$ is constant.

Proof: Consider the generalized Cauchy's integral formula

$$f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz \quad (1)$$

with C chosen as a circle with centre at z_0 and of radius r . Since $|f(z)|$ is bounded, $|f(z)| \leq M$.

Applying M-L inequality to (1)

$$|f^{(n)}(z_0)| = \frac{n!}{2\pi} \left| \oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz \right| \leq \frac{n!}{2\pi} \frac{M}{r^{n+1}} 2\pi r,$$

since $C : |z - z_0| = r$ and $L = \text{Length of } C = 2\pi r$

$$\text{or} \quad |f^{(n)}(z_0)| \leq \frac{n!M}{r^n} \quad (2)$$

which is known as **Cauchy's inequality**. From (2) for $n = 1$, we have

$$|f'(z_0)| \leq \frac{M}{r} \quad (3)$$

Since f is entire (analytic everywhere) and $|f|$ is bounded for all z , (3) is true for any r . As $r \rightarrow \infty$

$$|f'(z_0)| \rightarrow 0$$

Thus since z_0 is arbitrary, $f'(z) = 0$ for all z and therefore $f(z)$ is a constant.

*Joseph Liouville (1809–1882) French mathematician.

24.8 DETERMINATION OF ZEROS OF A COMPLEX POLYNOMIAL

WORKED OUT EXAMPLES

Example 1: Using argument principle prove that the complex polynomial equation

$$2z^4 - 3z^3 + 3z^2 - z + 1 = 0$$

has no roots on the real and imaginary axes and has one complex root in each quadrant.

Solution: Consider the complex polynomial function

$$f(z) = u + i v = 2z^4 - 3z^3 + 3z^2 - z + 1$$

- (i) To prove that $f(z)$ has no real roots. For $z = x, (x > 0)$ we have

$$f(x) = 2x^4 - 3x^3 + 3x^2 - x + 1.$$

Chapter 25

Conformal Mapping

INTRODUCTION

Suppose we are able to solve some problem for a simple domain such as a disk or half plane D . Further suppose we map this domain D conformally to another domain D^* in which the solution is sought. Then using such a mapping, from solution of D , we get a solution for D^* . Conformal mapping, which preserves angles in magnitude and sense is useful in solving boundary value problems in two-dimensional potential theory by transforming a complicated region to a simpler region. i.e., conformal mapping preserves solutions of two-dimensional Laplace equation. Bilinear transformation, mappings by z^n , e^z , $\sin z$, $\cos z$ are often used. Schwarz-Christoffel transformation maps polygons to upper half-plane and consequently to a unit disk.

25.1 MAPPING (or TRANSFORMATION or OPERATOR)

A real function $y = f(x)$ involving two variables x and y can be plotted as a plane graph in the xy -plane.

Since a complex function

$$w = f(z) = u(x, y) + iv(x, y)$$

of a complex variable $z = x + iy$ involves four real variables, x , y , $u(x, y)$, $v(x, y)$, two planes z -plane and w -plane are needed for the geometrical representation. The values of z are plotted in z -plane and the corresponding function values w , known as im-

ages of z , are plotted in the w -plane. In general the points on a curve c in the z -plane get mapped or transformed to points on an image curve c^* in the w -plane. Thus the function $w = f(z)$ is said to be a mapping or transformation from z -plane into w -plane.

Critical point of a function $w = f(z)$ is a point z_0 where $f'(z_0) \neq 0$.

25.2 CONFORMAL MAPPING

A mapping $w = f(z)$ is said to be conformal if the angle between any two smooth curves c_1, c_2 in the z -plane intersecting at the point z_0 is equal in magnitude and sense to the angle between their images c_1^*, c_2^* in the w -plane at the point $w_0 = f(z_0)$ (see Fig. 25.1).

Fig. 25.1

Thus conformal mapping preserves angles both in magnitude and sense [also known as conformal mapping of the first kind. Conformal mapping of the second kind (isogonal mappings) preserve

25.2 — HIGHER ENGINEERING MATHEMATICS—VI

angles only in magnitude but not in sense, which is reversed, like $w = \bar{z}$, where $\arg \bar{z} = -\arg z$.

Conformal mapping is used to map complicated regions conformally onto simpler, standard regions such as circular disks, half planes and strips for which the boundary value problems are easier.

Given two mutually orthogonal one-parameter families of curves say $\phi(x, y) = c_1$ and $\psi(x, y) = c_2$, their image curves in the w -plane $\phi(u, v) = c_3$ and $\psi(u, v) = c_4$ under a conformal mapping are also mutually orthogonal. Thus conformal mapping preserves the property of mutual orthogonality of system of curves in the plane.

Condition for Conformality

A mapping $w = f(z)$ is conformal at each point z_0 where $f(z)$ is analytic and $f'(z_0) \neq 0$ (Fig. 25.2).

Proof: Since f is analytic, f' exists and since $f' \neq 0$, we have at a point z_0

$$\begin{aligned} R_0 e^{i\theta_0} = f'(z_0) &= \lim_{\Delta z \rightarrow 0} \frac{f(z_0 + \Delta z) - f(z)}{\Delta z} \\ &= \lim_{\Delta z \rightarrow 0} \frac{\Delta w}{\Delta z} \\ &= \lim_{\Delta z \rightarrow 0} \left(\left| \frac{\Delta w}{\Delta z} \right| + i \arg \frac{\Delta w}{\Delta z} \right) \end{aligned}$$

Fig. 25.2

$$\text{So} \quad \theta_0 = \lim_{\Delta z \rightarrow 0} \left(\arg \frac{\Delta w}{\Delta z} \right)$$

$$\text{Since} \quad \Delta w = \frac{\Delta w}{\Delta z} \cdot \Delta z,$$

$$\arg \Delta w = \arg \frac{\Delta w}{\Delta z} + \arg \Delta z$$

As $\Delta z \rightarrow 0$

$$\beta = \theta_0 + \alpha$$

Thus the directed tangent to curve c at z_0 is rotated through an angle $\theta_0 = \arg f'(z_0)$, which is same for all curves through z_0 . Let α_1, α_2 be angles of inclination of two curves c_1 and c_2 and β_1 and β_2 be the corresponding angles for their images S_1 and S_2 ,

$$\text{Then} \quad \beta_1 = \alpha_1 + \theta_0 \quad \text{and} \quad \beta_2 = \alpha_2 + \theta_0$$

$$\text{Thus} \quad \beta_2 - \beta_1 = \alpha_2 - \alpha_1 = \gamma.$$

Hence the angle γ between the curves c_1 and c_2 and their images S_1 and S_2 is same both in magnitude and sense.

Result: An analytic function $f(z)$ is conformal everywhere except at its critical points where $f'(z) \neq 0$.

Note: Solutions of Laplace's equation are invariant under conformal transformation.

25.3 CONFORMAL MAPPING BY ELEMENTARY FUNCTIONS

General Linear Transformation or simply linear transformation defined by the function

$$w = f(z) = az + b \quad (1)$$

($a \neq 0$, and b are arbitrary complex constants) maps conformally the extended complex z -plane onto the extended w -plane, since this function is analytic and $f'(z) = a \neq 0$ for any z . If $a = 0$, (1) reduces to a constant function.

Special cases of linear transformation are

i. Identity transformation

$$w = z \quad (2)$$

for $a = 1, b = 0$, which maps a point z onto itself.

ii. Translation

$$w = z + b \quad (3)$$

for $a = 1$, which translates (shifts) z through a distance $|b|$ in the direction of b .

iii. Rotation

$$w = e^{i\theta_0} \cdot z \quad (4)$$

for $a = e^{i\theta_0}$, $b = 0$ which rotates (the radius vector of point) z through a scalar angle θ_0 (counterclockwise if $\theta_0 > 0$, while clockwise if $\theta_0 < 0$).

iv. Stretching (scaling)

$$w = az \quad (5)$$

for 'a' real stretches if $a > 1$ (contracts if $0 < a < 1$) the radius vector by a factor 'a'.

Thus the linear transformation (1) consists of rotation through angle $\arg a$, scaling by factor $|a|$, followed by translation through vector b . This transformation is used for constructing conformal mappings of "similar" figures.

Result: Linear transformation preserves circles i.e., a circle in the z -plane under linear transformation maps to a circle in the w -plane.

Consider any circle in the z -plane

$$A(x^2 + y^2) + Bx + Cy + D = 0 \quad (6)$$

From (1)

$$u + iv = w = az + b = a(x + iy) + (b_1 + ib_2)$$

$$\text{or } u = ax + b_1, v = ay + b_2$$

$$\text{or } x = \frac{u - b_1}{a}, y = \frac{v - b_2}{a}, a \neq 0 \quad (7)$$

Substituting (7) in (6), we get

$$A^*(u^2 + v^2) + B^*u + C^*v + D^* = 0 \quad (8)$$

which is a circle in the w -plane.

Here

$$A^* = \frac{A}{a^2}, B^* = \frac{B - 2Ab_1}{a}, C^* = \frac{C - 2Ab_2}{a},$$

$$D^* = D + A \left(\frac{b_1^2 + b_2^2}{a^2} \right) - \frac{Bb_1}{a} - \frac{Cb_2}{a}.$$

Thus circles are invariant under translation, rotation and stretching.

Inversion and Reflection Transformation

$$w = \frac{1}{z} \quad \text{for } z \neq 0 \quad (9)$$

In polar coordinates

$$Re^{i\phi} = \frac{1}{re^{i\theta}} = \frac{1}{r}e^{-i\theta}$$

so $R = \frac{1}{r}$, $\phi = -\theta$. Thus this transformation consists of an inversion in the unit circle ($Rr = 1$) followed by a mirror reflection about the real axis. Also $|w| = \frac{1}{|z|}$. So the unit circle $|z| = 1$ maps onto the unit circle $|w| = \frac{1}{1} = 1$. Further the interior of the unit circle $|z| = 1$ (points lying within $|z| = 1$) are transformed to the exterior of the unit circle $|w| = 1$ (points lying outside $|w| = 1$) or vice versa (Fig. 25.3).

Fig. 25.3

By associating $z = 0$ to $w = \infty$ (also $z = \infty$ to $w = 0$) (9) is valid for the extended complex plane.

Result: Circles are invariant under $w = \frac{1}{z}$.

In terms of cartesian coordinates

$$\begin{aligned} u(x, y) + iv(x, y) = w &= \frac{1}{z} = \frac{1}{x + iy} \\ &= \frac{x - iy}{(x + iy)(x - iy)} = \frac{x - iy}{x^2 + y^2} \end{aligned}$$

$$\text{Thus } u = \frac{x}{x^2 + y^2}, v = -\frac{y}{x^2 + y^2}.$$

$$\text{Similarly, } x = \frac{u}{u^2 + v^2}, y = -\frac{v}{u^2 + v^2} \quad (10)$$

Substituting (10) in the equation of any circle in z -plane given by (6), we get

$$D(u^2 + v^2) + Bu - Cv + A = 0 \quad (11)$$

which is a circle in w -plane.

Observations: From (6) and (11), note that

i. $A \neq 0, D \neq 0$, circles not passing through

25.4 — HIGHER ENGINEERING MATHEMATICS—VI

origin in z -plane maps to circles not passing through origin in w -plane.

- ii. $A = 0, D \neq 0$, straight lines (considered as the limiting case of circles) in z -plane maps to circles through origin in w -plane.
- iii. $A = 0, D = 0$, straight lines in z -plane maps to straight lines in w -plane and so on. Thus circles under $w = \frac{1}{z}$ are preserved.

WORKED OUT EXAMPLES

$$w = az + b \text{ and } w = \frac{1}{z}$$

Example 1: Find and plot the image of triangular region with vertices at $(0, 0)$, $(1, 0)$, $(0, 1)$ under the transformation $w = (1 - i)z + 3$ (Fig. 25.4).

Solution: $u + iv = w = (1 - i)(x + iy) + 3$

So $u(x, y) = x + y + 3$, $v(x, y) = y - x$

Fig. 25.4

$$AB: y = 0, u = x + 3, v = -x$$

$$\text{or } u = -v + 3 \quad \therefore v = 3 - u : A^*B^*$$

$$AC: x = 0, u = y + 3, v = y,$$

$$\text{or } u = v + 3 \quad \therefore v = u - 3 : A^*C^*$$

$$BC: x + y = 1, \quad \text{or substituting } u = (x + y) + 3 \\ = 1 + 3 = 4,$$

$$\text{i.e., } u = 4 : B^*C^*$$

So the image is the triangular region with vertices at $A^*(3, 0)$, $B^*(4, -1)$, $C^*(4, 1)$. Let $D(\frac{1}{4}, \frac{1}{4})$ be any interior point of ABC . Its image is $D^*(3.5, 0)$ which is also an interior point of $A^*B^*C^*$.

Note 1: The angles $\frac{\pi}{2}, \frac{\pi}{4}, \frac{\pi}{4}$ at A, B, C are preserved as $\frac{\pi}{2}, \frac{\pi}{4}, \frac{\pi}{4}$ at vertices A^*, B^*, C^* since given function is conformal (everywhere).

Note 2: Since $z_1 = 1 - i, r = \sqrt{2}$,

$$\theta = \frac{-\pi}{4} \text{ or } \frac{7\pi}{4}.$$

$$\text{Thus } 1 - i = \sqrt{2}e^{i7\pi/4}.$$

Rewriting

$$w = (1 - i)z + 3 = \sqrt{2}e^{i7\pi/4} \cdot z + 3$$

the above transformation first rotates the triangle ABC in the z -plane clockwise by $\frac{\pi}{4}$ (or anticlockwise $\frac{7\pi}{4}$) and stretches the triangle by a scaling factor $\sqrt{2}$ and then finally translates the triangle to distance 3 units to the right, resulting in the triangle $A^*B^*C^*$ in the w -plane. ($AB = 1, AC = 1, BC = \sqrt{2}$ while $A^*B^* = \sqrt{2}, A^*C^* = \sqrt{2}, BC = 2$).

Example 2: Find the graph the strip $1 < x < 2$ under the mapping $w = \frac{1}{z}$ (Fig. 25.5).

$$\text{Solution: } u + iv = w = \frac{1}{z} = \frac{x - iy}{x^2 + y^2}$$

$$\text{so } x = \frac{u}{u^2 + v^2}, \quad y = \frac{-v}{u^2 + v^2}$$

$$\text{Since } 1 < x < 2 \quad \text{so } 1 < \frac{u}{u^2 + v^2} < 2$$

$$\text{or } u^2 + v^2 - u < 0 \quad \text{and } 2(u^2 + v^2) - u > 0$$

Rewriting

$$\left(u - \frac{1}{2}\right)^2 + v^2 < \frac{1}{4} \quad \text{and} \quad \left(u - \frac{1}{4}\right)^2 + v^2 > \frac{1}{16}$$

$$\text{or } \left|w - \frac{1}{2}\right| < \frac{1}{2} \quad \text{and} \quad \left|w - \frac{1}{4}\right| > \frac{1}{4}$$

i.e., interior of the circle with centre at $(\frac{1}{2}, 0)$ and radius $\frac{1}{2}$ and exterior of the circle with centre at $(\frac{1}{4}, 0)$ and radius $\frac{1}{4}$.

Thus the infinite strip maps to the region shaded in the w -plane.

Fig. 25.5

EXERCISE

$$w = az + b \text{ and } w = \frac{1}{z}$$

1. Show that $w = iz$ is a rotation of the z -plane through an angle $\frac{\pi}{2}$ in the counterclockwise direction. Find and plot the image of the regions:

- (a) $0 < x < 1$ (b) $x > 2$ (c) $2 < x < 3$
(d) $1 < x < 2$ and $2 < y < 3$

Ans. $w = iz = e^{\frac{i\pi}{2}} \cdot re^{i\theta} = re^{i(\theta+\frac{\pi}{2})}$,
so $\phi = \theta + \frac{\pi}{2}$, $u = -y$, $v = x$,

- (a) $0 < v < 1$ (b) $v > 2$ (c) $2 < v < 3$
(d) $-2 > u > -3$, $1 < v < 2$.

2. Find and plot the rectangular region $0 \leq x \leq 2$
 $0 \leq y \leq 1$ under the transformations:

a. $w = z + (1 - 2i)$

b. $w = \sqrt{2}e^{\frac{\pi i}{4}}z$

c. $w = \sqrt{2}e^{\frac{\pi i}{4}}z + (1 - 2i)$.

Ans. a. $u = x + 1$, $v = y - 2$, $1 \leq u \leq 3$,
 $-1 \geq v \geq -2$, translation

b. $u = x - y$, $v = x + y$, $u = -v$, $u = v$,
 $v + u = 4$, $v - u = 2$ rotation through $\frac{\pi}{4}$
and stretching by $\sqrt{2}$

c. $u = x - y + 1$, $v = x + y - 2$, $u + v = -1$, $u + v = 3$, $u - v = 1$, $u - v = 3$,
rotation, stretching followed by translation.

3. Find and plot the image of the circle $|z| = c_1$ under the transformation $w = (1+i)z + 3 + 2i$.

Ans. $|w - (3 + 2i)| = \sqrt{2}c_1$, circle with centre at $3 + 2i$ and radius $\sqrt{2}c_1$

4. Determine the image of the regions under $w = \frac{1}{z}$

a. $x > 1$, $y > 0$ (b) $0 < y < \frac{1}{2c}$.

Ans. (a) $|w - \frac{1}{2}| < \frac{1}{2}$ (b) $u^2 + (v + c)^2 > c^2$

5. Determine and sketch the image of $|z - 3| = 5$ under $w = \frac{1}{z}$.

Ans. $|w + \frac{3}{16}| = \frac{5}{16}$.

6. Prove that the image of the hyperbola

$$x^2 - y^2 = 1 \text{ under } w = \frac{1}{z} \text{ is the lemniscate } r^2 = \cos 2\theta.$$

Hint: $R = \frac{1}{r}$, $\phi = -\theta$, $x = r \cos \theta$,
 $y = r \sin \theta$. Substitute in $x^2 - y^2 = 1$.

7. Find and draw the image of the infinite horizontal strip $2 < y < 4$ under $w = \frac{1}{z}$.

Ans. $|w + \frac{1}{4}| < \frac{1}{4}$ and $|w + \frac{1}{8}| > \frac{1}{8}$ region between the two circles with centre at $-\frac{1}{4}$, radius $\frac{1}{4}$ and with centre at $-\frac{1}{8}$ and radius $\frac{1}{8}$

8. Find the critical points of the mappings:

(a) $w = z^4$ (b) $w = e^{z^2}$ (c) $w = e^z$ (d) $w = \sin z$ (e) $w = z^2 + az + b$ (f) $w = z + \frac{1}{z}$ (g) $w = z^4 - z^2$ (h) $w = z^2 + \frac{1}{z^2}$.

Ans. (a) $z = 0$ (b) $z = 0$ (c) none (d) $z = \frac{n\pi}{2}$, n odd (e) $z = -\frac{a}{2}$ (f) $z = \pm 1$ (g) $z = 0, \pm \frac{1}{\sqrt{2}}$ (h) $w = \pm 1, \pm i$

9. Find an analytic function $w = u + iv = f(z)$ which maps the half plane $x \geq 0$ onto the region $u \geq 2$ such that $z = 0$ corresponds to $w = 2 + i$.

Hint: $w_1 = z$, $w_2 = w_1 + 2$, $w = w_2 + i$.

Ans. $w = z + 2 + i$.

25.4 TRANSFORMATION: $w = z^n$

where n is integer greater than 1

Rewriting, $Re^{i\phi} = w = z^n = (re^{i\theta})^n$

$$\text{or } R = r^n \text{ and } \phi = n\theta \quad (12)$$

Fig. 25.6

Thus angular region sector with central angle $\alpha = \frac{\pi}{n}$, $r > 0$, $0 \leq \theta \leq \frac{\pi}{n}$ in the z -plane under $w = z^n$ maps to the upper half plane ($v \geq 0$) in the w -plane

25.6 — HIGHER ENGINEERING MATHEMATICS—VI

(since $0 \leq n\theta = \phi \leq \pi$, $R > 0$ i.e., $v \geq 0$) (see Fig. 25.6).

The transformation $w = z^n$ is conformal every except at $z = 0$ and ∞ since z^n is entire and since $f'(z) = nz^{n-1}$ is non-zero and bounded everywhere except at $z = 0$ and ∞ . This transformation maps the sector $\theta_0 < \arg z = \theta < \theta_0 + \frac{2\pi}{n}$ onto the w -plane (cut along the ray $\arg w = \phi = n\theta_0$) since both the boundaries I and II of the sector say $0 \leq \theta \leq \frac{2\pi}{n}$ of the z -plane maps to the positive real axis of the w -plane) (see Fig. 25.7).

Fig. 25.7

Note: The angles at the origin are multiplied by a factor n in this mapping and the angular region is spread onto a half plane.

25.5 MAPPING $w = z^2$

In polar coordinates

$$Re^{i\phi} = w = (re^{i\theta})^2 = r^2 e^{i2\theta} \quad (13)$$

i.e., $R = r^2$, $\phi = 2\theta$

thus the angles at the origin are doubled. For example, the first quadrant in z -plane ($0 \leq \theta \leq \frac{\pi}{2}$) maps to the upper half plane in the w -plane ($0 \leq \phi \leq \pi$) (refer Fig. 25.8).

Fig. 25.8

The circle $r = r_0$ maps to circle $R = r_0^2$

The ray $\theta = \theta_0$ maps to ray $\phi = 2\theta_0$

In cartesian coordinates

$$\begin{aligned} u(x, y) + iv(x, y) &= w = z^2 = (x + iy)^2 \\ &= (x^2 - y^2) + i2xy \end{aligned}$$

$$\text{So } u(x, y) = x^2 - y^2, v(x, y) = 2xy \quad (14)$$

Case 1: If $u = u_0 = \text{constant}$ and $v = v_0 = \text{constant}$ then $x^2 - y^2 = u_0$ and $2xy = v_0$ represent equilateral hyperbolas (with the lines $y = \pm x$ and the coordinate axes $x = 0$, $y = 0$ as asymptotes respectively) which are orthogonal trajectories of each other (refer Fig. 25.9).

Fig. 25.9

Case 2: If $x = c_1 = \text{constant}$ and $y = c_2 = \text{constant}$ then eliminating x and y from (14) for $x = c_1$,

$$u = c_1^2 - y^2, v = 2c_1 y \quad \text{so} \quad u = c_1^2 - \frac{v^2}{4c_1^2}$$

which is a parabola with focus at origin, $v = 0$ as axis and open to the left. Similarly, $y = c_2$, $u = x^2 - c_2^2, v = 2c_2 x$, so $u = \frac{v^2}{4c_2^2} - c_2^2$ parabola open to the right (Fig. 25.10).

Fig. 25.10

These parabolas are orthogonal to each other. $w = z^2$ is conformal everywhere except at $z = 0$ where $w' = 2z = 0$.

WORKED OUT EXAMPLES

$$w = z^n \text{ and } w = z^2$$

Example 1: Describe the region onto which the sector $r < a, 0 \leq \theta \leq \frac{\pi}{4}$ is mapped by (a) $w = z^2$ (b) $w = z^3$ (c) $w = z^4$ (d) $w = iz^2$ (e) $w = \frac{i}{z^2}$

Solution: $Re^{i\phi} = w = z^2 = r^2 e^{i2\theta}$ so $R = r^2$, $\phi = 2\theta$

a. $R = r^2 < a^2$, $0 \leq \phi \leq \frac{\pi}{2}$ (Fig. 25.11)

Fig. 25.11

b. $w = z^3$, $R = r^3$, $\phi = 3\theta$, $R = r^3 < a^3$, $0 \leq \phi \leq \frac{3\pi}{4}$ (Fig. 25.12)

Fig. 25.12

c. $w = z^4$, $R = r^4 < a^4$, $0 \leq \phi \leq \pi$ (refer Fig. 25.13)

Fig. 25.13

d. $w = iz^2$, rotation of (Fig of a) by $\frac{\pi}{2}$ in counterclockwise (Fig. 25.14).

Fig. 25.14

e. $Re^{i\phi} = w_1 = \frac{1}{z^2} = \frac{1}{r^2 e^{i2\theta}} = \frac{1}{r^2} e^{-i2\theta}$

so $R = \frac{1}{r^2} > \frac{1}{a^2}$ and $\phi = -2\theta$ i.e., $0 \geq \theta \geq -\frac{\pi}{2}$ (refer Fig. 25.15).

Fig. 25.15

Sector in z -plane is inverted in w_1 -plane and then rotated through $\frac{\pi}{2}$ in counterclockwise direction.

Example 2: Find an analytic function $w = u + iv = f(z)$ such that the angular region $0 < \arg z < \frac{\pi}{3}$ maps onto the region $u \leq 1$ (refer Fig. 25.16).

Fig. 25.16

25.8 — HIGHER ENGINEERING MATHEMATICS—VI

Solution: z^3 maps the given region onto upper half plane in w_1 -plane, which rotated through $\frac{\pi}{2}$ in w_2 -plane and translated to the right by 1 in the w -plane.

Example 3: Plot the image of the region

$2 < |z| < 3$ and $|\arg z| < \frac{\pi}{4}$ under $w = z^2$ (see Fig. 25.17).

Fig. 25.17

Solution: $R = r^2$ so for $2 < r < 3$, $4 < R < 9$
Since $-\frac{\pi}{4} < \theta < \frac{\pi}{4}$
therefore

$$-\frac{\pi}{2} < \phi < \frac{\pi}{2}$$

Example 4: Determine and graph the image of $|z - a| = a$ under $w = z^2$ (Fig. 25.18).

Fig. 25.18

Solution: The given region is a circle in the z -plane with centre at $(a, 0)$ and radius a . i.e.,

$$z - a = ae^{i\theta} \quad \text{or} \quad z = a + ae^{i\theta} = a(1 + e^{i\theta})$$

$$\begin{aligned} \text{So } w = z^2 &= a^2(1 + e^{i\theta})^2 = a^2(1 + \cos \theta + i \sin \theta)^2 \\ &= 2a^2(\cos^2 \theta + \cos \theta + i \sin \theta \cos \theta + i \sin \theta) \end{aligned}$$

$$\begin{aligned} Re^{i\phi} = w &= 2a^2(1 + \cos \theta)(\cos \theta + i \sin \theta) \\ &= 2a^2(1 + \cos \theta)e^{i\theta} \end{aligned}$$

$$\begin{aligned} \text{Thus } R &= 2a^2(1 + \cos \theta) \\ &= 2a^2(1 + \cos \phi) \quad \text{since } \phi = \theta \end{aligned}$$

EXERCISE

$w = z^n$ and $w = z^2$

Determine and plot the images of the regions under the transformation $w = z^2$:

1. $|z| > 2$

Ans. $|w| > 4$

2. $|\arg z| \leq \frac{\pi}{2}$

Ans. $|\arg w| \leq \pi$

3. $\frac{1}{2} < |z| < 2$, $Re z \geq 0$

Ans. $\frac{1}{4} < |w| < 4$, $-\pi \leq \phi \leq \pi$

4. Show that $w = \frac{z^4 - i}{z^4 + i}$ maps $0 < \arg z < \frac{\pi}{4}$ onto $|w| = 1$.

Hint: $w_1 = z^4$ onto upper half plane,
 $w = \frac{w_1 - i}{w_1 + i}$ onto unit circle $|w| = 1$.

5. Find a transformation which will map an infinite sector of angle $\frac{\pi}{3}$ onto the interior of a unit circle.

Hint: $w_1 = z^3$ spreads to upper half plane, bi-linear transformation (B.T.) maps to unit circle.

Ans. $w = \frac{(z^3 - i)}{(z^3 + i)}$

6. Determine the region of the w -plane into which the region bounded by $x = 1$, $y = 1$, $x + y = 1$ is mapped by $w = z^2$. Show that angles are preserved (refer Fig. 25.19).

Fig. 25.19

Ans. $u = \frac{v^2}{4} - 1, u = 1 - \frac{v^2}{4}, v = \frac{1}{2}(1 - u^2)$

7. Find the region in z -plane whose image under $w = z^2$ is the rectangular domain in w -plane bounded by the lines $u = 1, u = 2, v = 1, v = 2$.

Ans. $1 < x^2 - y^2 < 2, \frac{1}{2} < xy < 1$ rectangular hyperbolas

8. Determine the image of the rectangle $a \leq x \leq b, c \leq y \leq d$ under $w = \sqrt{z}$.

Hint: Consider $w^2 = z$ and use above problem 7.

Ans. $a \leq u^2 - v^2 \leq b$ and $c \leq 2uv \leq d$ rectangular hyperbolas

9. Show that the image of the unit circle $|z| = 1$ under $w = 2z + z^2$ is a cardioid

$$R = 2(1 + \cos \phi).$$

25.6 TRANSFORMATION $w = e^z$

Rewriting

$$Re^{i\phi} = w = e^z = e^{x+iy} = e^x \cdot e^{iy}$$

$$\text{Therefore } R = e^x \text{ and } \phi = y \quad (1)$$

i.e., modulus of w is e^x and argument of w is y . The line $x = c = \text{constant}$ maps onto the circle $R = e^c$ (refer Fig. 25.20).

Fig. 25.20

The line $y = c$ maps onto the ray $\phi = c$. Thus

the rectangular region $a \leq x \leq b, c \leq y \leq d$ in the z -plane is mapped to the region $A^*B^*C^*D^*$ in the w -plane bounded by the concentric circles $R = e^a$ and $R = e^b$ and by the rays $\phi = c$ and $\phi = d$.

Note 1: Since $e^z \neq 0, w = 0$ is not mapped. Thus the origin in w -plane is excluded.

Note 2: This mapping is one to one if $d - c < 2\pi$.

Particular case: $c = 0, d = \pi$

Consider the rectangular region in z -plane $a \leq x \leq b, 0 \leq y \leq \pi$ (see Fig. 25.21). By (1),

Fig. 25.21

$$e^a \leq R = e^x \leq e^b \text{ and } 0 \leq \phi = y \leq \pi.$$

Thus the rectangular region maps onto the upper half of the annular ring $e^a < R < e^b, 0 \leq \phi \leq \pi$ (refer Fig. 25.22).

Fig. 25.22

Infinite Rectangular Strip

To find the image of the infinite rectangular strip in the z -plane given by $-\infty < x < \infty, 0 \leq y \leq \pi$ under the transformation $w = e^z$:

Case 1: Consider the left semi-infinite strip

$$-\infty < x \leq 0, 0 \leq y \leq \pi. \text{ By (1), } x = 0, R = e^0 = 1$$

and as $x \rightarrow -\infty, R = e^x \rightarrow 0$. Also $0 \leq \phi \leq \pi$

$$AB: -\infty < x < 0, y = 0 \text{ then } 0 < R < 1$$

$$\text{and } \phi = 0$$

$$BCD: x = 0, 0 \leq y \leq \pi \text{ then } R = 1$$

and $0 \leq \phi \leq \pi$
 $DE: -\infty < x < 0, y = \phi$ then $0 < R < 1$
and $\phi = \pi$.

Thus the left semi-infinite strip $ABCDE$ maps onto the semi circle $0 < R \leq 1, 0 \leq \phi \leq \pi$ given by $A^*B^*C^*D^*E^*$ in the w -plane (Fig. 25.23).

Fig. 25.23

Case 2: Right semi-infinite strip $0 \leq x < \infty, 0 \leq y \leq \pi$. By (1), $1 \leq R < \infty$ and $0 \leq \phi \leq \pi$. Thus the right semi-infinite strip maps onto the exterior of the semi-circle $|w| = 1$ in the upper half of w -plane.

Fundamental region of e^z

Since e^z is periodic with period $2\pi i$

$$e^{z+2\pi i} = e^z$$

The infinite strip $-\infty < x < \infty, -\pi < y \leq \pi$, is known as a fundamental region of e^z .

The transformation $w = e^z$ maps a fundamental region bijectively onto the entire w -plane.

Conformality

$w = e^z$ is conformal everywhere since e^z is analytic everywhere and has no critical points ($w' = e^z \neq 0$ for any z).

Mapping of Logarithmic Function

Since logarithm is the inverse of exponential function, the mapping logarithm can be easily obtained from those of the exponential function by interchanging the roles of z (z -plane) and w (w -plane).

WORKED OUT EXAMPLES

Example 1: Find and draw the image of the rectangular region $-1 \leq x \leq 3, -\pi \leq y \leq \pi$ in the z -plane under the transformation $w = e^z$.

Solution: By transformation $R = e^x, y = \phi$, we get for $-1 \leq x \leq 3, e^{-1} \leq R \leq e^3$ and for $-\pi \leq y \leq \pi, -\pi \leq \phi \leq \pi$. Thus the image is the annulus region bounded by the circles of radii e^{-1} and e^3 (Fig. 25.24).

Fig. 25.24

Example 2: Find an analytic function which maps the region R bounded by the positive x and y -axes and the hyperbola $xy = \frac{\pi}{2}$ in the first quadrant onto the upper half plane.

Solution: The transformation $w_1 = z^2$ maps the given region onto the semi-infinite strip $-\infty < u_1 < \infty, 0 \leq v_1 \leq \pi$ in the w_1 -plane. [$u_1 = x^2 - y^2, v_1 = 2xy$ so $OA: x=0, v_1=0, OB: y=0, v_1=0$ so BOA maps $v_1=0$ i.e., to $B^*O^*A^*, CDE: xy = \frac{\pi}{2}$ so $v_1 = 2xy = 2 \cdot \frac{\pi}{2} = \pi$, so CDE onto $C^*D^*E^*: v_1 = \pi$] (Fig. 25.25).

Fig. 25.25

Now the transformation $w = e^{w_1} = e^{z^2}$ transforms the semi-infinite strip onto the upper half plane in the w -plane.

EXERCISE

Find and graph the images of the regions under the mapping $w = e^z$:

1. $-1 < x < 1, \frac{-\pi}{2} < y < \frac{\pi}{2}$

Ans. $e^{-1} < R < e, \frac{-\pi}{2} < \phi < \frac{\pi}{2}$

Fig. 25.26

2. $-2 \leq x \leq 2, -\pi \leq y \leq \frac{-\pi}{2}$

Ans. $e^{-2} \leq R \leq e^2, -\pi \leq \phi \leq \frac{-\pi}{2}$

Fig. 25.27

3. Find the transformation which conformally maps the horizontal strip $0 < y < \pi$ onto the disk $|w| < 1$.

Ans. $w = f(z) = \frac{(e^z - i)}{(e^z + i)}$. Put $Z = e^z$ which transforms horizontal strip onto upper half plane, then B.T. $w = \frac{(z-i)}{(z+i)}$ maps upper half plane onto disk $|w| < 1$.

4. Find the transformation which maps the infinite strip $0 < y < a$ in the z -plane into the upper half plane of w -plane.

Ans. $w = e^{\frac{\pi z}{a}}$

5. Find the transformation which maps the annulus region $a < R < b$ in z -plane onto a rectangle in the w -plane.

Hint: $e^w = z$ transforms rectangles in w -plane onto annulus region in z -plane.

Ans. $w = \ln z$

6. Show that the transformation $w = \tan z$ transforms $|x| < \frac{\pi}{4}$ onto unit disk $|w| < 1$.

Hint: $w = \tan z = \frac{1}{i} \frac{e^{iz} - e^{-iz}}{e^{iz} + e^{-iz}} = \frac{-ie^{2iz} + i}{e^{2iz} + 1}$

Put $Z = e^{i2z}$, $w = \frac{-iZ + i}{Z + 1}$.

Vertical strip to right half plane to unit circle.

25.7 TRANSFORMATION $w = \sin z$

We know that

$$\begin{aligned} u + iv &= w = f(z) = \sin z \\ &= \sin x \cdot \cosh y + i \cos x \sinh y \end{aligned} \quad (1)$$

$$\text{so} \quad u(x, y) = \sin x \cdot \cosh y \quad (2)$$

$$v(x, y) = \cos x \sinh y \quad (3)$$

If $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$, then the mapping is one-to-one. If $x = c = \text{constant}$ then from (2) and (3)

$$u = \sin c \cosh y, \quad v = \cos c \sinh y,$$

$$\text{so} \quad 1 = \cosh^2 y - \sinh^2 y = \left(\frac{u}{\sin c} \right)^2 - \left(\frac{v}{\cos c} \right)^2$$

Thus the images of the vertical lines $x = \text{constant}$ are hyperbolas given by

$$\frac{u^2}{\sin^2 c} - \frac{v^2}{\cos^2 c} = 1 \quad (4)$$

If $y = c$ then from (2) and (3)

$$u = \sin x \cdot \cosh c, \quad v = \cos x \cdot \sinh c,$$

$$\text{so } 1 = \sin^2 x + \cos^2 x = \left(\frac{u}{\cosh c} \right)^2 + \left(\frac{v}{\sinh c} \right)^2$$

Thus the images of the horizontal lines $y = c$ are ellipses given by

$$\frac{u^2}{\cosh^2 c} + \frac{v^2}{\sinh^2 c} = 1 \quad (5)$$

The focii for the ellipses (5) and hyperbolas (4) are same given by $w = \pm 1$ (independent of the constant c) (Fig. 25.28).

Hence $w = \sin z$ transforms $x = c$ and $y = c$ lines into confocal hyperbolas (4) and confocal ellipses (5) respectively. The families of hyperbolas and ellipses are orthogonal to each other.

Fig. 25.28

Semi-infinite strip: $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}, y \geq 0$.
(see Fig. 25.29)

Fig. 25.29

From (2) and (3), $u = \sin x \cdot \cosh y$,
 $v = \cos x \sinh y$

$AB: x = \frac{\pi}{2}, y \geq 0$ so $v = 0, u = \cosh y \geq 1$

$BC: y = 0, 0 \leq x < \frac{\pi}{2}$ so $v = 0, u = \sin x$,
thus $0 \leq u \leq 1$

$CD: y = 0, -\frac{\pi}{2} \leq x \leq 0$, so $v = 0, u = \sin x$,
thus $-1 \leq u \leq 0$

$DE: x = -\frac{\pi}{2}, y \geq 0$, so $v = 0, u = -\cosh y \leq -1$

$CF: x = 0, y \geq 0$, so $u = 0, v = \sinh y \geq 0$.

Thus the upper semi-infinite strip in the z -plane under $w = \sin z$ transforms to the upper half plane in the w -plane.

Similarly, the lower semi-infinite strip $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}, y \leq 0$ maps to the lower half plane of the w -plane.

Cut

To find the image of the rectangle in the z -plane $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}, -1 \leq y \leq 1$; under $w = \sin z$ (see Fig. 25.30)

Fig. 25.30

Line by line correspondence:

$CB: y = 1, -\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$, upper portion of the ellipse

$$\frac{u^2}{\cosh^2 1} + \frac{v^2}{\sinh^2 1} = 1$$

since $v = \cos x \cdot \sinh 1 \geq 0$ for $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$

$EF: y = -1, -\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$, lower portion of the above ellipse since $v = -\cos x \cdot \sinh 1 \leq 0$ for $(-\frac{\pi}{2}, \frac{\pi}{2})$

$$BA : x = \frac{\pi}{2}, y > 0, \quad \text{so } v = 0, u = \cosh y \geq 1$$

$$AF : x = \frac{\pi}{2}, y < 0, \quad \text{so } v = 0, u = \cosh(-y) \\ = \cosh y \geq 1.$$

Thus BA and AF both get mapped onto the same line segment $v = 0, u \geq 1$ in the w -plane. $B^*A^*F^*$ is known as cut along the real axis.

$$CD : x = -\frac{\pi}{2}, y > 0, \quad \text{so } v = 0, u = -\cosh y \leq -1$$

$$DE : x = -\frac{\pi}{2}, y < 0, \quad \text{so } v = 0, u = -\cosh y \leq -1.$$

Thus CD and DE both map to the cut $C^*D^*E^*$. Hence the upper and lower sides of the rectangle are mapped onto semi-ellipses while the vertical sides onto $-\cosh 1 \leq u \leq -1$ and $1 \leq u \leq \cosh 1$ ($v = 0$).

Mapping $w = \sin z$ is conformal everywhere except at $z = \pm 1$ where it is not one-to-one. In general, $w = \sin z$ is conformal everywhere since $w = \sin z$ is analytic everywhere except at the critical points $z = (2n - 1)\frac{\pi}{2}$ where

$$w' = \cos z = 0 \quad (n = 0, \pm 1, \pm 2, \dots).$$

Successive Transformations

from one plane to another are equivalent to a single transformation.

1. $w = \cos z = \sin(z + \frac{\pi}{2})$

with $z^* = z + \frac{\pi}{2}$, $w = \cos z = \sin z^*$.

Thus the cosine transformation is the same mapping as sine preceded by a translation to the right through $\frac{\pi}{2}$ units.

2. $w = \sinh z = -i \sin(iz)$

with $w_1 = iz$, $w_2 = \sin w_1$, $w = -i w_2$

Hyperbolic sine consists of counterclockwise rotation through $\frac{\pi}{2}$, followed by sine transformation followed by clockwise rotation through $\frac{\pi}{2}$.

3. $w = \cosh z = \cos(iz)$

with $w_1 = iz$, $w = \cos(w_1)$

Hyperbolic cosine consists of counterclockwise rotation through $\frac{\pi}{2}$ followed by cosine transformation.

WORKED OUT EXAMPLES

Example 1: Find and graph the image of the region $0 < x < 2\pi$, $1 < y < 2$ in the z -plane under the mapping $w = \sin z$.

Solution: $u = \sin x \cosh y$; $v = \cos x \cdot \sinh y$.

The line $AGEKB$ in the z -plane given by $y = 1$ and $0 < x < 2\pi$ maps to the (inner) ellipse (Fig. 25.31).

Fig. 25.31

$$\frac{u^2}{\cosh^2 1} + \frac{v^2}{\sinh^2 1} = 1$$

Similarly, the line $CLFHD$ in the z -plane given by $y = 2$ and $0 < x < 2\pi$ maps to the (outer ellipse)

$$\frac{u^2}{\cosh^2 2} + \frac{v^2}{\sinh^2 2} = 1$$

The shaded rectangular strip in the z -plane maps to the elliptical annulus bounded by the above two ellipses with a cut along the positive imaginary axis.

Line $AD : x = 0, 1 < y < 2$ so $u = 0$,

$$v = \sinh y > 0$$

For $1 < y < 2$, $\sinh 1 < v < \sinh 2$

Line $BC : x = 2\pi, 1 < y < 2$ so $u = 0$,

$$v = \sinh y > 0 \quad \text{for } 1 < y < 2, \sinh 1 < v < \sinh 2.$$

Thus both the line segments AD and BC of z -plane get mapped onto the same line segment $u = 0, \sinh 1 < v < \sinh 2$. Thus there exists a cut along the positive imaginary axis.

$$GH : x = \frac{\pi}{2}, 1 < y < 2, \quad \text{so } v = 0, u = \cosh y$$

$$\text{thus } \cosh 1 < u < \cosh 2$$

25.14 — HIGHER ENGINEERING MATHEMATICS—VI

$$EF : x = \pi, 1 < y < 2, \quad \text{so } u = 0, v = -\sinh y$$

$$\text{thus } -\sinh 1 < v < \sinh 2$$

$$KL : x = \frac{3\pi}{2}, 1 < y < 2 \quad \text{so } v = 0, u = -\cosh y$$

$$\text{thus } -\cosh 1 < u < -\cosh 2.$$

Example 2: Find and graph the image of the region $0 \leq x \leq \frac{\pi}{2}$ in the z -plane under the mapping $w = \tan^2 \frac{z}{2}$ (Fig. 25.32).

Solution: $w = \tan^2 \frac{z}{2} = \frac{\sin^2 \frac{z}{2}}{\cos^2 \frac{z}{2}} = \frac{1 - \cos z}{1 + \cos z}$

Fig. 25.32

We know that $\cos z = \cos x \cdot \cosh y - i \sin x \sinh y$
 $ED : x = \frac{\pi}{2}, y \geq 0, \cos z = -i \sinh y$

$$w = \frac{1 - \cos z}{1 + \cos z} = \frac{1 + i \sinh y}{1 - i \sinh y}$$

$$|w| = \left| \frac{1 + i \sinh y}{1 - i \sinh y} \right| = \frac{\sqrt{1 + \sinh^2 y}}{\sqrt{1 + \sinh^2 y}} = 1 \quad \text{for any } y.$$

Thus the line $x = \frac{\pi}{2}$ is mapped onto the unit circle $|w| = 1$ in the w -plane.

The y -axis: $x = 0$ is mapped onto

$$w = \frac{1 - \cosh y}{1 + \cosh y}$$

w is purely real.

At $y = 0, w = u = 0, y > 0$ as $y \rightarrow \infty u \rightarrow -1$.
 Similarly as $y \rightarrow -\infty$ also $u \rightarrow -1$.

Thus both AB and BF maps onto the same interval (a cut) $-1 \leq u \leq 0$.

Any line $x = \alpha$, where $0 < \alpha < \frac{\pi}{2}$

$$|w| = \left| \frac{1 - \cos(\alpha + iy)}{1 + \cos(\alpha + iy)} \right|$$

$$= \sqrt{\frac{(1 - \cos \alpha \cosh y)^2 + (\sin \alpha \sinh y)^2}{(1 + \cos \alpha \cosh y)^2 + (\sin \alpha \sinh y)^2}} < 1$$

Since $-2 \cos \alpha \cosh y \leq 2 \cos \alpha \cosh y$

or $4 \cos \alpha \cosh y \geq 1$

which is true for $\cos \lambda$ with $0 < \alpha < \frac{\pi}{2}$ and $y \geq 0$.
 Hence any line $x = \alpha$ gets mapped to interior of $|w| = 1$.

EXERCISE

Find and graph the images of the following regions under $w = \sin z$: (Fig. 25.33)

1. $-\frac{\pi}{2} < x < \frac{\pi}{2}, 1 < y < 2$

Fig. 25.33

Ans. $y = c, \frac{u^2}{\cosh^2 c} + \frac{v^2}{\sinh^2 c} = 1$ where $c = 1, 2$
 bounded by inner and outer ellipses in the upper half plane.

2. Rectangular region $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}, 0 \leq y \leq \theta_0$
 (refer Fig. 25.34).

Ans.

Fig. 25.34

semi elliptic region in the upper half plane.

3. $-\pi \leq x \leq \pi, \theta_1 \leq y \leq \theta_2$ (refer Fig. 25.35).

Fig. 25.35

Region bounded by confocal ellipses with a cut along the negative imaginary axis.

25.8 JOUKVOWSKI'S (ZHUKOVSKY'S) TRANSFORMATION

$$w = z + \frac{a^2}{z} \quad (1)$$

is used in solutions of problems in hydro- and aerodynamics. (1) is analytic everywhere except at a simple pole $z = 0$. Since

$$\frac{dw}{dz} = \frac{z^2 - a^2}{z^2},$$

w' is non-zero everywhere except at $z = \pm a$.

Thus the Joukowski's transformation (function) is conformal everywhere except at the points $z = \pm a$ which correspond to $w = \pm 2a$ in the w -plane. Solving (1) for z , we get

$$z = \frac{w \pm \sqrt{w^2 - 4a^2}}{2}$$

so z is a double-valued function of w .

Rewriting (1) in polar coordinates

$$\begin{aligned} u + iv = w &= re^{i\theta} + \frac{a^2}{re^{i\theta}} = re^{i\theta} + \frac{a^2}{r}e^{-i\theta} \\ &= r(\cos \theta + i \sin \theta) + \frac{a^2}{r}(\cos \theta - i \sin \theta) \\ &= \left(r + \frac{a^2}{r}\right) \cos \theta + i \left(r - \frac{a^2}{r}\right) \sin \theta \end{aligned}$$

Thus $u(r, \theta) = \left(r + \frac{a^2}{r}\right) \cos \theta$, $v = \left(r - \frac{a^2}{r}\right) \sin \theta$ (2)

To find the image of circle $|z| = r_0$, eliminate the parameter θ from (2), then we have

$$\left(\frac{u}{r + \frac{a^2}{r}}\right)^2 + \left(\frac{v}{r - \frac{a^2}{r}}\right)^2 = \cos^2 \theta + \sin^2 \theta = 1 \quad (3)$$

For $r = r_0 = \text{constant}$, (3) represents an ellipse with focii at

$$\sqrt{\left(r + \frac{a^2}{r}\right)^2 - \left(r - \frac{a^2}{r}\right)^2} = \sqrt{4a^2} = \pm 2a$$

which are independent of r .

Thus the Joukowski's function (1) maps the family of concentric circles $|z| = r_0$ of the z -plane onto the family of confocal ellipses of the w -plane with focii at $w = \pm 2a$.

Special Case 1: $|z| = a$, circle.

As $r \rightarrow a$, $v=0$, $u = 2a \cos \theta$. Since $|\cos \theta| \leq 1$, $-2a \leq u \leq 2a$.

Thus the circle $|z| = a$ in the z -plane maps to the degenerated ellipse (3) which flattens to the line segment $v = 0$, $-2a \leq u \leq 2a$ on the real u -axis traversed twice.

Case 2: As $r \rightarrow 0$, the ellipse (3) is transformed into a circle of infinitely large radius (Fig. 25.36).

Fig. 25.36

To find the image of the ray $\arg z = \theta_0$, eliminate the parameter r from (2), and $\arg z = \theta = \theta_0 = \text{const}$, then we get

$$\begin{aligned} \left(\frac{u}{\cos \theta}\right)^2 - \left(\frac{v}{\sin \theta}\right)^2 &= \left(r + \frac{a^2}{r}\right)^2 - \left(r - \frac{a^2}{r}\right)^2 = 4a^2 \\ \text{or} \quad \frac{u^2}{4a^2 \cos^2 \theta_0} - \frac{v^2}{4a^2 \sin^2 \theta_0} &= 1 \end{aligned} \quad (4)$$

which represent hyperbola with focii at $w = \pm 2a$. Thus Joukowski's function defines a transformation of the orthogonal system of polar coordinates in z -plane, into an orthogonal curvilinear system of coordinates whose coordinate lines are the confocal families of ellipses and hyperbolas in the w -plane.

25.9 BILINEAR TRANSFORMATION

Bilinear transformation is the function w of a complex variable z of the form

$$w = f(z) = \frac{az + b}{cz + d} \quad (1)$$

25.16 — HIGHER ENGINEERING MATHEMATICS—VI

where a, b, c, d are complex or real constants subject to $ad - bc \neq 0$.

If $ad - bc = 0$, $f(z)$ would be identically constant. When (1) is cleared of fractions, it takes the form

$$Az w + Bz + Cw + D = 0$$

which is linear in z , linear in w or bilinear in z and w . Bilinear transformation (B.T.) (1) is also known as linear fractional transformation or Möbius transformation.

Differentiating (1) w.r.t. z , we get

$$\frac{dw}{dz} = \frac{ad - bc}{(cz + d)^2} \quad (2)$$

If $ad - bc \neq 0$, then $\frac{dw}{dz} \neq 0$ for any z and therefore Bilinear transformation is conformal for all z i.e., it maps z -plane conformally onto the w -plane.

If $ad - bc = 0$, then $\frac{dw}{dz} = 0$ for any z . Then every point of z -plane is critical and the function is not conformal.

For a choice of the constants a, b, c, d , we get special cases of Bilinear transformation as

$$w = z + b \quad \text{Translation}$$

$$w = az \quad \text{Rotation}$$

$$w = az + b \quad \text{Linear transformation}$$

$$w = \frac{1}{z} \quad \text{Inversion in the unit circle}$$

Thus B.T. can be considered as combination of these transformations.

Solving (1) for z , we find that inverse of the Bilinear transformation is

$$z = \frac{dw - b}{-cw + a} \quad (3)$$

which is again a Bilinear transformation.

From (1), observe that the point $z = -\frac{d}{c}$ corresponds to $w = \infty$, point at infinity in the w -plane. Similarly from (3), the point $w = \frac{a}{c}$ corresponds to $z = \infty$, point at infinity in the z -plane.

Fixed (or Invariant) Points

Fixed (or invariant) points of function $w = f(z)$ are points which are mapped onto themselves. i.e., $w = f(z) = z$.

Example:

$$w = z \quad \text{has every point a fixed point,}$$

$$w = \bar{z}, \quad \text{infinitely many}$$

$$w = \frac{1}{z} \quad \text{has two}$$

$$w = z + b \quad \text{has no fixed point.}$$

To obtain the fixed points of (1), solve

$$z = \frac{az + b}{cz + d}$$

which is a quadratic in z given by

$$cz^2 - (a - d)z - b = 0 \quad (4)$$

Thus the roots say α, β of (4) are the fixed points of (1). If the two roots of (4) are equal then the Bilinear transformation is said to be parabolic.

The quadratic with α, β as roots is

$$z^2 - (\alpha + \beta)z + \alpha\beta = 0$$

For any complex constant γ ,

$$z^2 - (\alpha + \beta)z + \gamma z - \gamma z + \alpha\beta = 0$$

$$z \left(z - (\alpha + \beta - \gamma) \right) = \gamma z - \alpha\beta$$

$$z = \frac{\gamma z - \alpha\beta}{z - (\alpha + \beta) + \gamma}$$

Thus the bilinear transformations whose fixed points α, β are given by

$$w = \frac{\gamma z - \alpha\beta}{z - (\alpha + \beta) + \gamma} \quad (5)$$

For various values γ , (5) gives B.T. with fixed points α, β .

Theorem 1: Circles are transformed into circles under Bilinear transformation.

Proof: By division,

$$w = \frac{az + b}{cz + d} = \frac{a \left(z + \frac{d}{c} \right) + b - \left(\frac{ad}{c} \right)}{c \left(z + \frac{d}{c} \right)}$$

$$\text{or} \quad w = \frac{a}{c} + \frac{bc - ad}{c^2} \cdot \frac{1}{z + \frac{d}{c}}.$$

$$\text{Put} \quad w_1 = z + \frac{d}{c}, \quad w_2 = \frac{1}{w_1}, \quad w_3 = \frac{bc - ad}{c^2} w_2$$

Then $w = w_3 + \frac{a}{c}$.

Here w_1, w_2, w_3, w are translation, inversion, rotation and translation respectively. All these transformations preserve circles. Thus the bilinear transformation can be considered as combination of translation, rotation, stretching and inversion passing from z -plane to w_1 -plane to w_2 -plane to w_3 -plane to w -plane. Hence under B.T. circles transform into circles.

The *cross-ratio* or *anharmonic ratio* of four numbers z_1, z_2, z_3, z_4 is the linear fraction given by

$$\frac{(z_1 - z_2)(z_3 - z_4)}{(z_1 - z_4)(z_3 - z_2)}.$$

Theorem 2: The cross-ratio of four points is invariant under a bilinear transformation.

Proof: Suppose w_1, w_2, w_3, w_4 are respectively the images of z_1, z_2, z_3, z_4 under the bilinear transformation

$$w = \frac{az + b}{cz + d}$$

$$\begin{aligned} \text{Then } w_i - w_j &= \frac{az_i + b}{cz_i + d} - \frac{az_j + b}{cz_j + d} \\ w_i - w_j &= \frac{(ad - bc)(z_i - z_j)}{(cz_i + d)(cz_j + d)} \end{aligned} \quad (6)$$

Now consider the cross-ratio of w_1, w_2, w_3, w_4 , and use (6). Then

$$\begin{aligned} \frac{(w_1 - w_2)(w_3 - w_4)}{(w_1 - w_4)(w_3 - w_2)} &= \frac{\frac{(ad - bc)(z_1 - z_2)}{(cz_1 + d)(cz_2 + d)} \frac{(ad - bc)(z_3 - z_4)}{(cz_3 + d)(cz_4 + d)}}{\frac{(ad - bc)(z_1 - z_4)}{(cz_1 + d)(cz_4 + d)} \frac{(ad - bc)(z_3 - z_2)}{(cz_3 + d)(cz_2 + d)}} \\ &= \frac{(z_1 - z_2)(z_3 - z_4)}{(z_1 - z_4)(z_3 - z_2)} \end{aligned}$$

Hence the cross-ratio is preserved under bilinear transformation.

Determination of Bilinear Transformation

A bilinear transformation can be uniquely determined by three given conditions. Although four constants a, b, c, d appear in (1), essentially they are three ratios of three of these constants to the fourth one.

To find the unique bilinear transformation which maps three given distinct points z_1, z_2, z_3 onto three

distinct images w_1, w_2, w_3 , consider w which is the image of a general point z under this transformation. Now by Theorem 2, the cross-ratio of the four points w_1, w_2, w_3, w must be equal to the cross-ratio of z_1, z_2, z_3, z . Hence the unique bilinear transformation that maps three given points z_1, z_2, z_3 onto three given images w_1, w_2, w_3 is given by

$$\frac{(w_1 - w_2)(w_3 - w)}{(w_1 - w)(w_3 - w_2)} = \frac{(z_1 - z_2)(z_3 - z)}{(z_1 - z)(z_3 - z_2)}.$$

Note 1: If one of these points is ∞ then the quotient of the two differences containing this point must be replaced by 1.

Note 2: The B.T. $w = e^{i\alpha} \left(\frac{z - z_0}{z - \bar{z}_0} \right)$ maps the half plane $y \geq 0$ onto the unit disk $|w| \leq 1$ for any arbitrary real α and $\text{Im}(z_0) > 0$.

WORKED OUT EXAMPLES

Example 1: Find the bilinear transformation that maps the points $0, 1, i$ in z -plane onto the points $1 + i, -i, 2 - i$ in the w -plane.

Solution: The required bilinear transformation is

$$\frac{(w_1 - w_2)(w_3 - w)}{(w_1 - w)(w_3 - w_2)} = \frac{(z_1 - z_2)(z_3 - z)}{(z_1 - z)(z_3 - z_2)}$$

$$\frac{(1 + i + i)(2 - i - w)}{(1 + i - w)(2 - i + i)} = \frac{(0 - 1)(i - z)}{(0 - z)(i - 1)}$$

$$\frac{(1 + 2i)(2 - i - w)}{2(1 + i - w)} = (i - 1) \left(\frac{i - z}{z} \right)$$

$$\frac{2 - i - w}{1 + i - w} = \frac{2(3i + 1)}{5} \left(\frac{i - z}{z} \right)$$

Solving for w ,

$$5z(2 - i - w) = 2(3i + 1)(1 + i - w)(i - z)$$

$$\text{or } w = \frac{(6i + 2)(1 + i)(i - z) - (2 - i)5z}{-5z + (6i + 2)(i - z)}$$

$$w = \frac{z(6 + 3i) + (8 + 4i)}{z(7 + 6i) + (6 - 2i)}.$$

Example 2:

a. Determine the linear fractional transformation that sends the points $z = 0, -i, 2i$ into the points $w = 5i, \infty, -\frac{i}{3}$ respectively.

25.18 — HIGHER ENGINEERING MATHEMATICS—VI

- b. What are the invariant points of this transformation. Find the image of $|z| < 1$ (interior of a unit circle) under this transformation.

Solution:

$$\text{a. } \frac{(0+i)(2i-z)}{(0-z)(2i+i)} = \frac{(5i-w_2)\left(-\frac{i}{3}-w\right)}{(5i-w)\left(-\frac{i}{3}-w_2\right)}$$

where $w_2 = \infty$. So

$$\frac{z-2i}{3z} = \lim_{w_2 \rightarrow \infty} \frac{\left(\frac{5i}{w_2} - 1\right)\left(\frac{i}{3} + w\right)}{(5i-w)\left(-\frac{i}{3w_2} + 1\right)}$$

$$\frac{z-2i}{3z} = \frac{\frac{i}{3} + w}{w-5i}.$$

Note: If one of points, in this case $w_2 = \infty$, then the quotient of the two differences which contain w_2 i.e., $\left(\frac{5i-w_2}{-\frac{i}{3}-w_2}\right)$ is replaced by 1 (which gives the above result).

Solving for w , we get

$$\frac{2i}{z} = \frac{2w+6i}{5i-w}$$

$$\text{or } w = \frac{-3iz-5}{z+i} = \frac{-3z+5i}{-iz+1}$$

- b. Invariant points are given by

$$w = z = \frac{-3z+5i}{-iz+1}$$

$z^2 + 4iz + 5 = 0$ which has two roots.

$z = \frac{-4i \pm 6i}{2} = i, -5i$ are the invariant points.

- c. Rewriting the bilinear transformation (Fig. 25.37)

$$z = \frac{w-5i}{iw-3}$$

Fig. 25.37

The image of $|z| < 1$ is given by

$$|z| = \left| \frac{w-5i}{iw-3} \right| < 1$$

$$|w-5i| < |iw-3|$$

$$|u+i(v-5)| < |-(3+v)+iu|$$

$$\text{or } u^2 + (v-5)^2 < (3+v)^2 + u^2$$

$$1 < v$$

Thus the interior of the unit circle $|z| = 1$ in the z -plane is mapped to the upper half plane above the line $v = 1$ (Fig. 25.38).

Fig. 25.38

Example 3: Determine the Möbius transformation having 1 and i as fixed (invariant) points and maps 0 to -1 .

Solution: The Möbius transformation having α and β as fixed points is given by

$$w = \frac{\gamma z - \alpha\beta}{z - \alpha - \beta + \gamma}$$

for various values of γ . For $\alpha = 1, \beta = i$, we have

$$w = \frac{\gamma z - i}{z - 1 - i + \gamma}$$

Since $z = 0$ is mapped to $w = -1$,

$$-1 = \frac{0 - i}{0 - 1 - i + \gamma}$$

$$\text{or } \gamma = 2i + 1$$

Thus the required transformation is

$$w = \frac{(2i+1)z - i}{z + i}$$

Example 4: Find a Bilinear transformation which maps the upper half of the z -plane into the interior of a unit circle in the w -plane. Verify the transformation (Fig. 25.39).

Solution: Suppose any three points in the upper half of z -plane say $A : -1, B : 0, C : 1$ gets mapped to any three points in the interior of the circle $|w| = 1$

Fig. 25.39

in the w -plane, say $A^* : -i$, $B^* : 1$, $C^* : i$. Thus the required bilinear transformation is the one which maps $-1, 0, 1$ from z -plane to $-i, 1, i$ in the w -plane. This is

$$\frac{(-1-0)(1-z)}{(-1-z)(1-0)} = \frac{(-i-1)(i-w)}{(-i-w)(i-1)}$$

$$\text{or} \quad \frac{1-z}{1+z} = \frac{1+iw}{i+w}$$

$$\text{Solving} \quad w = \frac{i-z}{i+z}$$

$$\text{Verification :} \quad |w| = \left| \frac{i-z}{i+z} \right| \leq 1$$

$$\text{or} \quad |i-z| \leq |i+z|$$

$$\sqrt{x^2 + (1-y)^2} \leq \sqrt{x^2 + (1+y)^2}$$

$$4y \geq 0$$

Thus the bilinear transformation $w = \frac{i-z}{i+z}$ transforms interior of unit circle in w -plane onto the upper half plane in z -plane.

$$\text{Also} \quad |w| = \left| \frac{i-z}{i+z} \right| = \sqrt{\frac{x^2 + (1-y)^2}{x^2 + (1+y)^2}}$$

For $y = 0$, $|w| = \frac{x^2+1}{x^2+1} = 1$. Thus the real axis ($y = 0$) gets mapped to the unit circle $|w| = 1$.

EXERCISE

1. Represent $w = \frac{z+i}{iz+4}$ as a composite of mappings.

Ans. $w = w_4 - i$, $w_4 = 5i w_3$, $w_3 = \frac{1}{w_2}$, $w_2 = w_1 + 4$, $w_1 = iz$, w_4, w_3 are rotations, w_2 is translation, w_3 is inversion.

2. Determine the cross-ratio (C.R.) of
 - a. the fourth roots of -1 .

Ans. $z_1 = \frac{1+i}{\sqrt{2}}$, $z_2 = \frac{1-i}{\sqrt{2}}$, $z_3 = \frac{-1-i}{\sqrt{2}}$, $z_4 = \frac{-1+i}{\sqrt{2}}$, $CR = -1$.

- b. Four complex sixth roots of 1.

Ans. $z_{1,2,3,4} = \pm \frac{1}{2} \pm \frac{\sqrt{3}}{2}i$, $CR = -\frac{1}{3}$.

3. Find the invariant (fixed) points of the transformation:

$$\text{a. } w = \frac{z-1}{z+1}.$$

$$\text{b. } w = \frac{6z-9}{z}.$$

$$\text{c. } w = (z-i)^2.$$

$$\text{d. } w = z^2.$$

$$\text{e. } w = \frac{(2z-5)}{(z+4)}.$$

Ans. a. $z = \pm i$.

$$\text{b. } z = 3.$$

$$\text{c. } z = \frac{(1+2i) \pm \sqrt{1+4i}}{2}.$$

$$\text{d. } z = 0, 1.$$

$$\text{e. } z = -1 \pm 2i.$$

4. Determine the bilinear transformations whose fixed points are

$$\text{a. } 1, -1$$

$$\text{b. } i, -i.$$

$$\text{c. } 1, 1.$$

Ans. a. $w = \frac{\gamma z + 1}{z + \gamma}$, for various γ .

$$\text{i.e., } \gamma = 0, w = \frac{1}{z},$$

$$\gamma = 1, w = \frac{z+1}{z+1}, \gamma = 2, w = \frac{2z-1}{z+2}.$$

$$\text{b. } w = \frac{\gamma z - 1}{z + \gamma}.$$

$$\text{c. } w = \frac{\gamma z - 1}{z - 2 + \gamma}.$$

Find the bilinear transformation that maps z_1, z_2, z_3 onto w_1, w_2, w_3 respectively:

$$5. \quad z = -1, 0, 1 \text{ onto } w = 0, i, 3i$$

$$\text{Ans. } w = \frac{-3i(z+1)}{(z-3)}$$

$$6. \quad z = 0, -i, -1 \text{ onto } w = i, 1, 0$$

$$\text{Ans. } w = -i \left(\frac{z+1}{z-1} \right)$$

$$7. \quad z = 1, i, -1 \text{ onto } w = 2, i, -2$$

$$\text{Ans. } w = \frac{-6z+2i}{iz-3}$$

$$8. \quad z = \infty, i, 0 \text{ onto } w = 0, i, \infty$$

$$\text{Ans. } w = -\frac{1}{z}$$

$$9. \quad z = 1, 0, -1 \text{ onto } w = i, 1, \infty$$

25.20 — HIGHER ENGINEERING MATHEMATICS—VI

Ans. $w = \frac{(-1+2i)z+1}{z+1}$

10. $z = 0, 1, \infty$ onto $w = -1, -i, 1$

Ans. $w = \frac{z-i}{z+i}$

11. $z = 0, i, \infty$ onto $w = 0, \frac{1}{2}, \infty$

Ans. $w = -\frac{iz}{2}$

12. $z = -1, i, 1+i$ onto $w = 0, 2i, 1-i$

Ans. $w = \frac{-2i(z+1)}{4z-1-5i}$

13. $z = -1, \infty, i$ onto $w = \infty, i, 1$

Ans. $w = \frac{iz+2+i}{z+1}$

Find the bilinear transformation

14. whose fixed points are $\frac{1}{2}$ and 2 and maps $\frac{(5+3i)}{4}$ into ∞ .

Ans. $w = \frac{z(1-4i)-2(1-i)}{2z(1-i)-(4-i)}$

15. having i as double fixed point and 1 goes to ∞

Ans. $w = \frac{[z(3-i)-(1+i)]}{[(1+i)(1-z)]}$

16. which maps $-1, 0, 1$ into $1, i, -1$.

Determine the image of the upper half plane.

Ans. $w = \frac{(z-i)}{(iz-1)}$, unit circle

17. which maps $z = 1, i, -1$ onto $w = i, 0, -i$. Find the image of $|z| < 1$. Determine fixed points.

Ans. $w = \frac{(1+iz)}{(1-iz)}$, $u > 0$, entire right half plane, fixed points are $-\frac{[1+i\pm\sqrt{6}i]}{2}$.

25.10 SCHWARZ*-CHRISTOFFEL** TRANSFORMATION

The determination of the specific function, which transforms conformally one given region to another, is a very difficult task. However, Schwarz-Christoffel transformation determines functions which conformally maps bounded (or unbounded) polygons to

upper half plane and consequently to any region into which the half-plane can be transformed such as a unit disk. The main difficulty in this transformation is the complexity of the Schwarz-Christoffel integral.

Let P denote a bounded (closed) polygon in the w -plane with n vertices at the points $A_1, A_2, \dots, A_n$. Let $\alpha_1\pi, \alpha_2\pi, \dots, \alpha_n\pi$ be the interior angles at these vertices respectively. Here $\alpha_1, \alpha_2, \dots, \alpha_n$ are positive constants. For a closed polygon, the sum of the interior angles is $(n-2)\pi$. Thus $(\alpha_1\pi + \alpha_2\pi + \dots + \alpha_n\pi) = (\alpha_1 + \alpha_2 + \dots + \alpha_n)\pi = (n-2)\pi$. So $\sum_{i=1}^n \alpha_i = n-2$ with

$n > 2$ and $0 < \alpha_i < 2$. Then the Schwarz-Christoffel transformation is defined by the function

$$w = f(z) = c \int_0^z \prod_{k=1}^n (z - a_k)^{\alpha_k - 1} dz + c_1 \quad (1)$$

transforms conformally the upper half plane in the z -plane onto the interior of the polygon P (see Fig. 25.40). Here $a_1, a_2, \dots, a_n$ are points on the x -axis (in z -plane), corresponding to the vertices $A_1, A_2, \dots, A_n$ of the polygon P . The real numbers $a_1, a_2, \dots, a_n$ are arranged in increasing such that $-\infty < a_1 < a_2 < \dots < a_n < \infty$.

Also c and c_1 are complex constants.

Fig. 25.40

*H.A. Schwarz (1843-1921), German mathematician

**E.B. Christoffel (1892-1900), Swiss mathematician

The points a_i lying on the real axis in the z -plane are singularities of the function (1). Points a_i 's are transformed by the function (1) into points A_i 's of the w -plane. In order to show that the line segments $a_k < x < a_{k+1}$ of the real axis in the z -plane are mapped by (1) onto straight line segments $A_k A_{k+1}$ of the polygon P of the w -plane, consider

$$\frac{dw}{dz} = f'(z) = c(z - a_1)^{\alpha_1 - 1} (z - a_2)^{\alpha_2 - 1} \times \dots \times (z - a_n)^{\alpha_n - 1} \quad (2)$$

we need the following two propositions.

Proposition I: Recall that a transformation $w - A_1 = (z - a_1)^{\alpha_1}$ with $\frac{dw}{dz} = \alpha_1(z - a_1)^{\alpha_1 - 1}$ maps the straight line Ba_1D on the real axis to $B^*A_1D^*$ with $(\alpha_1)\pi$ angle at the vertex A_1 .

Fig. 25.41

Proposition II: Recall that if S at w_0 is the image of the curve c at z_0 under the transformation $w = f(z)$ which is analytic and $f'(z_0) \neq 0$, then the tangent to S at w_0 is rotated through an angle $\arg f'(z_0)$. Thus the size of the angle through which tangent to S at w_0 to be rotated is determined by $\arg f'(z_0)$.

Fig. 25.42

(i.e.,) $\beta = \alpha + \arg f'(z_0)$. If c is straight line along x -axis, then $\alpha = 0$ and if $f'(z_0) = \text{constant}$, then S is also a straight line in w -plane.

Now from (2) $\arg dw = \arg c + (\alpha_1 - 1) \arg(z - a_1) + (\alpha_2 - 1) \arg(z - a_2) + \dots + (\alpha_n - 1) \arg(z - a_n) + \arg dz$ (3)

To determine the size of the angles between adjacent segments say $A_{i-1}A_i$ and A_iA_{i+1} of the polygonal line, consider the variation of the argument of $f'(z)$.

For $z = x < a_1$, the numbers $(z - a_1)$, $(z - a_2)$, $\dots$, $(z - a_n)$ are all negative real numbers and hence have π as their arguments. Generalizing this, we have

$$\arg(z - a_i) = \begin{cases} \pi & \text{if } z < a_i \\ 0 & \text{if } z > a_i \end{cases}$$

Note that dz is positive and its argument is zero. Thus when $z < a_1$, all the terms in (3) are constants and therefore $\arg dw$ remains constant. Thus the image point w traces a straight line in the w -plane.

Now as soon as z passes through a_1 , a_1 becomes less than z , so $(z - a_1)$ changes abruptly from negative to positive and therefore $\arg(z - a_1)$ changes abruptly from π to 0. Thus straight line $A_n A_1$ bends through an angle $\pi - \alpha_1 \pi$ since argument of dw changes by $\pi - \alpha_1 \pi$. Thus the interior angle at A_1 of the polygon P is $\alpha_1 \pi$. Now for $a_1 < z < a_2$, $\arg dw$ remains constant, but when z passes through a_2 , then $a_2 < z$ so $(z - a_2)$ is positive with argument zero. Then $\arg dw$ changes by $\pi - \alpha_2 \pi$ and so on. Thus when the point z traverses the entire real axis in the positive direction, its image w makes a complete circuit of the boundary of a closed polygon with interior angles $\alpha_1 \pi, \alpha_2 \pi, \dots, \alpha_n \pi$. Hence (1) maps the real axis of the z -plane onto some closed polygon line $A_1 A_2 \dots A_n$ whose sides are the straight line segments $A_k A_{k+1}$. Since w is analytic, (1) is conformal. Thus the Schwarz-Christoffel transformation which maps the upper half plane in z -axis onto the interior of a closed polygon in the w -plane is

$$w = f(z) = c \int_0^z (t - a_1)^{\alpha_1 - 1} (t - a_2)^{\alpha_2 - 1} \times \dots \times (t - a_n)^{\alpha_n - 1} dt + c \quad (5)$$

Here t is a dummy variable. The transformation (5) may be written as

$$w = f(z) = c g(z) + c_1$$

where $g(z)$ maps upper half plane in z -plane to the interior of some polygon in the w -plane. The second

25.22 — HIGHER ENGINEERING MATHEMATICS—VI

transformation $c g(z) + c_1$ then translates and rotates (contract $c < 0$ or magnify for $c > 0$) the polygon.

Note: To determine (5), three points of $a_1, a_2, \dots, a_n$ may be chosen arbitrarily.

In the case of an unbounded (open) polygon, the vertex A_n may be considered as a point at ∞ . Then (5) gets modified to

$$w = f(z) = c \int_0^z (t - a_1)^{\alpha_1 - 1} (t - a_2)^{\alpha_2 - 1} \times \dots \times (t - a_{n-1})^{\alpha_{n-1} - 1} dt + c_1 \quad (6)$$

The integrand in the Schwarz-Christoffel integral (6) does *not* contain the factor corresponding to the vertex A_n at infinity.

Proposition III: Recall that the bilinear transformation $w = e^{i\theta} \frac{z - z_0}{z - \bar{z}_0}$, $\text{Im} z_0 > 0$, $\theta \in R$ maps the upper half plane onto the interior of a unit disc $c : |w| = 1$.

To show that an interior point of the polygon in w -plane is mapped onto a interior point in the upper half plane, because of the above Proposition III, it is sufficient to prove that the interior point of the polygon is mapped onto an interior point of the unit disc $c : |z| = 1$. By Cauchy's integral formula, for any interior point b of the polygon P , we have

$$\frac{1}{2\pi i} \int_P \frac{1}{w - b} dw = 1.$$

Since $w - b = f(z) - b$ and $dw = f'(z)dz$, we have

$$1 = \frac{1}{2\pi i} \int_P \frac{dw}{w - b} = \frac{1}{2\pi i} \int_c \frac{f'(z)dz}{f(z) - b}$$

From the argument principle, the number of zeros of $f(z) - b$ inside c is one. Thus there is an interior point z_0 of c such that $f(z_0) = b$. Thus the interior point b of the polygon is mapped onto an interior point z_0 of c and hence the interior point of the upper half plane.

WORKED OUT EXAMPLES

Example 1: Determine the transformation that will map the region in the w -plane shown in the Fig. 25.43

onto the upper half plane of the z -plane. Obtain the transformation for (a) $\alpha = 0$ (b) $\alpha = \frac{\pi}{2}$.

Solution: From the Fig. 25.43, the interior angles of the polygon at the points $A(0, 0)$ is $\alpha_1\pi = \frac{\pi}{2} = \frac{1}{2}$ and at the point $B(0, b)$ is $\alpha_2\pi = (\pi + \alpha)$. The point A maps to $A^*(0, 0)$ and B maps to $B^*(1, 0)$ in the z -plane. Therefore the Schwarz-Christoffel transformation takes the form

$$w(z) = c \int (z - 0)^{k_1} (z - 1)^{k_2} dz + c_1$$

Here $k_1 = \alpha_1 - 1 = \frac{1}{2} - 1 = -\frac{1}{2}$, $k_2 = \alpha_2 - 1 = \frac{\pi + \alpha}{\pi} - 1 = \frac{\alpha}{\pi}$

Thus $w(z) = c \int_0^z t^{-\frac{1}{2}} (t - 1)^{\frac{\alpha}{\pi}} dt$ where t is the new dummy variable. Since B maps to B^* , $w = ib$ when $z = 1$. So

$$ib = c \int_0^1 t^{-\frac{1}{2}} (t - 1)^{\frac{\alpha}{\pi}} dt$$

or $c = ib/I$ where $I = \int_0^1 t^{-\frac{1}{2}} (t - 1)^{\frac{\alpha}{\pi}} dt$

Fig. 25.43

Thus the required Schwarz-Christoffel transformation is

$$w = c \int_0^z t^{-\frac{1}{2}} (t - 1)^{\frac{\alpha}{\pi}} dt$$

where $c = \frac{ib}{I}$ with $I = \int_0^1 t^{-\frac{1}{2}}(t-1)^{\frac{\alpha}{\pi}} dt$.

Case i For $\alpha = 0$, $I = \int_0^1 t^{-\frac{1}{2}} dt = 2\sqrt{t} \Big|_0^1 = 2$ so $c = \frac{ib}{2}$. Then

$$w = \frac{ib}{2} \int_0^z t^{-\frac{1}{2}} dt = \frac{ib}{2} 2\sqrt{t} \Big|_0^z = ib\sqrt{z}$$

Case ii For $\alpha = \frac{\pi}{2}$, $I = \int_0^1 t^{-\frac{1}{2}}(t-1)^{\frac{1}{2}} dt$

$$\text{or } I = i \int_0^1 t^{\frac{1}{2}-1}(1-t)^{\frac{3}{2}-1} dt = i\beta \left(\frac{1}{2}, \frac{3}{2} \right) = \frac{\Gamma\left(\frac{1}{2}\right)\Gamma\left(\frac{3}{2}\right)}{\Gamma\left(\frac{4}{2}\right)}.$$

$$I = i \frac{\sqrt{\pi} \cdot \frac{1}{2}\sqrt{\pi}}{1} = i\frac{\pi}{2}. \text{ Then } c = \frac{ib}{i\frac{\pi}{2}} = \frac{2b}{\pi}$$

$$\text{Now } \int_0^z t^{-\frac{1}{2}}(t-1)^{\frac{1}{2}} dt = i \int_0^z t^{-\frac{1}{2}}(1-t)^{\frac{1}{2}} dt$$

$$\text{put } \sqrt{t} = x, \frac{1}{2} \frac{1}{\sqrt{t}} dt = dx \text{ so}$$

$$i \int_0^z (1-t)^{\frac{1}{2}} \frac{dt}{\sqrt{t}} = 2i \int_0^{\sqrt{z}} \sqrt{1-x^2} dx$$

$$= 2i \left[\frac{1}{2} \sin^{-1} x + \frac{x\sqrt{1-x^2}}{2} \right] \Big|_{x=0}^{\sqrt{z}}$$

$$= 2i \left[\frac{1}{2} \sin^{-1} \sqrt{z} + \frac{\sqrt{z}\sqrt{1-z}}{2} \right]$$

Thus the transformation is

$$w(z) = \frac{2b}{\pi} \left[i \left\{ \sin^{-1} \sqrt{z} + \sqrt{z(1-z)} \right\} \right]$$

Example 2: Determine the integral which maps the rectangle in the w -plane shown in Fig. 25.44 onto the upper half of the z -plane.

Fig. 25.44

Solution: Let the vertices of the rectangle $PQRS$ be $P(u_0, 0)$, $Q(u_0, v_0)$, $R(-u_0, v_0)$, $S(-u_0, 0)$. The corresponding interior angles in the rectangle $PQRS$ are each $\frac{\pi}{2}$ i.e., $\alpha_1\pi = \alpha_2\pi = \alpha_3\pi = \alpha_4\pi = \frac{\pi}{2}$. Suppose the vertices P, Q, R, S maps to $P^*(1, 0)$, $Q^*\left(\frac{1}{k}, 0\right)$, $S^*(-1, 0)$, $R^*\left(-\frac{1}{k}, 0\right)$ respectively. Then $k_i = \alpha_i - 1 = \frac{1}{2} - 1 = -\frac{1}{2}$, for $i, 1, 2, 3, 4$. Then the required Schwarz-Christoffel transformation is

$$\begin{aligned} w(z) &= c \int_0^z (z-1)^{-\frac{1}{2}} \left(z - \frac{1}{k} \right)^{-\frac{1}{2}} (z+1)^{-\frac{1}{2}} \\ &\quad \left(z + \frac{1}{k} \right)^{-\frac{1}{2}} dz \\ &= c \int_0^z \frac{dt}{\sqrt{(t^2-1)\left(t^2-\frac{1}{k^2}\right)}} \end{aligned}$$

where t is the dummy variable.

$$\text{or } w(z) = kc \int_0^z \frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}}.$$

Since $P(u_0, 0)$ maps to $P^*(1, 0)$, we have $w = u_0$ when $z = 1$. Then $u_0 = kc \int_0^1 \frac{dt}{\sqrt{1-t^2}\sqrt{1-k^2t^2}}$.

Then $w(z) = \frac{u_0}{I} \int_0^z \frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}}$ where

$$I = \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}}$$

This integral $w(z)$ is known as *elliptic integral of the first kind*, which can not be expressed in terms of elementary functions.

EXERCISE

Find the Schwarz-Christoffel transformations which conformally maps the region in the w -plane to the upper half plane in the z -plane as shown in the following figures:

1.

Fig. 25.45

Semi-unifinte (right-open) strip $0 \leq v \leq \pi$.

Ans. $w = \cosh^{-1} z$ (or $z = \cosh w$).

Hint: $k_1 = k_2 = -\frac{1}{2}$, $w = k \int_0^z \frac{dt}{\sqrt{(t-1)(t+1)}}$, $k = 1$ since $P(0, i\pi)$ maps to $P^*(-1, 0)$ i.e., $w = i\pi$ when $z = -1$.

2.

Fig. 25.46

Ans. $w(z) = \frac{1}{c_1} \int_0^z t^{k_1} (1-t)^{k_2} dt$ where $k_1 = \frac{\alpha}{\pi} - 1$, $k_2 = \frac{\beta}{\pi} - 1$, $c_1 = \beta \left(\frac{\alpha}{\pi}, \frac{\beta}{\pi} \right)$.

Hint: For interior angles α, β ; $k_1 = \frac{\alpha}{\pi} - 1$, $k_2 = \frac{\beta}{\pi} - 1$, $w(z) = c \int_0^z (t-0)^{k_1} (t-1)^{k_2} dt$.

Note: For an isosceles triangle with $\alpha = \beta$, the transformation reduces to $w(z) = \frac{1}{c_1} \int_0^z \{t(1-t)\}^{k_1} dt$ where $k_1 = \frac{\alpha}{\pi} - 1$, $c_1 = \beta \left(\frac{\alpha}{\pi}, \frac{\alpha}{\pi} \right)$

3.

Fig. 25.47

Ans. $w = \sin^{-1} z$ or $z = \sin w$

Hint: Interior angles at A and B are $\frac{\pi}{2}$ each. So $k_1 = k_2 = \frac{\alpha_i}{\pi} - 1 = \frac{\pi}{2} \cdot \frac{1}{\pi} - 1 = -\frac{1}{2}$. Then $w(z) = c \int_0^z (z-1)^{-\frac{1}{2}} (z+1)^{-\frac{1}{2}} dz = c \int_0^z \frac{dt}{\sqrt{(t^2-1)}}$, $w(z) = ci \sin^{-1} z$, $c = 0$ since B maps to B^* , $u = -\frac{\pi}{2}i$ when $x = -1$.

4.

Fig. 25.48

Open region above (and to the left the) polygonal boundary in the w -plane.

Ans. $w(z) = c \int_0^z \sqrt{\frac{t-1}{t+1}} dt$

Hint: Here interior angles at B , $\alpha_1 = \frac{\pi}{2}$, at A , $\alpha_2 = \frac{3\pi}{2}$ so $k_1 = \frac{\alpha_1}{\pi} - 1 = \frac{\pi}{2} \frac{1}{\pi} - 1 = -\frac{1}{2}$, $k_2 = \frac{\alpha_2}{\pi} - 1 = \frac{3\pi}{2} \frac{1}{\pi} - 1 = \frac{1}{2}$.

5.

Fig. 25.49

Sector: $0 < \arg w = \theta < \alpha\pi$, $0 < \alpha < 2$.

Ans. $w(z) = \frac{c}{\alpha} z^\alpha$

Hint: Sector is polygon with vertices at $A(w=0)$ and $B(w=\infty)$, mapped to $A^*(z=0)$ and $B^*(z=\infty)$. Then $w(z) = c \int_0^z (t-0)^{k_1} dt$ where $k_1 = \frac{\alpha\pi}{\pi} - 1 = \alpha - 1$ so $w(z) = c \int_0^z t^{\alpha-1} dt = c \frac{t^\alpha}{\alpha} \Big|_0^z = \frac{c}{\alpha} z^\alpha$.

Note: In the integrand of the Schwarz-Christoffel integral, the factor corresponding to the point B is omitted.

6.

Fig. 25.50

Ans. $w = \ln z$

Hint: Interior angles at $P(0,0)$ and $Q(0,\pi)$ are π each so $k_1 = \frac{\alpha_1}{\pi} - 1 = \frac{\pi}{\pi} - 1 = 0$, $k_2 = 0$. The interior angle for point $R(w=\infty)$ is 0 so $k_3 = \frac{\alpha_3}{\pi} - 1 = \frac{0}{\pi} - 1 = -1$. Then $w(z) = \int_0^z (t-1)^0 (t-0)^{-1} (t+1)^0 dt$, $w = \int_0^z \frac{dt}{t} = \ln z$.

Note: The infinite strip may be considered as the limiting form of a rhombus with two of its opposite vertices moved to infinity.

7.

Fig. 25.51

25.26 — HIGHER ENGINEERING MATHEMATICS—VI

Ans. $w(z) = \frac{2}{\pi} [\sin^{-1} \sqrt{z} - (1 - 2z)\sqrt{z - z^2}]$

8.

Fig. 25.52

Ans. $w(z) = \frac{h}{\pi} \left[\ln \left(\frac{1 + \sqrt{z}}{1 - \sqrt{z}} \right) - 2\sqrt{z} \right] = \frac{2h}{\pi} [\tanh^{-1} \sqrt{z} - \sqrt{z}]$

Probability

INTRODUCTION

In random phenomena, past information no matter how voluminous, will not allow to formulate a rule to determine precisely (uniquely) what will happen in future. The theory of probability is the study of such random phenomena which are not deterministic. In analyzing and interpreting data that involves an element of “chance” or uncertainty, probability theory plays a vital role in the theory and application of statistics. Blaise Pascal in the middle of 17th century was the first to use probability in problems of gambling. Laplace, De Moivre, Gauss, Poisson and Kolmogorov greatly contributed to the development of probability theory which finds application in engineering, biology, economics, computer science, politics, traffic control, medicine, meteorology, psychology, agriculture, geography and management of natural resources. We consider the Baye’s theorem (also known as theorem of inverse probability) which determines the probability of “causes.”

26.1 REVIEW OF SET THEORY

Set

A *Set* is well-defined collection of objects. Sets are denoted by capital letters $A, B, C, \dots$ and the objects also known as *elements* or *members* of the set by small letters $x, y, \dots$. If x is a member or element of A , it is denoted by $x \in A$. If y is *not* an element of B , then $y \notin B$.

Example 1: V = set of all vowels in English alphabet = $\{a, e, i, o, u\}$

2. N = set of natural numbers = $\{0, 1, 2, 3, \dots\}$

3. E = set of even numbers = $\{0, 2, 4, 6, 8, \dots\} = \{2n | n \in N\}$

Null set

A *Null set* or *empty set* is the unique set containing *no* elements. It is denoted by ϕ or $\{\}$.

Example 1: The set of women presidents of India is an empty set.

2. $\{n \in N : 3 < n < 4\}$ is an empty set

3. $\{x \in \text{Real} : x^2 + 3 = 0\}$ is an empty set.

Equality

Two sets are said to be equal if they contain the same elements.

Note: The order of listing is irrelevant. There is no advantage (or harm) in listing the elements more than once.

Example: Sets $A = \{1, 3, 5, 6\}$, $B = \{6, 5, 3, 1\}$, and $C = \{3, 5, 3, 6, 1, 6, 1, 5, 5\}$ are all equal. Neither order nor repetition is relevant.

Finite and Infinite Sets

If the number of elements in a set A is finite, then the set is said to be a finite set. The number of distinct

26.2 — HIGHER ENGINEERING MATHEMATICS—VII

elements in a finite set A is known as the *cardinality* or *size* of A and is denoted by $|A|$.

Example: $|\text{Set of vowels}| = 5$, $\text{Ex} : |\phi| = 0$,
 $\text{Ex} : |A| = |B| = |C| = 4$, $\text{Ex} : D = \{x^2 | x \in N, x^2 < 30\} = \{1, 4, 9, 16, 25\}$, then $|D| = 5$ when the number of elements is infinite, the set is said to be an infinite set.

Example: Set of natural numbers, set of real numbers are infinite sets.

Universal Set

Universal Set denoted by U is set containing all objects under study (or consideration).

Subset

A is a subset of B and is written as $A \subseteq B$ if every element of A as an element of B .

Example: ϕ is subset of any set A , i.e., $\phi \subseteq A$.

Example: Set of even numbers is a subset of set of integers.

Example: A is subset of itself: $A \subseteq A$.

Proper Subset

If B contains elements not in A , then the subset A is said to be proper subset of B , denoted by $A \subset B$.

Example: $A = \{4, 5, 6, \dots\}$, $B = \{6, 7\}$,

$C = \{4, 5, 6, 7\}$ then

(a) $A \subseteq C$ (b) $A \subset C$ (c) $B \subseteq C$ (d) $B \subset C$
(e) $B \not\subseteq A$ (f) $A \subseteq A$ (g) $A \not\subset A$ (i.e., A is not a proper subset of A itself) (h) $\phi \subset A$ (i) $\phi \subset B$
(k) $\phi \subset C$

Note: Only a set can be a subset of another set, while only elements can be members of a set.

Power Set

Power Set of A , denoted by $P(A)$, is the set (collection) of all subsets of A .

Example: $A = \{4, 5, 6, 7\}$ then the power set of A is $P(A) = \{\phi, \{4\}, \{5\}, \{6\}, \{7\}, \{4, 5\}, \{4, 6\}, \{4, 7\},$

$\{5, 6\}, \{5, 7\}, \{6, 7\}, \{4, 5, 6\}, \{4, 5, 7\}, \{4, 6, 7\}, \{5, 6, 7\}, \{4, 5, 6, 7\}\}$.

Result 1: If $|A| = n$, then the power set of a set A with n elements has 2^n elements i.e., $|P(A)| = 2^{|A|} = 2^n$

Example: $|A| = 4$, $P(A) = 2^4 = 16$

$P(\phi) = \{\phi\}$

$P(\{\phi\}) = \{\phi, \{\phi\}\}$

Result 2: For any $0 \leq k \leq n$, there are n_{c_k} subsets of size k .

Example: $A = \{4, 5, 6, 7\}$, $|A| = n = 4$, let $k = 2$. Then there are $n_{c_k} = 4_{c_2} = 6$ subsets of each size 2 namely $\{4, 5\}, \{4, 6\}, \{4, 7\}, \{5, 6\}, \{5, 7\}, \{6, 7\}$.

Ex: If a set A has 63 proper subsets then $|A| = 6$ since A is not a proper subset of A , there are 64 subsets = 2^6 so $|A| = 6$.

Ex: If set B has 64 subsets of odd cardinality, i.e., B has $2^6 (= 64)$ subsets of odd cardinality, so $|B| = 6 + 1 = 7$.

In general if B has 2^n subsets of odd cardinality then $|B| = n + 1$.

Set Operations

Union of A and B

$A \cup B = \{x | x \in A \text{ or } x \in B \text{ or both}\}$

Intersection of A and B

$A \cap B = \{x | x \in A \text{ and } x \in B\}$

Symmetric difference of A and B :

$A \Delta B = \{x | x \in A \cup B \text{ and } x \notin A \cap B\}$

Disjoint

A and B are disjoint or mutually disjoint when $A \cap B = \phi$.

Example: $A = \{4, 5, 6, 7, 8\}$, $B = \{3, 4, 6, 7\}$,
 $C = \{7, 8, 9\}$, $D = \{9, 10, 11\}$

Then (a) $A \cup B = \{3, 4, 5, 6, 7, 8\}$ (b) $A \cap B = \{4, 6, 7\}$ (c) $A \cup C = \{4, 5, 6, 7, 8, 9\}$, (d) $A \cap C = \{7, 8\}$, (e) $B \cap C = \{7\}$ (f) $A \cap D = \phi$ (g) $B \cap D = \phi$ (h) $C \cap D = \{9\}$ (i) $A \Delta B = \{3, 5, 8\}$ (j) $A \Delta C = \{4, 5, 6, 9\}$.

Relative Complement of A in B is

$$B - A = \{x \mid x \in B \text{ and } x \notin A\}$$

Example: (a) $B - A = \{3\}$ (b) $A - B = \{5, 8\}$
 (c) $C - D = \{7, 8\}$ (d) $D - C = \{10, 11\}$

Complement

Complement of A (w.r.t. the universal set U) is denoted by $\bar{A}$ of A^C or $(U - A)$ is given by $\{x \mid x \in U \text{ and } x \notin A\}$.

Inverse Laws

$$(a) A \cup A^C = U \quad (b) A \cap A^C = \phi$$

Example: $U = \{1, 3, 7, 9, 11\}$, $A = \{1, 3, 9\}$, $B = \{9, 11\}$, $C = \{1\}$ then

$$(a) A^C = \{7, 11\} \quad (b) B^C = \{1, 3, 7\}$$

$$(c) C^C = \{3, 7, 9, 11\} \quad (d) A \cup A^C = \{1, 3, 9\} \cup \{7, 11\} = \{1, 3, 7, 9, 11\} = U$$

$$(e) A \cap A^C = \{1, 3, 9\} \cap \{7, 11\} = \phi$$

Result: De Morgan's Laws

$$(a) (A \cup B)^C = A^C \cap B^C$$

$$(b) (A \cap B)^C = A^C \cup B^C$$

Counting

$$\text{Result: } (a) |A \cup B| = |A| + |B| - |A \cap B|$$

$$(b) |A \cup B \cup C| = |A| + |B| + |C| - |A \cap B| - |B \cap C| - |C \cap A| + |A \cap B \cap C|$$

Example: In a class, if 30 are studying mathematics, 25 are studying computer science and 15 are studying both, how many students are in the class?

$$|A| = 30, B = 25$$

$$|A \cap B| = 15$$

$$|A \cup B| = |A| + |B| - |A \cap B|$$

$$|A \cup B| = 30 + 25 - 15 = 40 = \text{No. of students in the class.}$$

Example: In a class of 57, if 23 students are studying Mathematics, 26 Physics, 30 Chemistry, 7 studying both Maths and Physics, 8 both Maths and Chemistry, 10 both Physics and Chemistry, find how many students are studying all three—Maths, Physics and Chemistry.

$$|M \cup P \cup C| = 57$$

Fig. 26.1

$$|M| = 23, |P| = 26,$$

$$|C| = 30, |M \cap P| = 7$$

$$|M \cap C| = 8, |P \cap C| = 10$$

So

$$|M \cup P \cup C| = |M| + |P| + |C| - |M \cap P| - |M \cap C|$$

$$- |P \cap C| + |M \cap P \cap C|$$

Then

$$57 = 23 + 26 + 30 - 7 - 8 - 10$$

$$+ |M \cap P \cap C|$$

$|M \cap P \cap C| = 3 = \text{no. students studying all three—Maths, Physics and Chemistry.}$

Fig. 26.2

Cartesian Product

Cartesian Product of two sets A and B, denoted by $A \times B$ is the set of all ordered pairs (a, b) where $a \in A$ and $b \in B$.

Example: $A = \{1, 2, 3\}$, $B = \{a, b\}$ then $A \times B = \{(1, a), (1, b), (2, a), (2, b), (3, a), (3, b)\}$

Note: If $|A| = m$, $|B| = n$, then $A \times B$ has $m \cdot n$ ordered pairs. Similarly we have cartesian product of

26.4 — HIGHER ENGINEERING MATHEMATICS—VII

three sets A , B , and C as

$$A \times B \times C = \{(a, b, c) | a \in A, b \in B, c \in C\}$$

Example: $A = \{3, 4, 5\}$, $B = \{d, e\}$, $c = \{0, 1\}$ then

$$A \times B \times C = (A \times B) \times C$$

$$\begin{aligned} &= \{(3, d), (3, e), (4, d), (4, e), (5, d), (5, e)\} \times C \\ &= \{(3, d, 0), (3, e, 0), (4, d, 0), (4, e, 0), (5, d, 0), \\ &\quad (5, e, 0), (3, d, 1), (3, e, 1), (4, d, 1), (4, e, 1), \\ &\quad (5, d, 1), (5, e, 1)\} \end{aligned}$$

26.2 REVIEW OF COUNTING

The Sum Rule

If a first task can be done in n_1 ways and a second task in n_2 ways and if these two tasks cannot be performed simultaneously, then there are $n_1 + n_2$ ways of performing either task.

Example: Suppose a university representative is to be chosen either from 200 teaching or 300 non-teaching employees. Then there are $200 + 300 = 500$ possible ways to pick this representative.

Extension of Sum Rule

If tasks $T_1, T_2 \dots T_m$ can be done in $n_1, n_2, \dots, n_m$ ways respectively and no two of these tasks can be performed at the same time, then the number of ways to do *one* of these tasks is $n_1 + n_2 + \dots + n_m$.

Example: If a student can choose a project from either 20 from Mathematics or 35 from computer science or 15 from Engineering then the student can choose *a* project in $20 + 35 + 15 = 70$ ways.

Fundamental principle of counting:

The Product Rule

Suppose a procedure can be broken down into two tasks T_1 and T_2 . If the first task T_1 can be performed in n_1 ways and the second task T_2 can be performed in n_2 ways *after* the first task T_1 has been done, then the total procedure can be carried out, in the designated order, in $n_1 \cdot n_2$ ways.

Example: A tourist can travel from Hyderabad to Tirupati in 4 ways (by plane, train, bus or taxi). He can travel from Tirupati to Tirumala hills in 5 ways (by bus, taxi, walk, rope way or motor cycle). Then the tourist can travel from Hyderabad to Tirumala hills in $4 \times 5 = 20$ ways.

Extension of Product Rule

Suppose a procedure consists of performing tasks $T_1, T_2, \dots, T_m$ in that order. Suppose task T_i can be performed in n_i ways, *after* the tasks $T_1, T_2, \dots, T_{i-1}$ are performed then the number of ways the procedure can be executed in the designated order is

$$n_1 \cdot n_2 \cdot n_3 \dots n_m.$$

Example 1: 'Charmas' brand shirt comes in 12 colors, has a male and female version, comes in 4 sizes for each sex comes in three makes economy, standard and luxury. Then the number of different types of shirts produced are $12 \times 2 \times 4 \times 3 = 288$ types.

Example 2: The number of elements (n -tuples) in the cartesian product of finite sets $A_1, A_2, \dots, A_m$ with $n_1, n_2, \dots, n_m$ elements respectively is $n_1, n_2 \dots n_m$ i.e., $|A_1 \times A_2 \times \dots \times A_m| = |A_1| \cdot |A_2| \dots |A_m| = n_1 \cdot n_2 \dots n_m$.

Example 3: A hotel offers 12 kinds of sweets, 10 kinds of hot tiffins and 5 kinds of beverages (hot tea, hot coffee, juice, coke, icecream). The breakfast consists of a sweet and a hot beverage or a hot tiffin and cold beverage. The number of ways in which the above breakfast can be ordered is $12 \times 2 + 10 \times 3 = 24 + 30 = 54$. Here we have applied both product rule and sum rule.

Permutation

A *Permutation* of a set of n distinct objects is an ordered arrangement of these n objects.

An r -*permutation* is an ordered arrangement of r elements taken from the n objects.

Example: $A = \{a, b, c, d\}$. Arrangements $dcba, cdab$ are permutation of A . Arrangements abc, abd, bcd, dbc , etc. are 3-permutations of A . Arrangements ab, ba, cd, dc , etc. are 2-permutations of A .

Result 1: The number of r -permutations of a set with n distinct elements is denoted by $P(n, r)$ and is given by

$$P(n, r) = n(n-1)(n-2) \cdots (n-r+1)$$

$$P(n, r) = \frac{n!}{(n-r)!}, 0 \leq r \leq n$$

Result 2: When $r = n$,
 $P(n, n) = n!$

Result 3: When $r = 0$, $P(n, 0) = 1$

Note that $P(n, r)$ counts the (linear) arrangements in which the objects *cannot* be repeated.

Example: The number of “words” of three distinct letters can be formed from the letters of the word JNTU is $P(4, 3) = 4P_3 = \frac{4!}{(4-3)!} = 24$.

Example: In how many ways can 8 men and 8 women be seated in a row if

- any person may sit next to any other
- men and women must occupy alternate seats
- Generalize this result for n men and n women.

Solution:

- Here men and women are indistinguishable, so these are 16 objects. The number of permutations from 16 objects with 16 chosen is $P(16, 16) = 16! = 20922789890000$

- Here men and women are distinct (different)

M	W	M	W	M	W	M	W	M	W	M	W	M	W	M	W
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

8. 8. 7. 7. 6. 6. 5. 5. 4. 4. 3. 3. 2. 2. 1. 1

The number of ways = $8!8!$

Alternatively women sits first followed by man, which gives another $8!8!$ ways.

Thus the number of ways men and women occupy alternatively is $8!8! + 8!8! = 2(8!)^2 = 3251404800$.

- Any person may sit: $(2n)!$
 Men and women sit alternatively $2(n!)^2$.

Combination

An r -combination is an unordered selection or combination of r elements from a set with n distinct

elements.

The number of combinations of size r from a set of size n is denoted by $C(n, r)$ and is given by

$$C(n, r) = \frac{P(n, r)}{r!} = \frac{n!}{r!(n-r)!}, 0 \leq r \leq n$$

Example: $A = \{a, b, c, d, e\}$. The number of 3-combinations are $C(5, 3) = \frac{5!}{3!2!} = 10$. They are $\{a, b, c\}$, $\{a, b, d\}$, $\{a, b, e\}$, $\{b, c, d\}$, $\{b, c, e\}$, $\{c, d, e\}$, $\{a, c, e\}$, $\{a, c, d\}$, $\{b, d, e\}$, $\{d, e, a\}$. Observe that the order is irrelevant in combinations. Thus $\{a, b, c\}$, $\{a, c, b\}$, $\{b, a, c\}$, $\{b, c, a\}$, $\{c, a, b\}$, $\{c, b, a\}$ are all one and the same 3-combination of a, b, c .

Example: A committee of 12 is to be selected from 10 men and 10 women. In how many ways can the selection be carried out if

- There are no restrictions
- There must be 6 men and 6 women
- There must be an even number of women
- There must be more women than men
- There must be at least 8 men.

Solution:

- No distinction between men and women. Problem is to choose 12 out of a set of 20 objects. So the number of ways 12 chosen out of 20 is $C(20, 12) = \frac{20!}{12!8!} = 125970$.
- First stage to choose 6 men out of 10, given by $C(10, 6)$. Second stage to choose 6 women out of 10 again $C(10, 6)$. Using product rule, the number of ways in which the committee will consist of 6 men and 6 women is $C(10, 6) \cdot C(10, 6) = (210)(210) = 44100$.
- If $2i$ even number of women are chosen, then the remaining $12 - 2i$ members of the committee should be men. By product rule $C(10, 2i)C(10, 12 - 2i)$ then the total number of ways is

$$\sum_{i=1}^5 \binom{10}{12-2i} \binom{10}{2i}$$

- (d) Since the strength of the committee is 12, there must be 7 or more women in the committee so that there are more women than men in the committee. Using product rule, the number of ways is

$$\sum_{i=7}^{10} \binom{10}{i} \binom{10}{12-i}$$

- (e) By similar argument

$$\sum_{i=8}^{10} \binom{10}{i} \binom{10}{12-i}$$

Permutation with Repetition

The number of arrangements of r objects from n objects with repetition is n^r .

Example: *String* is an arrangement made up of prescribed *alphabet* symbols.

By the rule of product there are 4^n strings of length n for the alphabet 0, 1, 2, 3. Thus the collection of all strings of length 10 made up from the alphabet 0, 1, 2, 3 is 4^{10} .

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| 0 | 0 | 0 | 1 | 2 | 3 | 1 | 2 | 3 | 3 |
|---|---|---|---|---|---|---|---|---|---|

 is one such string.

Combination with Repetition

The number of combinations of n objects taken r at a time, with repetition is $C(n+r-1, r) = \frac{(n+r-1)!}{r!(n-1)!}$

1. Permutation: $P(n, r) = \frac{n!}{(n-r)!}$, $0 \leq r \leq n$ (order important, no repetition)
2. Arrangement: n^r , $n, r \geq 0$ (order important, repetition allowed)
3. Combination: $C(n, r) = \frac{n!}{r!(n-r)!}$ for $0 \leq r \leq n$. (order irrelevant, repetition *not* allowed)
4. Combination with repetition

$$\binom{n+r-1}{r} \quad \text{with} \quad n, r \geq 0$$

(order irrelevant)

26.3 INTRODUCTION TO PROBABILITY

A deterministic experiment is an experiment whose outcome or result is known with certainty or predictable, i.e., result is unique.

Example: Ohm's law $I = \frac{E}{R}$ determines the current uniquely (with certainty).

Trial is a single performance of an experiment.

A probabilistic or non-deterministic or random experiment is an experiment whose outcome or result is not unique and therefore cannot be predicted with certainty.

Examples:

- i. Tossing of a coin, head or tail may occur.
- ii. Throwing a die, 1, 2, 3, 4, 5, or 6 may appear.
- iii. Tensile strength of beam.
- iv. Life-time of a computer system.

Probability is a measure of certainty.

Sample space S of a random experiment is the set of all possible outcomes of the experiment.

Examples:

- i. Tossing of coin: $S = \{H, T\}$
- ii. Throwing a die: $S = \{1, 2, 3, 4, 5, 6\}$
- iii. Tensile strength of beam: $S = \{r \geq 0, r \text{ real}\}$.

Sample or sample point is a particular (outcome) element of S .

Event

Even is a subset of a sample space.

Example: Tossing of a die,

$$E_1 = \{\text{odd number}\} = \{1, 3, 5\}$$

$$E_2 = \{\text{even number}\} = \{2, 4, 6\}$$

$$E_3 = \{\text{prime number}\} = \{2, 3, 5\}$$

$$E_4 = \{\text{number greater than 2}\} = \{3, 4, 5, 6\}$$

Mutually exclusive events

Two events A and B are mutually exclusive if A and B can not happen (occur) simultaneously, i.e., $A \cap B = \phi$, i.e., A and B are disjoint.

Collectively exhaustive events

A list of events $A_1, A_2, \dots, A_n$ are said to be collectively exhaustive if $\bigcup_{i=1}^n A_i = S$.

Universal event

The entire sample space S is called a universal (or certain or sure) event.

The null set ϕ is called the null or impossible event.

Mathematical or classical or 'a priori' probability

If an event E can happen m ways out of possible n mutually exclusive, collectively exhaustive and equally likely ways then probability of event E , denoted by, $P(E)$ is defined as

$$P(E) = p = \frac{m}{n} = \frac{\text{Favourable cases for } E}{\text{Total cases}}$$

The probability of non-occurrence of event E (called its failure), denoted by $P(\text{not } E)$ or

$$\begin{aligned} q &= P(\text{not } E) = P(\bar{E}) = P(E^c) = P(\sim E) = \frac{n-m}{n} \\ &= 1 - \frac{m}{n} = 1 - p = 1 - P(E) \end{aligned}$$

Thus, $p + q = 1$ and $0 \leq p \leq 1$ and $0 \leq q \leq 1$.
Probability of a certain (sure) event is $\frac{n}{n} = 1$.

Probability of an impossible (null) event is $\frac{0}{n} = 0$.

Note: This definition fails when (i) The outcomes are not equally likely and (ii) Number of outcomes is infinite (not exhaustive).

Statistical or Empirical or Estimated (von mises) Probability

$$p = P(E) = \lim_{n \rightarrow \infty} \frac{m}{n}$$

where m is the number of times event E happens (occurs) in n trials assuming that the trials are performed under essentially homogeneous and identical conditions.

Note: This definition fails when (i) limit does not exist (ii) or is not unique.

A.N. Kolmogorov (in 1933) developed the axiomatic probability theory which includes the above two approaches as special cases (the classical theory corresponding to equiprobable spaces).

Axioms of Probability

1. For any event A of S

$$0 \leq P(A) \leq 1$$

i.e., probability is a numerical value lying between 0 and 1.

2. $P(S) = 1$ (sure event).

3. For any two mutually exclusive events A and B in S

$$P(A \cup B) = P(A) + P(B)$$

i.e., probability of sum is the sum of the probabilities (special addition rule).

Based on the above axioms (rules) the remaining probability theory is developed. For example, for any sequence of mutually exclusive events $A_1, A_2, A_3, \dots$ of S , we have

$$3a. P(A_1 \cup A_2 \cup A_3 \dots) = P(A_1) + P(A_2) + P(A_3) + \dots$$

Elementary Theorems

Theorem 1: $P(\phi) = 0$.

Proof:

$$S = S \cup \phi$$

$$P(S) = P(S \cup \phi) = P(S) + P(\phi)$$

by axiom 3 since S and ϕ are mutually exclusive

or $P(\phi) = 0$.

Theorem 2: $P(A^c) = 1 - P(A) \leq 1$.

Proof: A and A^c are mutually exclusive and

$$S = A \cup A^c$$

$$1 = P(S) = P(A \cup A^c) = P(A) + P(A^c)$$

where we have used axiom (2) and (3). Hence

$$P(A^c) = 1 - P(A) \leq 1$$

since $P(A) \geq 0$.

Additive Theorem or Rule or General Addition Rule of Probabilities

Theorem 3: If A and B are any two arbitrary events of S then

$$P(A \cup B) = P(A) + P(B) - P(A \cap B)$$

Proof:

$$A = (A \cap B^c) \cup (A \cap B)$$

$$B = (A \cap B) \cup (A^c \cap B)$$

Fig. 26.3

Note that $A \cap B^c$, $A \cap B$ and $A^c \cap B$ are mutually exclusive (i.e., they are mutually disjoint) (refer Fig. 26.3).

Applying axiom (3)

$$P(A) = P(A \cap B^c) + P(A \cap B)$$

$$P(B) = P(A \cap B) + P(A^c \cap B)$$

Adding

$$P(A) + P(B) = [P(A \cap B^c) + P(A \cap B) + P(A^c \cap B)] + P(A \cap B)$$

Observe that

$$A \cup B = (A \cap B^c) \cup (A \cap B) \cup (A^c \cap B)$$

$$\text{so } P(A) + P(B) = P(A \cup B) + P(A \cap B)$$

$$\text{or } P(A \cup B) = P(A) + P(B) - P(A \cap B).$$

Corollary 1: Since $P(A \cap B) \geq 0$ it follows that

$$P(A \cup B) \leq P(A) + P(B).$$

Corollary 2: General additive rule

Theorem 4: For any three arbitrary events A , B , C , (Fig. 26.4)

Fig. 26.4

$$P(A \cup B \cup C) = P(A) + P(B) + P(C) - P(A \cap B) - P(B \cap C) - P(C \cap A) + P(A \cap B \cap C)$$

Proof: Applying additive theorem for A and $B \cup C$, we have

$$P(A \cup (B \cup C)) = P(A) + P(B \cup C) - P\{A \cap (B \cup C)\}$$

Again applying additive theorem for $B \cup C$, we get

$$P(A \cup B \cup C) = P(A) + P(B) + P(C) - P(B \cap C)$$

$$- P\{(A \cap B) \cup (A \cap C)\}$$

Now using additive theorem for $(A \cap B) \cup (A \cap C)$, we have

$$P(A \cup B \cup C) = P(A) + P(B) + P(C) - P(B \cap C)$$

$$- \{P(A \cap B) + P(A \cap C)\}$$

$$- P\{(A \cap B) \cap (A \cap C)\}$$

$$= P(A) + P(B) + P(C) - P(A \cap B)$$

$$- P(B \cap C) - P(C \cap A) + P(A \cap B \cap C)$$

since $(A \cap B) \cap (A \cap C) = A \cap B \cap C$

Theorem 5: If $B \subset A$ then $P(B) \leq P(A)$.

Proof: $A = B \cup (A \cap B^c)$ and B , $A \cap B^c$ are mutually exclusive

$$\text{so } P(A) = P(B \cup (A \cap B^c)) = P(B) + P(A \cap B^c)$$

$$\text{i.e., } P(B) \leq P(A).$$

Conditional Probability

Although probability of an event E is with reference to the sample space S , on many occasions one is interested in finding the probability of E with respect to a *reduced* sample space. For example, consider the following table:

| | Employed | Unemployed | Total |
|--------|----------|------------|-------|
| Male | 160 | 140 | 300 |
| Female | 40 | 80 | 120 |
| Total | 200 | 220 | 420 |

Total sample space is 420 persons. If a person is male, what is the probability that he is unemployed? In this case we should consider only the reduced sample space of males (only) (since it is given or known that the person is male). Thus the required probability is

$$\frac{140}{300} = \frac{\text{unemployed and male}}{\text{male}}$$

Conditional Probability

Conditional probability of an event A given that B has happened, denoted by, $P(A/B)$ is defined as

$$P(A/B) = \frac{P(A \cap B)}{P(B)} \quad \text{if } P(B) > 0.$$

Also read as conditional probability of A given B .
Thus for the above example,

$$P(U/M) = \frac{140}{300}, P(E/M) = \frac{160}{300},$$

$$P(M/E) = \frac{160}{200}, P(F/E) = \frac{40}{200}, P(E/F) = \frac{40}{120} \text{ etc.}$$

General multiplicative rule

$$P(A \cup B) = P(B) P(A/B)$$

Similarly, $P(B/A) = \frac{P(A \cap B)}{P(A)}$ if $P(A) > 0$

$$\text{So } P(A \cap B) = P(A) P(B/A).$$

Corollary For any events $A_1, A_2, \dots, A_n$
 $P(A_1 \cap A_2 \cap \dots \cap A_n) = P(A_1) P(A_2/A_1) \times$
 $P(A_3/A_1 \cap A_2) \dots P(A_n/A_1 \cap A_2 \cap \dots \cap A_{n-1})$

Independent Events

Two events A and B are said to be independent if

$$P(B/A) = P(B)$$

or

$$P(A/B) = P(A)$$

i.e., the occurrence (or non-occurrence) of event A has no influence (or impact) on the occurrence (or non-occurrence) of B . Otherwise they are said to be *dependent*.

Special multiplication rule

If A and B are independent events then

$$P(A \cap B) = P(A)P(B)$$

i.e., in a sense probability of the product is the product of the probabilities.

Corollary For independent events
 $A_1, A_2, A_3, \dots$
 $P(A_1 \cap A_2 \cap A_3 \cap \dots) = P(A_1) P(A_2) P(A_3) \dots$

Partition

The family of sets $A_1, A_2, \dots, A_n$ is said to be a partition of S if

- i. $\bigcup_{i=1}^n A_i = S$ (collectively exhaustive)
- ii. $A_i \cap A_j = \phi$ for any i, j (mutually disjoint).

WORKED OUT EXAMPLES

Permutations

Example 1: (a) How many car number-plates can be made if each plate contains two different letters followed by three different digits? (b) Solve the problem if the first digit cannot be 0. Solve (a) and (b) with repetitions and without repetitions.

Solution: With repetitions:

a. $26 \times 26 \times 10 \times 10 \times 10 = 6,76,000$

b. $26 \times 26 \times 9 \times 10 \times 10 = 6,08,400$

without repetitions:

a. $26 \times 25 \times 10 \times 9 \times 8 = 4,68,000$

b. $26 \times 25 \times 9 \times 9 \times 8 = 4,21,200.$

Example 2: Determine the number of permutations that can be formed from all the letters of each word (i) queue (ii) committee (iii) proposition (iv) baseball.

Solution:

i. $n = 5, n_1 = 2, n_2 = 2, \frac{5!}{2!2!1!} = 30$

ii. $n = 9, n_1(m, m) = 2, n_2(t, t) = 2, n_3(ee) = 2,$
 $\frac{9!}{2!2!2!1!1!1!} = 45360$

iii. $n = 11, n_1 = (p, p) = 2, n_2 = (o, o, o) = 3,$
 $n_2 = (i, i) = 2, \frac{11!}{2!3!2!} = 1,66,3200$

iv. $\frac{8!}{2!2!2!} = 5040$

Combinations

Example 3: From five statisticians and six economists a committee consisting of three statisticians and two economists is to be formed. How many different committees can be formed if

- a. No restrictions are imposed?
- b. Two particular statisticians must be on the committee?
- c. One particular economist can not be on the committee?

Solution:

a. ${}^5C_3 \cdot {}^6C_2 = \frac{5!}{2!3!} \cdot \frac{6!}{2!4!} = 150.$

26.10 — HIGHER ENGINEERING MATHEMATICS—VII

- b. Two particular statisticians are chosen. To choose one statistician out of the remaining three statisticians $3C_1 \cdot 6C_2 = 45$.
- c. One particular economist is barred. So to choose two economists from the remaining five economists $5C_3 5C_2 = 100$.

Probability

Example 4: Determine the probability for each of the following events:

- a. A non-defective bolt will be found if out of 600 bolts already examined, 12 were defective.
- b. At least one head appears in a four tosses of a fair coin.
- c. The sum 8 appears in a single toss of pair of fair dice.
- d. The sum 7 or 8 or 12 appears in a single toss of a pair of fair dice.
- e. A king, ace, jack of clubs or queen of diamonds appear in drawing in a single card from a well shuffled ordinary deck of cards (i.e., without joker).

Solution:

- a. $P(\text{defective}) = \frac{12}{600} = \frac{1}{50}$
 $P(\text{non-defective}) = 1 - P(\text{defective})$
 $= 1 - \frac{1}{50} = \frac{49}{50} = 0.98$.
- b. $P(TTTT) = P(T)P(T)P(T)P(T) = \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{16}$
 $P(\text{at least one head}) = 1 - P(\text{all tails})$
 $= 1 - P(TTTT)$
 $= 1 - \frac{1}{16} = \frac{15}{16}$.

Note: Sample space $= \{H, T\} \times \{H, T\} \times \{H, T\} \times \{H, T\} = 2^4 = 16$.
 $\{HHHH, HHHT, HHTH, HTHH, HHTT, HTHT, HTTH, HTTT, THHH, THHT, THTH, TTHH, THTT, TTHT, TTTH, TTTT\}$

- c. The sum 8 can appear in the following cases
 $(6, 2), (5, 3), (4, 4), (2, 6), (3, 5)$ i.e., 5 cases
 Total number of cases $= 6 \times 6 = 36$ ways.
 $P(\text{sum 8}) = \frac{\text{Favourable cases}}{\text{Total cases}} = \frac{5}{36}$
- d. Sum 7 appears 6 ways as
 $(6, 1), (1, 6), (5, 2), (2, 5), (4, 3), (3, 4)$

Sum 12 appears in one way as $(6, 6)$

$$P(7 \text{ or } 8 \text{ or } 12) = P(7) + P(8) + P(12) = \frac{6}{36} + \frac{5}{36} + \frac{1}{36} = \frac{12}{36} = \frac{1}{3}.$$

e. $P(\text{king}) = \frac{4}{52}, P(\text{ace}) = \frac{4}{52},$

$$P(\text{jack of clubs}) = \frac{1}{52},$$

$$P(\text{queen of diamonds}) = \frac{1}{52},$$

$P(\text{king or ace or jack of clubs or queen of diamonds})$

$$= P(K) + P(A) + P(\text{jack of clubs})$$

$$+ P(\text{Queen of diamond})$$

$$= \frac{4}{52} + \frac{4}{52} + \frac{1}{52} + \frac{1}{52} = \frac{10}{52} = \frac{5}{26}.$$

Example 5: Find the probability that at least two 9's appear (as a sum) in four tosses of a pair of fair dice.

Solution: The sum 9 appears in the following four cases: $(3, 6), (6, 3), (4, 5), (5, 4)$.

$p = P(\text{sum 9 occurring in a single throw of a pair of fair dice}) = \frac{4}{36} = \frac{1}{9}.$

$$q = P(\text{sum 9 not occurring}) = 1 - p = 1 - \frac{1}{9} = \frac{8}{9}.$$

Sum 9 appears in all four tosses with probability

$$= P(9 \text{ and } 9 \text{ and } 9 \text{ and } 9) = P(9)P(9)P(9)P(9) = \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{1}{9}.$$

Sum 9 appears in three tosses and fails in one toss.

$$\text{Prob}(9 \text{ and } 9 \text{ and } 9 \text{ and } \bar{9}) = \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{8}{9}.$$

This can happen in $4C_1$, ways.

Sum 9 appears in two tosses and fails in two tosses

$$\text{Prob}(9 \text{ and } 9 \text{ and } \bar{9} \text{ and } \bar{9}) = \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{8}{9} \cdot \frac{8}{9}.$$

This can happen $4C_2$ ways.

Thus the probability of at least two 9's in four tosses $= P(\text{all 9's}) + P(\text{Three 9's and one } \bar{9}) + P(\text{Two 9's and two } \bar{9})$

$$= \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{1}{9} + 4C_1 \left(\frac{1}{9} \cdot \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{8}{9} \right) + 4C_2 \left(\frac{1}{9} \cdot \frac{1}{9} \cdot \frac{8}{9} \cdot \frac{8}{9} \right) = \frac{1}{6561} [1 + 4 \cdot 8 + 6 \cdot 64] = \frac{417}{6561}.$$

Example 6: If 4 tickets are drawn from tickets numbered 1 to 30 inclusive, determine the probability that the tickets marked 1 and 2 are among the four of them.

Solution: Total cases: $30C_4$

Since 1 and 2 must appear among the four, only two other tickets are to be chosen from the remaining 28 tickets in ${}^{28}C_2$ ways. Thus probability = $\frac{{}^{28}C_2}{{}^{30}C_4}$.

Example 7: Two marbles are drawn in succession from a box containing 10 red, 30 white, 20 blue and 15 orange marbles, with replacement being made after each drawing. Find the probability that (a) both are white (b) first is red and second is white (c) neither is orange. Solve this problem with no replacement after each drawing.

Solution: Total number of marbles = $10 + 30 + 20 + 15 = 75$. Let R = red, W = white, B = blue, O = orange.

- a. $P(\text{first marble drawn is white}) = \frac{30}{75}$.

After replacement, $P(\text{second is white}) = \frac{30}{75}$.

$P(\text{first is white and second is white})$

$$P(W) \cdot P(W) = \frac{30}{75} \cdot \frac{30}{75} = \frac{4}{25}$$

since the first and second drawings of marbles are independent.

- b. $P(\text{first is red}) = \frac{10}{75}$.

After replacement, $P(\text{second white}) = \frac{30}{75}$.

$$P(\text{first is red and second is white}) = \frac{10}{75} \cdot \frac{30}{75} = \frac{4}{75}.$$

- c. $P(\text{first is orange}) = \frac{15}{75}$, $P(\text{first is not orange}) = 1 - \frac{15}{75} = \frac{60}{75}$.

$$P(\text{second is orange}) = \frac{15}{75}.$$

$$P(\text{second is not orange}) = 1 - \frac{15}{75} = \frac{60}{75}.$$

$$P(\text{neither is orange}) = \frac{60}{75} \cdot \frac{60}{75} = \frac{16}{25}.$$

When no replacement is made:

- a. $P(\text{first is white}) = \frac{30}{75}$.

Since no replacement is made, the second drawing (event) depends (or influenced by) on the first drawing. Thus

$$P(\text{second is white}) = \frac{29}{74}.$$

$$P(\text{both white}) = \frac{30}{75} \cdot \frac{29}{74} = \frac{29}{185}.$$

- b. $P(\text{first is red}) = \frac{10}{75}$.

$$P(\text{second is white}) = \frac{30}{74}$$

(similar argument as above).

$$P(\text{first red and second white}) = \frac{10}{75} \cdot \frac{30}{74} = \frac{2}{37}.$$

- c. $P(\text{first is orange}) = \frac{15}{75}$.

$$P(\text{first is not orange}) = 1 - \frac{15}{75} = \frac{60}{75}.$$

Since no replacement is made, there are 74 marbles of which 15 are orange marbles because no orange marble was drawn in the first drawing.

$$P(\text{second is not orange}) = 1 - \frac{15}{74} = \frac{59}{74}.$$

$$P(\text{neither is orange}) = \frac{60}{75} \cdot \frac{59}{74} = \frac{118}{165}.$$

Finite probability spaces

Example 8: Three students A , B and C are in a swimming race. A and B have the same probability of winning and each is twice as likely to win as C . Find the probability that B or C wins.

Solution: Given that $P(A) = P(B) = 2P(C)$. Since only three students A , B , C are in race, the probability space is finite,

$$\text{i.e., } P(A) + P(B) + P(C) = 1$$

$$\text{or } (2 + 2 + 1)P(C) = 1 \text{ so } P(C) = \frac{1}{5}$$

$$\text{and } P(A) = \frac{2}{5} = P(B)$$

$$\text{Now } P(B \cup C) = P(B) + P(C) = \frac{2}{5} + \frac{1}{5} = \frac{3}{5}$$

Finite equiprobable spaces

Example 9: Of 10 girls in a class, 3 have blue eyes. If 2 of the girls are chosen at random, what is the probability that (i) both have blue eyes? (ii) neither has blue eyes? (iii) at least 1 has blue eyes?

Solution: All the girls are equally likely or equiprobable (indistinguishable). The number of ways 2 girls can be chosen from 10 girls is ${}^{10}C_2$.

- i. Favourable cases for both girls to have blue eyes: 3C_2

$$\text{Prob (both girls with blue eyes)} = \frac{\text{Favourable cases}}{\text{Total cases}} = \frac{{}^3C_2}{{}^{10}C_2} = \frac{1}{15}.$$

- ii. Favourable cases for non-blue eyed girls are 7C_2 .

$$P(\text{neither has blue eyes}) = \frac{{}^7C_2}{{}^{10}C_2} = \frac{7}{15}.$$

- iii. $P(\text{at least one blue eye})$

$$= 1 - P(\text{neither}) = 1 - \frac{7}{15} = \frac{8}{15}.$$

Example 10: A class consists of 6 girls and 10 boys. If a committee of 3 is chosen at random from

the class, find the probability that (i) 3 boys are selected (ii) exactly two boys are selected (iii) at least one boy is selected (iv) exactly two girls are selected.

Solution:

$$\text{i. } P(3B) = \frac{10C_3}{16C_3} = \frac{3}{14}$$

since favourable cases are $10C_3$ (3 out of 10 boys) and total cases are $16C_3$ (3 out of total 16 students).

$$\text{ii. } P(2B, 1G) = \frac{10C_2 \cdot 6C_1}{16C_3} = \frac{27}{56}$$

Boys selection is in $10C_2$ ways, while girls selection is in $6C_1$ ways. By counting principle, the number of ways these two can happen is $10C_2 \cdot 6C_1$.

$$\text{iii. } P(3G) = \frac{6C_3}{16C_3} = \frac{1}{28}$$

$$P(\text{at least one boy}) = 1 - P(3G) = 1 - \frac{1}{28} = \frac{27}{28}$$

$$\text{iv. } P(2G) = \frac{6C_2 \cdot 10C_1}{16C_3} = \frac{15}{56}$$

Independence

Example 11: If A and B are independent, prove that (a) A and B^c are independent (b) A^c and B are independent.

Solution: Given that A and B are independent i.e., $P(A \cap B) = P(A)P(B)$ (see Fig. 26.5)

Fig. 26.5

$$\begin{aligned} \text{a. } P(A \cap B^c) &= P(A) - P(A \cap B) \\ &= P(A) - P(A)P(B) \\ &= P(A)[1 - P(B)] \\ &= P(A)P(B^c) \end{aligned}$$

so A and B^c are independent.

$$\begin{aligned} \text{b. } P(B \cap A^c) &= P(B) - P(A \cap B) = P(B) - P(A)P(B) \\ &= P(B)[1 - P(A)] = P(B)P(A^c) \end{aligned}$$

so A and B^c are independent.

Example 12: Two aeroplanes bomb a target in succession. The probability of each correctly scoring a hit is 0.3 and 0.2 respectively. The score will bomb only if the first misses the target. Find the probability that

- the target is hit
- the target is hit by the second plane
- both fail to score hits.

Solution: A_1 : first aeroplane, A_2 : second aeroplane.

- $P(\text{target is hit}) = P(A_1 \text{ hits}) \text{ or } (A_1 \text{ fails and } A_2 \text{ hit}) = P(A_1 \text{ hits}) + P(A_1 \text{ fails and } A_2 \text{ hits})$, by addition theorem.

Since A_1 fails and A_2 hits are independent events, applying multiplication rule, we have

$$\begin{aligned} P(\text{target is hit}) &= P(A_1 \text{ hits}) + P(A_1 \text{ fails}) \cdot P(A_2 \text{ hits}) \\ &= 0.3 + (1 - 0.3)(0.2) = 0.44. \end{aligned}$$

- $P(\text{target hit by } A_2) = P(A_1 \text{ fails and } A_2 \text{ hits}) = P(A_1 \text{ fails}) \cdot P(A_2 \text{ hits}) = (0.7)(0.2) = 0.14$

- $P(\text{both fails}) = P(A_1 \text{ fails and } A_2 \text{ fails}) = P(A_1 \text{ fails}) \cdot P(A_2 \text{ fails}) = (1 - 0.3)(1 - 0.2) = (0.7)(0.8) = 0.56$

Example 13: A man alternatively tosses a coin and throws a die beginning with coin. What is the probability that he will get a head before he gets a 5 or 6 on the die?

$$\begin{aligned} \text{Solution: } P(\text{Head}) &= P(H) = \frac{1}{2} = P(\text{Tail}) = P(T) \\ P(5 \text{ or } 6 \text{ on die}) &= P(5) + P(6) = \frac{1}{6} + \frac{1}{6} = \frac{1}{3} \end{aligned}$$

$$\text{so } P(\text{not getting 5 or 6 on die}) = P(\widetilde{5 \text{ or } 6}) = \frac{2}{3}$$

Now he will succeed if

$$H \text{ or } (T \text{ and } \widetilde{5 \text{ or } 6}) \text{ or } [(T \text{ and } \widetilde{5 \text{ or } 6}) \text{ and } (T \text{ and } \widetilde{5 \text{ or } 6})H] \text{ or } \dots$$

These events H , $(T \text{ and } \widetilde{5 \text{ or } 6})$, etc. are mutually exclusive events.

By addition theorem,

$$\begin{aligned} P(\text{success}) &= P(H \text{ or } (T \widetilde{5 \text{ or } 6} H) \text{ or } (T \widetilde{5 \text{ or } 6} T \widetilde{5 \text{ or } 6} H) \text{ or } \dots) \\ &= P(H) + P(T \text{ and } \widetilde{5 \text{ or } 6} H) + \dots \end{aligned}$$

$$\begin{aligned}
 &+P(T \text{ and } 5 \text{ or } 6 \text{ and } T \text{ and } 5 \text{ or } 6 \text{ and } H) \\
 &+ \dots
 \end{aligned}$$

Since T , 5 or 6 are independent events, apply multiplication rule,

$$\begin{aligned}
 P(\text{success}) &= P(H) + P(T)P(5 \text{ or } 6)P(H) \\
 &\quad + P(T)P(5 \text{ or } 6)P(T)P(5 \text{ or } 6)P(H) + \dots \\
 &= \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{3} \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{3} \cdot \frac{1}{3} \cdot \frac{1}{2} + \dots \\
 &= \frac{1}{2} \left[1 + \frac{1}{3} + \left(\frac{1}{3}\right)^2 + \left(\frac{1}{3}\right)^3 + \dots \right] \\
 &= \frac{1}{2} \left[\frac{1}{1 - \frac{1}{3}} \right] = \frac{3}{4}
 \end{aligned}$$

since sum of geometric series is $\frac{a}{1-r}$, $a = 1$ first term, $r = \frac{1}{3}$ common ratio.

Example 14: Box A contains 5 red and 3 white marbles and box B contains 2 red and 6 white marbles (a) If a marble is drawn from each box, what is the probability that they are both of the same colour? (b) If 2 marbles are drawn from each box, what is the probability that all four marbles are of the same colour?

Solution: R_A : red marble from box A .

R_B : red marble from box B , W_A , W_B denote white marble from box A and B respectively.

a. Probability of both marbles same colour=

$$P((R_A \text{ and } R_B) \text{ or } (W_A \text{ and } W_B)) =$$

$$P(R_A \cap R_B \text{ or } W_A \cap W_B)$$

$$= P(R_A \cap R_B) + P(W_A \cap W_B)$$

Since R_A , R_B and W_A , W_B are independent events,

$$= P(R_A)P(R_B) + P(W_A)P(W_B)$$

$$= \frac{5}{8} \cdot \frac{2}{8} + \frac{3}{8} \cdot \frac{6}{8} = \frac{7}{16}.$$

b. Probability of each of the two marbles same colour

$$= [(\text{first and second from } A \text{ are red}) \text{ and } (\text{first and second from } B \text{ are red})]$$

$$\text{or } [(\text{first and second from } A \text{ are white}) \text{ and } (\text{first and second from } B \text{ are red})]$$

$$= P((R_{1A} \cap R_{2A} \cap R_{1B} \cap R_{2B}) \text{ or } (W_{1A} \cap W_{2A} \cap W_{1B} \cap W_{2B}))$$

$$= P(R_{1A} \cap R_{2A} \cap R_{1B} \cap R_{2B}) + P(W_{1A} \cap W_{2A} \cap W_{1B} \cap W_{2B})$$

$$\begin{aligned}
 &= P(R_{1A})P(R_{2A}/R_{1A}) \cdot P(R_{1B}) \cdot P(R_{2B}/R_{1B}) \\
 &\quad + P(W_{1A})P(W_{2A}/W_{1A}) \cdot P(W_{1B})P(W_{2B}/W_{1B}).
 \end{aligned}$$

Note that R_{1A} , R_{2A} are dependent events R_{1B} , R_{2B} are dependent events but $R_{1A} \cap R_{2A}$ and $R_{1B} \cap R_{2B}$ are independent events etc.

$$= \left(\frac{5}{8} \cdot \frac{4}{7}\right) \left(\frac{2}{8} \cdot \frac{1}{7}\right) + \left(\frac{3}{8} \cdot \frac{2}{7}\right) \left(\frac{6}{8} \cdot \frac{5}{7}\right) = \frac{55}{784}.$$

Conditional probability

Example 15: A die is tossed. If the number is odd, what is the probability that it is prime?

Solution: 2, 4, 6, are even, 1, 3, 5 are three odd numbers, of which two are prime numbers (namely 3 and 5) (refer Fig. 26.6).

Fig. 26.6

Conditional probability is w.r.t. the reduced sample space of odd numbers only. Thus

$$P(\text{Prime given odd}) = P(P/O) = \frac{\text{Favourable cases}}{\text{Total cases}} = \frac{2}{3}.$$

Example 16: Two digits are selected at random from the digits 1 through 9 (a) If the sum is odd, what is the probability that 2 is one of the numbers selected (b) If 2 is one of the digits selected, what is the probability that the sum is odd?

Solution: We know that even + even = even, odd + odd = even and odd + even = odd.

a. odd = {1, 3, 5, 7, 9}, even = {2, 4, 6, 8}

Since the sum is odd it must be the sum of an odd number and an even number i.e., odd = odd + even

$$P(2 \text{ selected}) = \frac{\text{Favourable cases for } 2}{\text{Total (even) cases}} = \frac{1}{4}.$$

b. 2 is selected, so the other number must be odd number

$P(\text{sum is odd}/2 \text{ is selected})$

$$= \frac{\text{Favourable case for odd}}{\text{Total cases}} = \frac{5}{8}.$$

26.14 — HIGHER ENGINEERING MATHEMATICS—VII

Sample space is reduced to 8 since 2 is already selected (removed from 9 digits).

Example 17: If A and B be events with $P(A) = \frac{1}{3}$, $P(B) = \frac{1}{4}$ and $P(A \cup B) = \frac{1}{2}$. Find (a) $P(A/B)$ (b) $P(B/A)$ (c) $P(A/B^c)$ (d) $P(A/B^c)$.

Solution:

$$\text{a. } P(A/B) = \frac{P(A \cap B)}{P(B)} = \frac{\frac{1}{12}}{\frac{1}{4}} = \frac{1}{3}$$

$$\text{Since } P(A \cup B) = P(A) + P(B) - P(A \cap B) \\ \frac{1}{2} = \frac{1}{3} + \frac{1}{4} - P(A \cap B) \text{ or } P(A \cap B) = \frac{1}{12}.$$

$$\text{b. } P(B/A) = \frac{P(A \cap B)}{P(A)} = \frac{\frac{1}{12}}{\frac{1}{3}} = \frac{1}{4}.$$

$$\text{c. } P(A \cap B^c) = P(A \setminus B) = P(A) - P(A \cap B) = \frac{1}{3} - \frac{1}{12} = \frac{1}{4}.$$

$$\text{d. } P(A/B^c) = \frac{P(A \cap B^c)}{P(B^c)} = \frac{\frac{1}{4}}{\frac{3}{4}} = \frac{1}{3}$$

$$\text{since } P(B^c) = 1 - P(B) = 1 - \frac{1}{4} = \frac{3}{4}.$$

Example 18: In a certain town 40% have brown hair, 25% have brown eyes and 15% have both brown hair and brown eyes. A person is selected at random from the town (Fig. 26.7).

- If he has brown hair, what is the probability that he has brown eyes also?
- If he has brown eyes, determine the probability that he does not have brown hair.
- Determine the probability that he has neither brown hair nor brown eyes.

Solution: Let BH : Brown hair, BE : Brown eyes.

- Probability that person has brown eyes given that he has brown hair is

$$P(BE/BH) = \frac{P(BE \cap BH)}{P(BH)} = \frac{15}{40} = \frac{3}{8}.$$

$$\text{b. } P(BH^c/BE) = \frac{P(BE \cap BH^c)}{P(BE)} = \frac{10}{25} = \frac{2}{5}.$$

Fig. 26.7

- $P(\text{neither } BH \text{ nor } BE)$

$$= P(BH^c \cap BE^c)$$

Using DeMorgan's law $A^c \cap B^c = (A \cup B)^c$, we have

$$= P((BH \cup BE)^c) = 1 - P(BH \cup BE)$$

by complementation.

$$= 1 - \frac{50}{100} = 1 - \frac{1}{2} = \frac{1}{2}.$$

Example 19: A box contains 9 tickets numbered 1 to 9 inclusive. If 3 tickets are drawn from the box one at a time, find the probability they are alternatively either odd, even, odd or even, odd, even.

Solution: 4 even numbers = {2, 4, 6, 8},

5 odd numbers = {1, 3, 5, 7, 9}.

Let e denote even and o denote odd number

$$P(oeo \text{ or } eoe) = P(oeo) + P(eoe)$$

since oeo and eoe are mutually exclusive. Now $\text{Prob}(\text{odd and even and odd}) = P(\text{odd})P(\text{even/given odd})P(\text{odd/given odd and even})$

$$\text{i.e., } P(oeo) = P(o)P(e/o)P(o/oe)$$

$$= \frac{5}{9} \cdot \frac{4}{8} \cdot \frac{4}{7} = \frac{10}{63}$$

Similarly,

$$P(eoe) = P(e)P(o/e)P(e/eo)$$

$$P(eoe) = \frac{4}{9} \cdot \frac{5}{8} \cdot \frac{3}{7} = \frac{5}{42}$$

$$\text{So } P(oeo \text{ or } eoe) = \frac{10}{63} + \frac{5}{42} = \frac{5}{18}.$$

Example 20: A class has 10 boys and 5 girls. Three students are selected at random, one after the other (see Fig. 23.8). Find probability that

- first two are boys and third is girl.
- first and third boys and second is girl.
- first and third of same sex and the second is of opposite sex.

Solution: B = Boy, G = Girl,

B_1 = first is boy, B_2 = second is boy, etc.

$$15$$

| |
|------|
| 10 B |
| 5 G |

Fig. 26.8

$$\text{a. } P(B_1 \text{ and } B_2 \text{ and } G_3) = P(B_1 B_2 G_3)$$

$$= P(B_1)P(B_2/B_1)P(G/B_1 B_2)$$

$$= \frac{10}{15} \cdot \frac{9}{14} \cdot \frac{5}{13} = \frac{15}{91}.$$

$$\text{b. } P(B_1 G_2 B_3) = P(B_1)P(G_2/B_1)P(B_3/B_1 G_2)$$

$$= \frac{10}{15} \cdot \frac{5}{14} \cdot \frac{9}{13} = \frac{15}{91}.$$

$$\text{c. } P(B_1 G_2 B_3 \text{ or } G_1 B_2 G_3) =$$

$$P(B_1 G_2 B_3) + P(G_1 B_2 G_3)$$

since $B_1 G_2 B_3$ and $G_1 B_2 G_3$ are mutually exclusive

$$= P(B_1)P(G_2/B_1)P(B_3/B_1 G_2)$$

$$+ P(G_1)P(B_2/G_1)P(G_3/G_1 B_2)$$

$$= \frac{10}{15} \cdot \frac{5}{14} \cdot \frac{9}{13} + \frac{5}{15} \cdot \frac{10}{14} \cdot \frac{4}{13} = \frac{5}{21}.$$

Example 21: Determine whether sex and blood group are independent from the following table:

| Blood Group | Male | Female | Total |
|-------------|------|--------|-------|
| O | 113 | 113 | 226 |
| A | 103 | 103 | 206 |
| B | 25 | 25 | 50 |
| AB | 10 | 10 | 20 |
| Total | 251 | 251 | 502 |

Solution:

$$P(O) = \frac{226}{502} = \frac{113}{251} = P(O/M)$$

$$P(M) = \frac{251}{502} = \frac{1}{2} = P(M/O) = \frac{113}{226}$$

So the events of blood group O and Male are independent events.

Similarly,

$$P(A) = \frac{206}{502} = P(A/M) = \frac{103}{251}$$

$$P(M) = \frac{251}{502} = \frac{1}{2} = P(M/A) = \frac{103}{206}$$

So group A and male sex are independent.

Similarly,

$$P(F) = \frac{251}{502} = \frac{1}{2} = P(F/O) = \frac{113}{226}$$

$$P(O) = \frac{226}{502} = \frac{113}{251} = P(O/F) = \frac{113}{251} \text{ etc.}$$

So O group and female sex are independent.

EXERCISE

Permutation

- Let $A = \{a, b\}$, $B = \{4, 3, 5\}$, $C = \{0, 1\}$. Construct the “tree diagram” of $A \times B \times C$ and then find $A \times B \times C$ (refer Fig. 26.9).

Ans. “tree” is constructed from left to right. $A \times B \times C$ consists of the ordered triples listed to the right of the “tree”.

Fig. 26.9

- If repetitions are not permitted (i) How many 3-digit numbers can be formed from the six digits 2, 3, 5, 6, 7 and 9? (ii) How many of these are less than 400? (iii) How many are even? (iv) How many are odd? (v) How many are multiples of 5?

Ans. (i) $6 \cdot 5 \cdot 4 = 120$ (ii) $2 \cdot 5 \cdot 4 = 40$ (iii) $5 \cdot 4 \cdot 2 = 40$ (iv) $5 \cdot 4 \cdot 4 = 80$ (v) $5 \cdot 4 \cdot 1 = 20$

- (a) In how many ways can 3 boys and 2 girls sit in a row? (b) In how many ways can they sit in a row if the boys and girls are each to sit

26.16 — HIGHER ENGINEERING MATHEMATICS—VII

together? In how many ways can they sit in a row if just girls sit together?

- Ans. a. $5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 = 5! = 120$
 b. $BBBGG$ or $GGBBB$: $3! \cdot 2! \cdot 2 = 24$
 c. $GGBBB$, $BGGBB$, $BBGGB$, $BBBGG$ ·
 $3! \cdot 2! \cdot 4 = 48$.

Combinations

4. A student is to answer 8 out of 10 questions in an exam. (i) How many choices has he? (ii) How many if he must answer the first three questions? (iii) How many if he must answer at least four of the first five questions?

- Ans. (i) ${}^{10}C_8 = {}^{10}C_2 = 45$ ways (ii) ${}^7C_5 = {}^7C_2 = 21$ (iii) All the first five, ${}^5C_3 = 10$ ways, 4 out of first five, ${}^5C_4 = 5$ ways and choose the other four out of last five, ${}^5C_1 = 5$ ways. Thus $5 \cdot 5 = 25$ ways. Hence

$$10 + 25 = 35 \text{ ways}$$

5. Compute the number of ordered partitions from $\{A_1, A_2, A_3\}$ of the set (box) of 7 marbles into cells A_1 containing 2 marbles, A_3 containing 3 marbles and A_2 containing 2 marbles.

$$\text{Ans. } \frac{7!}{2!5!} \cdot ({}^7C_2) ({}^5C_3) ({}^2C_2) = \frac{7!}{2!5!} \cdot \frac{5!}{3!2!} \cdot \frac{2!}{2!10!} \\ = \frac{7!}{2!3!2!}.$$

Finite equiprobable spaces

6. One card is selected at random from 50 cards numbered 1 to 50. Find the probability that the number on card is (i) divisible by 5 (ii) prime (iii) ends in digit 2.

- Ans. i. $P(\text{divisible by } 5) = \frac{10}{50} = \frac{1}{5}$
 ii. $P(\text{prime}) = \frac{15}{50}$
 iii. $P(\text{ends in digit } 2) = \frac{5}{50}$

Hint:

- i. 5, 10, 15, 20, 25, 30, 35, 40, 45, 50: 10
 ii. 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47: 15
 iii. 2, 12, 22, 32, 42: 5.

7. A pair of fair dice is tossed. Find probability that maximum of the two numbers is greater than 4.

$$\text{Ans. } \frac{{}^{20}C_1}{{}^{36}C_1} = \frac{20}{36} = \frac{5}{9}$$

Hint: 20 favourable cases such as (1, 5), (1, 6), (2, 5), (2, 6) ··· (6, 5), (6, 6).

8. Let A, B be events with $P(A \cup B) = \frac{7}{8}$, $P(A \cap B) = \frac{1}{4}$ and $P(A^c) = \frac{5}{8}$. Determine (a) $P(A)$ (b) $P(B)$ (c) $P(A \cap B^c)$, (d) $P(A^c \cap B)$ (e) $P(A^c \cup B^c)$ (f) $P(A^c \cap B^c)$.

- Ans. a. $P(A \cup B) = \frac{7}{8} = P(A) + P(B) - P(A \cap B)$,
 b. $P(A) + P(B) = \frac{9}{8}$, $P(A) = 1 - P(A^c) = 1 - \frac{5}{8} = \frac{3}{8}$, $P(B) = \frac{6}{8}$
 c. $P(A \cup B^c) = P(A \setminus B) = P(A) - P(A \cap B) = \frac{3}{8} - \frac{1}{4} = \frac{1}{8}$
 d. $P(A^c \cap B) = \frac{1}{2}$
 e. $P(A^c \cup B^c) = \frac{3}{4}$
 f. $\frac{1}{8}$.

9. a. Two digits are drawn in succession from tickets numbered 1 to 5. Determine the probability that an odd digit will be selected (i) first time (ii) second time (iii) both times.
 b. From 25 tickets marked 1 to 25 inclusive, one is drawn at random. Find the probability that
 i. it is a multiple of 5 or 7
 ii. it is a multiple of 3 or 7

- Ans. a. (i) $\frac{12}{20} = \frac{3}{5}$ (ii) $\frac{12}{20} = \frac{3}{5}$ (iii) $\frac{6}{20} = \frac{3}{10}$
 b. (i) $\frac{8}{25}$ (ii) $\frac{10}{25}$.

Probability

10. A lot contains 10 good articles, 4 with minor defects and 2 with major defects. 2 articles are chosen from the lot at random (without replacement). Find the probability that (i) both are good (ii) both have major defects (iii) at least one is good (iv) at most one is good (v) exactly one is good (vi) neither has major defects (vii) neither is good.

- Ans. i. $P(\text{both are good}) = \frac{{}^{10}C_2}{{}^{16}C_2} = \frac{3}{8}$
 ii. $P(\text{both have major defects}) = \frac{{}^2C_2}{{}^{16}C_2} = \frac{1}{120}$
 iii. $P(\text{at least one is good}) = \frac{{}^{10}C_1 \times {}^6C_1 + {}^{10}C_2}{{}^{16}C_2} = \frac{7}{8}$

$$\text{iv. } P(\text{at most one is good}) = \frac{{}^{10}C_0 \times {}^6C_2 + {}^{10}C_1 \times {}^6C_1}{{}^{16}C_2} \\ = \frac{5}{8}$$

$$\text{v. } P(\text{exactly one is good}) = \frac{{}^{10}C_1 \times {}^6C_1}{{}^{16}C_2} = \frac{1}{2}$$

$$\text{vi. } P(\text{neither has major defects}) = \frac{{}^{14}C_2}{{}^{16}C_2} = \frac{91}{120}$$

$$\text{vii. } P(\text{neither is good}) = P(\text{both are defected}) \\ = \frac{{}^6C_2}{{}^{16}C_2} = \frac{1}{8}$$

11. What is the probability that (a) non leap year
(b) leap year should have 53 sundays?

$$\text{Ans. (a) } \frac{1}{7} \quad \text{(b) } \frac{2}{7}$$

Hint:

$$\text{a. } \frac{365}{7} = 52 \text{ weeks} + 1 \text{ day:}$$

$$\text{b. } \frac{366}{7} = 52 \text{ weeks} + 2 \text{ days:}$$

$$SM, MT, TW, WTh, ThF, FS, SS^*$$

12. A bag contains 40 tickets numbered 1, 2, 3, ...
40 of which 4 are drawn at random and ar-
ranged in ascending order $t_1 < t_2 < t_3 < t_4$.
Find the probability of t_3 being 25.

$$\text{Ans. } \frac{{}^{24}C_2 \times {}^{15}C_1}{{}^{40}C_4} = \frac{414}{9139}$$

Hint: t_1, t_2 can come in ${}^{24}C_2$ ways
 t_4 in ${}^{15}C_1$ ways.

13. A bag contains eight white and six red marbles.
Find the probability of drawing two marbles of
the same colour.

$$\text{Ans. } \frac{{}^8C_2}{{}^{14}C_2} + \frac{{}^6C_2}{{}^{14}C_2} = \frac{28}{91} + \frac{15}{91} = \frac{43}{91}$$

14. A box I contains four tickets numbered 1,
2, 3, 4 and another box II contains six tick-
ets numbered 2, 4, 6, 7, 8, 9. If one of the
two boxes is chosen at random and a ticket is
drawn at random from the chosen box, find the
probabilities that the ticket drawn is numbered
(i) 2 or 4 (ii) 3 (iii) 1 or 9.

$$\text{Ans. i. } \frac{1}{2} \cdot \frac{2}{4} + \frac{1}{2} \cdot \frac{2}{6} = \frac{5}{12}$$

$$\text{ii. } \frac{1}{2} \cdot \frac{1}{4} + \frac{1}{2} \cdot 0 = \frac{1}{8}$$

$$\text{iii. } \frac{1}{2} \cdot \frac{1}{4} + \frac{1}{2} \cdot \frac{1}{6} = \frac{5}{24}$$

Independent trials

15. A missile hits its target with probability 0.3.
How many missiles should be fired so that there

is at least an 80% probability of hitting a target?

Ans. At least five missiles should be fired.

$$\text{Hint: } 1 - (\text{no hit}) = 1 - (1 - 0.3)^n \\ = 1 - (0.7)^n > 0.8$$

16. A cricket team wins (W) with probability
0.6, loses (L) with probability 0.3 and draws
(D) with probability 0.1. The team plays 3
games.

(i) Determine the elements of the event A that
the team wins at least twice and does not lose,
and find $P(A)$. (ii) Determine the elements of
the event B that the team wins, loses and draws
and find $P(B)$.

$$\text{Ans. i. } P(A) = P(WWW) + P(WWD) + P(WDW) \\ + P(DWW) = (0.6)(0.6)(0.6) \\ + (0.6)(0.6)(0.1) + (0.6)(0.1)(0.6) + (0.1) \\ (0.6)(0.6) = 0.324$$

$$\text{ii. } P(B) = P(WLD) + P(WDL) + P(LDW) \\ + P(DWL) + P(DLW) \\ = 6(0.6)(0.3)(0.1) = 0.108$$

17. A, B, C hit a target with probabilities $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}$
respectively. If all of them fire at the target, find
the probability P that (i) none of them hits the
target (ii) at least one of them hits the target.

$$\text{Ans. i. } P(\bar{A} \cap \bar{B} \cap \bar{C}) = P(\bar{A})P(\bar{B})P(\bar{C}) = \\ \frac{1}{2} \cdot \frac{1}{3} \cdot \frac{1}{4} = \frac{1}{24}$$

$$\text{ii. } P(\text{at least one hits}) = 1 - P(\text{no hit}) = 1 - \\ \frac{1}{24} = \frac{23}{24}$$

18. A and B alternately throw pair of dice. A wins
if he throws six before B throws seven and B
wins if he throws seven before A throws six.
If A begins, show that his chance of winning
is $\frac{30}{61}$.

$$\text{Ans. } P(6) = \frac{5}{36}, P(7) = \frac{1}{6},$$

$$P(A) = P(A \text{ or } \bar{A}\bar{B}A \text{ or } \bar{A}\bar{B}\bar{A}\bar{B}A \text{ or } \dots)$$

$$P(A) = P(A) + P(\bar{A}\bar{B}A) + P(\bar{A}\bar{B}\bar{A}\bar{B}A) + \dots$$

$$= P(A) + P(\bar{A}) \cdot P(\bar{B}) \cdot P(A) + \dots$$

$$= \frac{5}{36} + \frac{31}{36} \cdot \frac{5}{6} \cdot \frac{5}{36} + \dots$$

$$= \frac{5/36}{1 - (155/216)} = \frac{30}{61}$$

26.18 — HIGHER ENGINEERING MATHEMATICS—VII

19. A, B, C can hit a target with probability $\frac{3}{5}, \frac{2}{5}, \frac{3}{4}$ respectively. Determine the probability that (i) two shots hit (ii) at least two shots hit.

Ans. i. $\frac{3}{5} \cdot \frac{2}{5} (1 - \frac{3}{4}) + \frac{2}{5} \cdot \frac{3}{4} (1 - \frac{3}{5}) + \frac{3}{4} \cdot \frac{3}{5} (1 - \frac{2}{5}) = 0.45$

ii. $0.45 + P(\text{all hit}) = 0.45 + \frac{3}{5} \cdot \frac{2}{5} \cdot \frac{3}{4} = 0.63$

Conditional probability

20. A pair of fair dice is thrown. Find the probability p that the sum is 10 or greater if (i) a 5 appears on the first die (ii) a 5 appears on at least one of the dice.

Ans. i. $p = \frac{2}{6}$

Hint: 5 appears on first die:

(5, 1)(5, 2)(5, 3)(5, 4)(5, 5)(5, 6): 6

Favourable cases for sum ≥ 10 is (5, 5), (5, 6): 2

ii. $p = \frac{3}{11}$.

Hint: 5 appears on at least one of the dice (reduced sample space)

(5, 1), (5, 2), (5, 3), (5, 4), (5, 5), (5, 6)(1, 5), (2, 5), (3, 5), (4, 5), (6, 5): 11

Favourable cases for sum ≥ 10 is (5, 5), (5, 6), (6, 5): 3.

21. 2 digits are selected at random from the digits 1 through 9. If the sum is even, find the probability p that both the numbers are odd.

Ans. $p = \frac{10}{16}$

Hint: $e + e = e, o + d = e, 4C_2 = 6$ ways of two $e, 5C_2 = 10$ ways of two o . 16 ways to choose two for even sum.

22. A box contains 4 bad and 6 good tubes. 2 tubes are drawn out from the box at a time. One of them is found to be good. Determine the probability that the other one is also good.

Ans. $P(B/A) = \frac{P(A \cap B)}{P(A)} = \frac{1/3}{6/10} = \frac{5}{9}$ where

A : first is good

B : second is good.

23. A bag contains 10 gold and 8 silver coins. Two successive drawings of 4 coins are made such that (i) coins are replaced before the second trial (ii) coins are not replaced before the sec-

ond trial. Determine the probability that the first drawing will give 4 gold and the second four silver coins.

Ans. i. $P(A \cap B) = P(A)P(B) = \frac{10C_4}{18C_4} \cdot \frac{8C_4}{18C_4}$

ii. $P(A \cap B) = P(A)P(B/A) = \frac{10C_4}{18C_4} \cdot \frac{8C_4}{14C_4}$

24. Bag I contains 4 white, 3 black marbles and bag II contains 3 white, 5 black marbles. One marble is drawn from the bag I and placed unseen in the bag II. Determine the probability that a marble *now* drawn from bag II is black.

Ans. $P[(B_1 \cap B_2) \text{ or } (W_1 \cap B_2)]$

$= P(B_1 \cap B_2) + P(W_1 \cap B_2)$

$= P(B_1)P(B_2/B_1) + P(W_1)P(B_2/W_1)$

$= \frac{3}{7} \cdot \frac{6}{9} + \frac{4}{7} \cdot \frac{5}{9} = \frac{38}{63}$.

26.4 THEOREM OF TOTAL PROBABILITY (or THE RULE OF ELIMINATION)

Theorem: Let $B_1, B_2, \dots, B_k$ constitute a partition of the sample space S with $P(B_i) \neq 0$ for $i = 1, 2, \dots, k$. Then for any event A of S

$$P(A) = \sum_{i=1}^k P(B_i \cap A) = \sum_{i=1}^k P(B_i)P(A/B_i)$$

Proof: Since $B_1, B_2, \dots, B_k$ constitute a partition

$$S = \bigcup_{i=1}^k B_i$$

Fig. 26.10

and $B_i \cap B_j = \phi$ for any i and j , i.e., their union is S and B_i 's are mutually disjoint sets. Now (refer Fig. 26.10)

$$A = A \cap S = A \cap \left(\bigcup_{i=1}^k B_i \right)$$

$$\begin{aligned}
 &= A \cap (B_1 \cup B_2 \cup \dots \cup B_k) \\
 &= (A \cap B_1) \cup (A \cap B_2) \cup \dots \cup (A \cap B_k).
 \end{aligned}$$

The sets $A \cap B_1, A \cap B_2, \dots, A \cap B_k$ are all mutually disjoint sets. Applying the additive rule for mutually exclusive events, we have

$$\begin{aligned}
 P(A) &= P[(A \cap B_1) \cup (A \cap B_2) \cup \dots \cup (A \cap B_k)] \\
 &= P(B_1 \cap A) + P(B_2 \cap A) + \dots + P(B_k \cap A)
 \end{aligned}$$

Now applying multiplicative rule

$$P(A) = \sum_{i=1}^k P(B_i \cap A) = \sum_{i=1}^k P(B_i)P(A/B_i).$$

WORKED OUT EXAMPLES

Theorem on total probability

Example 1: Police plan to enforce speed limits by using radar traps at 4 different locations within the city limits. The radar traps at each of these locations L_1, L_2, L_3, L_4 are operated for 40%, 30%, 20% and 30% of the time. If a person who is speeding on his way to work has probabilities of 0.2, 0.1, 0.5 and 0.2 respectively of passing through these locations, what is the probability that he will be fined (for over speed)?

Solution: A : event of passing through locations and caught by radar traps.

By theorem on total probability

$$\begin{aligned}
 P(A) &= P(L_1)P(A/L_1) + P(L_2)P(A/L_2) \\
 &\quad + P(L_3)P(A/L_3) + P(L_4)P(A/L_4). \\
 &= (0.4)(0.2) + (0.3)(0.1) + (0.2)(0.5) + (0.3)(0.2) \\
 &= 0.27.
 \end{aligned}$$

Example 2: Suppose colored balls are distributed in three indistinguishable boxes as follows:

| | Box 1 | Box 2 | Box 3 |
|-------|-------|-------|-------|
| Red | 2 | 4 | 3 |
| White | 3 | 1 | 4 |
| Blue | 5 | 3 | 3 |
| Total | 10 | 8 | 10 |

A box is selected at random from which a ball is selected at random. What is the probability that the ball is colored (i) red (ii) white (iii) black?

Solution: A : colour of the ball (red, white or black)

$$\text{Box 1} = B_1, \text{Box 2} = B_2, \text{Box 3} = B_3$$

By theorem on total probability

$$\begin{aligned}
 P(\text{red colour}) &= P(B_1)P(A/B_1) + P(B_2)P(A/B_2) \\
 &\quad + P(B_3)P(A/B_3)
 \end{aligned}$$

Since the three boxes are indistinguishable, probability of choosing them is $\frac{1}{3}$ i.e., $P(B_1) = P(B_2) = P(B_3) = \frac{1}{3}$. Thus

$$P(R) = \frac{1}{3} \cdot \frac{2}{10} + \frac{1}{3} \cdot \frac{4}{8} + \frac{1}{3} \cdot \frac{3}{10} = \frac{1}{3}$$

since $P(\text{Red given box 1}) = \frac{2}{10}$, $P(R/B_2) = 4/8$, $P(R/B_3) = 3/10$ etc.

Similarly,

$$\begin{aligned}
 P(W) &= \frac{1}{3} \cdot \frac{3}{10} + \frac{1}{3} \cdot \frac{1}{8} + \frac{1}{3} \cdot \frac{4}{10} = \frac{198}{720} \\
 P(B) &= \frac{1}{3} \cdot \frac{5}{10} + \frac{1}{3} \cdot \frac{3}{8} + \frac{1}{3} \cdot \frac{3}{10} = \frac{94}{240}.
 \end{aligned}$$

EXERCISE

Theorem on total probability

- Three machines A, B and C produce respectively 50%, 30% and 20% of the total number of items of a factory. The percentage of defective output of these machines are 3%, 4% and 5%. If an item is selected at random, find the probability that the item is defective.

Ans. $P(\text{defective})$

$$\begin{aligned}
 &= P(A)P(D/A) + P(B)P(D/B) + P(C)P(D/C) \\
 &= (0.5)(0.03) + (0.3)(0.04) + (0.2)(0.05) \\
 &= 0.037
 \end{aligned}$$

26.20 — HIGHER ENGINEERING MATHEMATICS—VII

2. The probability that X, Y, Z will be elected as president of a club are 0.3, 0.5 and 0.2 respectively. The probability that membership fees of club are increased is 0.8 if X is elected president, is 0.1 if Y is elected and is 0.4 if Z is elected. What is the probability that there will be an increase in membership fee?

Ans. $P(\text{fee increased}) = (0.3)(0.8) + (0.5)(0.1) + (0.2)(0.4) = 0.37$

3. Box I contains 10 white and 3 black balls while Box II contains 3 white and 5 black balls. Two balls are drawn at random from Box I and placed in Box II. Then 1 ball is drawn at random from box II. What is the probability that it is a white ball?

Ans. 59/130

Hint: B_1 : event of drawing 2 white balls, from Box I

B_2 : 2B from Box I, B_3 : one W and one B from Box I.

A : drawing W from box II (after transfer)

$$\begin{aligned} P(A) &= P(B_1)P(A/B_1) + P(B_2)P(A/B_2) \\ &\quad + P(B_3)P(A/B_3) \\ &= \frac{10C_2}{13C_2} \cdot \frac{5}{10} + \frac{3C_2}{13C_2} \cdot \frac{3}{10} \cdot \frac{10C_1 3C_1}{13C_2} \cdot \frac{4}{10} \end{aligned}$$

26.5 BAYES' THEOREM (or BAYES' RULE)

Theorem 1: Let the sample space S be partitioned into k subsets $B_1, B_2, \dots, B_k$ with $P(B_i) \neq 0$ for $i = 1, 2, \dots, k$. For any arbitrary event A in S with $P(A) \neq 0$,

$$P(B_r/A) = \frac{P(B_r \cap A)}{\sum_{i=1}^k P(B_i \cap A)} = \frac{P(B_r)P(A/B_r)}{\sum_{i=1}^k P(B_i)P(A/B_i)} \quad (1)$$

for $r = 1, 2, \dots, k$

Proof: From the definition of conditional probability

$$P(B_r/A) = \frac{P(B_r \cap A)}{P(A)} \quad (2)$$

From the theorem of total probability or the rule of elimination

$$P(A) = \sum_{i=1}^k P(B_i \cap A) = \sum_{i=1}^k P(B_i)P(A/B_i) \quad (3)$$

Also from the multiplication rule

$$P(B_r \cap A) = P(B_r)P(A/B_r) \quad (4)$$

Substituting (3), (4) in (2), we get (1).

Note: Bayes' theorem is also known as formula for the probability of "causes", i.e., probability of a particular (cause) B_r given that event A has happened (already).

$P(B_i)$ is 'a priori probability' known even before the experiment, $P(A/B_i)$ "likelihoods" and $P(B_i/A)$ 'posteriori probabilities' determined after the result of the experiment.

WORKED OUT EXAMPLES

Bayes' theorem

Example 1: In a certain college 25% of boys and 10% of girls are studying mathematics. The girls constitute 60% of the student body. (a) What is the probability that mathematics is being studied? (b) If a student is selected at random and is found to be studying mathematics, find the probability that the student is a girl? (c) a boy?

Solution: Given that $P(\text{Boy}) = P(B) = \frac{40}{100} = \frac{2}{5}$;
 $P(\text{Girl}) = P(G) = \frac{60}{100} = \frac{3}{5}$,
 probability that maths is studied given that the student is a boy $= P(M/B) = \frac{25}{100} = \frac{1}{4}$.
 Similarly, $P(M/G) = \frac{10}{100} = \frac{1}{10}$

a. Probability that maths is studied

$$= P(M) = P(G)P(M/G) + P(B)P(M/B)$$

by theorem on total probability

$$P(M) = \frac{3}{5} \cdot \frac{1}{10} + \frac{2}{5} \cdot \frac{1}{4} = \frac{4}{25}$$

b. Bayes' theorem:

Probability that a maths student is a girl

$$= P(G/M) = \frac{P(G)P(M/G)}{P(M)} = \frac{\frac{3}{5} \cdot \frac{1}{10}}{\frac{4}{25}} = \frac{3}{8}$$

c. Probability that a maths student is a boy

$$= P(B/M) = \frac{P(B)P(M/B)}{P(M)} = \frac{\frac{2}{5} \cdot \frac{1}{4}}{\frac{4}{25}} = \frac{5}{8}$$

Example 2: A businessman goes to hotels X, Y, Z 20%, 50%, 30% of the time, respectively. It is known that 5%, 4%, 8% of the rooms in X, Y, Z hotels have faulty plumbing. (a) Determine the probability that the businessman goes to hotel with faulty plumbing (b) What is the probability that businessman's room having faulty plumbing is assigned to hotel Z?

Solution: A : event of faulty plumbing

$$B_1 = X, B_2 = Y, B_3 = Z$$

a. By theorem on total probability

$$\begin{aligned} P(\text{Faulty plumbing}) &= P(A) = \sum_{i=1}^3 P(B_i)P(A/B_i) \\ &= P(X)P(A/X) + P(Y)P(A/Y) + P(Z)P(A/Z) \end{aligned}$$

It is known (given) that

$$P(B_1) = P(X) = \frac{20}{100} = 0.2,$$

$$P(B_2) = P(Y) = \frac{50}{100} = 0.5,$$

$$P(B_3) = P(Z) = 0.3$$

$$P(A/X) = \frac{5}{100} = 0.05,$$

$$P(A/Y) = \frac{4}{100} = 0.04,$$

$$P(A/Z) = \frac{8}{100} = 0.08.$$

Thus

$$\begin{aligned} P(\text{Faulty plumbing}) &= P(A) = (0.2)(0.05) \\ &\quad + (0.5)(0.04) + (0.3)(0.08) \\ &= 0.054. \end{aligned}$$

b. $P(\text{Assigned to hotel Z given that room has faulty plumbing}) = P(Z/A).$

By Bayes' theorem

$$P(Z/A) = \frac{P(Z)P(A/Z)}{P(A)} = \frac{(0.3)(0.08)}{0.054} = \frac{4}{9}.$$

EXERCISE

Bayes' theorem

- Companies B_1, B_2, B_3 produce 30%, 45% and 25% of the cars respectively. It is known that 2%, 3% and 2% of the cars produced from B_1, B_2 and B_3 are defective. (a) What is the probability that a car purchased is defective? (b) If a car purchased is found to be defective what is the probability that this car is produced by company B_3 ?

Ans: a. $P(\text{Defective}) = (0.3)(0.02) + (0.45)(0.03) + (0.25)(0.02) = 0.0245$

$$\text{b. } P(B_3/D) = \frac{(0.25)(0.02)}{P(D)} = 10/49.$$

- Of the three men, the chances that a politician, a businessman and an academician will be appointed as a vice-chancellor of a university are 0.50, 0.30 and 0.20 respectively. Probability that research is promoted by these people if they are appointed as V.C. are 0.3, 0.7 and 0.8 respectively. (a) Determine the probability that research is promoted in the university. (b) If research is promoted in the university, what is the probability that the V.C. is an academician? (c) A businessman?

Ans: a. $P(\text{Research}) = (0.5)(0.3) + (0.3)(0.7) + (0.2)(0.8) = 0.52$

$$\text{b. } P(\text{Academician/Research}) = \frac{(0.2)(0.8)}{0.52} = 0.30769$$

$$\text{c. } P(\text{Businessman/Research}) = \frac{(0.3)(0.7)}{0.52} = 0.4038.$$

- Suppose three companies X, Y, Z produce T.V's. X produce twice as many as Y while Y and Z produce the same number. It is known that 2% of X, 2% of Y and 4% of Z are defective. All the TV's produced are put into one shop and then one TV is chosen at random.

a. What is the probability that the TV is defective?

26.22 — HIGHER ENGINEERING MATHEMATICS—VII

b. Suppose a TV chosen is defective, what is the probability that this TV is produced by company X?

$$\begin{aligned} \text{Ans: a. } P(D) &= P(X)P(D/X) + P(Y)P(D/Y) + P(Z)P(D/Z) \\ &= \frac{1}{2}(0.02) + \frac{1}{4}(0.02) + \frac{1}{4}(0.04) = 0.025 \end{aligned}$$

$$\text{b. } P(X/D) = \frac{(0.02)(\frac{1}{2})}{0.025} = 0.40$$

4. Box I contains 1 white, 2 red, 3 green balls, Box II contains 2 white, 3 red, 1 green balls, Box III contains 3 white, 1 red, 2 green balls. Two balls are drawn from a box chosen at random. These are found to be one white and one red. Determine the probability that the balls so drawn came from box II.

$$\text{Ans: } \frac{6}{11}$$

Hint: $P(I) = P(II) = P(III) = \frac{1}{3}$,
A: event: 2 balls white and red drawn

$$P(A/I) = (1C_1)(2C_1)/6C_2 = \frac{2}{15},$$

$$P(A/II) = (2C_1)(3C_1)/6C_2 = \frac{2}{5},$$

$$P(A/III) = (3C_1)(1C_1)/6C_2 = \frac{1}{5},$$

$$P(II/A) = \frac{\frac{1}{3} \cdot \frac{2}{5}}{\frac{1}{3} \cdot \frac{2}{15} + \frac{1}{3} \cdot \frac{2}{5} + \frac{1}{3} \cdot \frac{1}{5}} = \frac{6}{11}.$$

5. For a certain binary communication channel, the probability that a transmitted '0' is received as a '0' is 0.95 and the probability that a transmitted '1' is received as '1' is 0.90. If the probability that a '0' is transmitted is 0.4, find the probability that (i) a '1' is received (ii) a '1' was transmitted given that a '1' was received.

$$\text{Ans: i. } 0.56 \quad \text{ii. } 27/28$$

Hint: A = event of transmitting '1',
 $\bar{A}$ = event of transmitting '0'

B = event of receiving '1', $\bar{B}$ = event of receiving '0'.

$$\text{i. } P(B) = P(A)P(B/A) + P(\bar{A})P(B/\bar{A}) = (0.6)(0.9) + (0.4)(0.05) = 0.56$$

$$\text{ii. } P(A/B) = \frac{P(A)P(B/A)}{P(B)} = \frac{(0.6)(0.9)}{0.56} = \frac{27}{28}.$$

6. A student has to answer a multiple-choice question with 5 alternatives. What is the probability that the student knew the answer given that he answered it correctly?

Ans: $5p/(4p + 1)$ where p = probability that he knew the correct answer.

Hint: B_1 : knew right answer, B_2 : guesses right answer, A: gets the right answer

$$P(B_1/A) = \frac{(p)(1)}{(p)(1) + (1-p)\left(\frac{1}{5}\right)}$$

$$\text{since } P(A/B_2) = \frac{1}{5}.$$

Chapter 27

Probability Distributions

INTRODUCTION

Probability distribution is the theoretical counterpart of frequency distribution, and plays an important role in the theoretical study of populations. A probability model can be developed, for a given idealized conditions in a game of chance by incorporating all the factors that have a bearing on this game. In building such model, the empirical data of frequency distribution, A.M., variance etc. are to be taken into account. In the discrete case we consider discrete uniform distribution, Binomial, Hypergeometric, Poisson distributions. The continuous probability distributions we study are uniform distribution, normal distribution, exponential, gamma, Weibull distributions which are of great practical importance.

Recall that in a random experiment, the outcomes (or results) are governed by chance mechanism and the sample space S of such a random experiment consists of all outcomes of the experiment. When the elements (outcomes/events) of the sample space are non-numeric, they can be quantified by assigning a real number to every event of the sample space. This assignment rule, known as the random variable (R.V.), provides the power of abstraction and thus discards unimportant finest-grain description of the sample space.

A **random variable** X on a sample space S is a function $X: S \rightarrow R$ from S to the set of real numbers R , which assigns a real number $X(s)$ to each sample point s of S (refer Fig. 27.1).

Fig. 27.1

Range space R_X : is the set of all possible values of X is a subset of real numbers R .

Although X is called a random “variable” note that it is infact a “single-valued function”.

Notation: If R.V. is denoted by X , then x (corresponding small letter) denotes one of its values.

Discrete

A R.V. X is said to be discrete R.V. if its set of possible outcomes, the sample space S , is countable (finite or an unending sequence with as many elements as there are whole numbers).

Continuous

A R.V. X is said to be continuous R.V. if S contains infinite numbers equal to the number of points on a line segment.

27.1 PROBABILITY DISTRIBUTIONS

Discrete Probability Distributions

Each event in a sample space has certain probability (or chance) of occurrence (or happening). A formula

27.2 — HIGHER ENGINEERING MATHEMATICS—VII

representing all these probabilities which a discrete R.V. assumes, is known as the discrete probability distribution.

Example: Let X denote the discrete R.V. which denotes the minimum of the two numbers that appear in a single throw of a pair of fair dice. Then X is a function from the sample space S consisting of 36 ordered pairs $\{(1, 1), (1, 2), \dots, (6, 6)\}$ to a subset of real numbers $\{1, 2, 3, 4, 5, 6\}$.

The event minimum 5 can appear in the following cases (occurrences) (5, 5), (5, 6), (6, 5). Thus R.V. X assigns to this event of the sample space a real number 3. The probability of such an event happening is $\frac{3}{36}$ since there are 36 exhaustive cases. This is represented as

$$P(X = x_i) = p_i = f(x_i) = P(X = 5) = f(5) = \frac{3}{36}.$$

Calculating in a similar way the other probabilities, the distribution of probabilities of this discrete R.V. is denoted by the discrete probability distribution as follows:

| | | | | | | |
|--------------|-----------------|----------------|----------------|----------------|----------------|----------------|
| $X = x_i$ | 1 | 2 | 3 | 4 | 5 | 6 |
| $P(X = x_i)$ | $\frac{11}{36}$ | $\frac{9}{36}$ | $\frac{7}{36}$ | $\frac{5}{36}$ | $\frac{3}{36}$ | $\frac{1}{36}$ |
| $= f(x_i)$ | | | | | | |
| $= p_i$ | | | | | | |

Discrete probability distribution, probability function or probability mass function of a discrete R.V. X is the function $f(x)$ satisfying the following conditions:

- i. $f(x) \geq 0$
- ii. $\sum_x f(x) = 1$
- iii. $P(X = x) = f(x)$.

Thus probability distribution is the set of ordered pairs $(x, f(x))$, i.e., outcome x and its probability (chance) $f(x)$.

Cumulative distribution or simply *distribution* of a discrete R.V. X is $F(x)$ defined by

$$F(x) = P(X \leq x) = \sum_{t \leq x} f(t) \quad \text{for } -\infty < x < \infty.$$

It follows that

$$F(-\infty) = 0, \quad F(+\infty) = 1,$$

$$p(x_j) = P(X = x_j) = F(x_j) - F(x_{j-1}).$$

Continuous Probability Distributions

For a continuous R.V. X , the function $f(x)$ satisfying the following, is known as the probability density function (P.D.F.) or simply density function (Fig. 27.2).

Fig. 27.2

- i. $f(x) \geq 0$
- ii. $\int_{-\infty}^{\infty} f(x)dx = 1$
- iii. $P(a < X < b) = \int_a^b f(x)dx = \text{area under } f(x) \text{ between ordinates } x = a \text{ and } x = b.$

Note 1: $P(a < X < b) = P(a \leq X < b)$
 $= P(a < X \leq b) = P(a \leq X \leq b)$

i.e., inclusion or non-inclusion of end points, does not change the probability, which is *not* the case in the discrete distributions.

Note 2: Probability at a point,

$$P(X = a) = \int_{a-\Delta x}^{a+\Delta x} f(x)dx.$$

Cumulative Distribution

For a continuous R.V. X , with P.D.F. $f(x)$, the cumulative distribution $F(x)$ is defined as

$$F(x) = P(X \leq x) = \int_{-\infty}^x f(t)dt, \quad -\infty < x < \infty$$

It follows that

$$F(-\infty) = 0, \quad F(+\infty) = 1, \quad 0 \leq F(x) \leq 1$$

for $-\infty < x < \infty$.

$$f(x) = \frac{dF(x)}{dx} = F'(x) \geq 0 \quad \text{and}$$

$$P(a < X < b) = F(b) - F(a).$$

Expectation

The behaviour of a R.V. (either discrete or continuous) is completely characterized by the distribution function $F(x)$ or density $f(x)$ [$P(x_i)$ in discrete case]. Instead of a function, a more compact description can be made by a single numbers such as mean (expectation), median and mode known as measures of central tendency of the R.V. X .

Expectation or mean or expected value

Expectation or mean or expected value of a random variable X , denoted by $E(X)$ or μ , is defined as

$$E(X) = \begin{cases} \sum_i x_i f(x_i), & \text{if } X \text{ is discrete} \\ \int_{-\infty}^{\infty} x f(x) dx, & \text{if } X \text{ is continuous} \end{cases}$$

Note 1: x is median if $P(X < x) \leq \frac{1}{2}$ and $P(X > x) \leq \frac{1}{2}$.

Note 2: x is mode for which $f(x)$ or $P(x_i)$ attains its maximum.

Variance

Variance characterizes the variability in the distributions, since two distributions with *same* mean can still have different dispersion of data about their means.

Variance of R.V. X is

$$\sigma^2 = E[(X - \mu)^2] = \sum_x (X - \mu)^2 f(x), \text{ for } X \text{ discrete}$$

$$\sigma^2 = E[(X - \mu)^2] = \int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx,$$

for X continuous.

Standard deviation (S.D.) denoted by σ , is the positive square root of variance.

Result: $\sigma^2 = E(X^2) - \mu^2$

$$\begin{aligned} \text{Since } \sigma^2 &= \sum_x (x - \mu)^2 f(x) = \sum_x (x^2 - 2\mu x + \mu^2) f(x) \\ &= \sum_x x^2 f(x) - 2\mu \sum_x x f(x) + \mu^2 \sum_x f(x) \\ &= E(X^2) - 2\mu \cdot \mu + \mu^2 \cdot 1 = E(X^2) - \mu^2 \end{aligned}$$

$$\text{Since } \mu = \sum_x x f(x), \sum_x f(x) = 1.$$

Similar result follows for continuous R.V. X , with $\sum$ replaced by integration from $-\infty$ to ∞ .

Note 1: In a gambling game, expected value E of the game is considered to be the value of the game to the player. Game is favourable to the player if $E > 0$, unfavourable if $E < 0$, fair if $E = 0$.

Note 2: Mathematical expectation $E = a_1 p_1 + a_2 p_2 + \dots + a_k p_k$ where the probabilities of obtaining the amounts $a_1, a_2, \dots$ or a_k are $p_1, p_2, \dots p_k$ respectively.

27.2 CHEBYSHEV'S THEOREM

Theorem: Let μ and σ be the mean and standard deviation of a random variable X with probability density $f(X)$. Then the probability that X will assume a value within k standard deviations of the mean is at least $1 - \frac{1}{k^2}$, for any positive constant k . Symbolically

$$P(\mu - k\sigma < X < \mu + k\sigma) = P(|X - \mu| < k\sigma) \geq 1 - \frac{1}{k^2}$$

Proof: By definition

$$\begin{aligned} \sigma^2 &= \text{variance} = E[(X - \mu)^2] = \int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx \\ &= \int_{-\infty}^{\mu - k\sigma} (x - \mu)^2 f(x) dx + \int_{\mu - k\sigma}^{\mu + k\sigma} (x - \mu)^2 f(x) dx \\ &\quad + \int_{\mu + k\sigma}^{\infty} (x - \mu)^2 f(x) dx \end{aligned}$$

Since the second integral on the R.H.S. is non-negative, we get an inequality of the form

$$\sigma^2 \geq \int_{-\infty}^{\mu - k\sigma} (x - \mu)^2 f(x) dx + \int_{\mu + k\sigma}^{\infty} (x - \mu)^2 f(x) dx$$

For the first integral $x \leq \mu - k\sigma$ and for the second integral $x \geq \mu + k\sigma$. In either case, we have

$$\begin{aligned} x - \mu &\leq -k\sigma \quad \text{or} \quad x - \mu \geq k\sigma \quad \text{i.e.,} \quad |x - \mu| \geq k\sigma \\ \text{or} \quad (x - \mu)^2 &\geq k^2 \sigma^2. \end{aligned}$$

Replacing $(x - \mu)^2$ by $k^2 \sigma^2$ in the two integrals,

$$\sigma^2 \geq \int_{-\infty}^{\mu - k\sigma} k^2 \sigma^2 f(x) dx + \int_{\mu + k\sigma}^{\infty} k^2 \sigma^2 f(x) dx$$

Rewriting

$$P(|X - \mu| \geq k^2 \sigma^2) = \int_{-\infty}^{\mu - k\sigma} f(x) dx + \int_{\mu + k\sigma}^{\infty} f(x) dx \leq \frac{1}{k^2}$$

By complementation rule,

$$\int_{\mu - k\sigma}^{\mu + k\sigma} f(x) dx = 1 - \left[\int_{-\infty}^{\mu - k\sigma} f(x) dx + \int_{\mu + k\sigma}^{\infty} f(x) dx \right]$$

$$\begin{aligned} \text{Hence } P(|X - \mu| < k\sigma) &= P(\mu - k\sigma < X < \mu + k\sigma) \\ &= \int_{\mu - k\sigma}^{\mu + k\sigma} f(x) dx \geq 1 - \frac{1}{k^2} \end{aligned}$$

Note 1: Put $k\sigma = C > 0$ then

$$P\{|X - \mu| \geq C\} \leq \frac{\sigma^2}{C^2}$$

$$\text{i.e., } P\{|X - E(X)| \geq C\} \leq \frac{\text{var}(X)}{C^2}$$

$$\text{or } P\{|X - \mu| < C\} \geq 1 - \frac{\sigma^2}{C^2}$$

$$\text{i.e., } P\{|X - E(X)| < C\} \geq \frac{1 - \text{var}(X)}{C^2}$$

Note 2: Chebyshev's theorem (1853) is "distribution-free" since it is applicable to any unknown distribution and gives only the lower bound for the probability.

WORKED OUT EXAMPLES

Chebyshev's theorem

Example 1: Determine the smallest value of k in the Chebyshev's theorem for which the probability is (a) at least 0.95 (b) at least 0.99.

Solution: From Chebyshev's theorem, we have the probability as

$$P(|X - \mu| < k\sigma) \geq 1 - \frac{1}{k^2}$$

$$\text{a. Probability} = 0.95 \geq 1 - \frac{1}{k^2} \quad \text{or } k^2 \leq \frac{1}{0.05} \\ \therefore k = \sqrt{20} = 4.472$$

$$\text{b. Probability} = 0.99 \geq 1 - \frac{1}{k^2} \quad \text{or } k^2 \leq \frac{1}{0.01} \\ \therefore k = 10$$

Example 2: Find the probability, using Chebyshev's theorem, that the number of driving licences X issued by Road Transport Authority (R.T.A.) in a specific month is between 64 and 184 if the number of driving licences issued X is a random variable with $\mu = 124$ and $\sigma = 7.5$.

Solution: $X = \mu \pm k\sigma$,

$$\text{For 64, } 64 = 124 - k(7.5) \quad \therefore k = 8$$

$$\text{For 184, } 184 = 124 + k(7.5) \quad \therefore k = 8$$

$$P(|X - \mu| < \sigma) \geq 1 - \frac{1}{k^2} = 1 - \frac{1}{8^2} = 0.984375$$

Example 3: Suppose the amount of thiamine in a slice of 'modern' bread is a random variable X with $\mu = 0.260$ mg and $\sigma = 0.005$ mg. Using Chebyshev's theorem, between what values must be the thiamine content of (a) at least $\frac{35}{36}$ of all slices of 'modern' bread (b) at least $\frac{143}{144}$ of all slices of the 'modern' bread, lies.

Solution: By Chebyshev's theorem

$$P(|X - \mu| < k\sigma) \geq 1 - \frac{1}{k^2}$$

$$\text{a. Given } \frac{35}{36} = 0.972 \geq 1 - \frac{1}{k^2} \quad \therefore k \leq 6, \\ \mu = 0.26, \sigma = 0.005$$

$$\text{For } \mu - k\sigma = 0.260 - 6(0.005) = 0.230$$

$$\text{For } \mu + k\sigma = 0.260 + 6(0.005) = 0.290$$

Thus at least $\frac{35}{36}$ of all slices of bread will contain thiamine between 0.230 and 0.290.

$$\text{b. Given } \frac{143}{144} = 0.993 \geq 1 - \frac{1}{k^2} \quad \therefore k \leq 12$$

$$\text{For } \mu - k\sigma = 0.260 - 12(0.005) = 0.200$$

$$\text{For } \mu + k\sigma = 0.260 + 12(0.005) = 0.320$$

Thus at least $\frac{143}{144}$ of all slices of bread will contain thiamine between 0.200 and 0.320.

EXERCISE

Chebyshev's theorem

- Suppose X is a random variable such that $E(X) = 3$ and $E(X^2) = 13$. Calculate a lower bound for the probability that X lies between -2 and 8 using Chebyshev's theorem.

$$\text{Hint: } E(X) = \mu = 3, \sigma^2 = E(X^2) - \{E(X)\}^2 \\ = 13 - 9 = 4, \sigma = 2.$$

$$P\{3 - 2k < X < 3 + 2k\} \geq 1 - \frac{1}{k^2}, \text{ choose } k = \frac{5}{2}.$$

$$\text{Ans. } P(-2 < X < 8) \geq 1 - \frac{1}{\left(\frac{5}{2}\right)^2} = \frac{21}{25} = 0.84$$

2. The number of patients requiring I.C.U. in a hospital in a random variable with $\mu = 18$ and $\sigma = 2.5$. Determine the probability that there will be between 8 and 28 patients.

$$\text{Ans. } k = \frac{28-18}{2.5} = \frac{18-8}{2.5} = 4, \text{ the probability is at least } 1 - \frac{1}{4^2} = \frac{15}{16}$$

3. Let X be a random variable with an unknown probability distribution, with mean $\mu = 8$ and variance $\sigma^2 = 9$. Determine

$$(i) P(|X - 8| \geq 6) \quad (ii) P(-4 < X < 20)$$

$$\text{Ans. i. } P(|X - 8| \geq 6) = 1 - P(|X - 8| < 6) \\ = 1 - P(-6 < (X - 8) < 6) \\ = 1 - P[8 - (2)(3) < X < 8 + (2)(3)] \leq \frac{1}{4}$$

$$\text{ii. } P(-4 < X < 20) = \\ P[8 - (4)(3) < X < 8 + (4)(3)] \geq \frac{15}{16}.$$

4. Let X be the discrete random variable denoting the number appearing in a single throw of a fair die. Let $E(X) = \mu$

Using Chebyshev's theorem prove that

$$P[|X - \mu| > 2.5] < 0.47$$

while the actual probability is zero.

$$\text{Ans. } E(X) = \frac{1}{6}(1 + 2 + 3 + 4 + 5 + 6) = \frac{7}{2}, \\ E(X^2) = \frac{91}{6}$$

$$\text{var}(X) = E(X^2) - [E(X)]^2 = \frac{91}{6} - \frac{49}{4} = 2.9167$$

Choose $k = 2.5$

$$P\{|X - \mu| > 2.5\} < \frac{2.9167}{6.25} = 0.47$$

$$\text{Actual probability} = p = P\{|X - 3.5| > 2.5\} \\ = P\{X \text{ lies outside the limits } (3.5 - 2.5, 3.5 + 2.5)\} \\ = P\{X \text{ lies outside } (1, 6)\} = 0$$

since impossible event.

5. Apply Chebyshev's theorem to calculate

$$(i) P(5 < X < 15) \quad (ii) P(|X - 10| \geq 3)$$

$$(iii) P(|X - 10| < 3)$$

for a random variable X with mean $\mu = 10$ and variance $\sigma^2 = 4$.

Hint:

$$\text{i. } \mu - k\sigma = 10 - k2 = 5$$

$$\therefore k = \frac{5}{2}, \mu + k\sigma = 10 + k2 = 15$$

$$P(5 < X < 15) = P(10 - 2k < X <$$

$$10 + 2k) \geq 1 - \frac{1}{k^2} = 1 - \frac{4}{25} = \frac{21}{25}$$

$$\text{ii. } |X - 10| \geq 3 \quad \text{or} \quad -3 < X - 10 < 3 \quad \text{or} \\ 10 - 3 < x < 10 + 3$$

$$7 < x < 13 : \mu + k\sigma = 10 + 2k = 13 \text{ and } 10 - 2k = 7$$

$$\text{Choose } k = \frac{3}{2}$$

$$P(|X - 10| \geq 3) \leq \frac{1}{k^2} = \frac{4}{9}$$

$$\text{iii. } P(|X - 10| < 3) \leq 1 - \frac{4}{9} = \frac{5}{9}$$

$$\text{Ans. (i) at least } \frac{21}{25} \quad (ii) \text{ at most } \frac{4}{9} \quad (iii) \text{ at least } \frac{5}{9}$$

Theoretical probability distributions

Generally, frequency distributions are formed from the observed or experimental data. However, frequency distributions of certain populations can be deduced mathematically by fitting a theoretical probability distributions under certain assumptions.

Example: The shoes-industry should know the 'sizes' of foot of the population, the food industry the 'tastes' (menu) of the population, etc.

Three such important theoretical probability distributions in order of their discovery are:

- Binomial (due to James Bernoulli, 1700).
- Normal (due to De-Moivre 1733) also credited to Laplace (1774), Gauss (1809).
- Poisson (due to S.D. Poisson 1837).

Discrete probability distributions: Binomial, Poisson, geometric, negative binomial, hypergeometric, multinomial, multivariate hypergeometric distributions.

Continuous probability distributions: Uniform (rectangular), normal, Gamma, exponential, χ^2 , Beta, bivariate normal, 't', 'F', distributions.

WORKED OUT EXAMPLES

Discrete probability distributions

Example 1: Prove that (a) $E(kX) = kE(X)$ (b) $E(X+k) = E(X)+k$ (c) $E(X+Y) = E(X)+E(Y)$.

Solution:

$$\text{a. } E(kX) = \frac{\sum k f_i x_i}{\sum f_i} = k \frac{\sum f_i x_i}{\sum f_i} = kE(X)$$

$$\text{b. } E(X+k) = \frac{\sum f_i (x_i+k)}{\sum f_i} = \frac{\sum f_i x_i}{\sum f_i} + k \frac{\sum f_i}{\sum f_i} = E(X) + k$$

$$\text{c. } E(X+Y) = \frac{\sum f_i (x_i+y_i)}{\sum f_i} = \frac{\sum f_i x_i}{\sum f_i} + \frac{\sum f_i y_i}{\sum f_i} = E(X) + E(Y)$$

Note 1: Above results can be proved for continuous case by ‘replacing’ $\sum$ by $\int_{-\infty}^{\infty}$.

Note 2: Above results are rewritten in ‘ μ ’ notation as (a) $\mu_{kX} = k\mu_X$ (b) $\mu_{X+k} = \mu_X + k$ (c) $\mu_{X+Y} = \mu_X + \mu_Y$.

Example 2: Prove that (a) $\text{Var}(X+k) = \text{Var}(X)$ (b) $\text{Var}(kX) = k^2 \text{Var}(X)$. Hence $\sigma_{X+k} = \sigma_X$ and $\sigma_{kX} = |k|\sigma_X$.

Solution:

$$\begin{aligned} \text{a. } \text{Var}(X+k) &= \sum (x_i+k)^2 f(x_i) - \mu_{X+k}^2 \text{ by using the result } \text{Var}(X) = E(X^2) - \mu_X^2 \\ &= \sum (x_i^2 + k^2 + 2kx_i) f(x_i) - (\mu_X + k)^2 \\ &= \sum x_i^2 f_i + k^2 \sum f_i + 2k \sum x_i f_i - (\mu_X^2 + k^2 + 2\mu_X k) \\ &= \sum x_i^2 f_i + k^2 + 2k\mu_X - \mu_X^2 - 2k\mu_X - k^2 \\ &= (\text{Var}(X) + \mu_X^2) - \mu_X^2 = \text{Var}(X) \end{aligned}$$

$$\begin{aligned} \text{b. } \text{Var}(kX) &= \sum (kx_i)^2 f_i - \mu_{kX}^2 \\ &= k^2 \sum x_i^2 f_i - (k\mu_X)^2 = k^2 \left(\sum x_i^2 f_i - \mu_X^2 \right) \\ &= k^2 \text{Var}(X). \end{aligned}$$

Example 3: Determine the discrete probability distribution, expectation, variance, S.D. of a discrete random variable (D.R.V.) X which denotes the minimum of the two numbers that appear when a pair of fair dice is thrown once.

Solution: The total number of cases are $6 \times 6 = 36$. The minimum number could be 1, 2, 3, 4, 5, 6, i.e., $X(s) = X(a, b) = \min\{a, b\}$. The number 6 will appear only in one case (6, 6), so

$$f(6) = P(X=6) = P(\{(6,6)\}) = \frac{1}{36}.$$

For minimum 5, favourable cases are (5, 5), (5, 6), (6, 5) so

$$f(5) = P(X=5) = \frac{3}{36}.$$

For minimum 4, favourable cases are (4, 4), (4, 5), (4, 6), (5, 4) so

$$f(4) = P(X=4) = \frac{5}{36}.$$

For minimum 3: (3, 3), (3, 4), (3, 5), (3, 6), (6, 3), (5, 3), (4, 3) so

$$f(3) = P(X=3) = \frac{7}{36}.$$

For minimum 2: (2, 2), (3, 3), (2, 4), (2, 5), (2, 6), (6, 2), (5, 2), (4, 2), (3, 2) so

$$f(2) = P(X=2) = \frac{9}{36}.$$

Similarly,

$$f(1) = P(X=1) = \frac{11}{36}.$$

Thus the required discrete probability distribution

| $X = x_i$ | 1 | 2 | 3 | 4 | 5 | 6 |
|--------------|-----------------|----------------|----------------|----------------|----------------|----------------|
| $P(X = x_i)$ | $\frac{11}{36}$ | $\frac{9}{36}$ | $\frac{7}{36}$ | $\frac{5}{36}$ | $\frac{3}{36}$ | $\frac{1}{36}$ |
| $= f(x_i)$ | | | | | | |
| $= f_i$ | | | | | | |

Mean = Expectation = $E(X) = \sum x_i f_i$

$$\begin{aligned} E(X) &= 1 \cdot \frac{11}{36} + 2 \cdot \frac{9}{36} + 3 \cdot \frac{7}{36} + 4 \cdot \frac{5}{36} + 5 \cdot \frac{3}{36} \\ &\quad + 6 \cdot \frac{1}{36} = 2.5 \end{aligned}$$

$\text{Var}(X) = \sum x_i^2 f_i - \mu^2$

$$\begin{aligned} &= 1 \cdot \frac{11}{36} + 4 \cdot \frac{9}{36} + 9 \cdot \frac{7}{36} + 16 \cdot \frac{5}{36} + 25 \cdot \frac{3}{36} \\ &\quad + 36 \cdot \frac{1}{36} - (2.5)^2 \end{aligned}$$

$$\sigma^2 = 1.9745, \text{ so } \sigma = \text{S.D.} = 1.4.$$

Example 4: A player tosses 3 fair coins. He wins Rs. 500 if 3 heads occur, Rs. 300 if 2 heads occur, Rs. 100 if one head occurs. On the other hand, he loses Rs. 1500 if 3 tails occur. Find the value of the game to the player. Is it favourable?

Solution: Let $X = \text{D.R.V.} = \text{number of heads occurring in 3 tosses of a fair coin}$. The sample space S is

$$S = \{H, T\} \times \{H, T\} \times \{H, T\} \\ = \{HHH, HHT, HTH, HTT, THH, THT, TTH, TTT\}.$$

$$\text{Probability of all 3 heads} = P(X = 3) = \frac{1}{8}$$

$$\text{Probability of all 3 tails} = P(X = 0) = \frac{1}{8}$$

$$\text{Probability of 2 heads} = P(X = 2) = \frac{3}{8},$$

$$P(X = 1) = \frac{3}{8}$$

Discrete probability distribution is

| $X = x_i$ | 0 | 1 | 2 | 3 |
|--------------|---------------|---------------|---------------|---------------|
| $P(X = x_i)$ | $\frac{1}{8}$ | $\frac{3}{8}$ | $\frac{3}{8}$ | $\frac{1}{8}$ |
| $= f(x_i)$ | $\frac{1}{8}$ | $\frac{3}{8}$ | $\frac{3}{8}$ | $\frac{1}{8}$ |

Expected value of the game

$$= 500 \cdot \frac{1}{8} + 300 \cdot \frac{3}{8} + 100 \cdot \frac{3}{8} - 1500 \cdot \frac{1}{8} \\ = \frac{200}{8} = 25 \text{ rupees.}$$

Game is favourable to the player since $E > 0$.

Continuous probability distributions

Example 5: Suppose a continuous R.V. x has the probability density

$$f(x) = \begin{cases} k(1 - x^2) & \text{for } 0 < x < 1 \\ 0 & \text{elsewhere} \end{cases}$$

(a) Find k (b) Find $P(0.1 < x < 0.2)$ (c) $P(x > 0.5)$
Using distribution function, determine the probabilities that (d) x is less than 0.3 (e) between 0.4 and 0.6
(f) Calculate mean and variance for the probability density function.

Solution:

a. Since $\int_{-\infty}^{\infty} f(x)dx = 1$ so

$$\int_{-\infty}^{\infty} f(x)dx = \int_0^1 k(1 - x^2)dx = k\left(x - \frac{x^3}{3}\right)\Bigg|_0^1 \\ = \frac{2}{3}k = 1 \quad \therefore k = \frac{3}{2}.$$

b. $P(0.1 < x < 0.2) = \int_{0.1}^{0.2} k(1 - x^2)dx \\ = \frac{3}{2}\left(x - \frac{x^3}{3}\right)\Bigg|_{0.1}^{0.2} = 0.1465.$

c. $P(x > 0.5) = \int_{0.5}^{\infty} f(x)dx = \int_{0.5}^1 f(x)dx \\ = \frac{3}{2}\left(x - \frac{x^3}{3}\right)\Bigg|_{0.5}^1 = 0.3125.$

d. Distribution function:

$$F(x) = \int_{-\infty}^x f(t)dt \text{ so}$$

$$F(x) = \int_0^x \frac{3}{2}(1 - x^2)dx = \frac{3}{2}\left(x - \frac{x^3}{3}\right)$$

$$F(x < 0.3) = \int_{-\infty}^{0.3} f(t)dt = \frac{3}{2}\left(x - \frac{x^3}{3}\right)\Bigg|_0^{0.3} \\ = 0.4365$$

e. $F(0.4 < x < 0.6) = F(b) - F(a) \\ = F(0.6) - F(0.4)$

$$= \frac{3}{2}\left(x - \frac{x^3}{3}\right)\Bigg|_{0.4}^{0.6} = 0.224.$$

f. Mean $= \mu = \int_{-\infty}^{\infty} xf(x)dx = \int_0^1 x\left\{\frac{3}{2}(1 - x^2)\right\}dx$

$$= \frac{3}{2}\left(\frac{x^2}{2} - \frac{x^4}{4}\right)\Bigg|_0^1 = \frac{3}{8}$$

$$\text{Variance} = \int_{-\infty}^{\infty} (x - \mu)^2 f(x)dx$$

$$= \int_0^1 \left(x - \frac{3}{8}\right)^2 \frac{3}{2}(1 - x^2)dx = \frac{19}{320}$$

$$\text{or variance} = \int_0^1 x^2 \{k(1 - x^2)\}dx - \mu^2$$

$$= k\left(\frac{x^3}{3} - \frac{x^5}{5}\right)\Bigg|_0^1 - \mu^2 = \frac{19}{320}.$$

Example 6: The daily consumption of electric power (in millions of kW-hours) is a R.V. having the

$$\text{P.D.F.} \quad f(x) = \begin{cases} \frac{1}{9}xe^{-x/3}, & x > 0 \\ 0, & x \leq 0 \end{cases}$$

If the total production is 12 million kW-hours, determine the probability that there is power cut (shortage) on any given day.

27.8 — HIGHER ENGINEERING MATHEMATICS—VII

Solution: Probability that the power consumed is between 0 to 12 is

$$\begin{aligned} P(0 \leq x \leq 12) &= \int_0^{12} f(x) dx = \int_0^{12} \frac{1}{9} x e^{-x/3} dx \\ &= -\frac{x}{3} e^{-x/3} - e^{-x/3} \Big|_0^{12} = 1 - 5e^{-4} \end{aligned}$$

Power supply is inadequate if daily consumption exceeds 12 million kW, i.e.,

$$\begin{aligned} P(x > 12) &= 1 - P(0 \leq x \leq 12) = 1 - [1 - 5e^{-4}] = 5e^{-4} \\ &= 0.0915781 \end{aligned}$$

Example 7: (a) Find the mean and variance of a uniform (rectangular) distribution (b) Determine its cumulative distribution function (Fig. 27.3).

Fig. 27.3

Solution: The uniform distribution is defined by

$$\begin{aligned} f(x) &= k = \text{constant in } (a, b) \\ &= 0 \quad \text{elsewhere} \end{aligned}$$

$$\text{Since } 1 = \int_{-\infty}^{\infty} f(x) dx = \int_a^b k dx = k(b-a),$$

$$\text{so } k = \frac{1}{b-a}$$

$$\text{Thus } f(x) = \begin{cases} \frac{1}{b-a}, & \text{for } a < x < b \\ 0, & \text{elsewhere} \end{cases}$$

$$\begin{aligned} \text{Mean} = \mu &= \int_a^b x f(x) dx = \int_a^b x \cdot \frac{dx}{b-a} \\ &= \frac{1}{b-a} \cdot \frac{x^2}{2} \Big|_a^b = \frac{b^2 - a^2}{2(b-a)} \\ \mu &= \frac{b+a}{2} \end{aligned}$$

$$\text{Variance} = \int_a^b x^2 f(x) dx - \mu^2 = \frac{1}{b-a} \cdot \int_a^b x^2 dx - \mu^2$$

$$\begin{aligned} \sigma^2 &= \frac{1}{b-a} \frac{x^3}{3} \Big|_a^b - \mu^2 = \frac{b^3 - a^3}{3(b-a)} - \left(\frac{b+a}{2} \right)^2 \\ &= \frac{(b-a)^2}{12} \end{aligned}$$

Cumulative distribution $F(x)$:

$$\text{i. When } x \leq a, \quad F(x) = \int_{-\infty}^x f(x) dx = \int_{-\infty}^x 0 dx = 0$$

so $F(x) = 0$

$$\begin{aligned} \text{ii. When } a < x < b, \\ F(x) &= \int_{-\infty}^x f(x) dx = \int_{-\infty}^a 0 \cdot dx + \int_a^x \frac{1}{b-a} dx \\ F(x) &= \frac{x-a}{b-a} \end{aligned}$$

$$\begin{aligned} \text{iii. When } x \geq b, \quad F(x) &= \int_{-\infty}^x f(x) dx = \int_{-\infty}^a 0 dx \\ &+ \int_a^b \frac{1}{b-a} dx + \int_b^x 0 dx = \frac{b-a}{b-a} = 1. \end{aligned}$$

Thus

$$f(x) = \begin{cases} 0, & \text{when } x \leq a \\ \frac{x-a}{b-a}, & \text{when } a < x < b \\ 1, & \text{when } x \geq b. \end{cases}$$

EXERCISE

Probability distributions

1. Calculate μ , σ^2 , σ for

$$\text{a. } \begin{array}{ccccc} x_i & 2 & 3 & 8 \\ f_i & \frac{1}{4} & \frac{1}{2} & \frac{1}{4} \end{array}$$

$$\text{b. } \begin{array}{cccccc} x_i & -1 & 0 & 1 & 2 & 3 \\ f_i & .3 & .1 & .1 & .3 & .2 \end{array}$$

$$\begin{aligned} \text{Ans. a. } \mu &= 2 \cdot \frac{1}{4} + 3 \cdot \frac{1}{2} + 8 \cdot \frac{1}{4} = 4, \\ \sigma^2 &= (2-4)^2 \frac{1}{4} + (3-4)^2 \frac{1}{2} + (8-4)^2 \frac{1}{4} \\ &= 5.5 \\ \sigma &= 2.3 \quad [\text{or } \sigma^2 = 4 \cdot \frac{1}{4} + 9 \cdot \frac{1}{2} + 64 \cdot \frac{1}{4} - 4^2 \\ &= 5.5] \end{aligned}$$

$$\begin{aligned} \text{b. } \mu &= -1 \cdot (.3) + 0 \cdot (.1) + 1 \cdot (.1) \\ &+ 2 \cdot (.3) + 3 \cdot (.2) = 1.0 \\ \sigma^2 &= 4 \cdot (.3) + 0 \cdot (.1) + 1 \cdot (.1) + 4 \cdot (.3) + 9 \cdot (.2) \\ &= 2.4, \sigma = 1.5 \end{aligned}$$

2. Determine the expected number of families to have (a) 2 boys and 2 girls (b) at least one boy (c) no girls (d) at most two girls, out of 800 families with 4 children each. Assume equal probabilities for boys and girls.

$$\text{Ans. (a) } 37.5\% \quad \text{(b) } 93.75\% \quad \text{(c) } 6.25\% \quad \text{(d) } 68.75\%$$

Hint: X : No boys in a family. P.D.F.

| | | | | | |
|----------|----------------|----------------|----------------|----------------|----------------|
| X | 0 | 1 | 2 | 3 | 4 |
| $p(x_i)$ | $\frac{1}{16}$ | $\frac{4}{16}$ | $\frac{6}{16}$ | $\frac{4}{16}$ | $\frac{1}{16}$ |

Percentage of families = $\frac{6}{16} \times 100 = 37.5\%$
for (a) etc.

3. A box contains 8 items of which 2 are defective. A person draws 3 items from the box. Determine the expected number of defective items he has drawn.

Ans. $0 \cdot \frac{20}{56} + 1 \cdot \frac{30}{56} + 2 \cdot \frac{6}{56} = \frac{3}{4}$

Hint:

| | | | |
|----------|--------------------------|--------------------------|--------------------------|
| X | 0 | 1 | 2 |
| $f(x_i)$ | $\frac{6c_3 2c_0}{8c_3}$ | $\frac{6c_2 2c_1}{8c_3}$ | $\frac{6c_1 2c_2}{8c_3}$ |

Here X is the number of defectives.

4. A stake of Rs. 44 is to be won between 2 players A and B , whoever gets 6 in a throw of die alternatively. Determine their respective expectations if A starts the game.

Ans. $E(A) = \frac{6}{11} \times 44 = \text{Rs. } 24,$

$E(B) = \frac{5}{11} \times 44 = \text{Rs. } 20$

Hint: $P(A \text{ wins}) = \frac{1}{6} + \frac{5}{6} \cdot \frac{5}{6} \cdot \frac{1}{6} +$

$\frac{5}{6} \cdot \frac{5}{6} \cdot \frac{5}{6} \cdot \frac{1}{6} + \dots = \frac{1}{6} \frac{1}{1 - (\frac{5}{6})^2} = \frac{6}{11}$

$p = \text{probability of } 6 = \frac{1}{6}, \text{ prob no } 6 = \frac{5}{6}.$

5. A person wins Rs. 80 if 3 heads occur, Rs. 30 if 2 heads occur, Rs. 10 if only one head occurs in a single toss of 3 fair coins. If the game is to be fair, how much should he lose if no heads occur?

Ans. Rs. 200

Hint: $0 = \text{Expectation} = 80 \cdot \frac{1}{8} + 30 \cdot \frac{3}{8} + 10 \cdot \frac{3}{8} - x \cdot \frac{1}{8}$

6. Find the mean and variance of P.D.F.

$$f(x) = \begin{cases} \frac{1}{4} e^{-x/4} & \text{for } x > 0 \\ 0 & \text{elsewhere.} \end{cases}$$

Ans. $\mu = \int_0^\infty \frac{1}{4} e^{-x/4} dx = \frac{e^{-x/4}}{-1/4} = 4 \cdot 1 = 4$

$$\sigma^2 = \int_0^\infty (x - 4)^2 \frac{1}{4} e^{-x/4} dx = \int_0^\infty x^2 \frac{1}{4} e^{-x/4} dx - \mu^2 = 96 - 16 = 80$$

7. If P.D.F. $f(x) = k(x + 3)$ in $(2, 8)$, determine

(a) $P(3 < x < 5)$ (b) $P(x \geq 4)$

(c) $P(|x - 5| < 0.5)$

Ans. $k = \frac{1}{48},$ (a) $\frac{7}{24}$ (b) $\frac{3}{4}$

(c) $P(4.5 < x < 5.5) = \frac{1}{6}.$

8. Find the mean and variance of the “exponential” distribution $f(x) = \frac{1}{b} e^{-x/b}$ for $x > 0, b > 0.$

Ans. $\mu = b, \sigma^2 = b^2$

Hint: $\mu = \int_0^\infty x \cdot \frac{1}{b} e^{-x/b} dx = b \Gamma(2) = b,$

$$\sigma^2 = \int_0^\infty x^2 \frac{1}{b} e^{-x/b} dx - \mu^2 = b^2 \Gamma(3) - b^2 = 2b^2 - b^2 = b^2$$

27.3 DISCRETE UNIFORM DISTRIBUTION

Discrete uniform distribution is the simplest of all discrete probability distribution. The discrete random variable assumes each of its values with the same (equal) probability. In this equiprobable or uniform space each sample point is assigned equal probabilities.

Example 1: In the tossing of a fair die, each sample point in the sample space $\{1, 2, 3, 4, 5, 6\}$ is assigned with the same (uniform) probability $\frac{1}{6}$ i.e. $p(x) = \frac{1}{6}$ for $x = 1, 2, 3, 4, 5, 6$. In particular, if the sample space S contains k points, then probability of each point is $\frac{1}{k}$. Thus in the discrete uniform distribution, the discrete random variable X assigns equal probabilities to all possible values of X . Therefore the probability mass function $f(X)$ has the form

$$f(X) = \frac{1}{k} \text{ for } X = x_1, x_2, \dots, x_k \quad (1)$$

or equivalently

| | | | | | |
|--------|---------------|---------------|---------------|---------|---------------|
| X | x_1 | x_2 | x_3 | $\dots$ | x_k |
| $f(X)$ | $\frac{1}{k}$ | $\frac{1}{k}$ | $\frac{1}{k}$ | $\dots$ | $\frac{1}{k}$ |

Here the constant K which is the *parameter* completely determines the discrete uniform distribution (1). The mean and variance of (1) are given by

$$\mu = E(X) = \sum_{i=1}^k x_i f(x_i) = \sum_{i=1}^k x_i \cdot \frac{1}{k} = \frac{\sum_{i=1}^k x_i}{k}$$

and

$$\begin{aligned}\sigma^2 &= E((X - \mu)^2) = \sum_{i=1}^k (x_i - \mu)^2 f(x_i) \\ &= \sum_{i=1}^k \frac{(x_i - \mu)^2}{k} \\ \sigma^2 &= \frac{1}{k} \sum_{i=1}^k (x_i - \mu)^2\end{aligned}$$

The discrete uniform distribution is of particular importance in lotteries.

WORKED OUT EXAMPLES

Example 2: If a ticket is drawn from a box containing 10 tickets numbered 1 to 10 inclusive. Find the probability that the number x drawn is (a) less than 4 (b) even number (c) prime number (d) find the mean and variance of the random variable X .

Solution: (a) since each ticket has the same probability for being drawn, the probability distribution is discrete uniform distribution given by $f(x) = \frac{1}{10}$ for $x = 1, 2, 3, \dots, 10$. Now

$$P(x < 4) = \sum_{x=0}^3 P(x) = \sum_{x=0}^3 \frac{1}{10} = \frac{1}{10}(1 + 1 + 1) = \frac{3}{10}$$

(b) 2, 4, 6, 8, 10 are even numbers each with probability $\frac{1}{10}$ probability of even number = $\frac{5}{10} = \frac{1}{2}$ (c) 2, 3, 5, 7 are prime prob. of prime = $\frac{4}{10} = \frac{2}{5}$. (d) Mean = $E(x) =$

$$\sum_{x=1}^{10} x P(x) = \sum_{x=1}^{10} x \cdot \frac{1}{10} = \frac{1}{10}(1 + 2 + 3 + \dots + 10)$$

$$\text{Mean} = \mu = \frac{1}{10} \cdot \frac{10(10+1)}{2} = \frac{11}{2} = 5.5$$

$$\text{Variance} = \sigma^2 = \sum_{x=1}^{10} (x - \mu)^2 p(x)$$

$$\begin{aligned}&= \frac{1}{10} [(1 - 5.5)^2 + (2 - 5.5)^2 + (3 - 5.5)^2 \\ &\quad + \dots + (10 - 5.5)^2]\end{aligned}$$

$$\sigma^2 = 8.25$$

$$(\text{or } \sigma^2 = E(x^2) - \{E(x)\}^2 = \sum x^2 \cdot P(x) - (5.5)^2)$$

$$\begin{aligned}&= \frac{1}{10} \cdot \frac{n(n+1)(2n+1)}{6} - (5.5)^2 \\ &= \frac{1}{10} \cdot \frac{10(10+1)(20+1)}{6} - (5.5)^2\end{aligned}$$

$$38.5 - 30.25 = 8.25)$$

EXERCISE

1. Determine the probability that an odd number appears in the toss of a fair die.

$$\text{Ans. } \frac{3}{6}$$

2. Find the probability that at least one head appears in the throw of three fair coins.

$$\text{Ans. } \frac{7}{8}$$

3. If a card is selected at random from an ordinary pack of 52 cards, find the probability that (a) card is a spade (b) card is a face card i.e., Jack, queen or king (c) card is a spade face card.

$$\text{Ans. } \frac{13}{52} \text{ (b) } \frac{12}{52} \text{ (c) } \frac{3}{52}$$

Hint: (a) 13 spade cards available. So $\frac{\binom{13}{1}}{\binom{52}{1}}$

$$\text{(b) 12 face cards so } \frac{\binom{12}{1}}{\binom{52}{1}}$$

$$\text{(c) 3 spade face cards so } \frac{\binom{3}{1}}{\binom{52}{1}}.$$

Note: Each card has the same probability $\frac{1}{52}$.

4. Find the probability that a card drawn at random from 50 cards numbered 1 to 50 is (a) prime, (b) ends in the digit 2, (c) divisible by 5.

$$\text{Ans. (a) } \frac{3}{10} \text{ (b) } \frac{1}{10} \text{ (c) } \frac{1}{5}$$

5. Two marbles are drawn from a box containing 4 red and 8 black marbles. Find the probability that (a) both are red (b) both are black (c) at least one is red.

$$\text{Ans. (a) } \frac{\binom{4}{2}}{\binom{12}{2}} = \frac{1}{11},$$

$$\text{(b) } \frac{\binom{8}{2}}{\binom{12}{2}} = \frac{14}{33} \text{ (c) } 1 - \frac{14}{33} = \frac{19}{33}$$

6. If two cards are drawn from an ordinary pack of 52 cards, determine the probability that (a) both are spades (b) one is a spade and one is a heart.

$$\text{Ans. (a) } \frac{\binom{13}{2}}{\binom{52}{2}} = \frac{78}{1326} = \frac{1}{17}$$

$$(b) (13.13) \left/ \binom{15}{2} \right. = \frac{13}{102}$$

27.4 BINOMIAL DISTRIBUTION

Binomial distribution (B.D.) due to James Bernoulli (1700) is a discrete probability distribution. The Bernoulli process has the following properties:

- i. An experiment is repeated n number of times, called n trials where n is a fixed integer.
- ii. The outcome of each trial is classified into two mutually exclusive (dichotomus) categories arbitrarily called a “success” and a “failure”.
- iii. Probability of success, denoted by p , remains constant for all trials.
- iv. The outcomes are independent (of the outcomes of the previous trials).

Each trial in the Bernoulli process is known as Bernoulli trial.

The binomial random variable X is the *number* of successes in n Bernoulli trials. X is discrete since X takes only integer values (we ‘count’ the number of successes).

Binomial distribution is thus the probability distribution of this discrete random variable X , and is given by

$$b(x; n, p) = \binom{n}{x} p^x q^{n-x}, x = 0, 1, 2, \dots, n \quad (1)$$

where n is the number of trials and p is the probability of success in any trial. The probability of x successes is p^x and remaining failures is q^{n-x} . This can happen in n_{C_x} ways. By multiplication rule, the probability of x successes in n trials is $\binom{n}{x} p^x q^{n-x}$.

Note that the $(n + 1)$ terms of the binomial expansion

$$\begin{aligned} (q + p)^n &= \binom{n}{0} q^n + \binom{n}{1} p q^{n-1} + \binom{n}{2} p^2 q^{n-2} \\ &\quad + \dots + \binom{n}{n} p^n \\ &= b(0; n, p) + b(1; n, p) + b(2; n, p) \\ &\quad + \dots + b(n; n, p) \\ &= \sum_{x=0}^n b(x; n, p) \end{aligned}$$

correspond to various values of $b(x; n, p)$ for $x = 0, 1, 2, \dots, n$.

Since $p + q = 1$, it follows that

$$\sum_{x=0}^n b(x; n, p) = 1.$$

B.D. is characterized by the parameter p and the number of trials n .

The mean μ of B.D. is np and the variance σ^2 of B.D. is npq . (see Worked Out Example 1 on page 27.11)

The binomial sums

$$B(r; n, p) = \sum_{x=0}^r b(x; n, p)$$

are tabulated (see A2 to A7)

since

$$\frac{n_{C_{x+1}}}{n_{C_x}} = \frac{n!}{(x+1)!(n-x-1)!} \frac{x!(n-x)!}{n!} = \left(\frac{n-x}{x+1} \right)$$

The recurrence relation for B.D. is

$$b(x+1; n, p) = \left(\frac{n-x}{x+1} \right) \left(\frac{p}{q} \right) b(x; n, p).$$

WORKED OUT EXAMPLES

Binomial distribution

Example 1: Find the (a) mean and (b) variance of B.D.

Solution:

$$\begin{aligned} \text{a. mean} = \mu &= \text{expectation} = \sum_{x=0}^n x P(x) \\ &= \sum_{x=0}^n x b(x; n, p) = \sum_{x=0}^n x \frac{n!}{x!(n-x)!} p^x q^{n-x} \\ &= np \sum_{x=1}^n \frac{(n-1)!}{(n-x)!(x-1)!} p^{x-1} q^{n-x}, \text{ put } x-1 = x^* \\ &= np \sum_{x^*=0}^{n-1} \frac{(n-1)!}{(n-x^*-1)x^*!} p^{x^*} q^{n-x^*-1} \\ &= np(p+q)^{n-1} = np \quad \text{since } p+q = 1. \end{aligned}$$

$$\begin{aligned}
 \text{b. Variance } \sigma^2 &= \sum_{x=0}^n (x - \mu)^2 p(x) \\
 &= \sum_{x=0}^n (x^2 - 2\mu x + \mu^2) p(x) \\
 &= \sum_{x=0}^n x^2 p(x) - 2\mu \sum_{x=0}^n x p(x) + \mu^2 \sum_{x=0}^n p(x) \\
 &= \sum_{x=0}^n x^2 p(x) - 2\mu \cdot np + \mu^2 \cdot 1 \\
 \because \sum_{x=0}^n x p(x) &= \mu, \quad \sum_{x=0}^n p(x) = 1 \\
 &= \sum_{x=0}^n x^2 p(x) - n^2 p^2 \quad \text{since } \mu = np
 \end{aligned}$$

Consider

$$\begin{aligned}
 \sum_{x=0}^n x^2 p(x) &= \sum_{x=1}^n x^2 \frac{n!}{(n-x)!x!} p^x q^{n-x} \\
 &= \sum_{x=1}^n [x(x-1) + x] \frac{n!}{(n-x)!x!} p^x q^{n-x} \\
 &= \sum_{x=2}^n \frac{x(x-1)n!}{(n-x)!x!} p^x q^{n-x} + \sum_{x=1}^n x \frac{n!}{(n-x)!x!} p^x q^{n-x} \\
 &= \sum_{x=2}^n \frac{n!}{(n-x)!(x-2)!} p^x q^{n-x} + np \\
 &= n(n-1)p^2 \sum_{x=2}^n \frac{(n-2)!}{(n-x)!(x-2)!} p^{x-2} q^{n-x} + np \\
 &= n(n-1)p^2 \cdot (q+p)^{n-2} + np \\
 &= n(n-1)p^2 + np \quad \text{since } p+q=1
 \end{aligned}$$

Thus

$$\begin{aligned}
 \sigma^2 &= n(n-1)p^2 + np - n^2 p^2 = np - np^2 \\
 \sigma^2 &= np(1-p) = npq.
 \end{aligned}$$

Example 2: Determine the probability of getting 9 exactly twice in 3 throws with a pair of fair dice.

Solution: In a single throw of a pair of fair dice, 9 can occur in 4 ways: (6, 3), (3, 6), (5, 4), (4, 5) out of $6 \times 6 = 36$ ways. Thus

p = probability of occurrence of 9 in one throw = $\frac{4}{36} = \frac{1}{9}$.

n = number of trials = 3.

Probability of getting 9 exactly twice in 3 throws

$$= b\left(2; 3, \frac{1}{9}\right) = {}^3C_2 \left(\frac{1}{9}\right)^2 \left(\frac{8}{9}\right)^{3-2} = 3 \cdot \frac{1}{9} \cdot \frac{1}{9} \cdot \frac{8}{9} = \frac{8}{243}.$$

Example 3: Out of 800 families with 5 children each, how many would you expect to have (a) 3 boys (b) 5 girls (c) either 2 or 3 boys. Assume equal probabilities for boys and girls.

Solution: Probability of boy = $P(B) = p = \frac{1}{2}$, and probability of girl = $P(G) = q = \frac{1}{2}$.

n = number of trials = 5, X = no. of boys in a family

a. Probability of a family having 3 boys

$$\begin{aligned}
 &= P(X=3) = {}^5C_3 \left(\frac{1}{2}\right)^3 \left(\frac{1}{2}\right)^{5-3} \\
 &= \frac{5!}{2!3!} \left(\frac{1}{2}\right)^5 = \frac{10}{32} = \frac{5}{16}
 \end{aligned}$$

Expected number of families having 3 boys out of 5 children = $800 \left(\frac{5}{16}\right) = 250$, i.e., 250 families have 3 boys out of 5 children.

b. $P(X=0) = P(\text{all girls}) = \left(\frac{1}{2}\right)^5 = \frac{1}{32}$

Expectation = $800 \times \frac{1}{32} = 25$.

c. $P(X=2) = P(2 \text{ boys}) = {}^5C_2 \left(\frac{1}{2}\right)^5 = \frac{5}{8}$

Expectation = $800 \times \frac{5}{8} = 500$.

Example 4: Determine the probability distribution of the number of bad eggs in a box of 6 chosen at random if 10% of eggs are bad, in a large consignment.

Solution: Probability of a bad egg = $p = \frac{10}{100} = 0.1$. Let X = number of bad eggs, $n = 6$. The required B.D. = $b(x; 6, 0.1) = {}^6C_x (.1)^x (.9)^{6-x}$, for $x = 0, 1, 2, 3, 4, 5, 6$.

| | | | | | | | |
|----------|-------|--------|-------|-------|----------|----------|---|
| X : | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
| $P(X)$: | .5311 | .35429 | 0.098 | 0.015 | 0.001215 | 0.000054 | 0 |

Example 5: Assume that 50% of all engineering students are good in mathematics. Determine the probabilities that among 18 engineering students (a)

exactly 10 (b) at least 10 (c) at most 8 (d) at least 2 and at most 9, are good in maths.

Solution: Let X = number of engineering students who are good in maths:

$$p = \text{prob of good in maths} = \frac{50}{100} = \frac{1}{2}, n = 18$$

$$b(x; n, p) = b(x; 18, \frac{1}{2}) = {}^{18}C_x \left(\frac{1}{2}\right)^x \left(\frac{1}{2}\right)^{18-x}$$

a. Exactly 10 students out of 18 are good in maths

$$P(X = 10) = {}^{18}C_{10} \left(\frac{1}{2}\right)^{10} \left(\frac{1}{2}\right)^8 = .1670$$

From tables (A2 to A7)

$$\begin{aligned} P(X = 10) &= \sum_{x=0}^{10} b\left(x; 18, \frac{1}{2}\right) - \sum_{x=0}^9 b\left(x; 18, \frac{1}{2}\right) \\ &= .7597 - .5927 = .1670 \end{aligned}$$

$$\begin{aligned} \text{b. } P(X \geq 10) &= \sum_{x=10}^{18} {}^{18}C_x \left(\frac{1}{2}\right)^x \left(\frac{1}{2}\right)^{18-x} \\ &= \sum_{x=0}^{18} b\left(x; 18, \frac{1}{2}\right) - \sum_{x=0}^9 b\left(x; 18, \frac{1}{2}\right) \\ &= 1 - .5927 = .4073 \end{aligned}$$

$$\begin{aligned} \text{c. } P(X \leq 8) &= \sum_{x=0}^8 {}^{18}C_x \left(\frac{1}{2}\right)^x \left(\frac{1}{2}\right)^{18-x} = .4073 \\ \text{from table with } n &= 18, x = 8, p = \frac{1}{2}. \end{aligned}$$

$$\begin{aligned} \text{d. } P(2 \leq x \leq 9) &= \sum_{x=2}^9 {}^{18}C_x \left(\frac{1}{2}\right)^x \left(\frac{1}{2}\right)^{18-x} \\ &= \sum_{x=0}^9 b\left(x; 18, \frac{1}{2}\right) - \sum_{x=0}^1 b\left(x; 18, \frac{1}{2}\right) \\ &= .5927 - .0007 = .5920. \end{aligned}$$

Example 6: The probability of a man hitting a target is $\frac{1}{3}$. (a) If he fires 5 times, what is the probability of his hitting the target at least twice? (b) How many times must he fire so that the probability of his hitting the target at least once is more than 90%?

Solution: Probability of hitting = $p = \frac{1}{3}$

probability of no hit (or failure) = $q = \frac{2}{3}$

a. X = number of hits (successes), $n = 5$

$$\begin{aligned} P(X \geq 2) &= \sum_{x=2}^5 {}^5C_x \left(\frac{1}{3}\right)^x \left(\frac{2}{3}\right)^{5-x} \\ &= 1 - \sum_{x=0}^1 {}^5C_x \left(\frac{1}{3}\right)^x \left(\frac{2}{3}\right)^{5-x} \\ &= 1 - \left(\frac{2}{3}\right)^5 - {}^5C_1 \left(\frac{1}{3}\right) \left(\frac{2}{3}\right)^4 = \frac{131}{243}. \end{aligned}$$

b. The probability of not hitting the target is q^n in n trials (fires). Thus to find the smallest n for which the probability of hitting at least once $1 - q^n$ is more than 90%.

$$\text{i.e., } 1 - q^n > 0.9$$

$$\text{or } 1 - \left(\frac{2}{3}\right)^n > 0.9 \quad \text{i.e., } \left(\frac{2}{3}\right)^n < 0.1$$

For $n = 6$, $2^6 = 64 < (0.1)3^6 = 72.9$ this is true. In other words, he must fire 6 times.

Example 7: If X be a binomially distributed random variable with $E(X) = 2$ and $\text{Var}(X) = \frac{4}{3}$, find the distribution of X .

Solution: We know that $E(X) = \text{mean} = np = 2$ and $\text{Var}(X) = \text{Variance} = npq = \frac{4}{3}$. or $\frac{npq}{np} = \frac{4}{3} \frac{1}{2} = \frac{2}{3}$ or $q = \frac{2}{3}$ so $p = \frac{1}{3}$. Thus $n \frac{1}{3} = 2$ or $n = 6$.

Hence the B.D. is $b(x; 6, \frac{1}{3})$

| x_i | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|----------|------------------|-------------------|-------------------|-------------------|------------------|------------------|-----------------|
| $f(x_i)$ | $\frac{64}{729}$ | $\frac{192}{729}$ | $\frac{240}{729}$ | $\frac{160}{729}$ | $\frac{60}{729}$ | $\frac{12}{729}$ | $\frac{1}{729}$ |

Example 8: Fit a binomial distribution to the following data:

| X | 0 | 1 | 2 | 3 | 4 |
|-----|----|----|----|----|---|
| f | 30 | 62 | 46 | 10 | 2 |

Solution: Here n = no. of trials = 4 and

$$N = \text{total frequency} = \sum_{i=0}^4 f_i = 30 + 62 + 46 + 10 + 2 = 150.$$

27.14 — HIGHER ENGINEERING MATHEMATICS—VII

Mean of the binomial distribution is

$$\mu = np = \frac{\sum f_i x_i}{\sum f_i} = \frac{0(30)+1(62)+2(46)+3(10)+4(12)}{150}$$

$$np = 4p = \frac{192}{150} \quad \therefore p = \frac{192}{600} = 0.32$$

Thus the binomial distribution that fits the given data is $b(x; 4, 0.32) = 4C_x (.32)^x (.68)^{4-x} = p(x)$

| $x :$ | 0 | 1 | 2 | 3 | 4 |
|----------------------------------|-------|-----|--------|--------|--------|
| $P(x) :$ | .2138 | 0.4 | 0.2866 | 0.0866 | 0.0133 |
| Expected frequency = | 32 | 60 | 43 | 13 | 2 |
| $N \times P(x)$
$= (150)P(x)$ | | | | | |

Hint: Use the recurrence relation

$$b(x+1; n, p) = \left(\frac{n-x}{x+1} \right) \frac{p}{q} b(x; n, p)$$

EXERCISE

Binomial distribution

1. A fair coin is tossed 6 times. Find the probability of getting (a) exactly 2 heads (b) at least four heads (c) no heads (d) at least one head.

Ans. (a) $\frac{15}{64}$ (b) $\frac{11}{32}$ (c) $\frac{1}{64}$ (d) $\frac{63}{64}$

Hint:

a. $b(2; 6, \frac{1}{2}) = 6C_2 \left(\frac{1}{2}\right)^2 \left(\frac{1}{2}\right)^4$

b. $\sum_{x=4}^6 b(x; 6, \frac{1}{2}) = \frac{15}{64} + \frac{6}{64} + \frac{1}{64}$

c. $1 - q^6 = 1 - \left(\frac{1}{2}\right)^6$

2. A fair die is tossed 7 times. Determine the probability that a 5 or a 6 appears (a) exactly 3 times (b) never occurs.

Ans. (a) $\frac{560}{2187}$ (b) $\frac{2059}{2187}$

Hint: (a) $b(3; 7, \frac{1}{3})$ (b) $1 - q^7 = 1 - \left(\frac{2}{3}\right)^7$

3. Team A has probability $\frac{2}{3}$ of winning whenever it plays. If A plays 4 games, find the probability that A wins (i) exactly 2 games (ii) at least 1 game (iii) more than half of the games.

Ans. (i) $P(2) = b(2; 4, \frac{2}{3}) = \frac{8}{27}$ (ii) $1 - q^4 = 1 - \left(\frac{1}{3}\right)^4 = \frac{80}{81}$ (iii) $P(3) + P(4) = \frac{32}{81} + \frac{16}{81} = \frac{16}{27}$

4. How many dice must be thrown so that there is a better than even chance of obtaining a six?

Ans. 4 dice

Hint: Find n such that $\left(\frac{5}{6}\right)^n < \frac{1}{2}$.

5. A man hits a target with probability $\frac{1}{4}$.

(i) Determine the probability of hitting at least twice when he fires 7 times (ii) How many times must he fire so that the probability of his hitting the target at least once is greater than $\frac{2}{3}$?

Ans. i. $1 - P(0) - P(1) = 1 - \frac{2187}{16384} - \frac{5103}{16384} = \frac{4547}{8192}$

ii. $n = 4$

Hint: Find n such that $1 - q^n > \frac{2}{3}$.

6. The probability that a pen manufactured by a company will be defective is 0.1. If 12 such pens are examined, find the probability that (a) exactly two (b) at least two (c) none, will be defective.

Ans. (a) 0.2301 (b) 0.3412 (d) 0.2833

7. In sampling a large number of parts manufactured by a machine, the mean number of defectives in a sample of 20 is 2. Out of 1000 such samples, how many would be expected to contain at least 3 defective parts?

Ans. 323

Hint: Mean $= 2 = np = 20p$, $p = 0.1$,

$$P(X \geq 3) = 1 - \sum_{x=0}^2 b(x; 20, 0.1) = 0.323$$

Expected number $= 1000 \times 0.323 = 323$.

8. The probability that a patient recovers from a disease is 0.4. If 15 persons have such a disease, determine the probability that (a) exactly 5 survive (b) at least 10 survive (c) from 3 to 8 survive.

Ans. a. $P(X=5) = b(5; 15, 0.4) = \sum_{x=0}^5 b(x, 15, 0.4) - \sum_{x=0}^4 b(x; 15, 0.4) = 0.4032 - 0.2173$

$$= 0.1859.$$

$$\begin{aligned} \text{b. } P(X \geq 10) &= 1 - P(X < 10) \\ &= 1 - \sum_{x=0}^9 b(x; 15, 0.4) = 1 - 0.9662 \\ &= 0.0338. \end{aligned}$$

$$\begin{aligned} \text{c. } P(3 \leq X \leq 8) &= \sum_{x=3}^{\infty} = \sum_{x=0}^{\infty} - \sum_{x=0}^2 \\ &= 0.9050 - 0.0271 = 0.8779. \end{aligned}$$

9. A manufacturer of fax machine claims that only 10% of his machines require repairs within one year. If 5 of 20 of his machines required repairs within 1 year, does this tend to support or refute the claim?

Ans. Reject (refute) the claim since probability is very small.

$$\begin{aligned} \text{Hint: } \sum_{x=5}^{20} b(x; 20, 0.10) &= 1 - \sum_{x=0}^4 b(x; 20, 0.10) \\ &= 1 - 0.9568 = 0.0432. \end{aligned}$$

10. Two dice are thrown 120 times. Find the average number of times in which the number on first dice exceeds the number on the second dice.

$$\text{Ans. } E(X) = np = 120 \left(\frac{5}{12} \right) = 50$$

Hint: Successful are (2, 1), (3, 1), (3, 2), (4, 1), (4, 2), (4, 3), (5, 1), (5, 2), (5, 3), (5, 4), (6, 1), (6, 2), (6, 3), (6, 4), (6, 5), $p = \frac{15}{6.6} = \frac{5}{12}$.

11. A communication system consists of n components, each of which will independently function with probability p . The total system will be able to operate effectively if at least one half of its components function. For what values of p is a 5-component system more likely to operate effectively than a 3-component system?

$$\text{Ans. } p \geq \frac{1}{2}$$

$$\begin{aligned} \text{Hint: } P(X \geq 3) &= \sum_{x=3}^5 b(x; 5, p) \geq P(X \geq 2) \\ &= \sum_{x=2}^3 b(x; 3, p). \end{aligned}$$

Fitting of binomial distribution

Fit a B.D. to the following data:

| | | | | | | | | |
|-----|------|---|----|----|----|---|---|---|
| 12. | $x:$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
| | $f:$ | 5 | 18 | 28 | 12 | 7 | 6 | 4 |

$$\text{Ans. } 4 \quad 15 \quad 25 \quad 22 \quad 11 \quad 3 \quad 0$$

Hint: $n = 6, p = 0.4, N = 80$

| | | | | | | | | | | | | |
|-----|------|---|----|----|----|---|---|---|---|---|---|----|
| 13. | $x:$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| | $f:$ | 6 | 20 | 28 | 12 | 8 | 6 | 0 | 0 | 0 | 0 | 0 |

$$\text{Ans. } 6.9 \quad 19.1 \quad 24 \quad 17.8 \quad 8.6 \quad 2.9 \quad .7 \quad .1 \quad 0 \quad 0 \quad 0$$

Hint: $n = 10, N = 80, p = 0.2175$

| | | | | | | | |
|-----|------|----|-----|-----|-----|-----|----|
| 14. | $x:$ | 0 | 1 | 2 | 3 | 4 | 5 |
| | $f:$ | 38 | 144 | 342 | 287 | 164 | 25 |

$$\text{Ans. } 33.2 \quad 161.9 \quad 316.2 \quad 308.7 \quad 150.7 \quad 29.4$$

Hint: $n = 5, p = 0.494$

15. Seven coins are tossed and number of heads noted. The experiment is repeated 128 times with the following data:

| | | | | | | | | |
|--------------|---|---|----|----|----|----|---|---|
| No. of heads | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| Frequencies | 7 | 6 | 19 | 35 | 30 | 23 | 7 | 1 |

Fit a binomial distribution assuming

- coin is unbiased
- nature of coin is not known.

$$\text{Ans. i. } 1, 7, 21, 35, 35, 21, 7, 1$$

$$\text{Hint: } p = \frac{1}{2}, N = 128.$$

$$\text{ii. } 1, 8, 23, 36, 34, 19, 6, 1$$

$$\text{Hint: } n = 7, N = 128, .$$

$$np = \frac{433}{128} = 3.3828, p = 0.48326$$

27.5 HYPERGEOMETRIC DISTRIBUTION

The binomial distribution quite frequently arises from a random experiment in which sampling is done *with* replacement. In contrast, the hypergeometric distribution arises from random experiments in which sampling is done *without* replacement. It is very useful in quality control and analysis of the opinion surveys. Consider a population of N units in which each unit is classified into two dichotomous classes (arbitrarily known as “success” and “failure”) according to whether the unit does or does not possess

a certain property under consideration. Let k be the number of successes and $N - k$ be the failures in the population.

Draw a random sample of size n without replacement from the population. Let X be the discrete random variable which denotes the number of successes in the sample. Then the probability distribution of x is known as hypergeometric distribution and is given by $h(x; N, n, k) = \frac{\binom{k}{x} \binom{N-k}{n-x}}{\binom{N}{n}}$,

$$x = 0, 1, 2, \dots, n \quad (1)$$

The integer x should lie in the interval $\max(0, n - N + k) \leq x \leq \min(n, k)$.

Here $\binom{N}{n}$ is the number of ways of choosing a sample of size n from a population N , $\binom{k}{x}$ is the number of ways in which x successes is chosen from a total of k successes and finally $\binom{N-k}{n-x}$ gives the number of ways of getting $(n-x)$ failures out of the (remaining) $N-k$ failures. The hypergeometric distribution (1) has N, n, k as the three parameters.

Book work I Prove that mean of hypergeometric distribution is $\frac{nk}{N}$.

$$\text{Proof: Mean} = E(x) = \sum_{x=0}^n x \frac{\binom{k}{x} \binom{N-k}{n-x}}{\binom{N}{n}} =$$

$$k \sum_{x=1}^n \frac{(k-1)!}{(x-1)!(k-x)!} \frac{\binom{N-k}{n-x}}{\binom{N}{n}} = k \sum_{x=1}^n \frac{\binom{k-1}{x-1} \binom{N-k}{n-x}}{\binom{N}{n}}$$

$$\text{Now } \binom{N}{n} = \frac{N!}{n!(N-n)!} = \frac{N}{n} \binom{N-1}{n-1} \text{ so}$$

$$E(x) = \frac{nk}{N} \sum_{y=0}^{n-1} \frac{\binom{k-1}{y} \binom{N-1-(k-1)}{n-1-y}}{\binom{N-1}{n-1}}$$

$$= \frac{nk}{N} \cdot 1 = \frac{nk}{N}$$

Here $y = x - 1$ and the summation represents the sum of all probabilities in hypergeometric experiment $(n-1)$ sample is drawn from a population of $(N-1)$ containing $(k-1)$ successes.

Book work II Prove that the variance of hypergeometric distribution is $\frac{nk(N-k)(N-n)}{N^2(N-1)}$.

Proof: $\text{Var}(X) = E(X^2) - \{E(X)\}^2$
Now $E(X^2) = E\{X(X-1) + X\} = E\{X(X-1)\} + E(X)$

Consider

$$\begin{aligned} E\{X(X-1)\} &= \sum_{x=0}^n x(x-1) \frac{\binom{k}{x} \binom{N-k}{n-x}}{\binom{N}{n}} \\ &= \sum_{x=0}^n x(x-1) \cdot \frac{k!}{x!(k-x)!} \frac{\binom{N-k}{n-x}}{\binom{N}{n}} \\ &= \frac{k(k-1)}{\binom{N}{n}} \sum_{x=2}^n \frac{(k-2)!}{(x-2)!(k-2-(x-2))!} \times \\ &\quad \times \binom{N-2-(k-2)}{n-2-(x-2)} \end{aligned}$$

Now

$$\binom{N}{n} = \frac{N!}{n!(N-n)!} = \frac{N(N-1) \cdot (N-2)!}{n(n-1) \cdot (n-2)!(N-n)!}$$

So,

$$\begin{aligned} E\{X(X-1)\} &= \frac{k(k-1)n(n-1)}{N(N-1)} \times \\ &\quad \times \sum_{y=0}^{n-2} \frac{\binom{k-2}{y} \binom{N-2-(k-2)}{n-2-y}}{\binom{N-2}{n-2}} \\ &= \frac{k(k-1)n(n-1)}{N(N-1)} \cdot 1 \end{aligned}$$

Here $y = x - 2$ and the summation is one because it is the sum of the probabilities for $y = 0$ to $n - 2$. Thus

$$\begin{aligned}\text{var}(X) &= E(X^2) - \{E(X)\}^2 = E\{X(X-1)\} \\ &\quad + E(X) - \{E(X)\}^2 \\ &= \frac{k(k-1)n(n-1)}{N(N-1)} + \frac{nk}{N} - \frac{n^2k^2}{N^2} = \\ &= \frac{nk}{N^2(N-1)} \{N(N-1) + N(k-1)(n-1) - (N-1)nk\} \\ &= \frac{nk}{N^2(n-1)} \{N^2 - Nn - Nk + nk\}. \\ \sigma^2 &= \text{var}(X) = \frac{nk(N-k)(N-n)}{N^2(N-1)} \\ &= \frac{N-n}{N-1} \cdot n \cdot \frac{k}{N} \left(1 - \frac{k}{N}\right)\end{aligned}$$

Introducing $p = \frac{k}{N}$ which is the proportion successes in the population, the mean and variance of the hypergeometric distribution are written as

$$\mu = n \cdot \frac{k}{N} = np \quad \text{and}$$

$$\sigma^2 = \left(\frac{N-n}{N-1}\right) n \cdot p(1-p) = \left(\frac{N-n}{N-1}\right) npq.$$

Observe that the mean of the hypergeometric distribution and the mean of binomial distribution are same, while the variances differ by the factor $\left(\frac{N-n}{N-1}\right)$, known as “finite population correction factor”, which tends 1 as $N \rightarrow \infty$. Thus binomial distribution may be viewed as a large population edition of the hypergeometric distribution, since sampling from the finite population with replacement amounts to sampling from the infinite population (without replacement).

Approximation of the Hypergeometric Distribution by the Binomial Distribution

Book work III Show that hypergeometric distribution tends to binomial distribution as $N \rightarrow \infty$ and $\frac{k}{N} \rightarrow p$.

Proof: Consider

$$\begin{aligned}h(x; N, n, k) &= \frac{\binom{k}{x} \binom{N-k}{n-x}}{\binom{N}{n}} \\ &= \frac{k!}{x!(k-x)!} \frac{(N-k)!}{(n-x)!(N-k-n+x)!} \frac{n!(N-n)!}{N!} \\ &= \frac{k(k-1)(k-2)\dots(k-(x-1))}{x!} \times \\ &\quad \times \frac{(N-k)(N-k-1)\dots(N-k-(n-k-1))}{(n-k-1)!} \times \\ &\quad \times \frac{n!}{N(N-1)(N-2)\dots(N-(n-1))} \\ &= \frac{n!}{x!(n-x)!} \times\end{aligned}$$

$$\begin{aligned}&\left[\left(\frac{k}{N}\right) \left(\frac{k}{N} - \frac{1}{N}\right) \left(\frac{k}{N} - \frac{2}{N}\right) \dots \left(\frac{k}{N} - \frac{(x-1)}{N}\right) \right] \\ &\quad \times \frac{\left(1 - \frac{k}{N}\right) \left(1 - \frac{k}{N} - \frac{1}{N}\right) \dots \left(1 - \frac{(n-k-1)}{N}\right)}{\left(1 - \frac{1}{N}\right) \left(1 - \frac{2}{N}\right) \dots \left(1 - \frac{n-1}{N}\right)}\end{aligned}$$

Letting $N \rightarrow \infty$ and putting $\frac{k}{N} = p$ we get

$$\begin{aligned}\lim_{N \rightarrow \infty} h(x; N, n, k) &= \binom{n}{x} p \cdot (p-0)(p-0) \dots (p-0) \times (1-p)(1-p-0) \dots (1-p) \\ &= \binom{n}{x} p^x (1-p)^{n-x} = b(x; p, 1-p)\end{aligned}$$

WORKED OUT EXAMPLES

Example 1: Out of 60 applicants to a university 40 are from the south. If 20 applicants are selected at random, find the probability that (a) 10 (b) not more than 2, are from south.

Solution: The total number of ways in which 20 applicants are selected from 60 is $\binom{60}{20}$.

(a) The number of ways in which 10 applicants from south are selected from 40 south applicants is $\binom{40}{10}$.

27.18 — HIGHER ENGINEERING MATHEMATICS—VII

Now out of the total 20 selected the remaining 10 non-south applicants will be selected from 20(60-40 south) non-south applicants, which is $\binom{20}{10}$.

Thus the probability that 10 out of 20 applicants are

$$\text{from south is } \frac{\binom{40}{10} \binom{20}{10}}{\binom{60}{20}} = \frac{(\frac{40!}{10!30!})(\frac{20!}{10!10!})}{(\frac{60!}{20!40!})} =$$

$$0.0373613$$

or population size $N = 60$,

sample size $n = 20$

number of south applicants $k = 40$. Let x denote the number of applicants from the south. Then the hypergeometric distribution is $h(x; N, n, k) =$

$$\frac{\binom{k}{x} \binom{N-k}{n-x}}{\binom{N}{n}} \text{ for } x = 0, 1, 2, \dots, n.$$

$$\text{Here } h(10; 60, 20, 40) = \frac{\binom{40}{10} \binom{60-40}{20-10}}{\binom{60}{20}} =$$

$$0.03736$$

(b) Probability that $x \leq 2$ is

$$P(x \leq 2) = \sum_{x=0}^2 h(x; N, n, k) = \sum_{x=0}^2 h(x; 60, 20, 40)$$

$$= h(0; 60, 20, 40) + h(1; 60, 20, 40) + h(2; 60, 20, 40)$$

$$\begin{aligned} &= \frac{\binom{40}{0} \binom{60-40}{20-0}}{\binom{60}{20}} + \frac{\binom{40}{1} \binom{60-40}{20-1}}{\binom{60}{20}} \\ &\quad + \frac{\binom{40}{2} \binom{60-40}{20-2}}{\binom{60}{20}} \\ &= \frac{(40c_0)(20c_{20}) + (40c_1)(20c_{19}) + (40c_2)(20c_{18})}{60c_{20}} \end{aligned}$$

Example 2: Solve (a) of the above problem using Binomial approximation. Explain the accuracy obtained. What is the finite population correlation factor.

Solution: As $N \rightarrow \infty$, Binomial approximation is

$$P(X = x) = \binom{n}{x} p^x q^{n-x}.$$

Here the probability of (south) success is $p = \frac{40}{60} = \frac{2}{3}$ and probability of (non-south) failure is $q = \frac{20}{60} = \frac{1}{3}$ and $n = 20$ and $x = 10$.

Now using binomial approximation we have $P(X = x) =$ probability of 10 south applicants out of 20 applicants $= \binom{20}{10} \left(\frac{2}{3}\right)^{10} \left(\frac{1}{3}\right)^{10}$

$$= 0.0542591$$

From hypergeometric distribution the probability is 0.03736. The accuracy is less since $N = 60$ is not very large more so compared with $n = 20$. Finite

population correction factor $= \frac{N-n}{N-1} = \frac{60-20}{60-1} =$

$$0.6779$$

Example 3: Find the mean and variance and standard deviation of the random variable X in (a) of above example.

$$\text{Solution: Mean} = \frac{nk}{N} = \frac{20(40)}{60} = 1.3333$$

$$\begin{aligned} \text{Variance} &= \frac{N-n}{N-1} \cdot n \cdot \frac{k}{N} \cdot \left(1 - \frac{k}{N}\right) \\ &= \left(\frac{60-20}{60-1}\right) \cdot 20 \cdot \frac{40}{60} \cdot \left(1 - \frac{40}{60}\right) = 0.30131 \end{aligned}$$

$$\text{Standard deviation} = 0.5489$$

EXERCISE

- Find the probability of selecting 5 cards of which 3 are red and 2 are black from an ordinary deck of 52 playing cards.

$$\text{Ans. } \frac{\binom{26}{3} \binom{26}{2}}{\binom{52}{5}} = 0.3251$$

- Determine the probability that exactly one defective is found in a sample of 5 from a lot of 40 components containing 3 defectives (in the entire lot).

$$\text{Ans. } \frac{\binom{3}{1} \binom{37}{4}}{\binom{40}{5}} = 0.3011$$

- Find the mean and variance of the random variable X in the above example 2.

Ans. Mean = $\frac{5.3}{40} = 0.375$, $\sigma^2 = 0.3113$

4. (a) Determine the probability that exactly 3 computers are defective out of 10 computers purchased from a lot of 5000 computers containing 1000 defective computers. (b) Use binomial approximation and explain the accuracy. (c) what is the finite population correction factor.

Ans. (a) $h(3; 5000, 10, 1000) = 0.2015$
 (b) $h(3; 5000, 10, 1000) \simeq b(3; 10, 0.2)$

$$= \sum_{x=0}^3 b(x; 10, 0.2) - \sum_{x=0}^2 b(x; 10, 0.2) = 0.8791 - 0.6778 = 0.2015$$

since $N = 5000$ large compared to sample $n = 10$, the accuracy achieved is high.

(c) $\frac{N-n}{N-1} = \frac{5000-10}{5000-1} = 0.9982$

5. TV's are shipped in lots of 50. A shipment is accepted if a sample of 5 TV's inspected from this lot, does not contain any defective TV. If one or more are found defective, the entire shipment is rejected. Suppose the lot of 50 contains 3 defective TV's. Determine the probability that 100% inspection is required?

Ans. $P(X \geq 1) = 1 - P(X = 0)$

$$= 1 - \left\{ \frac{\binom{3}{0} \binom{47}{5}}{\binom{50}{5}} \right\} = 0.28$$
 where X is the number of defective TV's.

6. Suppose a shipment of 100 cars contain 25 defectives. Determine the probability that 2 cars out of a sample of 10 cars drawn from the lot are defective. Use binomial approximation also.

Ans. $h(2; 10, 25, 100) = 0.292$
 $b(2; 10, 0.25) = 0.282$

7. Find the probability of getting 3 blue marbles if 5 marbles are drawn (one after the other without replacement) from a box containing 6 blue and 4 red marbles.

Ans. $\frac{\binom{6}{3} \binom{4}{2}}{\binom{10}{5}} = \frac{10}{21} = 0.4762$

8. A committee of 2 is chosen from five faculty members out of which 3 are doctorate and 2

are post-graduates. If X denotes the number of doctorates in the committee, obtain the probability distribution of X .

| | | | | |
|------|--------|----------------|-----------------|----------------|
| | X | 0 | 1 | 2 |
| Ans. | $P(x)$ | $\frac{2}{20}$ | $\frac{12}{20}$ | $\frac{6}{20}$ |

Hint: $h(x; 5, 2, 3)$ for $x = 0, 1, 2$.

9. Let X be the number of defective motors in a sample of 6 drawn from a lot of 12 motors containing four defectives. Compute (a) $P(X = 1)$ (b) $P(X \geq 4)$ (c) $P(1 \leq X \leq 3)$.

Ans. (a) 0.242 (b) 0.030 (c) 0.939

10. A box contains 12 red and 8 black marbles. If 5 marbles are drawn successively (without replacement) from the box, find the probability that (a) 3 are red and 2 are black (b) at least 3 are red (c) all the 5 are of the same colour.

Ans. (a) $\frac{385}{969}$ (b) $\frac{682}{969}$ (c) $\frac{53}{969}$

Hint: (a) $\frac{\binom{12}{3} \binom{8}{2}}{\binom{20}{5}}$
 (b) $\sum_{x=3}^5 \frac{\binom{12}{x} \binom{8}{5-x}}{\binom{20}{5}}$
 (c) $\left\{ \frac{\binom{12}{5} \binom{8}{0}}{\binom{20}{5}} + \frac{\binom{12}{0} \binom{8}{5}}{\binom{20}{5}} \right\}$

27.6 POISSON DISTRIBUTION

Poisson* distribution is the discrete probability distribution of a discrete random variable x , which has no upper bound. It is defined for non-negative values of x as follows:

$$f(x, \lambda) = P(X = x) = \frac{\lambda^x e^{-\lambda}}{x!} \text{ for } x = 0, 1, 2, \dots \quad (1)$$

Here $\lambda > 0$ is called the parameter of the distribution. Note that in binomial distribution the number of successes (occurrence of an event) out of a total definite number of n trials is determined, whereas in Poisson distribution the number of successes at a random point of time and space is determined.

* Simeon Denis Poisson (1781–1840) French mathematician.

27.20 — HIGHER ENGINEERING MATHEMATICS—VII

Poisson distribution (P.D.) is suitable for 'rare' events for which the probability of occurrence p is very small and the number of trials n is very large. Also binomial distribution can be approximated by Poisson distribution when $n \rightarrow \infty$ and $p \rightarrow 0$ such that $\lambda = np = \text{constant}$.

Examples of rare events:

- i. Number of printing mistakes per page.
- ii. Number of accidents on a highway.
- iii. Number of defectives in a production centre.
- iv. Number of telephone calls during a particular (odd) time.
- v. Number of bad (dishonoured) cheques at a bank.

Result 1: Since $\sum_{x=0}^{\infty} f(x, \lambda) = \sum_{x=0}^{\infty} p(X = x) = \sum_{x=0}^{\infty} \frac{e^{-\lambda} \lambda^x}{x!} = e^{-\lambda} \sum_{x=0}^{\infty} \frac{\lambda^x}{x!} = e^{-\lambda} e^{\lambda} = 1$, Therefore (1) is a probability function.

Result 2: Arithmetic mean of Poisson distribution

$$\begin{aligned}\bar{X} = E(X) &= \sum_{x=0}^{\infty} x P(X = x) = \sum_{x=0}^{\infty} x \cdot \frac{e^{-\lambda} \lambda^x}{x!} \\ &= \lambda e^{-\lambda} \sum_{x=1}^{\infty} \frac{\lambda^{x-1}}{(x-1)!} = \lambda e^{-\lambda} \sum_{m=0}^{\infty} \frac{\lambda^m}{m!} \\ &= \lambda e^{-\lambda} \cdot e^{\lambda} = \lambda\end{aligned}$$

Thus the parameter λ is the A.M. of P.D.

Result 3: Variance of Poisson distribution

$$\begin{aligned}&= E[(x - \bar{X})^2] = \sum_{x=0}^{\infty} (x - \bar{X})^2 P(X = x) \\ &= \sum (x^2 + \bar{X}^2 - 2\bar{X}x) P = \sum x^2 P + \bar{X}^2 \sum P - 2\bar{X} \sum x P \\ &= \sum x^2 P + \bar{X}^2 - 2\bar{X} \bar{X} = \sum x^2 P + \lambda^2 - 2\lambda^2 \\ &= \sum x^2 P - \lambda^2.\end{aligned}$$

But

$$\sum x^2 P = \sum_{x=0}^{\infty} [x(x-1) + x] e^{-\lambda} \frac{\lambda^x}{x!}$$

$$\begin{aligned}&= e^{-\lambda} \sum_{x=0}^{\infty} \frac{\lambda^x \cdot x(x-1)}{x!} + e^{-\lambda} \sum_{x=0}^{\infty} \frac{\lambda^x \cdot x}{x!} \\ &= \lambda^2 e^{-\lambda} \sum_{x=2}^{\infty} \frac{\lambda^{x-2}}{(x-2)!} + \lambda e^{-\lambda} \sum_{x=1}^{\infty} \frac{\lambda^{x-1}}{(x-1)!} \\ &= \lambda^2 e^{-\lambda} e^{\lambda} + \lambda e^{-\lambda} e^{\lambda} = \lambda^2 + \lambda\end{aligned}$$

Thus

$$\text{Variance} = \sum x^2 p - \lambda^2 = (\lambda^2 + \lambda) - \lambda^2 = \lambda$$

Hence the variance of P.D. = mean of P.D.

Result 4: Recurrence formula

$$\frac{P(x+1)}{P(x)} = \frac{e^{-\lambda} \lambda^{x+1}}{(x+1)!} \cdot \frac{x!}{e^{-\lambda} \lambda^x} = \frac{\lambda}{x+1}$$

Thus

$$P(x+1) = \left(\frac{\lambda}{x+1} \right) P(x).$$

Result 5: Poisson distribution function

$$F(x; \lambda) = \sum_{k=0}^x \frac{e^{-\lambda} \lambda^k}{k!}$$

has been tabulated (see A8 to A11)

Then $f(x; \lambda) = F(x; \lambda) - F(x-1; \lambda)$.

Theorem: Prove that Poisson distribution is the limiting case of binomial distribution for very large trials with very small probability, i.e., $f(x; \lambda) = \lim_{\substack{n \rightarrow \infty \\ p \rightarrow 0}} b(x; n, p)$ such that $\lambda = np = \text{constant}$.

Proof: Put $p = \frac{\lambda}{n}$ in binomial distribution

$$\begin{aligned}b(x; n, p) &= \frac{n!}{x!(n-x)!} \cdot \left(\frac{\lambda}{n} \right)^x \left(1 - \frac{\lambda}{n} \right)^{n-x} \\ &= \frac{n(n-1)(n-2) \cdots (n-(x-1))}{x!} \cdot \frac{\lambda^x}{n^x} \times \\ &\quad \times \left(1 - \frac{\lambda}{n} \right)^{n-x} \\ &= \frac{n^x \cdot 1 \cdot \left(1 - \frac{1}{n} \right) \left(1 - \frac{2}{n} \right) \cdots \left(1 - \frac{(x-1)}{n} \right)}{x!} \cdot \frac{\lambda^x}{n^x} \times \\ &\quad \times \left(1 - \frac{\lambda}{n} \right)^{n-x}\end{aligned}$$

Taking the limit as $n \rightarrow \infty$, we have

$$\lim_{n \rightarrow \infty} b(x; n, p) = \frac{1}{x!} \lambda^x \cdot e^{-\lambda} = \frac{\lambda^x e^{-\lambda}}{x!}$$

since

$$\lim_{n \rightarrow \infty} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) \cdots \left(1 - \frac{x-1}{n}\right) = 1 \cdot 1 \cdots 1 = 1$$

and

$$\lim_{n \rightarrow \infty} \left(1 - \frac{\lambda}{n}\right)^{n-x} = \left[\left(1 - \frac{\lambda}{n}\right)^{n/\lambda}\right]^\lambda \times \left[1 - \frac{\lambda}{n}\right]^{-x} = e^{-\lambda}.$$

Note: $\lim_{n \rightarrow \infty} \left(1 - \frac{x}{n}\right)^n = e^{-x}$

Thus binomial probabilities for large n and small p are often approximated by means of poisson distribution with mean $\lambda = np$.

Example: For $n = 3000$, $p = 0.005$, the probability of 18 successes by binomial distribution is given by $b(18; 3000, .005) = 3000C_{18}(.005)^{18}(.995)^{2982}$ which involves prohibitive amount of work. Instead using Poisson distribution as an approximation, we get $\lambda = 3000 \times .005 = 15$. Probability of 18 success = $f(18, 15) = 0.8195$ from table (A8 to A11).

General rule: Poisson approximation to B.D. is used whenever $n \geq 20$ and $p \leq 0.05$. For $n \geq 100$, approximation is excellent provided $\lambda = np \leq 10$.

WORKED OUT EXAMPLES

Poisson distribution

Example 1: A distributor of bean seeds determines from extensive tests that 5% of large batch of seeds will not germinate. He sells the seeds in packets of 200 and guarantees 90% germination. Determine the probability that a particular packet will violate the guarantee.

Solution: The probability of a seed not germinating = $p = \frac{5}{100} = 0.05$

λ = mean number of seeds, in a sample of 200,
which do not germinate

$$= np = 200 \times 0.05 = 10$$

Let $X = \text{R.V.} = \text{number of seeds that do not germinate}$

A packet will violate guarantee if it contains more than 20 non-germinating seeds.

Probability that the guarantee is violated

$$\begin{aligned} &= P(X > 20) = 1 - P(X \leq 20) = 1 - \sum_{x=0}^{20} \frac{e^{-10} 10^x}{x!} \\ &= 1 - F(20, 10) = 1 - .9984 = 0.0016 \end{aligned}$$

where cumulative distribution function F is read for $x=20$ and $\lambda=10$ from the tables (A8 to A11).

Example 2: The average number of phone calls/minute coming into a switch board between 2 and 4 PM is 2.5. Determine the probability that during one particular minute there will be (a) 0 (b) 1 (c) 2 (d) 3 (e) 4 or fewer (f) more than 6 (g) at most 5 (h) at least 20 calls.

Solution: $\lambda = 2.5$, $f(x; \lambda) = f(x; 2.5) = \frac{(2.5)^x (e^{-2.5})}{x!}$
Let $X = \text{R.V.} = \text{number of phone calls/minute during that (odd) 2 and 4 PM.}$

a. $f(0; 2.5) = e^{-2.5} = .08208$

b. $f(1; 2.5) = .2052$

c. $f(2; 2.5) = .2565$

d. $f(3; 2.5) = .2138$

e. $P(X \leq 4) = \sum_{x=0}^4 f(x; 2.5) = F(4; 2.5) = .8912$

(read from tables A8 to A11)

f. $P(X > 6) = 1 - P(X \leq 6) = 1 - \sum_{x=0}^6 f(x; 2.5)$

$$= 1 - F(6; 2.5) = 1 - .9858 = 0.0142$$

g. $P(X \leq 5) = \sum_{x=0}^5 f(x; 2.5) = F(5; 2.5) = .9580$

h. $P(X \geq 2.0) = 1 - P(X \leq 19) = 1 - \sum_{x=0}^{19} f(x; 2.5)$
 $= 1 - F(19; 2.5) = 1 - 1 = 0.$

Example 3: Suppose that on the average one person in 1000 makes a numerical error in preparing income tax return (ITR). If 10000 forms are selected at random and examined, find the probability that 6, 7 or 8 of the forms will be in error.

27.22 — HIGHER ENGINEERING MATHEMATICS—VII

Solution: Let $X = \text{R.V.} = \text{number ITR forms containing a numerical error}$. Essentially this is a binomial experiment with 10000 trials and probability (of success) $p = \frac{1}{1000} = 0.001$. So by B.D. probability of 6, 7 or 8 error forms =
 $P(X = 6, 7 \text{ or } 8)$

$$= P(6) + P(7) + P(8) = \sum_{x=6}^8 b(x; 10000, 0.001)$$

$$= \sum_{x=6}^8 10000C_x (.001)^x (.999)^{10000-x}$$

which involves cumbersome lengthy calculations. Since n is large and p is small, approximate the binomial probabilities by Poisson distribution with $\lambda = np = 10000 \times \frac{1}{1000} = 10$.

Probability of 6, 7 or 8 error ITR forms =
 $P(X = 6, 7 \text{ or } 8)$

$$\begin{aligned} &= \sum_{x=6}^8 f(x; 10) = \sum_{x=6}^{\infty} \frac{e^{-10}(10)^x}{x!} \\ &= e^{-10} \left[\frac{10^6}{6!} + \frac{10^7}{7!} + \frac{10^8}{8!} \right] = .2657 \end{aligned}$$

Instead, using tables A8 to A11, we get the result in a simpler way

$$= F(8; 10) - F(5; 10) = .3328 - .0671 = .2657.$$

Example 4: Fit a Poisson distribution to the following data:

| | | | | | |
|-------------------------------|----|----|----|----|---|
| X_i : | 0 | 1 | 2 | 3 | 4 |
| Observed frequencies
f_i | 30 | 62 | 46 | 10 | 2 |

| | | | | | | | | | | | |
|---------------|-------|------|------|------|------|------|-----|------|------|------|------|
| x : | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| $f(x, 3.2)$: | 0.041 | .130 | .209 | .223 | .178 | .114 | .06 | .028 | .011 | .004 | .002 |

Solution: To fit a Poisson distribution, determine the only parameter λ of the distribution from the given data. Since λ is the arithmetic mean,

$$\lambda = \frac{\sum_{i=0}^4 f_i X_i}{\sum f_i X_i} = \frac{0 \times 30 + 1 \times 62 + 2 \times 46 + 3 \times 10 + 4 \times 2}{150}$$

$$= \frac{192}{150} = 1.28$$

Thus the Poisson distribution that “fits” to the given data is $P(X) = \frac{e^{-1.28}(1.28)^X}{X!}$.

Here total frequency $N = \sum_{i=0}^4 f_i = 150$

Expected frequency = (Total frequency) $\times$ Probability

| | | | | | |
|---------------------|--------------|--------------|--------------|--------------|-------------|
| X_i : | 0 | 1 | 2 | 3 | 4 |
| $P(X_i)$: | 0.27803 | .35588 | .22776 | .09718 | .031097 |
| $(N)(P(X_i))$ | | | | | |
| =Expected frequency | 41.7045 | 53.382 | 34.164 | 14.577 | 4.6646 |
| | ≈ 42 | ≈ 53 | ≈ 34 | ≈ 15 | ≈ 5 |

EXERCISE

Poisson distribution

- Determine the probability that 2 of 100 books bound will be defective if it is known that 5% of books bound at this bindery are defective.
 (a) use B.D. (b) use Poisson approximation to B.D.

Ans. a. $b(2; 100, 0.5) = \binom{100}{2} (0.05)^2 (.95)^{98}$
 $= 0.081$

b. $f(2; 5) = \frac{5^2 e^{-5}}{2!} = 0.084$ with
 $\lambda = np = 100(0.05) = 5$

- Find the probabilities that 0, 1, 2, 3, 4, ... of 3840 generators fail if the probability of failure is $\frac{1}{1200}$.

Ans.

Hint: $\lambda = 3840 \times \frac{1}{1200} = 3.2$. Use tables (A8 to A11) and the identity $f(x; \lambda) = F(x; \lambda) - F(x - 1; \lambda)$.

- On an average, 1.3 gamma particles/millisecond come out of a radioactive substance, determine (a) mean (b) variance

(c) probability of more than one gamma particles emanate from the substance.

Ans. (a)(b): $\lambda = \sigma^2 = 1.3$ (c) $1 - P(X = 0) = 1 - e^{-1.3} = 0.727$

4. Determine the probability p that there are 3 defective items in a sample of 100 items if 2% of items made in this factory are defective.

Ans. $p = f(3; 2) = \frac{2^3 e^{-2}}{3!} = 0.180$ with
 $\lambda = np = 100(0.02) = 2$

5. Suppose 300 misprints are distributed randomly throughout a book of 500 pages. Find the probability P that a given page contains (i) exactly two misprints (ii) two or more misprints.

Ans. i. $f(2; 0.6) = \frac{(0.6)^2 e^{-0.6}}{2!} = 0.0988 \approx 0.1$

ii. $P = 1 - P(0 \text{ or } 1 \text{ misprint})$
 $= 1 - (0.549 + 0.329) = 0.122$

6. In a factory producing blades, the probability of any blade being defective is 0.002. If blades are supplied in packets of 10, determine the number of packets containing (a) no defective (b) one defective and (c) two defective blades respectively in a consignment of 10000 packets.

Ans. a. $10000 \times P(0) = 10000 \times e^{-0.02}$
 $= 10000 \times .9802 = 9802$
 i.e., 9802 packets do not have any defective blades.

b. $10000 \times (0.02)(.9802) = 196$

c. $10000 \times \frac{(0.02)^2}{2!} \cdot 9802 = 2$

Hint: $\lambda = np = 10 \times 0.002 = 0.02$.

7. A manufacturer of cotter pins knows that 5% of his product is defective. Pins are sold in boxes of 100. He guarantees that not more than 10 pins will be defective. Determine the probability that a box will fail to meet the guarantee.

Ans. $P(X > 10) = 1 - P(X \leq 10)$
 $= 1 - \sum_{x=0}^{10} \frac{e^{-5} 5^x}{x!} = 1 - F(10, 5)$
 $= 1 - .9863 = 0.0137$

Hint: $\lambda = np = 100 \times 0.05 = 5$

8. On an average 20 red blood cells are found in a fixed volume of blood for a normal person. Determine the probability that the blood sample of a normal person will contain less than 15 red cells.

Ans. $P(X < 15) = \sum_{x=0}^{14} \frac{e^{-20} (20)^x}{x!} = F(14, 20)$
 $= 0.105$

Hint: $\lambda = 20$.

9. Two shipments of computers are received. The first shipment contains 1000 computers with 10% defectives and the second shipment contains 2000 computers with 5% defectives. One shipment is selected at random. Two computers are found good. Find the probability that the two computers are drawn from the first shipment.

Ans. 0.183

Hint: $q_1 = 0.1, p_1 = 0.9, q_2 = 0.05,$
 $p_2 = 0.95$

$\lambda_1 = n_1 p_1 = (1000)(0.9) = 900,$

$\lambda_2 = n_2 p_2 = (2000)(.95) = 1900$

C: two computers good, A: first shipment,
 B: second shipment.

$$P(A/C) = \frac{P(A)P(C/A)}{P(A)P(C/A) + P(B) \cdot P(C/B)}$$

where

$$P(A) = P(B) = \frac{1}{2}, P(C/A) = \frac{e^{-900} (900)^2}{2!},$$

$$P(C/B) = \frac{e^{-1900} (1900)^2}{2!}.$$

10. Given that the probability of an accident in an industry is 0.005 and assuming the accidents are independent (a) determine the probability that in any given period of 400 days, there will be an accident one day? (b) What is the probability that there are at most three days with an accident?

Ans. (a) $P(X = 1) = e^{-2} 2^1 = 0.271$

27.24 — HIGHER ENGINEERING MATHEMATICS—VII

$$(b) P(X \leq 3) = \sum_{x=0}^3 \frac{e^{-2} 2^x}{x!} = 0.857$$

Hint: $\lambda = np = 400(0.005) = 2$.

11. If one in every 1000 of computers produced is defective, determine the probability that a random sample of 8000 will yield fewer than 7 defective computers?

$$\text{Ans. } P(X < 7) = \sum_{x=0}^6 b(x; 8000, 0.001) \\ \simeq \sum_{x=0}^6 f(x; 8) = 0.3134$$

Hint: B.D. calculation is very hard, approximate it by P.D. with $\lambda = np = (8000)(0.001) = 8$.

12. Suppose the average number of telephone calls coming into a telephone exchange between 10 AM to 11 AM is 2, while between 11 AM to 12 noon is 6, determine the probability that more than five calls come in between 10 AM to 12 noon, assuming that calls are independent.

$$\text{Ans. } P(x > 5) = 1 - P(x \leq 5) = 1 - \sum_{x=0}^5 \frac{e^{-8} 8^x}{x!} = \\ 1 - 0.1912 = 0.8088$$

Hint: P.D. is additive: $X = X_1 + X_2$, $\lambda = \lambda_1 + \lambda_2 = 2 + 6 = 8$.

Fitting of Poisson distribution

Fit a Poisson distribution to the following data:

| | | | | | | | | | | |
|----|--------------------|----|-----|-----|----|----|----|---|---|---|
| 1. | $x:$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| | Observed frequency | 56 | 156 | 132 | 92 | 37 | 22 | 4 | 0 | 1 |
| | f_i | | | | | | | | | |

$$\text{Ans. } 69.6 \quad 137.25 \quad 135.33 \quad 88.95 \quad 43.85 \quad 17.29 \\ 5.68 \quad 1.60 \quad 0.3942$$

Hint: $\lambda = \frac{\sum f_i x_i}{N} = \frac{986}{500} = 1.972$.

| | | | | | | |
|----|--------|-----|----|----|---|---|
| 2. | $x:$ | 0 | 1 | 2 | 3 | 4 |
| | $f_i:$ | 122 | 60 | 15 | 2 | 1 |

$$\text{Ans. } 121 \quad 61 \quad 15 \quad 2 \quad 0$$

Hint:

$$\lambda = \sum \frac{f_i x_i}{N} = \frac{60+36+6+4}{200} = 0.5; e^{-0.5} = 0.61$$

| | | | | | | | |
|----|--------|-----|-----|----|----|---|---|
| 3. | $x:$ | 0 | 1 | 2 | 3 | 4 | 5 |
| | $f_i:$ | 142 | 156 | 69 | 27 | 5 | 1 |

$$\text{Ans. } 147.15 \quad 147.15 \quad 73.58 \quad 24.53 \quad 6.13 \quad 1.23$$

Hint: $\lambda = \frac{\sum f_i x_i}{\sum f_i} = \frac{400}{400} = 1$.

4. Determine the number of pages expected with 0, 1, 2, 3, and 4 errors in 1000 pages of a book if on the average two errors are found in five pages.

| | | | | | | |
|------|--------------------------|-------|--------|---------|-------|--------|
| Ans. | $x:$ | 0 | 1 | 2 | 3 | 4 |
| | $P(x):$ | .6703 | .26812 | .053624 | .0071 | .00071 |
| | Expected number of pages | 670 | 268 | 54 | 7 | 1 |

Hint: $\lambda = 2/5 = 0.4$, $e^{-0.4} = .6703$,

Expected number of pages = $1000 \times P(x)$.

| | | | | | | |
|----|------|-----|----|----|---|---|
| 5. | $x:$ | 0 | 1 | 2 | 3 | 4 |
| | $f:$ | 109 | 65 | 22 | 3 | 1 |

$$\text{Ans. } 108.7 \quad 66.3 \quad 20.2 \quad 4.1 \quad 0.7$$

Hint: $\lambda = \frac{65+44+9+4}{200} = \frac{122}{200} = 0.61$.

27.7 POISSON PROCESS

Poisson process is a random process in which the number of events (or successes) x occurring in a time interval of length say T is counted. It is a continuous parameter, discrete state process. By dividing T into n equal parts of length Δt , we have $T = n \cdot \Delta t$.

Assume that

1. The probability of success (or occurrence of an event) in a given time interval is proportional to the length of the interval, i.e., $p \propto \Delta t$ or $p = \alpha \Delta t$ where α is the proportionality constant.
2. The occurrences of events are independent, i.e., probability of success in an interval of time (or space) does not depend on the what happened prior to that time or any other interval.
3. The probability of more than one success during a small time interval Δt is negligible.

As $n \rightarrow \infty$, the probability of x successes (or occurrence of an event) during a time interval T is governed by the Poisson distribution with the

parameter

$$\lambda = n \cdot p = \left(\frac{T}{\Delta t} \right) (\alpha \Delta t) = \alpha T$$

Thus α is the average (mean) number of successes (occurrences) per unit time.

WORKED OUT EXAMPLES

Poisson process

Example: Average rate of arrival of persons in a queue is 1.5 per minute. Determine the probability that (a) at most four persons will arrive in any given minute (b) at least five will arrive during an interval of 2 minutes (c) at most 20 will arrive during an interval of 6 minutes.

Solution: α = arrival rate = 1.5.

Let X be number of persons arriving in queue

a. T = time interval = 1 minute

$$\lambda = \alpha T = (1.5)(1) = 1.5$$

$$P(X \leq 4) = \sum_{x=0}^4 f(x; 1.5) = F(4; 1.5) = .981.$$

b. T = time interval = 2 minutes

$$\lambda = \alpha T = (1.5)(2) = 3.0$$

$$\begin{aligned} P(X \geq 5) &= 1 - P(X < 5) = 1 - \sum_{x=0}^4 f(x, 3) \\ &= 1 - F(4, 3) = 1 - .815 = .185. \end{aligned}$$

c. T = time interval = 6 minutes

$$\lambda = \alpha T = (1.5)(6) = 9$$

$$P(X \leq 20) = \sum_{x=0}^{20} f(x; 9) = F(20, 9) = 1.0.$$

EXERCISE

Poisson process

1. The average rate of phone calls received is 0.6 calls per minute at an office. Determine the

probability that (a) there will be one or more calls in a minute (b) there will be at least three calls during 4 minutes.

$$\begin{aligned} \text{Ans. a. } f(x \geq 1; 0.6) &= 1 - F(0, 0.6) \\ &= 1 - .549 = .451 \end{aligned}$$

$$\begin{aligned} \text{b. } f(x \geq 3; 2.4) &= 1 - F(2, 2.4) \\ &= 1 - .570 = .430 \end{aligned}$$

2. On an average six bad cheques per day are received by a bank. Find the probability that the bank will receive (a) on any given day four bad cheques (b) 10 bad cheques on any two consecutive days.

$$\text{Ans. a. } f(4; 6) = e^{-6} 6^4 / 4! = 0.135$$

$$\begin{aligned} \text{b. } f(10; 12) &= F(10, 12) - F(9, 12) \\ &= .347 - .242 = 0.105 \end{aligned}$$

3. At an airport, the average number of aeroplanes arriving is 10. There are only 15 runways in the airport. Determine the probability that an aeroplane will be refused landing on any given day.

$$\begin{aligned} \text{Ans. } P(X \geq 15) &= 1 - \sum_{x=0}^{15} f(x, 10) = 1 - F(15, 10) \\ &= 1 - .09513 = .0487 \end{aligned}$$

4. The number of e-mails received by a computer is at the rate of two per 3 minutes. Determine the probability that five or more e-mails are received in a duration of 9 minutes.

$$\begin{aligned} \text{Ans. } \sum_{x=5}^{\infty} f(x, 6) &= 1 - F(4; 6) = 1 - 0.285 \\ &= 0.7149 \end{aligned}$$

Hint: By reproductive property of Poisson process

$\lambda = \lambda_1 + \lambda_2 + \lambda_3 = 2 + 2 + 2 = 6$ for R.V. X_1, X_2, X_3 in 3 minutes duration, so $X = X_1 + X_2 + X_3$.

5. On an average two emergency cases are received in a week (7 days) period at a hospital. Determine the probability that there are
 - a. three or less emergency cases in 2 weeks period
 - b. exactly eight emergency cases in 3 weeks period.

$$\text{Ans. a. } F(3; 4) = \sum_{x=0}^3 f(x; 4) = 0.4335$$

$$\begin{aligned} \text{b. } f(8; 6) &= F(8; 6) - F(7; 6) \\ &= .8472 - .7440 = 0.1032. \end{aligned}$$

and

$$\begin{aligned} \sigma^2 &= E(X^2) - \mu^2 = \frac{b^3 - a^3}{(b - a) \cdot 3} - \left(\frac{b + a}{2} \right)^2 \\ &= \frac{(b - a)^2}{12} \end{aligned}$$

27.8 CONTINUOUS UNIFORM DISTRIBUTION

The probability density function $f(X)$ of a continuous random variable X having *uniform* distribution over the interval $[a, b]$ is given by

$$U[a, b] = f(X) = \begin{cases} K, & \text{constant } a \leq x \leq b \\ 0, & \text{otherwise} \end{cases}$$

Here X is uniformly distributed over the interval $[a, b]$. Since $\int_{-\infty}^{\infty} f(x) dx = 1$ we have $\int_a^b K dx = 1$ or $(b - a)K = 1$ or $K = \frac{1}{b - a}$. So the constant k is the reciprocal of the length of the interval. Thus the continuous uniform distribution takes the form

$$U[a, b] = f(X) = \begin{cases} \frac{1}{b - a} & \text{if } a \leq x \leq b \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

Fig. 27.4

The density (1) is uniform in value over the interval $[a, b]$. The uniform distribution (1) is also known as *rectangular* distribution since the graph of the distribution is rectangular. The constants a and b , which are known as the parameters, completely determine the distribution (1). Since

$$\begin{aligned} E(X^K) &= \int_a^b x^K f(x) dx = \int_a^b x^K \left(\frac{1}{b - a} \right) dx \\ &= \frac{1}{b - a} \left(\frac{b^{K+1} - a^{K+1}}{K + 1} \right) \end{aligned}$$

we get the mean and variance of the uniform distribution as

$$\mu = E(X) = \frac{b^2 - a^2}{(b - a)^2} = \frac{b + a}{2}$$

Solving $a = \mu - \sqrt{3}\sigma$, $b = \mu + \sqrt{3}\sigma$

The cumulative distribution function $F(x)$:

- (i) when $x \leq a$, $F(x) = \int_{-\infty}^x 0 dx = 0$
- (ii) when $a \leq x \leq b$, $F(x) = \int_{-\infty}^x = \int_{-\infty}^a 0 + \int_a^x \frac{1}{b - a} \cdot dx = 0 + \frac{1}{b - a}(x - a) = \frac{x - a}{b - a}$
- (iii) when $x > b$, $F(x) = \int_{-\infty}^x = \int_{-\infty}^a 0 + \int_a^b \frac{1}{b - a} dx + \int_b^x 0 = \frac{1}{b - a} \cdot (b - a) = 1$

Thus

$$F(x) = \begin{cases} 0 & \text{when } x < a \\ \frac{x - a}{b - a} & \text{when } a \leq x \leq b \\ 1 & \text{when } x > b \end{cases}$$

Fig. 27.5

Now for any subinterval $[c, d]$ where $a \leq c < d \leq b$. The probability that x lies in the interval $[c, d]$ is given by

$$\begin{aligned} P(c \leq X \leq d) &= \int_c^d f(x) dx \\ &= \int_c^d \frac{1}{b - a} dx = \frac{d - c}{b - a}. \end{aligned}$$

Thus the probability depends only on the length of the interval $(d - c)$ but not on the location of that interval in $[a, b]$. Therefore in continuous uniform distribution, the probability is *same* (uniform) for *all* subintervals having the *same* length.

WORKED OUT EXAMPLES

Example 1: If X is uniformly distributed in $-2 \leq x \leq 2$, find (a) $P(X < 1)$ (b) $P(|X - 1| \geq 1/2)$.

Solution: (a) Since $X < 1$, it lies in the interval $[-2, 1]$, of length 3. Then

$$P(X < 1) = \frac{1 - (-2)}{2 - (-2)} = \frac{3}{4}$$

(b) If $|X - 1| \geq \frac{1}{2}$ then $X \geq \frac{3}{2}$ and $x \leq \frac{1}{2}$ i.e. x lies in the two intervals $[\frac{3}{2}, 2]$ and $[-2, \frac{1}{2}]$. So

$$\begin{aligned} P(|X - 1| \geq \frac{1}{2}) &= P(-2 \leq X \leq \frac{1}{2}) \\ &\quad + P(\frac{3}{2} \leq X \leq 2) \\ &= \frac{\frac{1}{2} - (-2)}{2 - (-2)} + \frac{2 - \frac{3}{2}}{2 - (-2)} \\ &= \frac{\frac{5}{2} + \frac{1}{2}}{4} = \frac{3}{4} \end{aligned}$$

Example 2: If X is uniformly distributed in $[-\alpha, \alpha]$ with $\alpha > 0$ then determine α such that $P(X > 1) = \frac{1}{3}$.

Solution: If $\alpha < 1$, then $P(X > 1)$ should be zero since X lies outside the given interval $[-\alpha, \alpha]$. Therefore α must be greater than 1. Now $P(X > 1) = \frac{\alpha - 1}{\alpha - (-\alpha)} = \frac{\alpha - 1}{2\alpha} = \frac{1}{3}$ (given). So $1 - \frac{1}{\alpha} = \frac{2}{3}$ or $\alpha = 3$.

Example 3: A bus travels between two cities A and B which are 100 miles apart. If the bus has a

breakdown, the distance X of the point of breakdown from city A has a uniform distribution $U[0, 100]$.

- There are service garages in the city A , city B and midway between cities A and B . If a breakdown occurs, a tow truck is sent from the garage closest to the point of breakdown. What is the probability that the tow truck has to travel more than 10 miles to reach the bus.
- Would it be more “efficient” if the three service garages were placed at 25, 50 and 75 miles from city A ? Explain.

Solution:

- If the bus breakdown in the intervals $[10, 40]$ miles or $[60, 90]$ miles, then the bus have to be towed for more than 10 miles.

So probability that the bus has to be towed for more than 10 miles = probability that X lies in the intervals $[10, 40]$ or $[60, 90]$. Thus the required probability is given by

$$\begin{aligned} P(10 < X < 40 \text{ or } 60 < X < 90) \\ &= P(10 < X < 40) + P(60 < X < 90) \\ &= \frac{40 - 10}{100 - 0} + \frac{90 - 60}{100 - 0} \\ &= \frac{3}{10} + \frac{3}{10} = \frac{3}{5} \end{aligned}$$

- Suppose three garages are placed at 25, 50 75 miles from city A .

In this case, the bus is to be towed for more than 10 miles if the bus breakdown in any one of the four intervals $(10, 15)$, $(35, 40)$, $(60, 65)$ or $(85, 90)$ miles. Probability is given by

$$\begin{aligned} P(10 < X < 15 \text{ or } 35 < X < 40 \\ \text{or } 60 < X < 65 \text{ or } 85 < X < 90) \end{aligned}$$

27.28 — HIGHER ENGINEERING MATHEMATICS—VII

$$\begin{aligned}
 &= P(10 < X < 15) + P(35 < X < 40) \\
 &+ P(60 < X < 65) + P(85 < x < 90) \\
 &= \frac{15-10}{100-0} + \frac{40-35}{100-0} + \frac{65-60}{100-0} + \frac{90-85}{100-0} \\
 &= \frac{20}{100} = \frac{1}{5}.
 \end{aligned}$$

Since the probability is small ($\frac{1}{5}$) compared to ($\frac{3}{5}$) in the case a, b is more “effective”.

EXERCISE

1. A point is chosen at random from the line segment $[0, 2]$. What is the probability that the chosen point lies (a) $1 \leq X \leq \frac{3}{2}$ (b) $X \geq \frac{3}{2}$ (c) $X \leq 1$ (d) $x \geq 3$
- Ans. (a) $(\frac{3}{2} - 1) \frac{1}{2} = \frac{1}{4}$ (b) $(2 - \frac{3}{2}) \frac{1}{2} = \frac{1}{4}$ (c) $(1 - 0) \frac{1}{2} = \frac{1}{2}$ (d) 0.

Hint: $f(x) = \frac{1}{2-0} = \frac{1}{2}$

2. If X is uniformly distributed in $[-\alpha, \alpha]$ with $\alpha > 0$. Then find α such that $P(X < \frac{1}{2}) = 0.7$.
- Ans. $\alpha = \frac{5}{4}$
3. If a conference room cannot be reserved for more than 4 hours, find the probability that a given conference lasts more than three hours.
- Ans. $\frac{1}{4}$

Hint: $f(x) = \frac{1}{4}, P(X \geq 3) = (4 - 3) \frac{1}{4} = \frac{1}{4}$.

4. The daily amount X of coffee, in liters dispensed by a machine is uniformly distributed with $a = 7, b = 10$. Determine the probability that the amount of coffee dispensed by the machine will be (a) at most 8.8 (b) more than 7.4 but less than 9.5 (c) at least 8.5 litres.
- Ans. a) 0.6 b) 0.7 (c) 0.5
- Hint:** $f(x) = \frac{1}{10-7} = \frac{1}{3}$
5. The driving time X from house to bus station is uniformly distributed $U[10, 50]$. If it takes 2 minutes to board the bus, determine the probability that person catches the 6.00 pm bus if he starts at 5.43 pm at his house.

Ans. $P(X \leq 15) = \frac{15-10}{50-10} = \frac{1}{8} = 0.125$

Hint: Maximum time to catch bus is $6.0 - 5.43 - 0.2 = 15$ minutes.

6. Find the third and fourth moment about the mean of a uniform distribution.

Ans. $0, (b-a)^4/80$

Hint: $\mu_r = E\{(X - \mu)^r\} = \int_a^b \left\{x - \frac{(b+a)}{2}\right\}^r \frac{1}{b-a} dx = \begin{cases} 0 & \text{if } r \text{ is odd} \\ \frac{1}{r+1} \left(\frac{b-a}{2}\right)^r & \text{if } r \text{ is even} \end{cases}$

7. A bus arrives every 10 minutes at a bus stop. Assuming waiting time X for bus is uniformly distributed find the probability that a person has to wait for the bus (a) for more than 7 minutes (b) between 2 and 7 minutes

Ans. (a) $\frac{10-7}{10-0} = \frac{3}{10} = 0.3$ (b) $\frac{7-2}{10-0} = \frac{5}{10} = \frac{1}{2} = 0.5$

8. If X is uniformly distributed with mean 1 and variance $\frac{4}{3}$ find $P(X < 0)$.

Ans. $\frac{1}{4}$

Hint: Mean = $\frac{b+a}{2} = 1$, variance = $\frac{(b-a)^2}{12} = \frac{4}{3}$, $a = -1, b = 3$ $f(x) = \frac{1}{3-(-1)} = \frac{1}{4}$, $P(X < 0) = \frac{0-(-1)}{1} \frac{1}{4} = \frac{1}{4}$.

27.9 NORMAL DISTRIBUTION

Normal probability distribution or simply normal distribution is the probability distribution of a continuous random variable X , known as normal random variable or normal variate. It is given by

$$N(\bar{X}, \sigma) = f(X) = Y(X) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}(X-\bar{X})^2/\sigma^2} \quad (1)$$

Here $\bar{X}$ = Arithmetic mean, σ = standard deviation, are the two parameters of the continuous distribution (1). Normal distribution (N.D.) is also known as Gaussian distribution (due to Karl Friedrich Gauss and also credited to de Moivre and Laplace). This theoretical distribution (1) is most important, simple, useful and is the corner stone of modern statistics because (a) discrete probability distributions such as Binomial, Poisson,

Hypergeometric can be approximated by N.D. (b) sampling distributions 't', F , χ^2 tend to be normal for large samples and (c) it is applicable in statistical quality control in industry.

Properties of Normal Distribution (N.D.)

1. The graph of the N.D. $y = f(X)$ in the XY -plane is known as normal curve (N.C.). N.C. is (a) symmetric about y-axis (b) it is bell shaped (c) the mean, median and mode coincide and therefore N.C. is unimodal (has only one maximum point). (d) N.C. has inflection points at $\bar{x} \pm \sigma$. (e) N.C. is asymptotic to both positive x-axis and negative x-axis (see Fig. 27.6).

Fig. 27.6

2. Area under the normal curve is unity.
3. Probability that the continuous random variable X lies between X_1 and X_2 is denoted by probability $P(X_1 \leq X \leq X_2)$ and is given by

$$P(X_1 \leq X \leq X_2) = \int_{X_1}^{X_2} \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-\bar{x}}{\sigma}\right)^2} dx \quad (2)$$

Since (2) depends on the two parameters $\bar{x}$ and σ , we get different normal curves for different values of $\bar{x}$ and σ and it is an impracticable task to plot all such normal curves. Instead, by introducing

$$Z = \frac{x - \bar{x}}{\sigma}$$

the R.H.S. integral in (2) becomes independent (dimensionless) of the two parameters $\bar{x}$ and σ . Here Z is known standard (or standardized) variable (variate).

4. Change of scale from x-axis to z-axis.

$$P(X_1 \leq X \leq X_2) = \int_{X_1}^{X_2} \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-\bar{x}}{\sigma}\right)^2} dx$$

$$\begin{aligned} P(Z_1 \leq Z \leq Z_2) &= \int_{Z_1}^{Z_2} \frac{1}{\sigma\sqrt{2\pi}} e^{-Z^2/2} \sigma dZ \\ &= \int_{Z_1}^{Z_2} \frac{1}{\sqrt{2\pi}} e^{-Z^2/2} dZ \end{aligned} \quad (3)$$

where

$$Z_1 = \frac{X_1 - \bar{X}}{\sigma}, \quad Z_2 = \frac{X_2 - \bar{X}}{\sigma}.$$

5. Error function or probability integral is defined as

$$P(Z) = \frac{1}{\sqrt{2\pi}} \int_0^Z e^{-Z^2/2} dZ \quad (4)$$

Now (3) can be written using (4) as

$$\begin{aligned} P(Z_1 \leq Z \leq Z_2) &= \int_{Z_1}^{Z_2} \frac{1}{\sqrt{2\pi}} e^{-Z^2/2} dZ \\ &= P(Z_2) - P(Z_1) \end{aligned} \quad (5)$$

Normal distribution $N(\bar{x}, \sigma)$ transformed by the standard variable Z is given by

$$N(0, 1) = Y(Z) = \frac{1}{\sqrt{2\pi}} e^{-Z^2/2}$$

with mean 0 and standard deviation 1. $N(0, 1)$ is known as "Standard Normal Distribution" and its normal curve as standard normal curve (Fig. 27.7). The probability integral (4) is tabulated for various values of Z varying from 0 to 3.9 and is known as normal table (see A12). Thus the entries in the normal table gives (represents) the area under the normal curve between the ordinates $Z = 0$ to Z (shaded in the figure). Since normal curve is symmetric about y-axis, the area from 0 to $-Z$ is same as the area from 0 to Z . For this reason, normal table is tabulated only for positive values of Z . Hence the determination of normal probabilities (3) reduce to the determination of areas under

Fig. 27.7

27.30 — HIGHER ENGINEERING MATHEMATICS—VII

the normal curve by (5) (see Fig. 27.7). Therefore

$$\begin{aligned} P(X_1 \leq X \leq X_2) &= P(Z_1 \leq Z \leq Z_2) = P(Z_2) - P(Z_1) \\ &= (\text{Area under the N.C. from 0 to } Z_2) \\ &\quad - (\text{Area under the N.C. from 0 to } Z_1) \end{aligned}$$

6. Area under the N.C. is distributed as follows:

68.27% area lies between $\bar{X} - \sigma$ to $\bar{X} + \sigma$

i.e., between $-1 \leq Z \leq 1$

94.45% area lies between $\bar{X} - 2\sigma$ to $\bar{X} + 2\sigma$

i.e., between $-2 \leq Z \leq 2$

99.73% area lies between $\bar{X} - 3\sigma$ to $\bar{X} + 3\sigma$

i.e., between $-3 \leq Z \leq 3$

Note: 50% area in the Z-interval $(-.745, +.745)$

99% area in the Z-interval $(-2.58, +2.58)$

Arithmetic Mean of Normal Distribution

By definition

the A.M. of a continuous distribution $f(x)$ is given by

$$\text{A.M.} = \frac{\int_{-\infty}^{\infty} x f(x) dx}{\int_{-\infty}^{\infty} f(x) dx}.$$

Consider the normal distribution with B, C as the parameters, i.e., $N(B, C) = f(x) = \frac{1}{c\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-B}{c}\right)^2}$. Then

$$\text{A.M.} = \bar{X} = \int_{-\infty}^{\infty} x \cdot \frac{1}{c\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-B}{c}\right)^2} dx$$

since $\int_{-\infty}^{\infty} f(x) dx = \text{area under the normal curve} = 1$

Put $\frac{x-B}{c} = z$ so $x = B + cz, dx = cdz$

$$\begin{aligned} \text{So } \bar{X} &= \int_{-\infty}^{\infty} (B + cz) \frac{1}{c\sqrt{2\pi}} e^{-\frac{1}{2}z^2} cdz \\ &= B \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} dz + \frac{c}{\sqrt{2\pi}} \int_{-\infty}^{\infty} z e^{-\frac{1}{2}z^2} dz \\ &= B + \frac{c}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-\frac{1}{2}z^2} d\left(\frac{z^2}{2}\right) \end{aligned}$$

since $\int_{-\infty}^{\infty} f(x) dx = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} dz = 1$.

$$= B + \frac{c}{\sqrt{2\pi}} \frac{e^{-\frac{z^2}{2}}}{-1} \Big|_{-\infty}^{\infty} = B + 0$$

So $\bar{X} = B$.

Variance for Normal Distribution

By definition

$$\begin{aligned} \text{Variance} &= \int_{-\infty}^{\infty} (x - \bar{x})^2 f(x) dx \\ &= \int_{-\infty}^{\infty} x^2 f(x) dx + \bar{x}^2 \int_{-\infty}^{\infty} f(x) dx \\ &\quad - 2\bar{x} \int_{-\infty}^{\infty} x f(x) dx \\ &= \int_{-\infty}^{\infty} x^2 f(x) dx + \bar{x}^2 - 2\bar{x}\bar{x} \end{aligned}$$

since $\int_{-\infty}^{\infty} f(x) dx = 1$ and $\int_{-\infty}^{\infty} x f(x) dx = \bar{x}$.

Consider the first integral in the R.H.S.

$$\int_{-\infty}^{\infty} x^2 f(x) dx = \int_{-\infty}^{\infty} x^2 \frac{1}{c\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-B}{c}\right)^2} dx$$

Put $\frac{x-B}{c} = z$ so $x = \bar{x} + cz, dx = cdz$

$$\begin{aligned} \int_{-\infty}^{\infty} x^2 f(x) dx &= \int_{-\infty}^{\infty} (\bar{x} + cz)^2 \frac{1}{c\sqrt{2\pi}} e^{-\frac{1}{2}z^2} cdz \\ &= \frac{1}{\sqrt{2\pi}} \left[c^2 \int_{-\infty}^{\infty} z^2 e^{-\frac{1}{2}z^2} dz \right. \\ &\quad \left. + \bar{x}^2 \int_{-\infty}^{\infty} e^{-\frac{1}{2}z^2} dz + 2c\bar{x} \int_{-\infty}^{\infty} z e^{-\frac{1}{2}z^2} dz \right] \\ &= \frac{-c^2}{\sqrt{2\pi}} \int_{-\infty}^{\infty} z d\left(e^{-\frac{1}{2}z^2}\right) + \bar{x}^2 \cdot 1 + 2c\bar{x} \cdot 0 \\ &= \frac{-c^2}{\sqrt{2\pi}} z e^{-\frac{1}{2}z^2} \Big|_{-\infty}^{\infty} + \frac{c^2}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-\frac{1}{2}z^2} dz + \bar{x}^2 \\ &= 0 + c^2 \cdot 1 + \bar{x}^2 \end{aligned}$$

Substituting this value

$$\text{Variance} = \int_{-\infty}^{\infty} x^2 f(x) dx - \bar{x}^2 = [c^2 + \bar{x}^2] - \bar{x}^2 = c^2$$

Thus the standard deviation (s.d.), of N.D. is c .

Book Work: Show that the area under the normal curve is unity.

Proof: Normal probability distribution is given by

$$y = f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\bar{x})^2/2\sigma^2}$$

Then the area A under the normal curve is

$$A = \int_{-\infty}^{\infty} \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\bar{x})^2/2\sigma^2} dx$$

Put $\frac{x-\bar{x}}{\sigma} = z$, so $dx = \sigma dz$

or $A = \int_{-\infty}^{\infty} \frac{1}{\sigma\sqrt{2\pi}} e^{-z^2/2} \sigma dz = \sqrt{\frac{2}{\pi}} \int_0^{\infty} e^{-z^2/2} dz$

or $A \cdot A = \left[\sqrt{\frac{2}{\pi}} \int_0^{\infty} e^{-x^2/2} dx \right] \left[\sqrt{\frac{2}{\pi}} \int_0^{\infty} e^{-y^2/2} dy \right]$

Here x, y are dummy variables (Fig. 27.8).

$$A^2 = \frac{2}{\pi} \int_0^{\infty} \int_0^{\infty} e^{-(x^2+y^2)/2} dx dy$$

Put $x = r \cos \theta$, $y = r \sin \theta$, $J = \text{Jacobian} = r$
Limits for $r : 0$ to ∞ , $\theta = 0$ to 2π (to cover the first quadrant $0 < x < \infty$, $0 < y < \infty$)

Fig. 27.8

So
$$A^2 = \frac{2}{\pi} \int_0^{\pi/2} \int_0^{\infty} e^{-\frac{r^2}{2}} r dr d\theta$$
$$= \int_0^{\infty} e^{-\frac{r^2}{2}} d\left(\frac{r^2}{2}\right) = \left. \frac{e^{-\frac{r^2}{2}}}{-1} \right|_0^{\infty} = 1$$

Thus $A = \text{area under the normal curve} = 1$.

Book Work: Prove that for normal distribution the mean deviation from the mean equals to $\frac{4}{5}$ of standard deviation approximately.

Proof: Let $\bar{x}$ and σ be the mean and standard deviation of the normal distribution. Then by definite mean deviations from the mean $= \int_{-\infty}^{\infty} |x - \bar{x}| f(x) dx$

$$= \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} |x - \bar{x}| e^{-\frac{(x-\bar{x})^2}{2\sigma^2}} dx$$

$$= \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} \sigma |z| e^{-\frac{1}{2}z^2} \sigma dz$$

where $z = \frac{x-\bar{x}}{\sigma}$ and $dx = \sigma dz$.

$$= \sigma \sqrt{\frac{2}{\pi}} \int_0^{\infty} z e^{-\frac{z^2}{2}} dz = \sigma \sqrt{\frac{2}{\pi}} \left[-e^{-\frac{z^2}{2}} \right]_0^{\infty} = \sqrt{\frac{2}{\pi}} \sigma$$

$$= 0.7979\sigma \approx 0.8\sigma = \frac{8}{10}\sigma = \frac{4}{5}\sigma$$

Fitting of Normal Distribution

Given any frequency distribution, a normal distribution (i.e., a normal curve) can be fitted to it using

$$N(\bar{X}, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-\bar{X}}{\sigma}\right)^2}$$

Here $\bar{X}$ = A.M. and σ = s.d. are calculated from the given frequency distribution.

Procedure

Consider a frequency distribution (F.D.)

$$\begin{array}{ll} L_1 - U_1 & f_1 \\ L_2 - U_2 & f_2 \\ \vdots & \vdots \\ L_n - U_n & f_n \end{array}$$

and $N = \text{total frequency} = \sum_{i=1}^n f_i$

Let $\bar{X}$ and σ be the A.M. and S.D. of the F.D.

Here L_i, U_i are the true lower and upper limits of the i th class.

- I. Compute standard variable $z_i = \frac{X_i - \bar{X}}{\sigma}$ for each of the true lower limit X_i of the n classes (there will be $n + 1$ such quantities).
- II. Compute area under N.C. (from normal table A12) from 0 to z_i .
- III. Normal probability of a class is obtained by taking the difference between the successive areas calculated in step II. (when z_i 's are of opposite sign, add the successive areas).
- IV. Expected or theoretical frequencies are obtained by multiplying probabilities in III by N , the total frequency of the F.D.

WORKED OUT EXAMPLES

Normal distribution

Example 1: Find the area A under the normal curve:

- to the left of $z = -1.78$
- to the left of $z = 0.56$
- to the right of $z = -1.45$
- corresponding to $z \geq 2.16$
- corresponding to $-0.80 \leq z \leq 1.53$
- to the left of $z = -2.52$ and to right of $z = 1.83$

Solution: Refer to normal table (A12)

- $A = 0.5 - \text{Area}(0 \text{ to } -1.78)$ (Fig. 27.9)
 $= 0.5 - \text{Area}(0 \text{ to } 1.78)$ due to symmetry
 $= 0.5 - 0.4625 = 0.0375$ (from table)

Fig. 27.9

- $A = 0.5 + \text{Area from } 0 \text{ to } 0.56$ (Fig. 27.10)
 $= 0.5 + 0.2123$ (from table)
 $= 0.7123$

Fig. 27.10

- $A = 0.5 + \text{Area from } 0 \text{ to } -1.45$ (Fig. 27.11)
 $= 0.5 + \text{Area from } 0 \text{ to } 1.45$
 $= 0.5 + 0.4265 = 0.9265$

Fig. 27.11

- $A = 0.5 - A(0 \text{ to } 2.16)$
 $= 0.5 - 0.4846 = 0.0154$ (Fig. 27.12)

Fig. 27.12

- $A = \text{Area from } (0 \text{ to } -0.8) + \text{Area from } (0 \text{ to } 1.53)$
 $= \text{Area from } (0 \text{ to } 0.8) + \text{Area from } (0 \text{ to } 1.53)$
 $= 0.4370 + 0.2881 = 0.7251$ (Fig. 27.13)

Fig. 27.13

- $A = [0.5 - A(0 \text{ to } 2.52)] + [0.5 - A(0, 1.83)]$
 $= (0.5 - 0.4941) + (0.5 - 0.4664)$
 $= 0.0059 + 0.0336$
 $= 0.0395$ (Fig. 27.14)

Fig. 27.14

Example 2: If z is normally distributed with mean 0 and variance 1, find

- $P(z \geq -1.64)$
- $P(-1.96 \leq z \leq 1.96)$
- $P(z \leq 1)$
- $P(z \geq 1)$

Solution:

- $$P(z \geq -1.64) = 0.5 + A(0 \text{ to } -1.64) \text{ (Fig. 27.15)}$$

$$= 0.5 + A(0 \text{ to } 1.64)$$

$$= 0.5 + 0.4495 = 0.9495$$

Fig. 27.15

- $$P(-1.96 \leq z \leq 1.96)$$

$$= 2A(0 \text{ to } 1.96) \text{ by symmetry}$$

$$= 2(0.4750) = 0.9500 \text{ (Fig. 27.16)}$$

Fig. 27.16

- $$P(z \leq 1) = 0.5 + A(0 \text{ to } 1)$$

$$= 0.5 + 0.3413$$

$$= 0.8413 \text{ (Fig. 27.17)}$$

Fig. 27.17

- $$P(z \geq 1) = 0.5 - A(0 \text{ to } 1)$$

$$= 0.5 - 0.3413 = 0.1587 \text{ (Fig. 27.18)}$$

Fig. 27.18

Example 3: Determine the value of z such that (a) area to the right of z is 0.2266 (b) area to the left of z is 0.0314.

Solution: Here the areas (entries of the normal table) are given, the values of z (1st column) are determined.

- Since area $0.2266 < \frac{1}{2}$ is to the right of z , z must be positive such that area from 0 to z is $0.5 - 0.2266 = 0.2734$. From normal table for area 0.2734, the value of z is 0.75 (Fig. 27.19).

Fig. 27.19

- Since area $0.134 < \frac{1}{2}$ is to the left of z , z must be negative. So determine z such that area from 0 to z is $0.5 - 0.134 = 0.4686$. From table A12, $z = -1.86$ (Fig. 27.20).

Fig. 27.20

Example 4: Find the (a) mean and (b) standard deviation of an examination in which grades 70 and

27.34 — HIGHER ENGINEERING MATHEMATICS—VII

88 correspond to standard scores of -0.6 and 1.4 respectively.

Solution: Standard variable $z = \frac{X - \bar{X}}{\sigma}$.

$$\begin{aligned} \text{Here } -0.6 &= \frac{70 - \bar{X}}{\sigma} \quad \text{so } \bar{X} - 0.6\sigma = 70 \\ 1.4 &= \frac{88 - \bar{X}}{\sigma} \quad \text{so } \bar{X} + 1.4\sigma = 88 \end{aligned}$$

Solving $\bar{X} = 75.4$, $\sigma = 9$ are the mean and standard deviation.

Example 5: Determine the minimum mark a student must get in order to receive an A grade if the top 10% of the students are awarded A grades in an examination where the mean mark is 72 and standard deviation is 9.

Solution: The 0.1 area to the right of z corresponds to the top 10% of the students (see Fig. 27.21). From table if area from 0 to z is 0.4, then $z = 1.28$. Given $\bar{X} = 72$, $\sigma = 9$, we have $1.28 = z = \frac{X - \bar{X}}{\sigma} = \frac{X - 72}{9}$,

$$X = 72 + 11.52 = 83.52 \approx 84$$

Fig. 27.21

So a student must get a minimum (or more) of 84 marks to get an A grade.

Example 6: Find the mean and standard deviation of a normal distribution in which 7% of the items are under 35 and 89% are under 63 (see Fig. 27.22).

Fig. 27.22

Solution: Let X be the continuous random variable. Given that $P(X < 35) = 0.07 < \frac{1}{2}$. So z must be negative such that area from 0 to z is $0.5 - 0.07 = 0.43$. From normal table $z = -1.48$.

Given that $P(X < 63) = 0.89 > \frac{1}{2}$. So z must be positive such that area from 0 to z is $0.89 - 0.5 = 0.39$ (Fig. 27.23).

Fig. 27.23

From normal table $z = 1.23$.

Since $z = \frac{X - \bar{X}}{\sigma}$, we have

$$\begin{aligned} -1.48 &= \frac{35 - \bar{X}}{\sigma} \quad \text{or } \bar{X} - 1.48\sigma = 35 \\ 1.23 &= \frac{63 - \bar{X}}{\sigma} \quad \text{or } \bar{X} + 1.23\sigma = 63 \end{aligned}$$

Solving the arithmetic mean $\bar{X} = 50.3$ and standard deviation $\sigma = 10.33$.

Example 7: When the mean of marks was 50% and S.D. 5% then 60% of the students failed in an examination. Determine the 'grace' marks to be awarded in order to show that 70% of the students passed. Assume that the marks are normally distributed.

Solution: Let X be the marks obtained in the exam. Given $\bar{X} = 50$, $\sigma = \text{s.d.} = 5$.

Before grace marks were awarded, 60% failed. Since 60% failure corresponds 0.6 area, z_1 must be positive (Fig. 27.24). Determine z_1 such that the area to its left is 0.6. The value of z_1 for which the area is 0.1 is 0.25.

Fig. 27.24

$$0.25 = z_1 = \frac{X_1 - 0.5}{0.05} \quad \text{so} \quad X_1 = 0.5125$$

After grace marks were awarded, 70% passed examination. The area 0.70 ($> \frac{1}{2}$) corresponds pass students (Fig. 27.25). Determine z_2 such that the area to its right is 0.7. So z_2 must be negative and from table, $z_2 = -0.52$. Then

$$z_2 = -0.52 = \frac{X - 0.5}{0.05} \quad \text{or} \quad X_2 = 0.4740$$

Fig. 27.25

Thus the minimum pass mark for a student is 51.25 before grace while the minimum pass mark is 47.40 after grace. So grace marks awarded is $51.25 - 47.40 = 3.85$.

Example 8: Assume that the ‘reduction’ of a person’s oxygen consumption during a period of Transcendental Meditation (T.M.) is a continuous random variable X normally distributed with mean 37.6 cc/mt and s.d. 4.6 cc/mt. Determine the probability that during a period of T.M. a person’s oxygen consumption will be reduced by (a) at least 44.5 cc/mt (b) at most 35.0 cc/mt (c) anywhere from 30.0 to 40.0 cc/mt.

Solution: $z = \frac{X - \bar{X}}{\sigma} = \frac{X - 37.6}{4.6}$

a. For $X = 44.5$, $z = \frac{44.5 - 37.6}{4.6} = 1.5$ (Fig. 27.26)

$$P(X \geq 44.5) = P(z \geq 1.5) = 0.5 - 0.4332 = 0.068$$

Fig. 27.26

b. For $X = 35.0$, $z = \frac{35.0 - 37.6}{4.6} = -0.5652$ (Fig. 27.26)

$$P(X \leq 35) = P(z \leq -0.5652)$$

$$= 0.5 - 0.2157$$

$$= 0.2843.$$

Fig. 27.27

c. For $X_1 = 30$, $z_1 = \frac{30 - 37.6}{4.6} = -1.6521$

For $X_2 = 40$, $z_2 = \frac{40 - 37.6}{4.6} = 0.52173$

(Fig. 27.26)

$$P(30 \leq X \leq 40) = P(-1.6521 \leq z \leq 0.52173)$$

$$= 0.4505 + 0.1985$$

$$= 0.6490.$$

Fig. 27.28

Example 9: The marks X obtained in mathematics by 1000 students in normally distributed with mean 78% and s.d. 11% (Fig. 27.29). Determine (a) how many students got marks above 90%? (b) what was the highest mark obtained by the lowest 10% of students? (c) semi-inter quartile range (d) within what limits did the middle 90% of students lie?

Solution: Here $z = \frac{X - \bar{X}}{\sigma} = \frac{X - 78}{11}$

a. For $X = 90$, $z = \frac{90 - 78}{11} = 1.09.$

27.36 — HIGHER ENGINEERING MATHEMATICS—VII

$$P(X > 0.9) = P(z > 1.09) = 0.5 - 0.3621 = 0.1379$$

Fig. 27.29

Number of students with marks above 90%

$$= 1000 \times P(X > 0.9) = 1000 \times 0.1379 = 137.9 \approx 138.$$

- b. The lowest 10% students constitute 0.1 area ($< \frac{1}{2}$) of extreme left tail. So z_1 must be negative. From table $0.4 = 0.5 - 0.1 = 0.5 - \text{Area } 0.1 \text{ from } 0 \text{ to } z_1$ so $z_1 = -1.28$.

$$\text{Thus } -1.28 = z_1 = \frac{X - 0.78}{0.11} \text{ or } X = 0.6392$$

(see Fig. 27.30)

Thus the highest mark obtained by the lowest 10% of students is $63.92 \approx 64\%$.

Fig. 27.30

- c. Quartiles Q_1, Q_2, Q_3 divide the area into four equal parts. The value of z_1 corresponding to the first quartile Q_1 is such that the area to its left is 0.25. From table $z_1 = -0.67$. Similarly, $z_3 = 0.67$ corresponding to Q_3 . Now $-0.67 = z_1 = \frac{X_1 - 0.78}{0.11}$. So the quartile mark is $X_1 = 0.7063 = 70.63\%$. Similarly, $X_3 = 85.37\%$. Thus the semi-inter quartile range $= \frac{Q_3 - Q_1}{2} = \frac{85.37 - 70.63}{2} = 7.37$ (Fig. 27.31).

- d. Middle 90% correspond to 0.9 area, leaving 0.05 area on both sides. Then the corresponding z 's are ± 1.64 (refer Fig. 27.32).

Fig. 27.31

$$1.64 = z_2 = \frac{X_2 - 0.78}{0.11} \text{ so } X_2 = 96.04$$

$$-1.64 = z_1 = X_1 - 0.78 \text{ so } X_1 = 59.96$$

Fig. 27.32

Thus the middle 90% have marks in between 60 to 96.

Example 10: Fit a normal distribution to the following data (frequency distribution):

| S. No. | Class | Observed frequency f_i |
|--------|-------|--------------------------|
| 1 | 5-9 | 1 |
| 2 | 10-14 | 10 |
| 3 | 15-19 | 37 |
| 4 | 20-24 | 36 |
| 5 | 25-29 | 13 |
| 6 | 30-34 | 2 |
| 7 | 35-39 | 1 |

$$\text{Total frequency} = \sum_{i=1}^7 f_i = 100$$

Solution:

| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|--------|-------|---------------------------------|---------------------------------|--|-------------------------|--------------------------------------|---|
| S. No. | Class | Frequency
f_i | True lower
class limit X_i | Standard variate
$z_i = \frac{X_i - 20}{5}$ | Area from
0 to z_i | Area for class
(Probability P) | Expected or
theoretical frequency
$= NP = 100P$ |
| 1 | 5–9 | 1 | 4.5 | −3.1 | 0.4990 | 0.0169 | 1.69 $\approx$ 2 |
| 2 | 10–14 | 10 | 9.5 | −2.1 | 0.4821 | 0.1178 | 11.78 $\approx$ 12 |
| 3 | 15–19 | 37 | 14.5 | −1.1 | 0.3643 | 0.3245 | 32.45 $\approx$ 32 |
| | | | 19.5 | −0.1 | 0.0398 | | |
| 4 | 20–24 | 36 | 24.5 | 0.9 | 0.3159 | 0.3557 | 35.57 $\approx$ 36 |
| 5 | 25–29 | 13 | 29.5 | 1.9 | 0.4713 | 0.1554 | 15.54 $\approx$ 16 |
| 6 | 30–34 | 2 | 34.5 | 2.9 | 0.4981 | 0.0268 | 2.68 $\approx$ 3 |

Note: Entries in column 7 are obtained by subtracting successive values in column 6 whenever they (in 6) are of the same sign. Add the values in column 6 when they are of opposite sign.

EXERCISE

Normal distribution

1. Determine the area under the normal curve

- between $z = -1.2$ and $z = 2.4$
- between $z = 1.23$ and $z = 1.87$
- between $z = -2.35$ and $z = -0.5$
- to the left of $z = -1.90$
- to the left of $z = 1.0$
- to the right of $z = -2.40$
- to the left of $z = -3.0$ and to the right of $z = 2.0$.

Ans. (a) 0.8767 (b) 0.0786 (c) 0.2991 (d) 0.0287 (e) 0.8413 (f) 0.9918 (g) 0.0241

2. Find the value of z such that

- area between -0.23 and z is 0.5722
- area between 1.15 and z is 0.0730
- area between $-z$ and z is 0.9.

Ans. (a) $z = 2.08$ (b) $z = 0.1625$
(c) $z = -1.65$ to $+1.65$

- Calculate the standard marks of two students whose marks are 93 and 62 in an examination given that the mean mark is 78 and s.d. is 10.
 - If the standard marks of two students are -0.6 and 1.2 , determine their respective marks.

Ans. (a) $z = 1.5, -1.6$ (b) $X = 72, 90$

- Determine the probability that the amount of cosmic radiation X a pilot of jet plane will be exposed is more than 5.20 m rem if X is normally distributed with mean 4.35 m rem and s.d. 0.59 m rem.

Ans. $P(X > 5.20) = P(z > 1.44)$
 $= 0.5 - 0.4251 = 0.0749$.

- Suppose the life span X of certain motors is normally distributed with mean 10 years and s.d. 2 years. If the manufacturer is ready to replace only 3% of motors that fail, how many years of guarantee can he offer (Fig. 27.33).

Ans. $-1.88 = z = \frac{X - \bar{X}}{\sigma} = \frac{X - 10}{2}$, $X = 6.24$ years

- Determine the expected number of boys whose weight is

- between 65 and 70 kg
- greater than or equal to 72 kg

Fig. 27.33

if the weight X of 800 boys follows normal distribution with $\bar{X} = 66$, $\sigma = 5$.

Ans. a. $P(65 \leq X \leq 70) = P(-0.20 < z < 0.80)$

$$= 0.0793 + 0.2881 = 0.3674$$

$$\text{Number} = 800(0.3674) = 294$$

b. $P(X \geq 72) = P(z \geq 1.2) = 0.5 - 0.3849$

$$= 0.1151$$

$$\text{Number of boys} = 800(0.1151) = 92$$

7. Calculate the mean and s.d. of a normal distribution in which 31% are under 45 and 8% are over 64.

Ans. $\bar{X} = 50$, $\sigma = 10$

8. Assume that the average life span of computers produced by a company is 2040 hours with s.d. of 60 hours. Find the expected number of computers whose life span is

- more than 2150 hours
 - less than 1950 hours
 - more than 1920 hours and less than 2160 hours
- from a pool of 2000 computers assuming that the life span X is normally distributed.

Ans. a. $P(X > 2150) = P(z > 1.833) =$

$$0.5 - 0.4664 = 0.0336.$$

Expected number of computers whose life span is more than 2150 hours = $2000(0.0336) = 67$.

b. $P(X < 1950) = P(z < -1.33)$

$$= 0.5 - 0.40821 = 0.0918$$

$$\text{Expected number} = 2000(0.0918) = 184$$

c. $P(1920 \leq X \leq 2160) = P(-2 \leq z \leq 2)$

$$= 2(0.4772) = 0.9544.$$

$$\text{Expected number} = 2000 \times 0.9544 = 1909.$$

9. If the top 15% of the students receives A grade and bottom 10% receives F grades in a mathematics examination, determine the

- minimum mark to get an A grade
- minimum mark to pass (not to get F grade).

Assume that the marks are normally distributed with mean 76 and s.d. 15.

Ans. (a) 92 (b) 57

10. A university awards distinction, first class, second class, third class or pass class according as the student gets 80% or more; 60% or more; between 45% and 60%; between 30% and 45%; or 30% or more marks respectively. If 5% obtained distinction and 10% failed, determine the percentage of students getting second class. Assume that marks X are normally distributed.

Ans. 34% second class.

Hint: $P(X < 30) = 0.10$ failed; $P(X \geq 80) = 0.05$ distinction, $\frac{30 - \bar{X}}{\sigma} = -1.28$, $\frac{80 - \bar{X}}{\sigma} = 1.64$, $\bar{X} = 52$, $\sigma = 17.12$

$$P(45 < X < 60) = P(-0.41 < z < 0.47) \leq 0.1591 + 0.1808 = 0.3399.$$

11. The amount of pollutant X released by an industry should lie between 30 and 35. Assume that X is normally distributed with mean $\bar{X} = 33$ and s.d. $\sigma = 3$. The industry gets a profit of Rs. 100 when $30 < X < 35$; Rs. 50 when $25 < X \leq 30$ or $35 \leq X < 40$ and incurs a fine of Rs. 60 otherwise. Determine the expected profit for the industry.

Ans. $100(0.5890) + 50(0.396) - 60(0.0137) = \text{Rs. } 79.$

EXERCISE

Fitting of normal distribution

1. Fit a normal curve to the following data:

| | | | | | |
|-----------|-------|-------|-------|-------|-------|
| Class | 60–62 | 63–65 | 66–68 | 69–71 | 72–74 |
| Frequency | 5 | 18 | 42 | 27 | 8 |

Ans. $4.13 \approx 4$ $20.68 \approx 21$ $38.92 \approx 39$

$$27.71 \approx 28 \quad 7.43 \approx 7$$

Hint: $\bar{X} = 67.45, \sigma = 2.92, N = 100$.

2. Fit a normal distribution to the following frequency distribution

| | | | | | |
|-------|---|---|---|---|----|
| x : | 2 | 4 | 6 | 8 | 10 |
| f : | 1 | 4 | 6 | 4 | 1 |

Ans. $0.97 \approx 1 \quad 3.9 \approx 4 \quad 6.1 \approx 6 \quad 3.9 \approx 4$
 $0.97 \approx 1.0$

Hint: $\bar{X} = 6, \sigma = 2, N = 16, x$ is taken as the mid value of the class, i.e., 2 is mid value of the class (1, 3), etc.

3. Fit a normal curve to the following observed data:

| | | | | |
|-------|---------|----------|-----------|-----------|
| Class | 9.3–9.7 | 9.8–10.2 | 10.3–10.7 | 10.8–11.2 |
| f | 2 | 5 | 12 | 17 |

| | | | | |
|-------|-----------|-----------|-----------|-----------|
| Class | 11.3–11.7 | 11.8–12.2 | 12.3–12.7 | 12.8–13.2 |
| f | 14 | 6 | 3 | 1 |

Ans. $1.704 \approx 2 \quad 5.562 \approx 6 \quad 11.7420 \approx 12$
 $15.624 \approx 16 \quad 13.942 \approx 14 \quad 7.62 \approx 8$
 $2.712 \approx 3 \quad 0.168 \approx 1$

Hint: $\bar{X} = 11.09, \text{s.d.} = 0.733, N = 60$.

4. Fit a normal distribution to the following data:

| | | | | |
|-------|---------|---------|---------|---------|
| Class | 150–158 | 159–167 | 168–176 | 177–185 |
| f | 9 | 24 | 51 | 66 |

| | | | | | |
|-------|---------|---------|---------|---------|---------|
| Class | 186–194 | 195–203 | 204–212 | 213–221 | 222–230 |
| f | 72 | 48 | 21 | 6 | 3 |

Ans. $9.0 \quad 25.4 \quad 51.5 \quad 71.2 \quad 67.8 \quad 44.6 \quad 20.2$
 $6.3 \quad 1.4$

Hint: $\bar{X} = 184.3, \sigma = 14.54, N = 300$.

27.10 NORMAL APPROXIMATION TO BINOMIAL DISTRIBUTION

For large n , the calculation of binomial probabilities is very cumbersome. In such cases they are computed by approximation procedures. For $n \rightarrow \infty$ and $p \rightarrow 0$ B.D. can be approximated by Poisson distribution with $\lambda = np$.

For $n \rightarrow \infty$ and $p \not\rightarrow 0$, i.e., p not close to 0 or 1, B.D. can be approximated by normal distribution.

Theorem: Let X be a binomial random variable

with mean $\bar{X} = np$ and s.d. $= \sqrt{npq}$ then the limiting form of the distribution of

$$z = \frac{X - np}{\sqrt{npq}}$$

as $n \rightarrow \infty$ is standard normal distribution $N(z; 0, 1)$.

Normal approximation to B.D. will be fairly good even when

- n is small and p is close to $\frac{1}{2}$
- both np and nq are ≥ 5 .

WORKED OUT EXAMPLES

Normal approximation to B.D.

Example 1: If 10% of the truck drivers on road are drunk determine the probability that out of 400 drivers randomly checked

- at most 32
- more than 49
- at least 35 but less than 47 drivers are drunk on the road.

Solution: Here p = probability of a driver drunk $= \frac{10}{100} = 0.1$ and $n = 400$ = no. of trials.

Let X = number of truck drivers drunk.

Here X is a binomial random variable with B.D. $= b(x; 400, 0.1)$. This B.D. can be approximated by normal distribution with A.M. $= \bar{X} = np = 400 \times \frac{10}{100} = 40$ and

$$\text{s.d.} = \sigma = \sqrt{npq} = \sqrt{400 \times \frac{10}{100} \times \frac{90}{100}} = 6.$$

- For $X = 32, z = \frac{X - \bar{X}}{\sigma} = \frac{31.5 - 40}{6} = -\frac{8.5}{6} = -1.416$ since X is treated as continuous variable, values upto and more than 31.5 will be rounded up to 32 (Fig. 27.34).

$$P(X < 32) = P(z \leq -1.416) = 0.5 - 0.4222 = 0.0778$$

Fig. 27.34

- b. Since 49.5 and above are rounded to 50, for $X > 49$, $z = \frac{49.5-40}{6} = 1.58$ (Fig. 27.35)

$$P(X > 49) = P(z \geq 1.58) = 0.5 - 0.4429 \\ = 0.0571$$

Fig. 27.35

- c. $X \geq 35$ includes values of X upto 34.5 and $x < 47$ includes values of X upto 46.5 (Fig. 27.36).

Fig. 27.36

$$z_1 = \frac{34.5 - 40}{6} = -0.916,$$

$$z_2 = \frac{46.5 - 40}{6} = 1.083$$

$$P(35 \leq X < 47) = P(-0.916 \leq z \leq 1.083) \\ = 0.3212 + 0.3599 = 0.681.$$

Example 2: A pair of dice is rolled 180 times. Determine the probability that a total of 7 occurs

- at least 25 times
- between 33 and 41 times inclusive
- exactly 30 times.

Solution: Sum 7 occurs in a single throw of a pair of dice as follows: (1, 6), (6, 1), (2, 5), (5, 2), (3, 4), (4, 3).

p = probability of 7 occurring = $\frac{6}{36} = \frac{1}{6}$, $n = 180$;
 X = number of occurrences of a sum of 7 in a pair of dice = a binomial random variable.

Treating X as a continuous R.V., B.D. = $b(x; 180, \frac{1}{6})$ can be approximated by normal distribution with A.M. = $\bar{X} = np = 180 \times \frac{1}{6} = 30$, $\sigma = \text{s.d.} = \sqrt{npq} = \sqrt{180 \cdot \frac{1}{6} \cdot \frac{5}{6}} = 5$

- a. For $X \geq 25$, X includes up to 24.5. Thus

$$z = \frac{24.5 - 30}{5} = -1.1$$

$$P(X \geq 25) = P(z \geq -1.1) = 0.5 + 0.3643 \\ = 0.8643 \text{ (Fig. 27.37)}$$

Fig. 27.37

- b. $P(33 \leq X \leq 41) = P(0.5 \leq z \leq 2.3)$
 $= 0.4893 - 0.1915 = 0.2978$ (Fig. 27.38)

$$\text{since } z_1 = \frac{32.5-30}{5} = 0.5, z_2 = \frac{41.5-30}{5} = 2.3$$

Fig. 27.38

- c. $P(X = 30) = P(29.5 \leq X \leq 30.5)$
 $= P(-0.1 \leq z \leq 0.1)$
 $= 2(0.0398) = 0.0796$ (Fig. 27.39)

$$\text{since } z_1 = \frac{29.5-30}{5} = -0.1, z_2 = \frac{30.5-30}{5} = 0.1.$$

Fig. 27.39

EXERCISE

Normal approximation of B.D.

- Determine the probability that by guess-work a student can correctly answer 25 to 30 questions in a multiple-choice quiz consisting of 80 questions. Assume that in each question with four choices, only one choice is correct and student has no knowledge.

$$\text{Ans. } P(25 \leq X \leq 30) = P(1.16 \leq z \leq 2.71) = 0.9960 - 0.8770 = 0.1196.$$

$$\text{Hint: } \bar{X} = np = (80)\left(\frac{1}{4}\right) = 20,$$

$$\sigma = \sqrt{npq} = \sqrt{80 \cdot \frac{1}{4} \cdot \frac{3}{4}} = 3.873$$

$$z_1 = \frac{24.5 - 20}{3.873} = 1.16, z_2 = \frac{30.5 - 20}{3.873} = 2.71.$$

- Find the probability that out of 100 patients
 - between 84 and 95 inclusive
 - fewer than 86, will survive a heart-operation given that the chances of survival is 0.9.

$$\text{Ans. } \mathbf{a.} \ P(84 \leq X \leq 95) = P(-2.166 \leq z \leq 1.833) = 0.4850 + 0.4664 = 0.9514$$

$$\text{Hint: } \bar{X} = np = (100)(0.9) = 90,$$

$$\sigma = \sqrt{npq} = \sqrt{(100)(0.9)(0.1)} = 3$$

$$z_1 = \frac{83.5 - 90}{3} = -2.1666, z_2 = \frac{95.5 - 90}{3} = 1.8333$$

$$\mathbf{b.} \ P(X < 86) = P(z_1 \leq -1.5) = 0.5 - 0.4332 = 0.0668$$

$$\text{Hint: } z_1 = \frac{85.5 - 90}{3} = -1.5.$$

- Find the probability P that the number of heads occurring, when a fair coin is tossed 12 times, is between 4 and 7 inclusive by (a) B.D. (b) normal approximation to B.D.

$$\begin{aligned} \text{Ans. } \mathbf{a.} \ P &= \sum_{x=4}^7 b\left(x; 12, \frac{1}{2}\right) = \sum_{x=4}^7 x C_4 \left(\frac{1}{2}\right)^x \left(\frac{1}{2}\right)^{12-x} \\ &= \frac{495 + 4096 + 924 + 792}{4096} = 0.7332 \end{aligned}$$

$$\begin{aligned} \mathbf{b.} \ P &= P(3.5 \leq X \leq 7.5) = \\ &P(-1.45 \leq z \leq -0.87) = \\ &= 0.4265 + 0.3078 = 0.7343 \end{aligned}$$

$$\text{Hint: } \bar{X} = np = 12 \cdot \frac{1}{2} = 6,$$

$$\sigma = \sqrt{npq} = \sqrt{12 \cdot \frac{1}{2} \cdot \frac{1}{2}} = 1.73.$$

- The probability that a patient needs an ICU is 0.05 in a hospital with 600 patients. How many ICU's should be available so that the probability of none of the patients of the hospital are turned away due to lack of ICU's is more than 0.90.

$$\begin{aligned} \text{Ans. } P(x < x_1) &= P(0 < z < z_1) > 0.90, \\ z_1 &= \frac{x_1 - 30}{5.3} \end{aligned}$$

$$\text{so } z_1 = 1.28 \text{ or } \frac{x_1 - 30}{5.3} = z_1 > 1.28 \text{ so } x_1 > 36.784 \approx 37$$

$$\begin{aligned} \text{Hint: } \bar{X} &= np = (600)(0.05) = 30, \\ \sigma &= \sqrt{npq} = \sqrt{(600)(0.5)(0.95)} = 5.3. \end{aligned}$$

27.11 ERROR FUNCTION

Error function of x (also known as error integral), denoted by $\operatorname{erf} x$, is defined as

$$\boxed{\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt} \quad (1)$$

Fig. 27.40

27.42 — HIGHER ENGINEERING MATHEMATICS—VII

It occurs in probability theory, thermodynamics, heat conduction problems. $\text{Erf}x$ is known as a 'special function', since (1) can not be evaluated in terms of 'elementary functions' by the usual methods of calculus.

Properties

1. $\text{erf}(0) = 0$
2. $\text{erf}(\infty) = \frac{2}{\sqrt{\pi}} \int_0^\infty e^{-t^2} dt = \frac{2}{\sqrt{\pi}} \frac{\sqrt{\pi}}{2} = 1$
3. It is defined for all x , $-\infty < x < \infty$, monotonically increasing in the interval $(0, \infty)$; passes through origin. Asymptotic to $y = \pm 1$.
4. It is an odd function since

$$\text{erf}(-x) = \frac{2}{\sqrt{\pi}} \int_0^{-x} e^{-t^2} dt = \frac{2}{\sqrt{\pi}} \int_0^x e^{-v^2} (-dv)$$

where $v = -t$

$$= -\frac{2}{\sqrt{\pi}} \int_0^x e^{-v^2} dv = -\text{erf}(x)$$

5. $\text{erf}(-\infty) = -\text{erf}(\infty) = -1$
6. $\text{erf}(x) + \text{erf}(-x) = \text{erf}(x) - \text{erf}(x) = 0$
7. Complementary error function of x , denoted by

$$\begin{aligned} \text{erfc}(x) &= 1 - \text{erf}(x) = \text{erf}(\infty) - \text{erf}(x) \\ &= \frac{2}{\sqrt{\pi}} \int_0^\infty e^{-t^2} dt - \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt \\ \text{erfc}(x) &= \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt \end{aligned}$$

8. $\text{erfc}(x) + \text{erfc}(-x) = [1 - \text{erf}(x)] + [1 - \text{erf}(-x)] = 2 - \text{erf}(x) + \text{erf}(x) = 2$
9. Probability integral (Normal distribution function) of mathematical statistics is defined as

$$\phi(\theta) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^\theta e^{-\omega^2/2} d\omega$$

put $t = \omega/\sqrt{2}$ in the error function (1); then

$$\text{erf}(\theta) = \frac{2}{\sqrt{2\pi}} \int_0^{\sqrt{2}\theta} e^{-\omega^2/2} d\omega$$

Thus the error function and probability integral

are related by

$$\text{erf}(\theta) = 2\phi(\sqrt{2}\theta) - 1 \quad \text{or}$$

$$\phi(x) = \frac{1}{2} + \frac{1}{2}\text{erf}\left(\frac{x}{\sqrt{2}}\right)$$

10. Approximate formula (due to C. Hastings Jr.)

$$\text{erf}(x) \approx 1 - (a_1 p + a_2 p^2 + a_3 p^3) e^{-x^2}$$

where $p = \frac{1}{1+0.47047x}$, $a_1 = 0.3480242$, $a_2 = -0.0958798$, $a_3 = 0.7478556$, accurate upto ± 0.000025 .

Note The factor $\frac{2}{\sqrt{\pi}}$ is included in the definition of error function to normalize it so that $\text{erf}(\infty) = 1$ since $\int_0^\infty e^{-t^2} dt = \frac{\sqrt{\pi}}{2}$.

11. $P(\mu - K\sigma \leq X \leq \mu + K\sigma) = \text{erf}\left\{\frac{K}{\sqrt{2}}\right\}$.

Let X denote the measured quantity in a certain experiment. Then the measurement error is indicated by the probability of an event such as $\mu - K\sigma \leq X \leq \mu + K\sigma$. Thus

$$\begin{aligned} P(\mu - K\sigma \leq X \leq \mu + K\sigma) &= N(\mu + K\sigma) - N(\mu - K\sigma) \\ &= \Phi(K) - \Phi(-K) \\ &= 2\Phi(K) - 1 \\ &= \text{erf}\left\{\frac{K}{\sqrt{2}}\right\} \quad \text{using above result 9.} \end{aligned}$$

For example, for $K = 3$, we get

$$P(\mu - 3\sigma \leq X \leq \mu + 3\sigma) = 0.977.$$

Thus, on the average in only 0.3 per cent of the trials, the Gaussian random variable deviates from its mean by more than ± 3 standard deviations.

WORKED OUT EXAMPLES

Example 1: Expand $\text{erf}(x)$ in ascending powers of x .

Solution: By definition

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt = \frac{2}{\sqrt{\pi}} \int_0^x \sum_{n=0}^{\infty} \frac{(-t^2)^n}{n!} dt$$

since $e^t = \sum_{n=0}^{\infty} \frac{t^n}{n!}$. Now carrying term by term integration, we have

$$\begin{aligned} \operatorname{erf}(x) &= \frac{2}{\sqrt{\pi}} \left[\int_0^x \left(1 - \frac{t^2}{1!} + \frac{t^4}{2!} - \frac{t^6}{3!} + \frac{t^8}{4!} + \cdots \right) dt \right] \\ &= \frac{2}{\sqrt{\pi}} \left[t - \frac{t^3}{3} + \frac{t^5}{5 \cdot 2!} - \frac{t^7}{7 \cdot 3!} + \frac{t^9}{9 \cdot 4!} + \cdots \right]_{t=0}^x \\ \operatorname{erf}(x) &= \frac{2}{\sqrt{\pi}} \left[x - \frac{x^3}{3} + \frac{x^5}{10} - \frac{x^7}{42} + \frac{x^9}{216} - \cdots \right] \end{aligned}$$

Example 2: Find $\frac{d}{dx}[\operatorname{erf}(ax)]$.

Solution: From the above result replacing x by ax we have

$$\begin{aligned} \operatorname{erf}(ax) &= \frac{2}{\sqrt{\pi}} \left[ax - \frac{a^3 x^3}{3} + \frac{a^5 x^5}{10} - \frac{a^7 x^7}{42} \right. \\ &\quad \left. + \frac{a^9 x^9}{216} - \cdots \right] \end{aligned}$$

Differentiating both sides w.r.t. 'x' we get

$$\begin{aligned} \frac{d}{dx}[\operatorname{erf}(ax)] &= \frac{2}{\sqrt{\pi}} \left[a - a^3 \cdot x^2 + a^5 \frac{x^4}{2!} - a^7 \frac{x^6}{3!} \right. \\ &\quad \left. + a^9 \frac{x^8}{4!} - \cdots \right] \\ &= \frac{2a}{\sqrt{\pi}} \left[1 - a^2 x^2 + \frac{(a^2 x^2)^2}{2!} - \frac{(a^2 x^2)^3}{3!} \right. \\ &\quad \left. + \frac{(a^2 x^2)^4}{4!} - \cdots \right] \\ &= \frac{2a}{\sqrt{\pi}} e^{-a^2 x^2} \end{aligned}$$

Example 3: Compute $\operatorname{erf}(0.5)$ correct to three decimal places.

Solution: Putting $x = 0.5$ in example 1, above, we have

$$\begin{aligned} \operatorname{erf}(0.5) &= \frac{2}{\sqrt{\pi}} \left[\frac{1}{2} - \left(\frac{1}{2} \right)^3 \frac{1}{3} + \left(\frac{1}{2} \right)^5 \frac{1}{10} \right. \\ &\quad \left. - \left(\frac{1}{2} \right)^7 \frac{1}{42} + \left(\frac{1}{2} \right)^9 \frac{1}{216} - \cdots \right] \end{aligned}$$

$$= \frac{0.922544642}{1.77245384} = 0.52049$$

Example 4: Show that

$$\int_0^{\infty} e^{-x^2-2ax} dx = \frac{\sqrt{\pi}}{2} e^{a^2} [1 - \operatorname{erf}(a)]$$

Solution: $\int_0^{\infty} e^{-x^2-2ax} dx = \int_0^{\infty} e^{-(x^2+2ax+a^2)} \cdot e^{a^2} dx = e^{a^2} \int_0^{\infty} e^{-(x+a)^2} dx$. Put $x+a=t$, so t varies from a to ∞ and $dx=dt$

$$\begin{aligned} &= e^{a^2} \int_a^{\infty} e^{-t^2} dt = e^{a^2} \cdot \frac{\sqrt{\pi}}{2} \operatorname{erfc}(a) \\ &= e^{a^2} \cdot \frac{\sqrt{\pi}}{2} [1 - \operatorname{erf}(a)] \end{aligned}$$

EXERCISE

1. Prove that $\frac{d}{dx}[\operatorname{erfc}(ax)] = -\frac{2a}{\sqrt{\pi}} e^{-a^2 x^2}$.

Hint: $\frac{d}{dx}[\operatorname{erfc}(ax)] = \frac{d}{dx}[1 - \operatorname{erf}(ax)] = -\frac{d}{dx}\operatorname{erf}(ax)$ use W.E. 2., above

2. Compute $\operatorname{erf}(0.3)$ correct to three decimal places.

Ans. 0.3248

Hint: Put $x = 0.3248$ in W.E. 1.

3. Prove that
 - (a) $\int_a^b e^{-t^2} dt = \frac{\sqrt{\pi}}{2} [\operatorname{erf}(b) - \operatorname{erf}(a)]$
 - (b) $\int_{-b}^b e^{-t^2} dt = \sqrt{\pi} \operatorname{erf}(b)$

Hint: (a) $\int_a^b = \int_a^0 + \int_0^b = \int_0^b - \int_0^a$

- (b) $\int_{-b}^b = \frac{\sqrt{\pi}}{2} [\operatorname{erf}(b) - \operatorname{erf}(-b)] = \frac{\sqrt{\pi}}{2} [\operatorname{erf}(b) + \operatorname{erf}(b)]$

4. Show that

$$\int_0^t \operatorname{erfc}(ax) dx = t \cdot \operatorname{erfc}(at) - \frac{e^{-a^2 t^2}}{a\sqrt{\pi}} + \frac{1}{a\sqrt{\pi}}$$

Hint: Integrating by parts

$$x \cdot \operatorname{erfc}(ax) \Big|_0^t - \int_0^t x \cdot d(\operatorname{erfc}(ax))$$

Use result in exercise example 1, then

$$= t \cdot \operatorname{erfc}(at) + \frac{a}{\sqrt{\pi}} \cdot \frac{e^{-a^2 x^2}}{a^2} \Big|_t^0$$

27.12 THE EXPONENTIAL DISTRIBUTION

Many scientific experiments involve the measurement of the duration of time X between an initial point of time and the occurrence of some phenomenon of interest. For example X is the life time of a light bulb which is turned on and left until it burns out. The continuous random variable X having the probability density function

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases}$$

Fig. 27.41

is said to have an *exponential distribution*. Here the only parameter of the distribution is λ which is greater than zero. This distribution, also known as the *negative exponential distribution*, is a special case of the gamma distribution (with $r = 1$). Examples of random variables modeled as exponential are

- (inter-arrival) time between two successive job arrivals
- duration of telephone calls
- life time (or time to failure) of a component or a product
- service time at a server in a queue
- time required for repair of a component

The exponential distribution occurs most often in applications of **Reliability Theory** and **Queuing Theory** because of the memoryless property and relation to the (discrete) **Poisson Distribution**. Exponential distribution can be obtained from the Poisson distribution by considering the inter-arrival times rather than the number of arrivals.

Mean and Variance

For any $r \geq 0$,

$$E(X^r) = \int_0^\infty x^r f(x) dx = \int_0^\infty x^r \lambda e^{-\lambda x} dx$$

put $\lambda x = t$, $x = \frac{t}{\lambda}$, $dx = \frac{1}{\lambda} dt$. Then

$$E(X^r) = \int_0^\infty \left(\frac{t}{\lambda}\right)^r \cdot \lambda \cdot e^{-t} \cdot \frac{1}{\lambda} dt = \frac{1}{\lambda^r} \int_0^\infty e^{-t} t^r dt$$

$$E(X^r) = \frac{\Gamma(r+1)}{\lambda^r}$$

In particular with $r = 0$,

$$\int_0^\infty f(x) dx = \Gamma(1) = 1$$

(i.e., $f(x)$ is a probability density function).

With $r = 1$, mean $= \mu = E(X) = \frac{\Gamma(2)}{\lambda} = \frac{1}{\lambda}$

with $r = 2$, variance $= \sigma^2 = E(X^2) - \{E(X)\}^2 = \frac{\Gamma(3)}{\lambda^2} - \frac{1}{\lambda^2}$

$$\sigma^2 = \frac{2}{\lambda^2} - \frac{1}{\lambda^2} = \frac{1}{\lambda^2}$$

Note: Both the mean and standard deviation of the exponential distribution are equal to $\frac{1}{\lambda}$.

Cumulative Distribution Function

$$F(x) = \int_0^x f(t) dt = \int_0^x \lambda e^{-\lambda t} dt = \frac{\lambda e^{-\lambda t}}{-\lambda} \Big|_{t=0}^x$$

$$F(x) = 1 - e^{-\lambda x} \text{ for } x \geq 0,$$

and $F(x) = 0$ when $x < 0$

$F(x)$ gives the probability that the “system” will “die” before x units of time have passed.

Probability Calculations

For any $a \geq 0$,

$$P(X \geq a) = P(X > a) = 1 - F(a) = e^{-\lambda a}$$

$$P(a \leq X \leq b) = P(a \leq X < b) = P(a < X < b)$$

$$= P(a < X \leq b) = F(b) - F(a)$$

$$= e^{-\lambda a} - e^{-\lambda b}$$

In table (A22) in appendix, the values of e^{-t} are tabulated for $t = 0.00(0.01)7.99$.

Corollary 1: $P(X > \frac{1}{\lambda}) = e^{-\lambda \frac{1}{\lambda}} = e^{-1} = 0.368 < \frac{1}{2}$

Survival Function

It gives the probability that the “system” survives more than x units of time and is given by

$$P(X > x) = 1 - F(x) = \begin{cases} 1 & \text{if } x < 0 \\ e^{-\lambda x} & \text{if } x \geq 0 \end{cases}$$

Memoryless or Markov Property

Among all distributions of non-negative continuous variables, only the exponential distributions have “no memory” (like the discrete geometric distribution) which results in analytical tractability.

For any $s > 0$, $t > 0$

$$\begin{aligned} P(X > s + t | X > s) &= \frac{P(\{X > s + t\} \cap \{X > s\})}{P(X > s)} \\ &= \frac{P(X > s + t)}{P(X > s)} \quad (1) \end{aligned}$$

When $X > s + t$ then X is also greater than s i.e., $X > s$. Since $\{X > s + t\} \cap \{X > s\} = \{X > s + t\}$

Thus the event $X > s$ in the numerator is redundant because both events can occur iff $X > s + t$.

Now

$$P(X > s + t | X > s) = \frac{e^{-\lambda(s+t)}}{e^{-\lambda s}} = e^{-\lambda t}$$

$$P(X > s + t | X > s) = P(X > t) \quad (2)$$

This memoryless property asserts that the conditional probability of additional waiting time is the *same* as the unconditional probability of the original waiting time. Thus the distribution of additional lifetime is exactly the same as the original distribution of lifetime, so at each point of time the component shows no effect of wear. In other words the distribution of “remaining” lifetime is independent of current age. In this sense, the exponential distribution has “no memory” of the past.

Combining (1) and (2) we have

$$\begin{aligned} P(X > s + t) &= P(X > s) \cdot P(X > s + t | X > s) \\ &= P(X > s) \cdot P(X > t) \end{aligned}$$

which yields the famous functional equations known as *Cauchy equation*.

$$h(s + t) = h(s)h(t), \quad s > 0, t > 0$$

Here $h(s) = P\{X > s\}$, $s > 0$.

Example: Suppose when a person arrives, one telephone booth has just been occupied (engaged) while another telephone booth has been occupied since (say 110 minutes) long. Then the probability distribution of the length of waiting time (to use the phone) will be the same for either phone booths. Therefore it does not matter which phone booth the person descides to wait!

WORKED OUT EXAMPLES

Example 1: Let the mileage (in thousands of miles) of a particular tyre be a random variable X having the probability density

$$f(x) = \begin{cases} \frac{1}{20}e^{-x/20} & \text{for } x > 0 \\ 0 & \text{for } x \leq 0 \end{cases}$$

Find the probability that one of these tyres will last (1) at most 10,000 miles (b) anywhere from 16,000 to 24,000 miles (c) at least 30,000 miles. (d) Find the mean (e) Find the variance of the given probability density function.

Solution: (a) Probability that a tyre will last almost 10,000 miles

$$\begin{aligned} &= P(X \leq 10) = \int_0^{10} f(x)dx \\ &= \int_0^{10} \frac{1}{20}e^{-x/20}dx \\ &= \frac{1}{20} \cdot e^{-x/20} \cdot \left(\frac{-20}{1}\right) \Big|_0^{10} \\ &= 1 - e^{-\frac{1}{2}} = 0.3934 \end{aligned}$$

$$\begin{aligned} \text{(b)} \quad P(16 \leq X \leq 24) &= \int_{16}^{24} f(x)dx \\ &= \int_{16}^{24} \frac{1}{20}e^{-x/20}dx \end{aligned}$$

$$= -e^{-\frac{x}{20}} \Big|_{16}^{24} = e^{-\frac{4}{5}} - e^{-\frac{6}{5}}$$

$$= 0.148$$

$$(c) P(X \geq 30) = \int_{30}^{\infty} f(x) dx$$

$$= \int_{30}^{\infty} \frac{1}{20} e^{-x/20} dx = -e^{-x/20} \Big|_{30}^{\infty} = e^{-\frac{3}{2}}$$

$$= 0.2231$$

$$(d) \text{ Mean } = \mu = \int_{-\infty}^{\infty} x \cdot f(x) dx$$

$$= \int_0^{\infty} x \cdot \frac{1}{20} e^{-\frac{x}{20}} dx$$

$$= - \int_0^{\infty} x \cdot d \left(e^{-\frac{x}{20}} \right)$$

$$= -x e^{-\frac{x}{20}} - 20 e^{-\frac{x}{20}} \Big|_0^{\infty} = 0 - (-20)$$

$$\mu = 20 = \frac{1}{\lambda}$$

$$(e) \text{ Variance } = \sigma^2 = \int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx$$

$$= \int_{-\infty}^{\infty} x^2 f(x) dx - \mu^2$$

Consider

$$\int_{-\infty}^{\infty} x^2 f(x) dx = \int_0^{\infty} x^2 \frac{1}{20} e^{-\frac{x}{20}} dx$$

$$= -x^2 e^{-\frac{x}{20}} \Big|_0^{\infty} + 2 \cdot 20 \cdot \int_0^{\infty} \frac{1}{20} \cdot x e^{-x/20} dx$$

$$= 0 + 2 \cdot 20 \cdot \mu = 2.20.20 = 2.20^2$$

$$\text{Then } \sigma^2 = \int_0^{\infty} x^2 f(x) dx - \mu^2 = 2.20^2 - 20^2$$

$$= 20^2 = \frac{1}{\lambda^2}$$

Example 2: The length of time for one person to be served at a cafeteria is a random variable X having an exponential distribution with a mean of 4 minutes. Find the probability that a person is served in less than 3 minutes on at least 4 of the next 6 days.

Solution: The probability that a person is served at a cafeteria in less than 3 minutes is

$$P(T < 3) = 1 - P(T \geq 3)$$

Since the mean $\mu = \frac{1}{\lambda} = 4$ or $\lambda = \frac{1}{4}$, the exponential distribution is $\frac{1}{4} e^{-\frac{x}{4}}$. Now

$$P(T < 3) = 1 - P(T \geq 3) = 1 - \int_3^{\infty} \frac{1}{4} e^{-\frac{t}{4}} dt$$

$$P(T < 3) = 1 - \frac{1}{4} e^{-\frac{t}{4}} \cdot \left(-\frac{4}{1} \right) \Big|_3^{\infty} = 1 - e^{-\frac{3}{4}}$$

Let X represent the number of days on which a person is served in less than 3 minutes. Then using the binomial distribution, the probability that a person is served in less than 3 minutes on at least 4 of the next 6 days is

$$P(X \geq 4) = \sum_{x=4}^6 {}^6C_x (1 - e^{-3/4})^x (e^{-3/4})^{6-x} = 0.3968$$

EXERCISE

1. Let T be the time (in years) to failure of certain components of a system. The random variable T has exponential distribution with mean time to failure $\beta = 5$. If 5 of these components are in different systems, find the probability that at least 2 are still functioning at the end of 8 years.

Ans. 0.2627

Hint: $P(T > 8) = \frac{1}{5} \int_8^{\infty} e^{-t/5} dt$

$$= e^{-8/5} \simeq 0.2, \quad P(X \geq 2) = \sum_{x=2}^{\infty} b(x; 5, 0.2) =$$

$$1 - \sum_{x=0}^1 b(x, 5, 0.2) = 1 - 0.7373$$

2. If a random variable X has the exponential distribution with mean $\mu = \frac{1}{\lambda} = \frac{1}{2}$ calculate the probabilities that (a) X will lie between 1 and 3 (b) X is greater than 0.5 (c) X is at most 4.

Ans. (a) 0.133 (b) 0.368 (c) 0.98168

Hint: PDF $f(x) = 2e^{-2x}$ (a) $\int_1^3 2e^{-2x} dx = e^{-2} - e^{-6}$

(b) $\int_{0.5}^{\infty} 2e^{-2x} dx = e^{-1}$ (c) $\int_0^4 2e^{-2x} dx = 1 - e^{-4}$

3. The life (in years) of a certain electrical switch has an exponential distribution with an average life of $\frac{1}{\lambda} = 2$. If 100 of these switches are installed in

different systems, find the probability that at most 30 fail during the first year.

Hint: $P(T > 1) = \int_1^\infty \frac{1}{2}e^{-\frac{t}{2}} dt = +e^{-\frac{1}{2}} = 0.606$

$$\text{Ans. } P(X \leq 30) = \sum_{x=0}^{30} b(x, 2, 0.606) = \sum_{x=0}^{30} {}^{100}C_x (0.606)^x (0.39346)^{100-x}$$

4. Suppose the life length X (in hours) of a fuse has exponential distribution with mean $\frac{1}{\lambda}$. Fuses are manufactured by two different processes. Process I yields an expected life length of 100 hours and process II yields an expected life length of 150 hours. Cost of production of a fuse by process I is Rs. C while by the Process II it is Rs $2C$. A fine of Rs K is levied if a fuse lasts less than 200 hours. Determine which process should be preferred?

Ans. Prefer Process I if $C > 0.13K$

Hint: $c_1 = c$ if $X > 200$
 $= c + k$ if $X \leq 200$

$$\begin{aligned} E(c_1) &= c \cdot P(X > 200) + (c + k)P(X \leq 200) \\ &= c \cdot e^{-\frac{1}{100} \cdot 200} + (c + k)(1 - e^{-\frac{1}{100} \cdot 200}) \\ &= k(1 - e^{-2}) + c \end{aligned}$$

$$E(c_2) = k(1 - e^{-4/3}) + 2c, \quad E(c_2) - E(c_1) = c - 0.13k$$

5. Suppose N_t be a discrete random variable denoting the number of arrivals in time interval $(0, t]$. Let X be the time of the next arrival, so X is the elapsed time between the occurrences of two successive events. Assuming that N_t is Poisson distributed with parameter λt , show that X is exponentially distributed.

Here λ is the expected numbers of events occurring in one unit of time.

$$\text{Ans. } P(X > t) = P(N_t = 0) = \frac{e^{-\lambda t}(\lambda t)^0}{0} = e^{-\lambda t}$$

6. If the average rate of job submission is $\lambda = 0.1$ jobs/second, find the probability that an interval of 10 seconds elapses without job submission.

$$\text{Ans. } P(X \geq 10) = \int_{10}^\infty 0.1e^{0.1t} dt = e^{-1} = 0.368$$

Hint: Assume that the number of arrivals/unit time is poisson distributed and the inter arrival time X is exponentially distributed with parameter λ .

7. Let the mileage (in thousands of miles) of a certain radial tyre is a random variable with exponential distribution with mean 40,000 miles. Determine the probability that the tyre will last (a) at least 20,000 km (b) at most 30,000 km.

$$\begin{aligned} \text{Ans. (a)} \quad P(X \geq 20,000) &= e^{-0.5} = 0.6065 \\ \text{(b)} \quad P(X \leq 30,000) &= 1 - e^{-0.75} = 0.5270 \end{aligned}$$

8. The amount of time (in hours) required to repair a T.V. is exponentially distributed with mean $\frac{1}{2}$. Find the (a) probability that the repair time exceeds 2 hours (b) the conditional probability that repair takes at least 10 hours given that already 9 hours have been spent repairing the TV.

$$\begin{aligned} \text{Ans. (a)} \quad P(X > 2) &= e^{-1} = 0.3679 \\ \text{(b)} \quad P(X \geq 10 | X > 9) &= P(X > 1) = e^{-0.5} = 0.6065 \\ &\text{(because of the memoryless property).} \end{aligned}$$

9. The duration of time X in seconds between presses of the white rat on a bar, which are periodically conditioned, has an exponential distribution with parameter $\lambda = 0.20$. Find the probability that the duration is more than one second but less than 3 seconds (b) more than 3 seconds.

$$\begin{aligned} \text{Ans. (a)} \quad P(1 \leq X \leq 3) &= e^{-0.2(1)} - e^{-(0.2)3} = 0.819 - 0.549 = 0.270 \\ \text{(b)} \quad P(X > 3) &= e^{-0.2(3)} = 0.549 \end{aligned}$$

10. The time X (seconds) that it takes a certain on-line computer terminal (the elapsed time between the end of user's inquiry and the beginning of the system's response to that inquiry) has an exponential distribution with expected time 20 seconds. Compute the probabilities (a) $P(X \leq 30)$ (b) $P(X \geq 20)$ (c) $P(20 \leq X \leq 30)$ (d) For what value of t is $P(X \leq t) = 0.5$ (i.e., t is the fiftieth percentile of the distribution)

$$\text{Ans. (a) } 0.777 \text{ (b) } 0.368 \text{ (c) } 0.145 \text{ (d) } 13.863$$

27.13 THE GAMMA DISTRIBUTION

Consider a system consisting of one original component and $(r - 1)$ spare components such that when the original component fails, one of the $(r - 1)$ spare components is used. If this component fails, one of the $(r - 2)$ spare components is used. System fails only when the original component and all the $(r - 1)$ spare components fail. Assume that the lifetimes $X_1, X_2, \dots, X_r$ of the r duplicates of the essential components have infinite lifetimes (except for the original component). Suppose each of the random variables $X_1, X_2, \dots, X_r$ have the same exponential distribution with parameter λ and are probabilistically independent. Then the lifetime (time until failure) of the entire system is the sum $Y = \sum_{i=1}^r X_i$ having the *gamma distribution* with density function

$$f(y) = \begin{cases} \frac{\lambda^r y^{r-1} e^{-\lambda y}}{\Gamma(r)}, & \text{if } y \geq 0 \\ 0, & \text{if } y < 0 \end{cases} \quad (1)$$

(1) is a skewed distribution.

The two parameters of (1) are the positive numbers λ and r (although r need *not* be an integer). If r is a positive integer, then gamma distribution (1) is known as *Erlang distribution*. Introducing $V = \lambda y$, (1) reduces to

$$\begin{aligned} f(v) &= \frac{1}{\lambda} f\left(\frac{v}{\lambda}\right) = \frac{1}{\lambda} \left\{ \lambda^r \left(\frac{v}{\lambda}\right)^{r-1} \cdot \frac{e^{-v}}{\Gamma(r)} \right\} \\ &= \begin{cases} \frac{v^{r-1} e^{-v}}{\Gamma(r)} & \text{if } v \geq 0 \\ 0 & \text{if } v < 0 \end{cases} \end{aligned} \quad (2)$$

The probability density function of the random variable V given by (2) is known as the “*standard gamma function*” with parameter r (and is independent of λ). When $r = 1$, the density function (2) reduces to the density function of exponential distribution with the parameter $\lambda = 1$. For large r (say $r \geq 50$) (2) resembles a normal distribution with mean and variance approximately equal to r . The gamma distribution with parameter $\lambda = \frac{1}{2}$ and $r = \frac{\nu}{2}$ (where ν is a positive integer) reduces to the chi-squared distribution with ν degrees of freedom credited to Karl Pearson (1857–1936) and F.R. Helmert (1843–1917).

The *incomplete gamma function* defined by

$$F_V(t) = \int_0^t \frac{v^{r-1} e^{-v}}{\Gamma(r)} dv = I_r(t), \quad t \geq 0 \quad (3)$$

is tabulated in the tables of the appendix A23 to A28 for $r = 1(1)5, t = 0.2(0.2)8.0(0.5)15.0$ and for $r = 6(1)10, t = 1.0(0.2)8.0(0.5)17.0$.

Now

$$P(Y \geq a) = P(Y > a) = 1 - F(a) = 1 - I_r(\lambda a)$$

and

$$P(a \leq Y \leq b) = F(b) - F(a) = I_r(\lambda b) - I_r(\lambda a)$$

Moments of the Gamma Distribution

For any $k \geq 0$,

$$\begin{aligned} E(Y^k) &= E\left(\frac{V^k}{\lambda^k}\right) = \frac{1}{\lambda^k} E(V^k) \\ &= \frac{1}{\lambda^k} \int_0^\infty v^k \cdot \left(\frac{v^{r-1} e^{-v}}{\Gamma(r)}\right) dv \\ &= \frac{1}{\lambda^k \Gamma(r)} \int_0^\infty v^{k+r-1} e^{-v} dv \end{aligned}$$

$$\text{Then } E(Y^k) = \frac{\Gamma(r+k)}{\lambda^k \Gamma(r)} \quad (4)$$

For $k = 0$ in (4) we have $\int_0^\infty f(y) dy = 1$ so $f(y)$ is a probability density function.

For $k = 1$, in (4) we get the mean $= \mu = E(Y) = \frac{\Gamma(r+1)}{\lambda \Gamma(r)} = \frac{r \Gamma(r)}{\lambda \Gamma(r)}$.

So $\mu = \frac{r}{\lambda}$. (5)

With $k = 2$ in (4), we get

variance $= \sigma^2 = E(Y^2) - \{E(Y)\}^2$

$$= \frac{\Gamma(r+2)}{\lambda^2 \Gamma(r)} - \frac{r^2}{\lambda^2}$$

$$\sigma^2 = \frac{r(r+1)\Gamma(r)}{\lambda^2 \Gamma(r)} - \frac{r^2}{\lambda^2} = \frac{r}{\lambda^2} \quad (6)$$

Thus the parameter r and λ are determined from (5) and (6) as

$$\lambda = \frac{\mu}{\sigma^2}, \quad r = \frac{\mu^2}{\sigma^2} \quad (7)$$

Relation Between Exponential, Gamma and Poisson Distributions

Suppose the lifetimes of a batch of components each have exponential distribution with parameter λ . Starting at time $t = 0$, the first component is used until its extinction (until it “dies” or “fails”). Replace the component by another instantaneously and wait until this new component also fails. Continuing this Process, stop at a given time t . Then the number of failed components L is a random variable having the Poisson distribution with $\lambda^* = \lambda t$. Also the lifetime of the entire process $Y = \sum_{i=1}^k X_i$ follows gamma distribution with parameters λ and k .

Let $X_1, X_2, \dots, X_k$ be the lifetimes of the first k components that have failed. Assume that each lifetime X_i has an exponential distribution with parameter λ and are probabilistically independent. Recall that, then $Y = \sum_{i=1}^k X_i$ has a gamma distribution with parameters λ and k . If $X_1 + X_2 + \dots + X_k$ (total lifetime of the process) $\leq t$ then in this case at least k components have all failed, (one after the other) before the time is up.

Now probability of the event that at least k components have failed at the time of termination of the experiment is given by

$$P(L \geq k) = P\{Y \leq t\} = I_k(\lambda t)$$

$$= \int_0^{\lambda t} \frac{v^{k-1} e^{-v}}{\Gamma(k)} dv$$

Integrating by parts, we have

$$\begin{aligned} &= \frac{v^{k-1}}{\Gamma(k)} \cdot \left(\frac{e^{-v}}{-1} \right) \Big|_{v=0}^{\lambda t} + \int_0^{\lambda t} \frac{(k-1)v^{k-2} \cdot e^{-v}}{\Gamma(k)} dv \\ &= -\frac{(\lambda t)^{k-1} e^{-\lambda t}}{(k-1)!} + \int_0^{\lambda t} \frac{v^{k-2} \cdot e^{-v}}{\Gamma(k-1)} dv. \end{aligned}$$

Integrating by parts $(k-1)$ more times,

$$P(L \geq k) = -\sum_{i=1}^{k-1} \frac{(\lambda t)^i e^{-\lambda t}}{i!} + \int_0^{\lambda t} \frac{e^{-v}}{\Gamma(1)} dv$$

But $\Gamma(1) = 1$ and $\int_0^{\lambda t} e^{-v} dv = \left. \frac{e^{-v}}{-1} \right|_0^{\lambda t} = 1 - e^{-\lambda t}$.

$$\text{Thus } P(L \geq k) = 1 - \sum_{i=0}^{k-1} \frac{(\lambda t)^i e^{-\lambda t}}{i!}$$

But

$$\begin{aligned} P(L = k) &= P(L \geq k) - P(L \geq k+1) \\ &= \left[1 - \sum_{i=0}^{k-1} \frac{(\lambda t)^i e^{-\lambda t}}{i!} \right] - \left[1 - \sum_{i=0}^k \frac{(\lambda t)^i e^{-\lambda t}}{i!} \right] \\ P(L = k) &= \frac{(\lambda t)^k e^{-\lambda t}}{k!} = \frac{\lambda^{*k} \cdot e^{-\lambda^*}}{k!}, \lambda^* = \lambda t \end{aligned}$$

Thus the probability distribution of the discrete random variable L is a Poisson (discrete) distribution with parameter $\lambda^* = \lambda t$.

The cumulative distribution of the gamma distribution of Y can be calculated in terms of tabulated cumulative distribution of the Poisson distribution from

$$F(t) = P(L \geq k) = P(Y \leq t) = 1 - \sum_{i=0}^{k-1} \frac{(\lambda t)^i e^{-\lambda t}}{i!}$$

WORKED OUT EXAMPLES

Example 1: The daily consumption of electric power (in millions of kW-hours) in a certain city is a random variable X having the probability density

$$f(x) = \begin{cases} \frac{1}{9} x e^{-x/3} & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases}$$

Find the probability that the power supply is inadequate on any given day if the daily capacity of the power plant is 12 million kW hours.

Solution: Observe that this is gamma distribution with $r = 2$ and $\lambda = \frac{1}{3}$. The power supply is inadequate when $X > 12$. Now $P(X > 12) = 1 - F(12) = 1 - I_2\left(\frac{1}{3} \cdot 12\right) = 1 - I_2(4)$. Using table A23 to A28, we get

$$P(X > 12) = 1 - 0.90892 = 0.09108$$

Example 2: The lifetime X (in months) of a computer has a gamma distribution with mean 24 months and standard deviation 12 months. Find the probability that the computer will

(a) last between 12 and 24 months.

27.50 — HIGHER ENGINEERING MATHEMATICS—VII

- (b) last at most 24 months.
 (c) Determine the median lifetime of X .
 (d) suppose that the test will actually be terminated after t months. Determine the value of t such that only one-half of 1% of all computers would still be functioning at termination.

Solution: Here $\mu = 24$, $\sigma = 12$. Then from (7)

$$\lambda = \frac{24}{12^2} = \frac{1}{6}, r = \left(\frac{\mu}{\sigma}\right)^2 = \left(\frac{24}{12}\right)^2 = 4$$

$$\begin{aligned} \text{(a)} P(12 < X < 24) &= F(24) - F(12) \\ &= I_4\left(\frac{1}{6} \cdot 24\right) - I_4\left(\frac{1}{6} \cdot 12\right) \\ &= I_4(4) - I_4(2) \end{aligned}$$

Using table A23 to A28 we get

$$P(12 < X < 24) = 0.56653 - 0.14288 = 0.42365.$$

$$\text{(b)} P(X \leq 24) = I_4\left(\frac{1}{6} \cdot 24\right) = I_4(4) = 0.56653$$

$$\text{(c)} \text{ median } \hat{x} \text{ is such that } P(X \leq \hat{x}) = \frac{1}{2}$$

Then $I_4\left(\frac{\hat{x}}{6}\right) = 0.5$. From table (see entry in the table A23 to A28) we get $\frac{\hat{x}}{6} = 4$ or $\hat{x} = 24$ months

(d) At the termination time t , only one-half of 1% computers are still functioning. So

$$P(X \leq t) = 1 - \frac{1}{2}(0.01) = 0.995$$

But $P(X \leq t) = I_4\left(\frac{1}{6}\hat{t}\right) = 0.995$ (given). From table A23 to A28, we have $I_4(11) = 0.995$. Therefore $\frac{\hat{t}}{6} = 11$ or $\hat{t} = 66$ months.

EXERCISE

- Suppose the reaction time X has a standard gamma distribution with $r = 2$. Find (a) $P(3 \leq X \leq 5)$ (b) $P(X > 4)$.
Ans. (a) $I_2(5) - I_2(3) = 0.95957 - 0.80085 = 0.15872$ (b) $P(X > 4) = 1 - P(X \leq 4) = 1 - I_2(4) = 1 - 0.90842 = 0.09158$
- Suppose that the time (in hours) taken by a homeowner to mow his lawns is a random variable X having a gamma distribution with parameters $r = 2$ and $\lambda = 2$. Find the probability that it takes (a) at most 1 hour (b) at least 2 hours (c) between 0.5 and 1.5 hours to mow the lawn.
Ans. (a) 0.594 (b) 0.092 (c) 0.537

- The survival time X (in weeks) of a male mouse exposed to radiation has a gamma distribution with $r = 8$ and $\lambda = \frac{1}{15}$. Find the probability that the mouse survives (a) between 60 and 120 weeks (b) at least 30 week. Find (c) mean (d) variance of X .

$$\text{Ans. (a)} P(60 \leq X \leq 120) = F\left(\frac{120}{15}, 8\right) - F\left(\frac{60}{15}, 8\right) = I_8(8) - I_8(4) = 0.547 - 0.051 = 0.496$$

$$\begin{aligned} \text{(b)} P(X \geq 30) &= 1 - P(X < 30) = \\ &= 1 - F\left(\frac{30}{15}, 8\right) = 1 - 0.00110 = 0.9989 \end{aligned}$$

- If Y has gamma distribution with $\lambda = 0.40$ and $r = 5$, find (a) $P(Y > 30)$ (b) $P(15 \leq Y \leq 20)$

$$\text{Ans. (a)} 1 - I_5(12) = 1 - 0.9924 = 0.0076$$

$$\text{(b)} I_5(8) - I_5(6) = 0.90037 - 0.71494 = 0.18543$$

- If a random variable X has the gamma distribution with $r = 2$ and $\lambda = \frac{1}{2}$ find (a) the mean (b) standard deviation (c) the probability that X will take a value less than 4.

$$\text{Ans. (a)} 4 \text{ (b)} 2.828 \text{ (c)} 0.5940$$

- The gross sales X in thousands of rupees is a random variable having gamma distribution with $\lambda = \frac{1}{2}$ and $r = 80000\sqrt{n}$ where n is the number of employees in the company. If the sales cost is Rs. 8000 per employee, how many employees should the company employ to maximise the expected profit.

$$\text{Ans. } n = 100,$$

Hint: $\mu = \frac{r}{\lambda} = 160000\sqrt{n}$, y = profit = total expected sales - total cost = $160000\sqrt{n} - 8000n$, $\frac{dy}{dn} = 0$ for $n = 100$.

$$\frac{d^2y}{dn^2} = -\frac{40000}{n^{3/2}} < 0$$

27.14 THE WEIBULL DISTRIBUTION

Lifetimes, waiting times, learning times, travelling times, duration of epidemics are some of the important examples of non-negative random variables whose variability can be explained in many cases by exponential and gamma distributions. However in certain cases Weibull distribution provides good probability model for describing “length of life” of objects having the ‘weakest link’ property. An object,

composed of a large number of separate parts, put under stress is said to have the *weakest link property* if the lifetime of the object is equal to the minimum lifetime of any of its parts.

Example: A chain is as strong as its weakest link.

The Weibull distribution was introduced in 1939 by the Swedish physicist *Waloddi Weibull* and is given by probability density function

$$f(x) = \begin{cases} \frac{\beta}{\alpha} \left(\frac{x-v}{\alpha}\right)^{\beta-1} \exp\left[-\left(\frac{x-v}{\alpha}\right)^\beta\right] & \text{if } x \geq v \\ 0 & \text{if } x < v \end{cases} \quad (3)$$

The three constants $\beta > 0$, $\alpha > 0$ and $v \geq 0$ are the parameters of the distribution. The smallest possible value of X is given by v . The constant β determines the shape of the density function (1). When $\beta = 1$ and $v = 0$, the Weibull distribution (1) reduces to the exponential distribution with the parameter $\lambda = \frac{1}{\alpha}$. If X has a Weibull distribution with parameters α, β, v then $Y = \left[\frac{(X-v)}{\alpha}\right]^\beta$ has an exponential distribution with the parameter $\lambda = 1$.

Since $X = \alpha Y^{1/\beta} + v$ so $\frac{dX}{dY} = \frac{\alpha}{\beta} Y^{\frac{1}{\beta}-1}$ and $f(X) = \frac{\beta}{\alpha} Y^{(\beta-1)/\beta} e^{-Y}$. Then the probability density function of Y is

$$\begin{aligned} f(y) &= f(x) \frac{dx}{dy} = \frac{\beta}{\alpha} y^{\frac{\beta-1}{\beta}} \cdot e^{-y} \cdot \frac{\alpha}{\beta} y^{\frac{1}{\beta}-1} \\ &= \begin{cases} e^{-y} & \text{if } y \geq 0 \\ 0 & \text{if } y < 0 \end{cases} \end{aligned}$$

which is an exponential distribution with parameter $\lambda = 1$.

The cumulative distribution of X is

$$F(x) = P(X \leq x) = \begin{cases} 1 - \exp\left[-\left(\frac{x-v}{\alpha}\right)^\beta\right] & \text{if } x \geq v \\ 0 & \text{if } x < v \end{cases} \quad (2)$$

Probabilities are calculated using $F(x)$.

Mean and Variance

$$\text{Mean} = \mu = E(X) = E(\alpha Y^{1/\beta} + v) = \alpha E(Y^{1/\beta}) + v$$

Since $E(X^r) = \frac{\Gamma(r+1)}{\lambda^r}$, with $r = \frac{1}{\beta}$ and $\lambda = 1$,

$$\text{Mean} = \mu = \frac{\alpha \Gamma\left(\frac{1}{\beta} + 1\right) + v}{1} \quad (3)$$

Consider

$$\begin{aligned} E(X^2) &= E\left(\left(\alpha Y^{1/\beta} + v\right)^2\right) = E(\alpha^2 Y^{2/\beta} + v^2 + 2\alpha v Y^{1/\beta}) \\ &= \alpha^2 E(Y^{2/\beta}) + 2v\alpha E(Y^{1/\beta}) + v^2 \end{aligned}$$

Now with $r = \frac{2}{\beta}$ and $\lambda = 1$, we get

$$\begin{aligned} \text{Variance} = \sigma^2 &= E(X^2) - \{E(X)\}^2 \\ &= \left[\alpha^2 \frac{\Gamma\left(\frac{2}{\beta} + 1\right)}{1^2} + 2v\alpha \frac{\Gamma\left(\frac{1}{\beta} + 1\right)}{1} + v^2 \right] - \\ &\quad - \left[\alpha \Gamma\left(\frac{1}{\beta} + 1\right) + v \right]^2 \\ \sigma^2 &= \alpha^2 \left\{ \Gamma\left(1 + \frac{2}{\beta}\right) - \left[\Gamma\left(1 + \frac{1}{\beta}\right) \right]^2 \right\} \quad (4) \end{aligned}$$

Median: $P(X \leq x) = F(x) = \frac{1}{2}$ or

$$1 - \exp\left[-\left(\frac{x-v}{\alpha}\right)^\beta\right] = \frac{1}{2}. \text{ Solving } x = \alpha(.693)^{\frac{1}{\beta}} + v$$

Observe that variance depends upon α and β but independent of v .

The *survival function* is given by

$$1 - F(x) = \begin{cases} 1 & \text{if } x < v \\ \exp\left[-\left(\frac{x-v}{\alpha}\right)^\beta\right] & \text{if } x \geq v \end{cases} \quad (5)$$

Exponential distribution is a special case of both the gamma and Weibull distributions.

Note that gamma distribution with λ and $r = 1$ is an exponential distribution with parameter λ . Similarly the Weibull distribution with $\alpha = \frac{1}{\lambda}$, $\beta = 1$ and $v = 0$ is an exponential distribution with parameter λ . Thus the gamma and Weibull distributions are generalization of the exponential distribution. However gamma distribution with $r \neq 1$ is *not* a Weibull distribution. Also Weibull distributions with $\beta \neq 1$ or $v \neq 0$ is not gamma distribution.

27.52 — HIGHER ENGINEERING MATHEMATICS—VII

With $\nu = 0$ the above results takes the following form:

The Weibull distribution is

$$f(x) = \begin{cases} \frac{\beta}{\alpha^\beta} x^{\beta-1} e^{-\frac{x^\beta}{\alpha^\beta}}, & \text{if } x \geq 0 \\ 0, & \text{if } x < 0 \end{cases}$$

put $\alpha^* = \alpha^{-\beta}$ (or $\alpha = (\alpha^*)^{-\frac{1}{\beta}}$) then

$$f(x) = \begin{cases} \alpha^* \beta e^{-\alpha^* x^\beta} \cdot x^{\beta-1}, & \text{if } x \geq 0 \\ 0, & \text{if } x < 0 \end{cases} \quad (6)$$

The cumulative distribution is

$$F(x) = \begin{cases} 1 - e^{-\alpha^* x^\beta}, & \text{if } x \geq 0 \\ 0, & \text{if } x < 0 \end{cases} \quad (7)$$

$$\text{Mean : } \mu = (\alpha^*)^{-\frac{1}{\beta}} \Gamma\left(\frac{1}{\beta} + 1\right) \quad (8)$$

$$\text{Variance : } \sigma^2 = (\alpha^*)^{-\frac{2}{\beta}} \left\{ \Gamma\left(1 + \frac{2}{\beta}\right) - \left[\Gamma\left(1 + \frac{1}{\beta}\right) \right]^2 \right\}$$

$$\text{Median : } \hat{x} = \alpha^{*- \frac{1}{\beta}} (0.693)^{\frac{1}{\beta}} = \left(\frac{0.693}{\alpha^*} \right)^{\frac{1}{\beta}} \quad (10)$$

The Weibull Failure Law

The (instantaneous) failure rate Z (also known as “hazard function”) associated with the random variable T is given by

$$Z(t) = \frac{f(t)}{1 - F(t)}$$

where $f(t)$ and $F(t)$ are the probability density function and cumulative distribution. $Z(t)$ is also known as mortality curve, life characteristic or lambda characteristic.

Suppose the life length T (or time to failure) of a component has the Weibull distribution

$$f(t) = \alpha^* \beta e^{-\alpha^* t^\beta}$$

with α^* and β as parameters and consequently has the cumulative distribution $F(t) = 1 - e^{-\alpha^* t^\beta}$, then the Weibull failure law is given by

$$Z(t) = \frac{f(t)}{1 - F(t)} = \frac{\alpha^* \beta e^{-\alpha^* t^\beta} \cdot t^{\beta-1}}{e^{-\alpha^* t^\beta}}$$

$$Z(t) = \alpha^* \beta t^{\beta-1} \quad (11)$$

Here the failure rate is proportional to t (unlike the only exponential distribution whose exponential failure law where $Z(t)$, the failure rate is constant).

WORKED OUT EXAMPLES

Example: Suppose the life time X (in hours) of a semiconductor is a random variable having the Weibull distribution with parameters. $\alpha^* = (200)^{-2.5}$, $\beta = 2.5$, $\nu = 0$. Determine the probability that the lifetime of the semiconductor is (a) at most 200, (b) less than 200, (c) more than 300, (d) between 100 and 200 hours. Find (e) the mean (f) variance (g) median of life time X .

Solution: Recall that the cumulative distribution with $\alpha^* = (200)^{-2.5}$, $\beta = 2.5$ is

$$F(x) = P(X \leq x) = 1 - e^{-\alpha^* x^\beta} = 1 - e^{-\left(\frac{x}{200}\right)^{2.5}}$$

(a) Probability that life time X of the semiconductor is at most 200 hours

$$\begin{aligned} &= P(X \leq 200) = F(200) \\ &= 1 - e^{-\left(\frac{200}{200}\right)^{2.5}} = 1 - e^{-1} = 1 - 0.36787 = 0.632 \end{aligned}$$

(b) $P(X < 200) = P(X \leq 200) = 0.632$

$$\begin{aligned} \text{(c)} \quad &P(X > 300) = 1 - F(300) = e^{-\left(\frac{300}{200}\right)^{2.5}} = \\ &e^{-\left(\frac{3}{2}\right)^{2.5}} = 0.0635 \end{aligned}$$

(d) $P(100 < X < 200) = F(200) - F(100)$

$$\begin{aligned} &= \left[1 - e^{-\left(\frac{200}{200}\right)^{2.5}} \right] - \left[1 - e^{-\left(\frac{100}{200}\right)^{2.5}} \right] \\ &= e^{-\left(\frac{1}{2}\right)^{2.5}} - e^{-1} = 0.83796 - 0.36789 \\ &= 0.4700 \end{aligned}$$

$$\begin{aligned} \text{(e) Mean: } \mu &= (\alpha^*)^{-\frac{1}{\beta}} \Gamma\left(\frac{1}{\beta} + 1\right) = \frac{\Gamma\left(\frac{1}{2.5} + 1\right)}{200} = \\ &200 \cdot \Gamma\left(\frac{2}{5} + 1\right) = \frac{400}{5} \Gamma\left(\frac{2}{5}\right) = 80 \cdot \Gamma(2/5) \end{aligned}$$

$$\begin{aligned} \text{(f) Variance} &= (\alpha^*)^{-\frac{2}{\beta}} \left[\Gamma\left(1 + \frac{2}{\beta}\right) - \left\{ \Gamma\left(1 + \frac{1}{\beta}\right) \right\}^2 \right] = \\ &= \left(\frac{1}{200}\right)^{-2} \left[\Gamma\left(1 + \frac{4}{5}\right) - \left\{ \Gamma\left(1 + \frac{2}{5}\right) \right\}^2 \right] \end{aligned}$$

$$= 40000 \left[\frac{4}{5} \cdot \Gamma\left(\frac{4}{5}\right) - \left\{ \frac{2}{5} \Gamma\left(\frac{2}{5}\right) \right\}^2 \right]$$

(g) Median: $\hat{x}$ middlemost value such that $P(X \leq \hat{x}) = \frac{1}{2}$. Then

$$F(\hat{x}) = 1 - e^{-\alpha^* \hat{x}^\beta} = \frac{1}{2}$$

So

$$\begin{aligned} \hat{x} = \text{median} &= (\alpha^*)^{-\frac{1}{\beta}} (.693)^{\frac{1}{\beta}} \\ &= 200(.693)^{\frac{1}{2.5}} = 200(.693)^{\frac{2}{5}} \\ &= 200(.86356) = 172.7123 \end{aligned}$$

EXERCISE

- Suppose the service life, in years, of a system is a random variable having a Weibull distribution with $\alpha^* = \frac{1}{2}$, $\beta = 2$. Find the probability that such a system will still be functioning after 2 years.

Ans. $P(X \geq 2) = 1 - F(2) = e^{-\alpha^* x^\beta} = e^{-\frac{1}{2}(2)^2} = e^{-2}$

- If the lifetime X of a hearing aid battery has Weibull distribution with $\alpha^* = 0.1$ and $\beta = 0.5$ determine the probability that such a battery (a) will function for more than 300 hours (b) will not last 100 hours. Find (c) mean (d) variance (e) median of X .

Ans. (a) $P(X \geq 300) = e^{-0.1(300)^{0.5}} = 0.177$
 (b) $P(X < 100) = 1 - e^{-0.1(100)^{0.5}} = 0.6321$
 (c) $\mu = \text{mean} = (0.1)^{-2} \Gamma\left(1 + \frac{1}{0.5}\right) = 200$ hours
 (d) Variance $= (0.1)^{-4} [\Gamma(1 + 4) - \Gamma^2(3)] = 20(.1)^{-4} = 200000$ hours
 (e) median $= (0.1)^{-2} (.693)^2 = 100(0.480) = 48$ hours

- Suppose the tensile strength X has Weibull distribution with $\alpha^* = (100)^{-20}$, $\beta = 20$. Find (a) $P(X \leq 105)$ (b) $P(98 \leq X \leq 102)$

Ans. (a) $1 - e^{-(105/100)^{20}} = 1 - 0.070 = 0.930$
 (b) $F(102) - F(98) = e^{-(.98)^{20}} - e^{-(1.02)^{20}} = .513 - .226 = 0.287$

- Let X , the corrosion weight loss of an alloy follows Weibull distribution with $\alpha = 4$, $\beta = 2$, $\nu = 3$. Find (a) $P(X > 3.5)$ (b) $P(7 \leq X \leq 9)$.

Ans. (a) $e^{-0.156} = 0.855$ (b) $e^{-1} - e^{-2.25} = 0.89 - 0.632 = 0.263$

Hint: Use (5): on page 27.51 $F(x) = 1 - \exp\left(\frac{x-3}{4}\right)^2$

- Suppose each of the 36 transistors in a system has life length, in years, having the Weibull distribution with $\alpha = 25$, $\beta = 2$. Find the probability that no transistor will have to be replaced during the first 2 months of use assuming that the transistors are functionally independent.

Hint:

$$P\left(X > \frac{2}{12}\right) = e^{-25\left(\frac{1}{6}\right)^2} = e^{-25/36}$$

Ans. $P(\text{no transistor replaced}) = (e^{-25/36})^{36} = e^{-25} = (1.38879) \times 10^{-11}$

- If the probability that the life length X (in years) of a computer exceeds 5 years is $e^{-0.25}$, determine α of the Weibull distribution of X with $\beta = 2$. Find the mean and variance of X .

Ans. $\alpha = \frac{1}{100}$, $\mu = 5\sqrt{\pi}$, $\sigma^2 = 100\left(1 - \frac{\pi}{4}\right)$

Hint: $P(X > 5) = e^{-25\alpha} = e^{-0.25}$ (given)

- Suppose the time to failure X in hours of a component is modeled by a Weibull distribution with parameter $\beta = 2$. If 15% of the components that have lasted 90 hours fail before 100 hours, find the parameter α .

Ans. $\alpha = 0.00008554 = (-\ln 0.85/1900)$

Hint:

$$F(x) = 1 - e^{-\alpha x^\beta} = 1 - e^{-\alpha x^2}$$

$$\begin{aligned} P(X < 100 | X > 90) &= \frac{P(90 < X < 100)}{P(X > 90)} \\ &= \frac{F(100) - F(90)}{1 - F(90)} \\ &= \frac{e^{-\alpha(90)^2} - e^{-\alpha(100)^2}}{e^{-\alpha(90)^2}} \\ &= 0.15 \text{ (given)} \end{aligned}$$

Chapter 28

Sampling Distribution

INTRODUCTION

Sampling distribution of a statistic is the theoretical probability distribution of the statistic which is easy to understand and is used in inferential or inductive statistics. A statistic is a random variable since its value depends on observed sample values which will differ from sample to sample. Whereas its particular value depends on a given set of sample values. Thus determination of sampling distribution of a statistic is essentially a mathematical problem.

Suppose we wish to compare the mean I.Q of students of one university with another university or to compare proportion of alcoholics among men with that among women or compare the variances of lifetimes of T.V. produced by one company with the variance of another company. In such statistical investigation of the study of two (or more) populations we compare their respective parameters.

The nearness of two quantities can be measured as follows. If the difference of the two quantities is close to zero, then the two quantities are very close to each other. Alternatively when the ratio of the two quantities is nearly equal to zero, then the two quantities are near to each other, otherwise they are far apart. By taking two random samples one from each population, we compare the corresponding sample analogues.

Statistical methods are used to study a process by analyzing the data, discrete or continuous, recorded as either numerical value or a descriptive representation to improve the “quality” of the process. Thus statistician is mainly concerned with the analysis of data about the characteristics of persons or objects or observations.

28.1 POPULATION AND SAMPLE

Population is the set or collection or totality of objects, animate or inanimate, actual or hypothetical, under study. Thus mainly population consists of sets of numbers, measurements or observations which are of interest.

Size

Size of the population N is the number of objects or observations in the population.

Population is said to be finite or infinite depending on the size N being finite or infinite.

Since it is impracticable or uneconomical or time consuming to study the entire population, a finite subset of the population known as *sample* is studied. Size of the sample is denoted by n . *Sampling* is the process of drawing samples from a given population.

Examples: (i) Population of India, Population of A.P. Estate (sample) (ii) Engineering colleges recognised by AICTE, Engineering colleges affiliated to JNTU (sample) (iii) Cars produced in India, Matiz cars (sample) (iv) Healthcare expenditure by Central Govt., Expenditure of A.P. Govt. (sample), Expenditure by district (sub sample), Expenditure in a district hospital (sub-sample) etc. (v) Number of software specialists by 2020.

Large sampling

If $n \geq 30$, the sampling is said to be large sampling.

Small sampling

If $n < 30$, the sampling is said to be small sampling or **exact sampling**.

Statistical Inference

Statistical inference or inductive statistics deals with the methods of drawing (arriving at) valid or logical generalizations and predictions about the population using the information contained in the sample alone, with an indication of the accuracy of such inferences.

Parameters

Statistical measures or constants obtained from the population are known as population parameters or simply parameters.

Example: Population mean, population variance. Similarly, statistical quantities computed from sample observations are known as sample statistics or briefly “**statistics**”.

Thus parameters refer to population while statistics refer to sample.

Examples: sample mean, sample variance etc.

Notation

μ, σ, p represent the population mean, population standard deviation, population proportion. Similarly, $\bar{X}, s, P$ denote sample mean, sample s.d., sample proportion.

Population $f(x)$

Population $f(x)$ is a population whose probability distribution is $f(x)$.

Example: If $f(x)$ is binomial, Poisson or normal, then the corresponding population is known as binomial population, Poisson population or normal population.

Since the samples must be representative of the population, sampling should be random.

Random sampling is one in which each member of the population has equal chances or probability of being included in the sample.

In **sampling with replacement**, each member of the population may be chosen more than once, since the member is replaced in the population.

Thus sampling from finite population with replacement can be considered theoretically as sampling from infinite population. Whereas, in **sampling without replacement**, an element of the population can not be chosen more than once, as it is not replaced.

Statistic

Statistic is a real valued function of the random sample. So statistic is a function of one or more random variables not involving any unknown parameter. Thus statistic is a function of samples observations only and is itself a random variable. Therefore a statistic must have a probability distribution.

Sample mean and sample variance are two important statistics which are measures of a random sample $X_1, X_2, \dots, X_n$ of size n .

$$\text{Sample mean} = \bar{X} = \frac{\sum_{i=1}^n X_i}{n}$$

(measure of central tendency)

Sample Variance

$$= S^2 = \frac{\sum_{i=1}^n (X_i - \bar{X})^2}{n - 1} = \frac{n \sum X_i^2 - (\sum X_i)^2}{n(n - 1)}$$

(measure of variability of data about the mean).

Sample standard deviation is the positive square root of the sample variance.

Degrees of Freedom (dof) of a statistic is a positive integer, denoted by ν , equals to $n - k$ where n is the number of independent observations of the random sample and k is the number of population parameters which are calculated using the sample data. Thus dof $\nu = n - k$ is the difference between n the sample size and k the number of independent constraints imposed on the observations in the sample.

28.2 SAMPLING DISTRIBUTION

Draw all possible samples of size n , from a given finite population of size N . Then the total number of *all* possible samples each of the same size n , which can be drawn from the population is given by $N_{C_n} = \frac{N!}{n!(N-n)!} = k$. Compute a statistic S (such as the mean, s.d., median, mode etc.) for each of these sample using the sample data $x_1, x_2, \dots, x_n$ by $S = S(x_1, x_2, x_3, \dots, x_n)$

| | | | | | |
|---------------|-------|-------|-------|-----|-------|
| Sample number | 1 | 2 | 3 | ... | k |
| Statistic S | S_1 | S_2 | S_3 | ... | S_k |

Sampling distribution (S.D.) of the statistic is the set of values $\{S_1, S_2, \dots, S_k\}$ of the statistic S obtained one for each sample. Thus sampling distribution describes how a statistic S will vary from one sample to the other of the same size. Although all the k samples are drawn from the given population, the members included in different samples are different. The difference in the value of the statistics, attributed to chance, is known as **sampling fluctuations**.

When the number of samples (each of the same size n) is infinitely large (i.e., sampling without replacement) then the probability distribution of the statistic is the sampling distribution of the statistic.

If the statistic S is mean, then the corresponding distribution of the statistics is known as sampling distribution of means. Thus if S is variance, proportion or medians etc., the associated distribution is known as sampling distribution of variances, sampling distribution of proportions etc. Now for each of these sampling distributions, the statistics mean, variance etc., can be computed as follows:

Mean of the sampling distribution of $S = \bar{S} = \frac{1}{k} \sum_{i=1}^k S_i$ variance of $S = \frac{1}{k} \sum_{i=1}^k (S_i - \bar{S})^2$

Thus we can have mean of the sampling distribution of means, variance of the sampling distribution of means, variance of the sampling distribution of variances etc.

Standard Error (S.E.)

Standard Error (S.E.) is the standard deviation of the sampling distribution of a statistic S . It gives an index of the precision of the estimate of the parameters. As the sample size n increases, S.E. decreases. Standard error plays an important role in large sample theory and forms the basis in tests of hypothesis.

Sampling distribution of statistics helps to learn information about the corresponding population parameters.

28.3 SAMPLING DISTRIBUTION OF MEANS: (σ KNOWN)

Sampling distribution of means (S.D.M.) $\bar{X}$ is the probability distribution of $\bar{X}$.

Finite Population

Consider a finite population of size N with mean μ and standard deviation σ . Draw *all* possible samples of size *without replacement* from this population. Let $\mu_{\bar{X}}$ and $\sigma_{\bar{X}}$ denote the mean and standard deviation of the sampling distribution of means. Suppose $N > n$. Then

$$\mu_{\bar{X}} = \mu \quad \text{and} \quad \sigma_{\bar{X}} = \frac{\sigma}{\sqrt{N}} \sqrt{\frac{N-n}{N-1}}$$

Here $\frac{N-n}{N-1}$ is known as finite population correction factor.

Infinite Population

Suppose the samples are drawn from an infinite population or sampling is done *with replacement* then

$$\mu_{\bar{X}} = \mu \quad \text{and} \quad \sigma_{\bar{X}} = \frac{\sigma}{\sqrt{n}}$$

Standard error of mean, $\sigma_{\bar{X}} = \frac{\sigma}{\sqrt{n}}$, measure the reliability of the mean as an estimate of the population mean μ .

$$\text{Standardized sample mean, } Z = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}}$$

Non-normal Population (Large Sample)

Consider a population with unknown (non-normal) distribution. Let the population mean μ and population variance σ be both finite. Let the population be finite or infinite. In case the population is finite assume that the population size N is at least twice the sample size n . Draw all possible samples of size n . Then the sampling distribution of $\bar{X}$ is approximately normally distributed with mean $\mu_{\bar{X}} = \mu$ and variance $\sigma_{\bar{X}}^2 = \sigma^2/n$ provided the sample size is large (i.e., $n \geq 30$).

Central Limit Theorem

Whenever n is large, the sampling distribution of $\bar{X}$ is approximately (nearly) normal with mean μ and variance σ^2/n regardless of the form of the population distribution. This is established by central limit theorem stated below (without proof).

Theorem: If $\bar{X}$ is the mean of a sample of size n drawn from a population with mean μ and finite

28.4 — HIGHER ENGINEERING MATHEMATICS—VII

variance σ^2 then the standardized sample mean

$$Z = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}}$$

is a random variable whose distribution function approaches that of the standard normal distribution $N(Z; 0, 1)$ as $n \rightarrow \infty$.

Normal Population (Small Sample)

Sampling distribution of $\bar{X}$ is normally distributed even for small samples of size $n < 30$ provided sampling is from normal population.

WORKED OUT EXAMPLES

Sampling distribution of means

Example 1: A population consists of four numbers 2, 3, 4, 5. Consider all possible distinct samples of size two with replacement. Find (a) the population mean (b) the population standard deviation (s.d.) (c) the sampling distribution of means (d) the mean of the S.D. of means (e) s.d. of S.D. of means. Verify (c) and (e) directly from (a) and (b) by use of suitable formulae.

Solution:

a. Mean of population

$$\mu = \frac{2 + 3 + 4 + 5}{4} = \frac{14}{4} = 3.5$$

b. s.d. of population

$$\begin{aligned}\sigma &= \sqrt{\frac{(2 - 3.5)^2 + (3 - 3.5)^2 + (4 - 3.5)^2 + (5 - 3.5)^2}{4}} \\ \sigma &= \sqrt{\frac{(1.5)^2 + (0.5)^2 + (0.5)^2 + (1.5)^2}{4}} \\ &= \sqrt{\frac{5}{4}} = \sqrt{1.25} = 1.118033\end{aligned}$$

c. Sampling with replacement (infinite population): The total number of samples with replacement is $N^n = 4^2 = 16$. Here N = population size and n = sample size. Listing all possible samples of size 2 from population 2, 3, 4, 5 with replacement, we get 16 samples:

| | | | |
|--------|--------|--------|--------|
| (2, 2) | (2, 3) | (2, 4) | (2, 5) |
| (3, 2) | (3, 3) | (3, 4) | (3, 5) |
| (4, 2) | (4, 3) | (4, 4) | (4, 5) |
| (5, 2) | (5, 3) | (5, 4) | (5, 5) |

Now compute the statistic the arithmetic mean for each of these 16 samples.

The set of 16 means $\bar{X}$ of these 16 samples, gives rise to the distribution of means of the samples known as sampling distribution of means (S.D.M.):

| | | | |
|-----|-----|-----|-----|
| 2 | 2.5 | 3 | 3.5 |
| 2.5 | 3 | 3.5 | 4 |
| 3 | 3.5 | 4 | 4.5 |
| 3.5 | 4 | 4.5 | 5 |

This S.D.M. can also be arranged in the form of frequency distribution

| | | | | | | | |
|--------------------------|---|-----|---|-----|---|-----|---|
| Sample mean: $\bar{X}_i$ | 2 | 2.5 | 3 | 3.5 | 4 | 4.5 | 5 |
| Frequency: f_i | 1 | 2 | 3 | 4 | 3 | 2 | 1 |

d. The mean of these 16 means is known as mean of the sampling distribution of means

$$\mu_{\bar{X}} = \frac{2 + 2(2.5) + 3(3) + 4(3.5) + 3(4) + 2(4.5) + 5}{16}$$

$$\mu_{\bar{X}} = \frac{56}{16} = 3.5$$

e. The variance of S.D.M. is

$$\begin{aligned}\sigma_{\bar{X}}^2 &= \frac{\sum f_i(\bar{X}_i - \mu_{\bar{X}})^2}{n} \\ &= \frac{1}{16} \left[1(2 - 3.5)^2 + 2(2.5 - 3.5)^2 + \right. \\ &\quad \left. \dots + 1(5 - 3.5)^2 \right] \\ &= \frac{(1.5)^2 + 2(1)^2 + 3(.5)^2 + 0 + 3(.5)^2 + 2(1)^2 + (1.5)^2}{16} \\ &= \frac{10}{16} = 0.625\end{aligned}$$

$$\text{s.d. of S.D.M. } \sigma_{\bar{X}} = 0.7905694$$

Verification:

$$\text{i. } \mu = 3.5 = \mu_{\bar{X}}$$

$$\text{ii. } \sigma_{\bar{X}} = 0.79056 = \frac{\sigma}{\sqrt{n}} = \frac{1.118033}{\sqrt{4}} = \frac{1.118033}{2} = 0.79057$$

Example 2: Solve the above Example 1 without replacement:

Solution:

a. $\mu = 3.5$

b. $\sigma = 1.118083$

c. Sampling without replacement (finite population). The total number of samples without replacement is $N_{C_n} = \frac{4!}{2!2!} = 6$. The six samples are

(2, 3) (2, 4) (2, 5) (3, 4) (3, 5) (4, 5)

compute the statistic A.M. for each of these samples:

$\bar{X}_i$: 2.5 3 3.5 3.5 4 4.5

The S.D.M. is

$\bar{X}_i$: 2.5 3 3.5 4 4.5

f_i : 1 1 2 1 1

d. $\mu_{\bar{X}} = \text{mean of S.D.M.}$

$$= \frac{2.5 + 3.0 + 2(3.5) + 4 + 4.5}{6} = \frac{21}{6}$$

$$\mu_{\bar{X}} = 3.5$$

e. $\sigma_{\bar{X}}^2 = \frac{(2.5-3.5)^2 + (3-3.5)^2 + 2(3.5-3.5)^2 + (4-3.5)^2 + (4.5-3.5)^2}{6} = \frac{2.5}{6} = 0.4166$

so $\sigma_{\bar{X}} = 0.645497$

Verification:

i. $\mu_{\bar{X}} = 3.5 = \mu$.

ii. $\sigma_{\bar{X}} = 0.4166 = \frac{\sigma}{\sqrt{n}} \sqrt{\frac{N-n}{N-1}} = \frac{1.11803}{\sqrt{2}} \sqrt{\frac{4-2}{4-1}} = 0.4166$

Sampling distribution of variances

Example 3: Find the mean and s.d. of sampling distribution of variances (S.D.V.) for the population 2, 3, 4, 5 by drawing samples of size two (a) with replacement (b) without replacement.

Solution:

a. with replacement: 16 samples with their corre-

sponding means are

| | | | |
|--------|--------|--------|--------|
| (2, 2) | (2, 3) | (2, 4) | (2, 5) |
| 2 | 2.5 | 3 | 3.5 |
| (3, 2) | (3, 3) | (3, 4) | (3, 5) |
| 2.5 | 3 | 3.5 | 4 |
| (4, 2) | (4, 3) | (4, 4) | (4, 5) |
| 3 | 3.5 | 4 | 4.5 |
| (5, 2) | (5, 3) | (5, 4) | (5, 5) |
| 3.5 | 4 | 4.5 | 5 |

compute the statistic variance for each of these 16 samples:

variance for sample (2, 2) with mean 2 is

$$= \frac{(2-2)^2 + (2-2)^2}{2} = 0$$

Similarly, variance for sample (2, 3) with mean

$$= \frac{(2-2.5)^2 + (3-2.5)^2}{2} = 0.25$$

Thus the variance for each of the 16 samples

| | | | |
|------|------|------|------|
| 0 | 0.25 | 1 | 2.25 |
| 0.25 | 0 | 0.25 | 1 |
| 1 | 0.25 | 0 | 0.25 |
| 2.25 | 1 | 0.25 | 0 |

Thus the S.D. of variances (with replacement) is

| | | | | |
|------------|---|------|---|------|
| S^2 : | 0 | 0.25 | 1 | 2.25 |
| Frequency: | 4 | 6 | 4 | 2 |

Mean of S.D. of variance = $\frac{4(0) + 6(0.25) + 4(1) + 2(2.25)}{16}$

$$\mu_{S^2} = \frac{10}{16} = 0.625$$

variance of S.D. of variance

$$= \frac{4(0-0.625)^2 + 6(0.25-0.625)^2 + 4(1-0.625)^2 + 2(2.25-0.625)^2}{16} = \frac{8.25}{16} = 0.515625$$

s.d. of S.D. of variance = $\sqrt{0.515625} = 0.7180$

28.6 — HIGHER ENGINEERING MATHEMATICS—VII

b. without replacement:

| | | | | | | |
|------------|--------|--------|--------|--------|--------|--------|
| Samples: | (2, 3) | (2, 4) | (2, 5) | (3, 4) | (3, 5) | (4, 5) |
| Means: | 2.5 | 3 | 3.5 | 3.5 | 4 | 4.5 |
| Variances: | 0.25 | 1 | 2.25 | 0.25 | 1 | 0.25 |

Thus the S.D. of variances (without replacement)

| | | | |
|------------------|------|---|------|
| σ_{S^2} : | 0.25 | 1 | 2.25 |
| Frequency: | 3 | 2 | 1 |

mean of S.D. of variances = $\frac{3(0.25)+2(1)+1(2.25)}{6}$

$$\mu_{S^2} = \frac{5}{6} = 0.8333$$

variance of S.D. of variances is

$$\begin{aligned}\sigma_{S^2}^2 &= \frac{3(0.25-0.8333)^2+2(1-0.8333)^2+1(2.25-0.8333)^2}{6} \\ &= \frac{3.08333}{6} = 0.51388\end{aligned}$$

s.d. of S.D. of variance = $\sqrt{0.51388} = 0.71686$.

EXERCISE

Sampling distribution

- Construct S.D. of means for the population 3, 7, 11, 15 by drawing samples of size two with replacement.

Determine (a) μ (b) σ (c) S.D.M. (d) $\mu_{\bar{X}}$ (e) $\sigma_{\bar{X}}$. Verify the results.

Hint: $4^2 = 16$ samples (3, 3), (3, 7), (3, 11), $\dots$, (15, 11), (15, 15)

Ans. a. $\mu = \frac{36}{4} = 9$

b. $\sigma^2 = \frac{80}{4} = 20$, $\sigma = 4.4721$

c. Means: 3 5 7 9 11 13 15
Frequency: 1 2 3 4 3 2 1

d. $\mu_{\bar{X}} = \frac{144}{16} = 9$

e. $\sigma_{\bar{X}}^2 = \frac{160}{16} = 10$, $\sigma_{\bar{X}} = 3.16227$.

Verification:

i. $\mu_{\bar{X}} = 9 = \mu$

ii. $\sigma_{\bar{X}} = 3.162 = \frac{\sigma}{\sqrt{n}} = \frac{4.4721}{\sqrt{2}} = 3.162$

- Solve the above problem if sampling is without replacement.

Hint: $N_{C_n} = 4C_2 = 6$ samples are (3, 7), (3, 11), (3, 15), (7, 11), (7, 15), (11, 15).

S.D.M.: 5, 7, 9, 9, 11, 13

$$\mu_{\bar{X}} = \frac{54}{6} = 9, \sigma_{\bar{X}} = \sqrt{\frac{40}{6}} = 2.58198$$

- Find standard error of sample means of size 2 drawn from a population 2, 3, 6, 8, 11 with replacement.

Hint: $N^n = 5^2 = 25$ samples (2, 2), (2, 3), (2, 6), $\dots$, (11, 8), (11, 11).

With means: 2 2.5 3 4 4.5 5 5.5 6 6.5 7 8 8.5 9.5 11

Frequency: 1 2 1 2 2 2 1 2 4 1 3 1 1

$$\mu_{\bar{X}} = \frac{150}{25} = 6.0, \mu = \frac{30}{5} = 6,$$

$$\sigma = \sqrt{10.8} = 3.29, \sigma_{\bar{X}}^2 = \sqrt{\frac{135}{25}} = 2.32$$

Ans. S.E. = $\sigma_{\bar{X}} = 3.29$

Verification:

$$\mu_{\bar{X}} = 6 = \mu, \sigma_{\bar{X}}^2 = 5.40 = \frac{\sigma^2}{n} = \frac{10.8}{2} = 5.40$$

- Solve the above problem without replacement.

Ans. $N_{C_n} = 5C_2 = 10$ samples (2,3), (2, 6), (2,8), $\dots$, (6, 11), (8, 11).

means: 2.5, 4, 5, 6.5, 4.5, 5.5, 7, 7, 8.5, 9.5

$$\mu_{\bar{X}} = 6 = \mu, \sigma_{\bar{X}}^2 = 4.05$$

$$= \frac{\sigma^2}{n} \left(\frac{N-n}{N-1} \right) = \frac{10.8}{2} \left(\frac{5-2}{5-1} \right) = 4.05$$

- Construct S.D.M. for the infinite population with distribution given by

| | | | | |
|----------|------|------|------|------|
| x : | 1 | 2 | 3 | 4 |
| $f(x)$: | 0.25 | 0.25 | 0.25 | 0.25 |

with $n = 2$, verify

Hint: $N^n = 4^2 = 16$ samples (1, 1), (1, 2), (1, 3) $\dots$, (4, 3), (4, 4).

Ans. $\mu = \frac{10}{4} = 2.5$, $\sigma^2 = \frac{5}{4} = 1.25$

| | | | | | | | |
|------------|---|-----|---|-----|---|-----|---|
| Means: | 1 | 1.5 | 2 | 2.5 | 3 | 3.5 | 4 |
| Frequency: | 1 | 2 | 3 | 4 | 3 | 2 | 1 |

$$\mu_{\bar{X}} = \frac{40}{16} = 2.5, \sigma_{\bar{X}}^2 = \frac{10}{16} = 0.625 = \frac{\sigma^2}{n} = \frac{1.25}{2}$$

6. Determine the mean and s.d. of S.D. of variances for the population 3, 7, 11, 15 with $n = 2$ and with sampling (a) with replacement (b) without replacement

Hint: $N^n = 4^2 = 16$ samples (3, 3), (3, 7), $\dots$, (15, 11), (15, 15)

| | | | | | | | |
|-------------|---|---|----|----|----|----|----|
| With means: | 3 | 5 | 7 | 9 | 11 | 13 | 15 |
| Frequency: | 1 | 2 | 3 | 4 | 3 | 2 | 1 |
| Variances: | 0 | 4 | 16 | 36 | | | |

Ans. (a) $\mu_{S^2} = 10$, (b) $\sigma_{S^2}^2 = \sqrt{\frac{2112}{16}} = 11.489$

7. Calculate the s.d. of S.D. of means for the population 16, 4, 12, 8, 24, 20 by drawing samples of size 2 without replacement. Verify the results.

Hint: S.D.M.:

| | | | | | | | | | |
|------------|---|---|----|----|----|----|----|----|----|
| Means: | 6 | 8 | 10 | 12 | 14 | 16 | 18 | 20 | 22 |
| Frequency: | 1 | 1 | 2 | 2 | 3 | 2 | 2 | 1 | 1 |

$N_{C_n} = 6C_2 = 15$ samples.

Ans. $\mu = \frac{84}{6} = 14$, $\mu_{\bar{X}} = \frac{210}{15} = 14$;
 $\sigma = 6.8313$, $\sigma_{\bar{X}} = 4.32$.

8. Find mean and s.d. of S.D.M. for population 1, 2, 3 with $n = 2$ and sampling (a) with replacement (b) without replacement. Verify results.

Ans. $\mu = 2$, $\sigma^2 = \frac{2}{3}$

a. $\mu_{\bar{X}} = \frac{18}{9} = 2$, $\sigma_{\bar{X}}^2 = \frac{1}{3} = \frac{\sigma^2}{2}$

b. $\mu_{\bar{X}} = 2$, $\sigma_{\bar{X}}^2 = \frac{1}{6} = \frac{\sigma^2}{n} \left(\frac{N-n}{N-1} \right) = \frac{2}{3} \cdot \frac{1}{2} \cdot \left(\frac{3-2}{3-1} \right) = \frac{1}{6}$ with $N = 3$, $n = 2$

WORKED OUT EXAMPLES

Sampling distribution of means (σ known)

Example 1: Determine the mean and s.d. of the sampling distribution of means of 300 random samples each of size $n = 36$ are drawn from a population of $N = 1500$ which is normally distributed with mean $\mu = 22.4$ and s.d. σ of 0.048, if sampling is done (a) with replacement and (b) without replacement.

Solution:

- a. with replacement

$$\mu_{\bar{X}} = \mu = 22.40$$

$$\sigma_{\bar{X}} = \frac{\sigma}{\sqrt{n}} = \frac{0.048}{\sqrt{36}} = 0.008$$

- b. without replacement

$$\mu_{\bar{X}} = \mu = 22.40$$

$$\sigma_{\bar{X}} = \frac{\sigma}{\sqrt{n}} \sqrt{\frac{N-n}{N-1}} = \frac{0.048}{\sqrt{36}} \sqrt{\frac{1500-36}{1500-1}} = 0.00790605$$

$$\sigma_{\bar{X}} \approx 0.008$$

Example 2: Determine the expected number of random samples having their means (a) between 22.39 and 22.41 (b) greater than 22.42 (c) less than 22.37 (d) less than 22.38 or more than 22.41, for the above Example 1.

Solution: $N =$ size of population $= 1500$

$n =$ sample size $= 36$

$N_S =$ number of samples $= 300$

$\mu =$ population mean $= 22.4$,

$\sigma =$ population s.d. $= 0.48$

use the standardized variable

$$Z = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} = \frac{\bar{X} - 22.4}{0.008}$$

- a. For $\bar{X} = 22.39$, $Z = \frac{22.39-22.4}{0.0079} = -1.26$ etc.

Fig. 28.1

$$P(22.39 < \bar{X} < 22.41) = P(-1.26 < Z < 1.26) \\ = 2(0.3962) = 0.7888$$

Expected number of samples $=$ (Total number of samples) $\times$ (probability) $= (N_S)P(\bar{X})$

Expected number of samples who have mean lying between 22.39 to 22.41 is $(300)(0.7924) = 236.6 \approx 237$

- b. $P(\bar{X} > 22.42) = P(Z > 2.50) = 0.5 - 0.4933 = 0.0062$

28.8 — HIGHER ENGINEERING MATHEMATICS—VII

Expected number of samples = $(0.00057) (300)$
 $= 1.86 \approx 2$

Fig. 28.2

c. $P(\bar{X} < 22.37) = P(Z < -3.8) =$
 $= 0.5 - 0.4999 = 0.0001$

Fig. 28.3

Expected number of samples = $(300) (0.0001)$
 $= 0.03 \approx 0$

d. $P(\bar{X} < 22.38) \text{ and } \bar{X} > 22.41)$
 $= P(Z < -2.53 \text{ and } Z > 1.26)$
 $= 0.0057 + 0.1038 = 0.1095$

Fig. 28.4

Expected number = $(300) (0.1095) = 32.85 \approx 33$.

EXERCISE

- Determine the probability that the sample mean area covered by a sample of 40 of 1 litre paint boxes will be between 510 to 520 square feet given that a 1 litre of such paint box covers on the average 513.3 square feet with s.d. of 31.5 s.ft.

Hint: $Z_1 = \frac{510-513.3}{31.5/\sqrt{40}} = -0.66$, $Z_2 = \frac{520-513.3}{31.5/\sqrt{40}} = 1.34$

Ans. $P(510 < \bar{X} < 520) = P(-0.66 < Z < 1.34)$
 $= 0.6553$

- Calculate the probability that a random sample of 16 computers will have an average life of less than 775 hours assuming that length of life of computers is approximately normally distributed with mean 800 hours and s.d. 40 hours.

Ans. $P(\bar{X} < 775) = P\left(Z < \frac{775-800}{10} = -2.5\right)$
 $= 0.0062$

- Determine the probability that $\bar{X}$ will be between 75 and 78 if a random sample of size 100 is taken from an infinite population having the mean $\mu = 76$ and the variance $\sigma^2 = 256$.

Hint: $Z_1 = \frac{75-76}{16/\sqrt{100}} = -0.625$, $Z_2 = \frac{78-76}{16/\sqrt{100}} = 1.25$

Ans. $P(75 < \bar{X} < 78) = P(-0.625 < Z < 1.25)$
 $= 0.3944 + 0.2324 = 0.6268$

- Find $P(\bar{X} > 66.75)$ if a random sample of size 36 is drawn from an infinite population with mean $\mu = 63$ and s.d. $\sigma = 9$.

Hint: $Z = \frac{66.75-63}{9/\sqrt{36}} = 2.5$

Ans. $P(\bar{X} > 66.75) = P(Z > 2.5)$
 $= 0.5 - 0.4938 = 0.0062$

- Calculate the mean and s.d. of the sampling distribution of means of 80 samples each of size 25 by sampling (a) with replacement (b) without replacement from a normal population of 3000 with mean 68 and s.d. 3.

Ans. a. $\bar{\mu}_X = 68 = \mu$, $\sigma_{\bar{X}} = \frac{\sigma}{\sqrt{n}} = \frac{3}{\sqrt{25}} = 0.6$

b. $\mu_{\bar{X}} = 68 = \mu$, $\sigma_{\bar{X}} = \frac{\sigma}{\sqrt{n}} \sqrt{\frac{N-n}{N-1}}$
 $= \frac{3}{\sqrt{25}} \sqrt{\frac{3000-25}{3000-1}} = 0.59759 \approx 0.6$

- Determine the expected number of samples whose mean (a) lies between 66.8 and 68.3 (b) is less than 66.4 for the above Example 5

Hint: $z_1 = \frac{(66.8-68.0)}{0.6} = -2.0$, $z_2 = \frac{68.3-68}{0.6} = 0.5$

Ans. a. $P(66.8 < \bar{X} < 68.3) = P(-2.0 < Z < 0.5)$
 $= 0.4772 + 0.1915 = 0.6687$

Expected number of samples with mean between 66.8 and 68.3 is = (number of samples) (probability) = (80)(0.6680) = 53.504 $\approx$ 54

Hint: $z = \frac{66.4-68}{0.6} = -2.67$.

$$\text{b. } P(\bar{X} < 66.4) = P(z < -2.67) \\ = 0.5 - 0.4962 = 0.0038$$

Expected number of samples = (80)(0.0038) = 0.304 $\approx$ 0.

28.4 SAMPLING DISTRIBUTION OF PROPORTIONS

Let p be the probability of occurrence of an event (called its success) and $q = 1 - p$ is the probability of non-occurrence (failure). Draw all possible samples of size n from an infinite population. Compute the proportion P of successes for each of these samples. Then the mean μ_P and variance σ_P^2 of the sampling distribution of proportions are given by

$$\mu_P = P \quad \text{and} \\ \sigma_P^2 = \frac{pq}{n} = \frac{p(1-p)}{n}$$

while population is binomially distributed, the sampling distribution of proportion is normally distributed whenever n is large. For finite population (with replacement) of size N ,

$$\mu_P = p \quad \text{and} \\ \sigma_P^2 = \frac{pq}{n} \left(\frac{N-n}{N-1} \right).$$

28.5 SAMPLING DISTRIBUTION OF DIFFERENCES AND SUMS

Let μ_{S_1} and σ_{S_1} be the mean and standard deviation of a sampling distribution of statistic S_1 obtained by computing S_1 for all possible samples of size n_1 drawn from population A . Similarly μ_{S_2} and σ_{S_2} be the mean and standard deviation of sampling distribution of statistic S_2 obtained by computing S_2 for all possible samples of size n_2 drawn from another different population B . Now compute the statistic $S_1 - S_2$, the difference of the statistic from all possible combinations of these samples from the two populations A and B . Then the mean $\mu_{S_1-S_2}$ and the

standard deviation $\sigma_{S_1-S_2}$ of the sampling distribution of differences are given by

$$\mu_{S_1-S_2} = \mu_{S_1} - \mu_{S_2} \quad \text{and} \\ \sigma_{S_1-S_2} = \sqrt{\sigma_{S_1}^2 + \sigma_{S_2}^2}$$

assuming that the samples are independent.

Sampling distribution of sum of statistics has mean $\mu_{S_1+S_2}$ and standard deviation $\sigma_{S_1+S_2}$ given by

$$\mu_{S_1+S_2} = \mu_{S_1} + \mu_{S_2} \quad \text{and} \\ \sigma_{S_1+S_2} = \sqrt{\sigma_{S_1}^2 + \sigma_{S_2}^2}$$

For example, for infinite population the sampling distribution of sums of means has mean $\mu_{\bar{X}_1+\bar{X}_2}$ and $\sigma_{\bar{X}_1+\bar{X}_2}$ given by

$$\mu_{\bar{X}_1+\bar{X}_2} = \mu_{\bar{X}_1} + \mu_{\bar{X}_2} = \mu_1 + \mu_2 \quad \text{and} \\ \sigma_{\bar{X}_1+\bar{X}_2} = \sqrt{\sigma_{\bar{X}_1}^2 + \sigma_{\bar{X}_2}^2} = \sqrt{\sigma_{\frac{1}{n_1}}^2 + \sigma_{\frac{2}{n_2}}^2}$$

For sampling distribution of differences of proportions we have

$$\mu_{P_1-P_2} = \mu_{P_1} - \mu_{P_2} = p_1 - p_2 \quad \text{and} \\ \sigma_{P_1-P_2} = \sqrt{\sigma_{P_1}^2 + \sigma_{P_2}^2} = \sqrt{\frac{p_1 q_1}{n_1} + \frac{p_2 q_2}{n_2}}$$

WORKED OUT EXAMPLES

Sampling distribution of differences and sums

Example 1: Let $U_1 = \{2, 7, 9\}$, $U_2 = \{3, 8\}$. Find
(a) μ_{U_1} (b) μ_{U_2} (c) $\mu_{U_1+U_2}$ (d) $\mu_{U_1-U_2}$ (e) σ_{U_1}
(f) σ_{U_2} (g) $\sigma_{U_1+U_2}$ (h) $\sigma_{U_1-U_2}$. Verify that
(i) $\mu_{U_1+U_2} = \mu_{U_1} + \mu_{U_2}$ (j) $\mu_{U_1-U_2} = \mu_{U_1} - \mu_{U_2}$
(k) $\sigma_{U_1 \pm U_2} = \sqrt{\sigma_{U_1}^2 + \sigma_{U_2}^2}$.

Solution:

$$\text{a. } \mu_{U_1} = \frac{2+7+9}{3} = \frac{18}{3} = 6$$

$$\text{b. } \mu_{U_2} = \frac{3+8}{2} = \frac{11}{2} = 5.5$$

c. Population consisting of the sums of any member of U_1 and any member of U_2 is

$$2+3=5, 7+3=10, \quad 9+3=12$$

$$2+8=10, 7+8=15, \quad 9+8=17$$

28.10 — HIGHER ENGINEERING MATHEMATICS—VII

i.e., $= U_1 + U_2 = \{5, 10, 12, 10, 15, 17\}$

$$\begin{aligned}\mu_{U_1+U_2} &= \frac{5 + 10 + 12 + 10 + 15 + 17}{6} = \frac{69}{6} = 11.5 \\ &= 11.5 = 6 + 5.5 = \mu_{U_1} + \mu_{U_2}\end{aligned}$$

- d. Population consisting of differences of any member of U_1 and any member of U_2 is

$$2 - 3 = -1, 7 - 3 = 4, 9 - 3 = 6$$

$$2 - 8 = -6, 7 - 8 = -1, 9 - 8 = 1$$

i.e., $U_1 - U_2 = \{-1, 4, 6, -6, -1, 1\}$

$$\begin{aligned}\mu_{U_1-U_2} &= \frac{-1 + 4 + 6 - 6 - 1 + 1}{6} = \frac{3}{6} \\ &= 0.5 = 6 - 5.5 = \mu_{U_1} - \mu_{U_2}\end{aligned}$$

- e. $\sigma_{U_1}^2$ = Variance of population U_1 (with mean 6)

$$= \frac{(2-6)^2 + (7-6)^2 + (9-6)^2}{3} = \frac{26}{3} = 8.66$$

$$\text{so } \sigma_{U_1} = \sqrt{8.66} = 2.9439$$

- f. $\sigma_{U_2}^2$ = Variance of population U_2 (with mean 5.5)

$$= \frac{(3-5.5)^2 + (8-5.5)^2}{2} = 6.25$$

$$\text{so } \sigma_{U_2} = \sqrt{6.25} = 2.5$$

- g. $\sigma_{U_1+U_2}^2$ = Variance of population $U_1 + U_2$ (with mean 11.5)

$$= \frac{(5-11.5)^2 + 2(10-11.5)^2 + (12-11.5)^2 + (15-11.5)^2 + (17-11.5)^2}{6}$$

$$= 14.9166$$

$$\text{so } \sigma_{U_1+U_2} = \sqrt{14.9166} = 3.86220$$

$$= \sqrt{\sigma_{U_1}^2 + \sigma_{U_2}^2} = \sqrt{8.66 + 6.25} = \sqrt{14.91} = 3.86220$$

- h. $\sigma_{U_1-U_2}^2$ = Variance of population $U_1 - U_2$ (with mean 0.5)

$$= \frac{89.50}{6} = 14.9166$$

$$\text{so } \sigma_{U_1-U_2} = \sqrt{14.9166} = 3.8622$$

$$= \sqrt{\sigma_{U_1}^2 + \sigma_{U_2}^2} = \sqrt{8.66 + 6.25} = \sqrt{14.91} = 3.86220.$$

Example 2: The mean voltage of a battery is 15 and s.d. is 0.2. Find the probability that four such

batteries connected in series will have a combined voltage of 60.8 or more volts.

Solution: Let mean voltage of batteries A, B, C, D be $\bar{X}_A, \bar{X}_B, \bar{X}_C, \bar{X}_D$. Then mean of the series of the four batteries connected is

$$\begin{aligned}\mu_{\bar{X}_A + \bar{X}_B + \bar{X}_C + \bar{X}_D} &= \mu_{\bar{X}_A} + \mu_{\bar{X}_B} + \mu_{\bar{X}_C} + \mu_{\bar{X}_D} \\ &= 15 + 15 + 15 + 15 = 60\end{aligned}$$

$$\begin{aligned}\sigma_{A+B+C+D} &= \sqrt{\sigma_A^2 + \sigma_B^2 + \sigma_C^2 + \sigma_D^2} \\ &= \sqrt{4(0.2)^2} = 0.4.\end{aligned}$$

Let X be the combined voltage of the series.

Fig. 28.5

60.8 in standard units is

$$\frac{X - \mu}{\sigma} = \frac{60.8 - 60}{0.4} = 2$$

so probability that combined voltage is more than 60.8

$$= P(X \geq 60.8) = P(Z > 2) = 0.5 - 0.4772 = 0.0228.$$

Example 3: Suppose the diameter of motor shafts in a lot have a mean of 0.249 inches and s.d. of 0.003 inches. The inner dia of bearings in another lot have a mean of 0.255 inches and s.d. of 0.002 inches.

- a. Find the mean and s.d. of clearances between shafts and bearings selected from these lots.

- b. If a shaft and bearing are selected at random, find the probability that the shaft will not fit inside the bearing. Assume that both dimensions are normally distributed.

Solution: Let $\bar{X}_B$ = mean diameter of bearing
 $\bar{X}_S$ = mean diameter of shaft.

It is given $\bar{X}_B = 0.255, \bar{X}_S = 0.249, \sigma_B = 0.002, \sigma_S = 0.003$.

- a. Then mean diameter of the difference in diameters of the bearing and the shaft is $\bar{X}_d$ given by

$$\bar{X}_d = \bar{X}_{B-S} = \bar{X}_B - \bar{X}_S = \mu_B - \mu_S$$

$$= 0.255 - 0.249 = 0.006$$

$$\sigma_d = \sigma_{\bar{X}_B - \bar{X}_S} = \sqrt{\sigma_{\bar{X}_B}^2 + \sigma_{\bar{X}_S}^2}$$

$$= \sqrt{(0.003)^2 + (0.002)^2} = 0.00360$$

- b. Shaft will not fit inside bearing if $d < 0$.
 0 in standard units is $z = \frac{0 - 0.006}{0.0036055} = -1.664$.
 Probability that shaft will not fit inside bearing

Fig. 28.6

$$= P(d < 0) = P(Z < -1.6641)$$

$$= 0.5 - 0.4515 = 0.0485.$$

EXERCISE

Sampling distribution of differences and sums

1. Let $U_1 = \{3, 7, 8\}$ and $U_2 = \{2, 4\}$. Calculate
 (a) μ_{U_1} (b) μ_{U_2} (c) $\mu_{U_1 - U_2}$ (d) σ_{U_1} (e) σ_{U_2}
 (f) $\sigma_{U_1 - U_2}$

Hint: $U_1 - U_2 : \{1, 5, 6, -1, 3, 4\}$

- Ans. a. $\mu_{U_1} = \frac{18}{3} = 6$,
 b. $\mu_{U_2} = \frac{6}{2} = 3$,
 c. $\mu_{U_1 - U_2} = 3 = \mu_{U_1} - \mu_{U_2} = 6 - 3$,
 d. $\sigma_{U_1} = \sqrt{\frac{14}{3}}$,
 e. $\sigma_{U_2} = 1$,
 f. $\sigma_{U_1 - U_2} = \sqrt{\frac{17}{3}} = \sqrt{\sigma_{U_1}^2 + \sigma_{U_2}^2}$

2. Three masses are measured as 62.34, 20.48, 35.97 kgs with s.d. 0.54, 0.21, 0.46 kgs. Find the mean and s.d. of the sum of the masses.

Ans. $\mu_{A+B+C} = \mu_A + \mu_B + \mu_C = 62.34 + 20.48 + 35.97 = 118.79$

$$\sigma_{A+B+C} = \sqrt{\sigma_A^2 + \sigma_B^2 + \sigma_C^2}$$

$$= \sqrt{(0.54)^2 + (0.21)^2 + (0.46)^2} = 0.74$$

3. The mean life time of light bulbs produced by a company is 1500 hours and s.d. of 150 hours.

Find the probability that lighting will take place for (a) at least 5000 h (b) at most 4200 h if three bulbs are connected such that when one bulb burns out, another bulb will go on. Assume that life times are normally distributed.

Ans. $\mu_{L_1+L_2+L_3} = \mu_{L_1} + \mu_{L_2} + \mu_{L_3} = 1500 + 1500 + 1500 = 4500$

$$\sigma_{L_1+L_2+L_3} = \sqrt{\sigma_{L_1}^2 + \sigma_{L_2}^2 + \sigma_{L_3}^2} = \sqrt{3(150)^2} = 260$$

- a. $P(X > 5000) = P\left(Z > \frac{5000 - 4500}{260}\right)$
 $= P(Z > 1.92) = 0.5 - 0.4726 = 0.0274$
 b. $P(X < 4200) = P\left(Z < \frac{4200 - 4500}{260}\right) =$
 $P(Z < -1.15) = 0.5 - 0.3749 = 0.1251$

4. Determine the probability that the mean breaking strength of cables produced by company B will be (a) at least 600 N more than (b) at least 450 N more than the cables produced by company A, if 100 cables of brand A and 50 cables of brand B are tested.

| Company | Mean breaking strength | s.d. | Sample size |
|---------|------------------------|-------|-------------|
| A | 4000 N | 300 N | 100 |
| B | 4500 N | 200 N | 50 |

Ans. $\mu_{\bar{X}_B - \bar{X}_A} = \mu_{\bar{X}_B} - \mu_{\bar{X}_A} = 4500 - 4000 = 500 \text{ N}$

$$\sigma_{\bar{X}_B - \bar{X}_A} = \sqrt{\frac{\sigma_B^2}{N_B} + \frac{\sigma_A^2}{N_A}} = \sqrt{\frac{(200)^2}{50} + \frac{(300)^2}{100}}$$

$$= \sqrt{1700} = 41.23$$

Fig. 28.7

- a. $P(\bar{X}_B - \bar{X}_A > 600)$
 $= P\left(Z > \frac{600 - 500}{41.23}\right)$
 $= P(Z > 2.4254) = 0.5 - 0.4922 = 0.0078$
 b. $P(\bar{X}_B - \bar{X}_A > 450) = P\left(Z > \frac{450 - 500}{41.23}\right)$
 $= P(Z > -1.2127) = 0.5 + 0.3869 = 0.8869$
5. Let $\bar{X}_A$ and $\bar{X}_B$ be the average drying times of two types of paints A and B, for samples of size

28.12 — HIGHER ENGINEERING MATHEMATICS—VII

$n_A = n_B = 18$. Suppose $\sigma_A = \sigma_B = 1$. Find $P(\bar{X}_A - \bar{X}_B > 1.0)$ assuming that the mean drying time is equal for the two types of paints.

Hint: $\sigma_{\bar{X}_A \bar{X}_B}^2 = \frac{\sigma_A^2}{n_A} + \frac{\sigma_B^2}{n_B} = \frac{1}{18} + \frac{1}{18} = \frac{1}{9}$

$$\text{Ans. } P(\bar{X}_A - \bar{X}_B > 1) = P\left(Z > \frac{1 - (\mu_A - \mu_B)}{\sigma_{\bar{X}_A - \bar{X}_B} / \sqrt{n}}\right) = P\left(\frac{1-0}{\sqrt{1/9}}\right) = P(Z > 3) = 1 - 0.9987 = 0.0013$$

28.6 SAMPLING DISTRIBUTION OF MEAN (σ UNKNOWN): t -DISTRIBUTION

Earlier in problems of inference on a population mean or the difference between two population means it was assumed that the population standard deviation σ is *known*. When σ is *unknown*, for large $n (\geq 30)$, σ can be replaced by the sample standard deviation s , calculated using the sample mean $\bar{x}$ by the formula $s^2 = \frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n-1}$. For small sample of size $n (< 30)$, the *unknown* σ can be substituted by s , provided we make an assumption that the sample is drawn from a normal population.

Result: Let $\bar{x}$ be the mean of a random sample of size n drawn from a normal population with mean μ and variance σ^2 then

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

is a random variable having the t -distribution with $\nu = n - 1$ degrees of freedom with probability density function.

$$f(t) = \frac{1}{\beta\left(\frac{1}{2}, \frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{(\nu+1)/2}}, -\infty < t < \infty$$

W.S. Gosset* first published in 1908, the probability distribution of t under the pseudonym “student”. So the t -distribution is also known as “student t -distribution”. 1925, R.A. Fisher used t -distribution to test the regression coefficient.

Here sample variance s is given by

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2.$$

Thus for *small* samples ($n < 30$) and with σ *unknown*, a natural statistic for inference on population mean μ is

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

with the underlying assumption of sampling from normal population. So the above result is more general than the central limit theorem since σ is not needed and less general than the central limit theorem since population is assumed to be normal.

Fig. 28.8

The t -distribution curve is symmetric about the mean 0, unimodal, bell shaped and asymptotic on both sides of t -axis. Thus the t -distribution curve is similar to normal curve. While the variance for normal distribution is 1, the variance for the t -distribution is more than one since it depends on the parameter ν . So the t -distribution is more variable. As $n \rightarrow \infty$, variance of t -distribution approaches 1.

Thus as $\nu = (n - 1) \rightarrow \infty$, t -distribution approaches the standard normal distribution. Infact for $n \geq 30$, standard normal distribution provides a good approximation to the t -distribution.

Critical values of t -distribution (see A13 to A14) is denoted by t_α which is such that the area under the curve to the **right** of t_α equals to α . Since the t -distribution is symmetric, it follows that

$$t_{1-\alpha} = -t_\alpha$$

i.e., the t -value leaving an area of $1 - \alpha$ to the right and therefore an area α to its left, is equal to the negative t -value which leaves an area α in the right

*William Sealy Gosset (1876–1937) English statistician.

tail of the distribution.

Fig. 28.9

Symmetry property of t -distribution.

The critical values t_{α} are tabulated in tables (A13 to A14) for various values of the parameter ν . In these tables, the left-hand column contains values of ν the column headings are areas α in the right-hand tail of the t -distribution, the entries are values of t_{α} .

Note 1: In the tables (A13 to A14), the areas are now the column heading and the entries are the t -values (which is the opposite in the normal tables where the entries are areas and column headings are z -values).

Note 2: Exactly 95% of the values of a t -distribution with $\nu = n - 1$ dof lies between $t_{-0.025}$ and $t_{0.025}$.

The t -distribution is extensively used in tests of hypothesis about one mean, or about equality of two means when σ is unknown.

WORKED OUT EXAMPLES

Example 1: Find (a) $t_{0.025}$ when $\nu = 14$ (b) $-t_{0.01}$ when $\nu = 10$ (c) $t_{0.995}$ when $\nu = 7$.

Solution: From tables (A13 to A14)

a. $t_{0.025} = 2.145$

b. $-t_{0.01} = -2.764$

c. $t_{0.995} = t_{1-0.005} = -t_{0.005} = -3.499$

Example 2: Find (a) $P(t < 2.365)$ when $\nu = 7$ (b) $P(t > 1.318)$ when $\nu = 24$ (c) $P(-1.356 < t < 2.179)$ with $\nu = 12$ (d) $P(t > -2.567)$ when $\nu = 17$.

Solution:

- a. When $t < 2.365$, $P(t < 2.365)$ is given by the area to the left of $t = 2.365$.

Fig. 28.10

From table, $t_{\alpha} = 2.365$ for $\nu = 7$ dof then $\alpha = 0.025$

$$\therefore P(t < 2.365) = 1 - 0.025 = 0.975$$

- b. When $t_{\alpha} = 1.318$ with $\nu = 24$ then $\alpha = 0.10$

Fig. 28.11

$$\therefore P(t > 1.318) \text{ is area to the right of } 1.318 \text{ is } 0.1$$

- c. When $t < 2.179$ with $\nu = 12$

Fig. 28.12

Area to the right of 2.179 is 0.025 when $t > -13.36$ with $\nu = 12$, area to the left is 0.10

$\therefore$ When $-1.356 < t < 2.179$ the area is

$$1 - 0.10 - 0.025 = 0.875$$

$$\therefore P(-1.356 < t < 2.179) = 0.875$$

- d. $P(t > -2.567) = 1 - 0.01 = 0.99$

Fig. 28.13

28.14 — HIGHER ENGINEERING MATHEMATICS—VII

Example 3: Find k for a random sample of size 24 from a normal distribution such that

- $P(-2.069 < t < k) = 0.965$
- $P(k < t < 2.807) = 0.095$
- $P(-k < t < k) = 0.90$

Solution:

- From table and symmetry, $t_{\alpha} = 2.069$ with $\nu = 24 - 1 = 23$,

Fig. 28.14

For $t_{\alpha} = 2.069$, area to the right is 0.025

For $-t_{\alpha} = -2.069$ area to the left is 0.025

The area to the right of k is $1 - 0.965 - 0.025 = 0.01$

$\therefore t_{0.01} = 2.50$ with $\nu = 23$ dof

$\therefore k = 2.500$

- $t_{\alpha} = 2.807$ with $\nu = 23$ dof

$\alpha = 0.005$

Fig. 28.15

Area to the left of k is

$$1 - 0.005 - 0.095 = 0.9$$

i.e., area to the right of k is 0.1.

$\therefore t_{0.1} = 1.319$ with $\nu = 23$

Hence $k = 1.319$

- Since $1 - 2\alpha = \text{area given} = 0.9$

$$\therefore \alpha = \frac{0.1}{2} = 0.05$$

Fig. 28.16

So $t_{0.05} = 1.714$ with $\nu = 23$ dof

Hence $k = 1.714$

Example 4: A process for making certain ball bearings is under control if the diameters of the bearings have a mean of 0.5000 cm. If a random sample of 10 of these bearings has a mean diameter of 0.5060 cm and s.d. of 0.0040 cm, is the process under control?

Solution:

$\bar{x} = 0.5060$ = sample mean,

$\mu = 0.5000$ = population mean,

n = sample size = 10

S = sample s.d. = 0.0040

Then $t = \frac{\bar{x} - \mu}{s/\sqrt{n}} = \frac{0.5060 - 0.5000}{0.0040/\sqrt{10}} = 4.7434$.

Here $\nu = n - 1 = 10 - 1 = 9$ dof

Fig. 28.17

Since $t_{\text{cal}} = 4.7334 > 3.250 = t_{\alpha}$ with $\alpha = 0.005$ and $\nu = 9$ dof, the process is not under control.

EXERCISE

- Find the t -value with $\nu = 14$ dof that leaves an area 0.025 to the left.

Ans. $t_{0.975} = -t_{0.025} = -2.145$

- Find $P(-t_{0.025} < t < t_{0.05})$

Hint: $t_{0.05}$ leaves an area 0.05 to the right, $-t_{0.025}$ leaves an area of 0.025 to the left. Total

$$\text{area} = 1 - 0.05 - 0.025 = 0.925.$$

Ans. 0.925

3. Find k such that $P(k < t < -1.761) = 0.045$ for a random sample of size 15 selected from a normal distribution.

Hint: 1.761 corresponds to $t_{0.05}$ with $\nu = 14$, so $-t_{0.05} = -1.761$ since k is to left, $-t_{0.05} = -1.761$ so $0.045 = 0.05 - \alpha$ or $\alpha = 0.005$, hence $k = -t_{0.005} = -2.977$.

Ans. $k = -t_{0.005} = -2.977$

4. Determine (a) $t_{0.01}$ with $\nu = 18$ (b) $t_{0.05}$ with $\nu = 12$ (c) $t_{-0.10}$ with $\nu = 15$

Ans. (a) 2.878 (b) 2.179 (c) 1.753

5. Find the 90th percentile of t -distribution with 10 dof.

Ans. 1.372

6. Find $P(t \geq 2.086)$ with 20 dof

Ans. 0.05

7. Find $P(-2.583 \leq t \leq 2.583)$ with 16 dof

Ans. $1 - 2(0.01) = 0.98$

8. Fuses produced by a company will blow in 12.40 minutes on the average when overloaded. Suppose the mean blow time of 20 fuses subjected to overload is 10.63 minutes and s.d. 2.48 mts. Does this information tend to support or refute the claim that the population mean blow time is 12.40 mts?

Ans. $t = \frac{10.63 - 12.4}{2.48/\sqrt{20}} = -3.19$, $\nu = 20 - 1 = 19$ dof

Data refutes the producer's claim since

$$t = -3.19 < -2.861$$

with probability $\alpha = 0.005$

9. A company claims that the mean life time of tube lights is 500 hours. Is the claim of the company tenable if a random sample of 25 tube lights produced by the company has mean 518 hours and s.d. 40 hours. Company is satisfied if t falls between $-t_{0.01}$ and $t_{0.01}$.

Ans. $t = \frac{\bar{x} - \mu}{s/\sqrt{n}} = \frac{518 - 500}{40/\sqrt{25}} = 2.25 < t_{\alpha} = 2.492$

Accept the claim of the company, $\nu = 24$ dof.

10. A random sample of size 25 from a normal population has the mean $\bar{x} = 47.5$ and s.d. = 8.4. Does this information tend to support or refute the claim that the mean of the population is 42.1.

Ans. Does not support the claim.

Ans. $t = \frac{\bar{x} - \mu}{s/\sqrt{n}} = \frac{47.5 - 42.1}{8.4/\sqrt{25}}$, $\nu = 24$ dof.

28.7 CHI-SQUARED DISTRIBUTION

Chi-squared distribution plays a very important role in estimation and hypothesis testing. It is a continuous probability distribution of a continuous random variable X , with density function given by

$$f(x) = \frac{1}{2^{v/2}\Gamma(v/2)} x^{v/2-1} e^{-x/2} \quad \text{for } x > 0$$

which is a special case of gamma distribution with $\alpha = v/2$ and $\beta = 2$. Here v is a positive integer is the only single parameter of the distribution. v is known as “degrees of freedom” (dof). Chi-squared distribution is extensively used in sampling distributions, analysis of variance (ANOVA) and non-parametric tests. It was first discovered by Helmer in 1876 and later independently by Karl Pearson in 1900.

It was mainly used as a measure of goodness of fit and to test the independence of attributes. Chi-squared distribution is denoted as χ^2 -distribution.

Properties of χ^2 -distribution

1. χ^2 -distribution curve is not a normal curve and lies completely in the first quadrant since χ^2 varies from 0 to ∞ . i.e., χ^2 -distribution is not symmetrical.
2. It depends only on ν , the dof.
3. It is unimodal curve with mode at $\chi^2 = (k - 1)$.
4. It is additive i.e., if χ_1^2 and χ_2^2 are two independent distributions with ν_1 and ν_2 dof then $\chi_1^2 + \chi_2^2$ will be chi-squared distribution with $(\nu_1 + \nu_2)$ dof.

Here α denotes the area under the chi-square distribution to the **right** of χ_{α}^2 . Thus α denotes the prob-

Fig. 28.18

ability that a random sample produces a χ^2 -value $> \chi^2_\alpha$. So χ^2_α represents the χ^2 -value such that the area under the chi-square curve to its (χ^2_α 's) right is equal to α .

For various values of α and ν , the values of χ^2_α are presented in the tables (A15 to A16)

In χ^2 table, the left-hand column contains values of ν , dof, the column headings are areas α in the right hand tail of χ^2 -distribution curve, the table entries are values of χ^2 .

28.8 SAMPLING DISTRIBUTION OF VARIANCE s^2

The theoretical sampling distribution of the sample variance for random samples from normal population is related to the chi-squared distribution as follows:

Let s^2 be the variance of a random sample of size n , taken from a normal population having the variance σ^2 . Then

$$\chi^2 = \frac{(n-1)s^2}{\sigma^2} = \sum_{i=1}^n \frac{(X_i - \bar{X})^2}{\sigma^2}$$

is a value of a random variable having the χ^2 -distribution with $\nu = n - 1$ dof.

Exactly 95% of χ^2 -distribution lies between $\chi^2_{0.975}$ and $\chi^2_{0.025}$. When σ^2 is too small, χ^2 -value falls to the right of $\chi^2_{0.025}$ and when σ^2 is too large, χ^2 falls to the left of $\chi^2_{0.975}$. Thus when σ^2 is correct, χ^2 -values falls to the left of $\chi^2_{0.975}$ or to the right of $\chi^2_{0.025}$.

28.9 F-DISTRIBUTION

Let s_1^2 be the sample variance of an independent sample of size n_1 drawn from a normal population $N(\mu_1, \sigma_1^2)$. Similarly, let s_2^2 be the sample variance in an independent sample of size n_2 drawn from another normal population $N(\mu_2, \sigma_2^2)$. Thus s_1^2 and s_2^2 are two variances of two random samples of sizes n_1 and n_2 respectively drawn from two normal population. In order to determine whether the two samples come from two populations having equal variances, consider the sampling distribution of the ratio of the variances of the two independent random sample defined by

$$F = \frac{s_1^2/\sigma_1}{s_2^2/\sigma_2} = \frac{\sigma_2^2 s_1^2}{\sigma_1^2 s_2^2}$$

which is an F -distribution with $\nu_1 = n_1 - 1$ and $\nu_2 = n_2 - 1$ degrees of freedom. Here F is used as mark of respect for Sir R.A. Fisher. F -distribution was worked out by G.W. Snedecor. Under the hypothesis that two normal populations have the same variance i.e., $\sigma_1^2 = \sigma_2^2$, we have

$$F_{\nu_1, \nu_2} = \frac{s_1^2}{s_2^2}$$

F determines whether the ratio of two sample variances s_1 and s_2 is too small or too large.

When F is close to 1, the two sample variances s_1 and s_2 are nearly same. It is customary, to take the larger sample variance as the numerator. F -distribution is related to the Beta distribution and the two parameters ν_1 and ν_2 are known as numerator and denominator degrees of freedom. The curve of the F -distribution depends not only on the two parameters ν_1 and ν_2 but also on the order in which they are stated. F -distribution is also known as *variance ratio distribution*. F is always a positive number. The F -distribution curve lies entirely in first quadrant and is unimodal.

$F_\alpha(\nu_1, \nu_2)$ is the value of F with ν_1 and ν_2 dof such that the area under the F -distribution curve to the **right** of F_α is α . In tables (A17 to A20) F_α is tabulated (prepared by Snedecor) for $\alpha = 0.05$ and $\alpha = 0.01$ for various combinations of the dof ν_1 and ν_2 . The values of $F_{0.95}$ and $F_{0.99}$ can be calculated from the above tables (A17 to A20) by using the following result.

Fig. 28.19

$$F_{1-\alpha}(v_1, v_2) = \frac{1}{F_{\alpha}(v_2, v_1)}$$

F -distribution is extremely useful in testing the equality of several population means, comparing sample variances, and forms the backbone of analysis of variance (ANOVA).

WORKED OUT EXAMPLES

F-distribution

Example 1: For an F -distribution find

- $F_{0.05}$ with $v_1 = 7$ and $v_2 = 15$
- $F_{0.01}$ with $v_1 = 24$ and $v_2 = 19$
- $F_{0.95}$ with $v_1 = 19$ and $v_2 = 24$
- $F_{0.99}$ with $v_1 = 28$ and $v_2 = 12$

Solution:

- From table $F_{0.05}$ with $v_1 = 7$ and $v_2 = 15$ is 2.71
- $F_{0.01}$ with $v_1 = 24$, $v_2 = 19$ is 2.92
- $F_{0.95}(19, 24) = \frac{1}{F_{0.05}(24, 19)} = \frac{1}{2.11} = 0.473933$
- $F_{0.99}(28, 12) = \frac{1}{F_{0.01}(12, 28)} = \frac{1}{2.90} = 0.34482$

Example 2: Determine the probability that the variance of the first sample of size $n_1 = 9$ will be at least 4 times as large as the variance of the second sample of size $n_2 = 16$ if the two samples are independent random samples from a normal population.

Solution: From table (A17 to A20) $F_{0.01} = 4.0$ for $v_1 = n_1 - 1 = 9 - 1$, $v_2 = n_2 - 1 = 16 - 1 = 15$, the desired probability is 0.01.

Example 3: The household net expenditure on health care in south and north India, in two samples of households, expressed as percentage of total income is shown the following table

| | |
|-------|---|
| South | 15.0, 8.0, 3.8, 6.4, 27.4, 19.0, 35.3, 13.6 |
| North | 18.8, 23.1, 10.3, 8.0, 18.0, 10.2, 15.2, 19.0, 20.2 |

Test the equality of variances of households net expenditure on health care in south and north India.

Solution: Let the net expenditure of the south and north be considered as $N(\mu_1, \sigma_1^2)$ and $N(\mu_2, \sigma_2^2)$ respectively.

- Null Hypothesis: $H_0 : \sigma_1^2 = \sigma_2^2$, i.e., equality of variances
- Alternate Hypothesis: $H_1 : \sigma_1^2 \neq \sigma_2^2$, i.e., difference in variances
- Computations: $n_1 = 8$, $n_2 = 9$,

$$\sum_{i=1}^8 x_{1i} = 15 + 8 + 3.8 + 6.4 + 27.4 + 19 + 35.3 + 13.6 = 128.5$$

$$\sum_{i=1}^8 x_{1i}^2 = (15)^2 + 8^2 + (3.8)^2 + (6.4)^2 + \dots + (13.6)^2 = 2887.21$$

$$\sum_{i=1}^9 x_{2i} = 142.8, \quad \sum_{i=1}^9 x_{2i}^2 = 2485.26.$$

$$\text{so } s_1^2 = \frac{1}{n_1 - 1} \left\{ \sum_{i=1}^8 x_{1i}^2 - \frac{(\sum x_{1i})^2}{n_1} \right\} = \frac{1}{7} \left\{ 2887.21 - \frac{(128.5)^2}{8} \right\} = 117.59696$$

$$\text{also } s_2^2 = \frac{1}{8} \left\{ 2485.26 - \frac{(142.8)^2}{9} \right\} = 27.4375$$

- Test statistic: $F = \frac{s_1^2}{s_2^2} = \frac{117.59696}{27.4375} = 4.28599$.
Variances are significantly different.

EXERCISE

F-distribution

1. Find the value of
 - a. $F_{0.05}$ for $\nu_1 = 15$ and $\nu_2 = 7$
 - b. $F_{0.95}$ for 12 and 15 dof
 - c. $F_{0.99}$ for 6 and 20 dof
 - d. $F_{0.95}$ for $\nu_1 = 10$, $\nu_2 = 20$

Ans. a. 3.51

$$\text{b. } F_{0.95}(12, 15) = \frac{1}{F_{0.05}}(15, 12) = \frac{1}{2.62} = 0.38$$

$$\text{c. } F_{0.99}(6, 20) = \frac{1}{F_{0.01}}(20, 6) = \frac{1}{7.4} = 0.135135$$

$$\text{d. } F_{0.95}(10, 20) = \frac{1}{F_{0.05}}(20, 10) = \frac{1}{2.77} = 0.36$$

2. Find the probability that the variance of the first sample will be at least 3 times as large as that of the second sample if two independent random samples of size $n_1 = 7$ and $n_2 = 13$ are taken from a normal population.

Hint: From table $F_{0.05} = 3.00$ for $\nu_1 = 7 - 1 = 6$ and $\nu_2 = 13 - 1 = 12$

Ans. 0.05

3. If independent random samples of size $n_1 = n_2 = 8$ come from normal populations having the same variance, what is the probability that either sample variance will be at least seven times as large as the other.

Hint: From table $F_{0.01} = 6.99 \approx 7$ for $\nu_1 = 8 - 1 = 7$, $\nu_2 = 8 - 1 = 7$

Ans. 0.01

4. Can we conclude that the two population variances are equal for the following data of post graduates passed out from a 'state' and 'private' university.

State: 8350 8260 8130 8340 8070

Private: 7890 8140 7900 7950 7840 7920

Hint: $n_1 = 5$, $n_2 = 6$, $\sum x_{1i} = 41150$, $\sum x_{1i}^2 = 338727500$

$$s_1^2 = \frac{63000}{4} = 15750, \sum x_{2i} = 47640,$$

$$\sum x_{2i}^2 = 378316200$$

$$s_2^2 = \frac{54600}{5} = 10920, F = \frac{15750}{10920} = 1.442$$

Ans. F -ratio is 1.44. The variances are not significantly different

5. Is there reason to believe that the life expected in south and north India is same or not from the following data.

South: 34.0, 39.2, 46.1, 48.7, 49.4, 45.9, 55.3, 42.7, 43.7

North: 49.7, 55.4, 57.0, 54.2, 50.4, 44.2, 53.4, 57.5, 61.9, 56.6, 58.2

$$\text{Hint: } s_1^2 = \frac{1}{8} \left\{ 18527.78 - \frac{(405)^2}{9} \right\} = 37.848$$

$$s_2^2 = \frac{1}{10} \left\{ 32799.91 - \frac{(598.5)^2}{11} \right\} = 23.607$$

Ans. Yes, variances of life expectancy is same for the south and north since $F = \frac{s_1^2}{s_2^2} = \frac{37.843}{23.607} = 1.603$

Chapter 29

Estimation and Test of Hypothesis

INTRODUCTION

By “estimate” we mean “judgement or opinion of the approximate size or amount”. For a trip from kakinada to Hyderabad by car we estimate the distance as 550 km, mileage/litre as 12 km, price/litre petrol as Rs 50 from which eventually estimate the entire cost of the trip. Also we might estimate the distance being between 500 to 600 km, mileage/litre as between 10 to 15 km, cost of petrol between Rs 45 to 55. In the first case, we are estimating distance, mileage, price as specific values or points. So this method of estimate is known as “point estimation” where as the second method is known as “interval estimation” since we are estimating the parameters enclosed in an interval.

Hypothesis testing main aim is to provide rules that lead to decision resulting in acceptance or rejection of statements about the population parameters. A man going to office on a cloudy day is in a dilemma whether to carry his umbrella or not. When the day begins he has to take the decision although he is not aware whether it rains or not. In any case, one of the following is going to happen.

- (i) He takes his umbrella and it rains (wise decision)
- (ii) He does not take his umbrella and it does not rain (wise decision again)
- (iii) He takes umbrella and does not rain (wrong decision)
- (iv) He does not take his umbrella and it rains (wrong decision).

The situations (iii) and (iv) are undesirable.

Test of goodness of fit is a statistical test which determines whether the sample data are in conformity with the hypothesized distribution. In fact this test literally tests how good the fit is. It is based on how close are the observed numbers and the numbers that we expect from the hypothesized distribution.

29.1 POINT ESTIMATION

Statistical Estimation

It is a part of statistical inference where a population parameter is estimated from the corresponding sample statistics. An estimate of the unknown true or exact value of the parameter or an interval in which the parameter is to be determined on the basis of sample data from the population.

Unbiased estimator

A statistic $\hat{\theta}$ is known as an unbiased estimator of the corresponding parameter θ if

$$E(\hat{\theta}) = E(\text{statistic}) = \text{parameter} = \theta$$

i.e., the mean of the sampling distribution of estimator equals to θ . Unbiasedness property is desirable, although not essential.

Point estimation

Point estimation of a parameter is a statistical estimation where the parameter is estimated by a single number (or value) from sample data.

Maximum Error of Estimate E

Since the sample mean estimate very rarely equals to the mean of population μ , a point estimate is generally accompanied with a statement of error which gives difference between estimate and the quantity to be estimated, the estimator. Thus error $= \bar{x} - \mu$. For large n , the random variable $\frac{\bar{x} - \mu}{\sigma/\sqrt{n}}$ is normal variate approximately. Then the inequality

$$-Z_{\alpha/2} \leq \frac{\bar{x} - \mu}{\sigma/\sqrt{n}} \leq Z_{\alpha/2}$$

is satisfied with probability $(1 - \alpha)$

$$\text{i.e., } |\bar{x} - \mu| \leq Z_{\alpha/2} \cdot \sigma/\sqrt{n}$$

Confidence interval for μ

A $(1 - \alpha)$ 100% confidence interval for μ is given by

$$\bar{x} - Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{x} + Z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

So the maximum error of estimate E with $(1 - \alpha)$ probability is given by

$$E = Z_{\alpha/2} \cdot \frac{\sigma}{\sqrt{n}}$$

Thus in the point estimation of population mean μ with sample mean $\bar{x}$ for a large random sample ($n \geq 30$), one can assert with probability $(1 - \alpha)$ that the error $|\bar{x} - \mu|$ will not exceed $Z_{\alpha/2} \sigma/\sqrt{n}$.

Sample Size

When α , E , σ are known, the sample size n is given by

$$n = \left(\frac{Z_{\alpha/2} \sigma}{E} \right)^2$$

when σ is unknown (or $n < 30$ small sample):

In this case, σ is replaced by s , the standard deviation of sample to determine E .

Thus the maximum error estimate

$$E = t_{\alpha/2} \frac{s}{\sqrt{n}}$$

with $(1 - \alpha)$ probability.

Here t -distribution is with $n - 1$ degrees of freedom.

WORKED OUT EXAMPLES

Example 1: The efficiency expert of a computer company tested 40 engineers to estimate the average

time it takes to assemble a certain computer component, getting a mean of 12.73 minutes and s.d. of 2.06 minutes. (a) If $\bar{x} = 12.73$ is used as a point estimate of the actual average time required to perform the task, determine the maximum error with 99% confidence (b) construct 98% confidence intervals for the true average time it takes to do the job (c) with what confidence can we assert that the sample mean does not differ from the true mean by more than 30 seconds.

Solution: Here $\bar{x} = 12.73$, $s = 2.06$, For 99%, $Z_{\alpha/2} = 2.575$

$$\begin{aligned} \text{a. Maximum error of estimate } E &= Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \\ &= (2.575) \frac{(2.06)}{(\sqrt{40})} = 0.8387 \end{aligned}$$

$$\begin{aligned} \text{b. For 98\% confidence, } E &= (2.33) \frac{(2.06)}{\sqrt{40}} = 0.758915, \text{ 98\% confidence interval limits are} \\ \bar{x} \pm Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \\ &= \bar{x} \pm E = 12.73 \pm 0.7589 \end{aligned}$$

i.e., confidence interval is (11.97, 13.4889)

$$\begin{aligned} \text{c. } \frac{30}{60} \text{ mts} &= \frac{1}{2} \text{ minute} = E = Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} = Z_{\alpha/2} \frac{2.06}{\sqrt{40}} \\ \therefore Z_{\alpha/2} &= 1.5350 \end{aligned}$$

From normal table (A850), the area corresponding to $Z_{\alpha/2} = 1.5350$ is 0.4370. Then the area between $Z_{-\alpha/2}$ to $Z_{\alpha/2}$ is $2(0.4370) = 0.8740$. Thus we can ascertain with 87.4% confidence.

Example 2: To estimate the average amount of time visitors take to move from one building to another in an office complex, the mean of a random sample of size n is used. Given $\sigma = 1.40$ minutes, determine how large should be the sample size if it is ascertained with 99% confidence that the error E is at most 0.25.

Solution:

$$n = \left(\frac{Z_{\alpha/2} \sigma}{E} \right)^2 = \left[\frac{(2.575)(1.40)}{0.25} \right]^2 = 207.98 \approx 208.$$

Example 3: Find the degree of confidence to assert that the average salary of school teachers is between Rs. 272 and Rs. 302 if a random sample of 100 such

teachers revealed a mean salary of Rs. 287 with s.d. of Rs. 48.

Solution: Standard variable corresponding to Rs. 272 is

$$Z_1 = \frac{272 - 287}{48/\sqrt{100}} = -3.125$$

For Rs. 302 is $Z_2 = \frac{302 - 287}{48/\sqrt{100}} = 3.125$

Let X be the mean salary of teacher, then

$$\begin{aligned} P(272 < X < 302) &= P(-3.125 < Z < 3.125) \\ &= 2(.499) = 0.9982 \end{aligned}$$

Thus we can ascertain with 99.82% confidence.

EXERCISE

- Using the mean of a random sample of size 150 to estimate the mean mechanical aptitude of mechanics of a large workshop and assuming $\sigma = 6.2$, what can we assert with 0.99 probability about the maximum size of the error.

Hint: $n = 150$, $\sigma = 6.2$, $Z_{0.005} = 2.575$,
 $E = 2.575 \left(\frac{6.2}{\sqrt{150}} \right) = 1.30$.

Ans: Can assert with 0.99 probability that the error will be at most 1.30.

- Assuming that the population standard deviation is 0.3, calculate the (a) 95% and (b) 99% confidence intervals for the mean lead concentration in a river if the mean lead concentration recovered from a sample of lead measurements in 36 different locations is 2.6 gms/ml.

Hint: $\bar{x} \pm Z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$, $\bar{x} = 2.6$, $n = 36$, $\sigma = 0.3$,
 $Z_{0.025} = 1.96$, $Z_{0.005} = 2.575$ from normal tables A11.

Ans: (a) $2.50 < \mu < 2.70$ (b) $2.47 < \mu < 2.73$

- For the above Example 2, if we want to be 99% confident that our estimate of μ is off by less than 0.01, how large a sample should be chosen?

Ans: $n = \left[\frac{(2.575)(2.3)}{0.01} \right]^2 = 5967.5625 \approx 5968$
 i.e., we can be 99% confident that a random sample of size 5968 will provide an estimate

of $\bar{x}$ differing from μ by an amount less than 0.01.

- (σ unknown) Determine 99% confidence interval for the mean of contents of soft drink bottles if contents of 7 such soft drink bottles are 10.2, 10.4, 9.8, 10.0, 9.8, 10.2, 9.6 ml.

Hint: $\bar{x} = 10.0$, $s = 0.283$ are the mean and s.d. for given data. $t_{0.005} = 3.707$ with 6 dof

Ans: $10 \pm (3.707) \left(\frac{0.283}{\sqrt{7}} \right)$ i.e., 10 ± 2.64575 or (7.354, 12.6458)

- The pulse rate of 50 yoga practitioners decreased on the average by 20.2 beats/minute with s.d. of 3.5. (a) If $\bar{x} = 20.2$ is used as a point estimate of the true average decrease in the pulse rate, what can we assert with 95% confidence about the maximum error E . (b) Construct 99% confidence intervals for the true average decrease in pulse rate.

Ans: a. $E = Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} = Z_{0.025} \frac{3.5}{\sqrt{50}} = 1.96 \frac{(3.5)}{\sqrt{50}} = 0.97015$

b. C.I.: $\bar{x} \pm Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} = 20.2 \pm 2.575 \frac{3.5}{\sqrt{50}}$;
 $19.229 < \mu < 21.17015$

- For the above Example 5, how large a sample should we take in order to assert with 95% confidence that the mean of the sample is off by at most 0.50?

Ans: $n = \left[\frac{(1.96)(3.5)}{0.50} \right]^2 = (13.72)^2 = 188.23 \approx 188$.

29.2 INTERVAL ESTIMATION

Point estimates rarely coincide with quantities they are intended to estimate. So instead of point estimation where the quantity to be estimated is replaced by a single value a better way of estimation is interval estimation, which determines an interval in which the parameter lies. For a given sample of values of a population, interval estimation consists of determining an interval whose two end points are computed from the sample data. The interval esti-

29.4 — HIGHER ENGINEERING MATHEMATICS—VII

mate thus constructed is such that the probability of the parameter lying in the interval can be determined. Accuracy of the estimate is indicated by the length of the interval. Thus **interval estimates** are intervals for which one can be $(1 - \alpha)$ 100% confident that the parameter under investigation lies in this interval. Such an interval is known as **confidence interval** for the parameter with (having) $1 - \alpha$ or $(1 - \alpha)$ 100% degree of confidence. The two end points of the confidence interval are known as **confidence limits** or **fiducial limits** or **critical values** or confidence coefficients. **Confidence level** denoted by α is the percentage of confidence.

Consider a large random sample of size $n (\geq 30)$ from a population with *unknown* mean μ and *known* variance σ^2 . Then the **large-sample confidence interval for μ** :

$$\bar{x} - Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{x} + Z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

Note 1: Confidence interval is exact for random samples from normal populations.

Note 2: Confidence interval provides good approximation for large samples ($n \geq 30$) from non-normal populations also.

Small-sample confidence interval for μ : (when $n < 30$, assuming sampling from normal population)

$$\bar{x} - t_{\alpha/2} \frac{s}{\sqrt{n}} < \mu < \bar{x} + t_{\alpha/2} \frac{s}{\sqrt{n}}$$

| Confidence level α | 99.73% | 99% | 98% | 96% | 95.5% | 95% | 90% | 80% | 68.27% | 50% |
|---------------------------|--------|------|------|------|-------|------|-------|------|--------|-------|
| $Z_{\alpha/2}$ | 3.00 | 2.58 | 2.33 | 2.05 | 2.00 | 1.96 | 1.645 | 1.28 | 1.00 | 0.675 |

WORKED OUT EXAMPLES

Example: A random sample of 10 ball bearings produced by a company have a mean diameter of 0.5060 cm with s.d 0.004 cm. Find the maximum error estimate E and 95% confidence interval for the actual mean dia of ball bearings produced by this company assuming sampling from normal population.

Solution: Sample size $= n = 10 < 30$, so use t -distribution (small sampling).
Maximum error estimate at 95% confidence is

$$E = t_{\alpha/2} \frac{\sigma}{\sqrt{n}} = (2.262) \frac{(0.004)}{\sqrt{10}} = 0.00286$$

since $t_{0.025}$ with $n - 1 = 10 - 1 = 9$ dof is 2.262.
95% confidence interval limits are $\bar{x} \pm t_{\alpha/2} \frac{\sigma}{\sqrt{n}}$
 $= 0.5060 \pm (2.262) \frac{(0.004)}{\sqrt{10}}$.
95% confidence interval is (0.5031, 0.5089).

EXERCISE

1. If on the average, the test strips painted across heavily travelled roads in 15 different locations, disappeared after they had been crossed by 146692 cars with s.d. 14380 cars, calculate 99% confidence intervals for the true average number of cars it takes to wear off the paint, assuming normal population.

Hint: $n = 15 < 30$, $t_{0.005}$ with 14 dof is 2.977, $\bar{x} = 146692$, $\sigma = 14380$,

$$\text{C.I. } (146692 \pm \frac{(2.977)(14380)}{\sqrt{15}}).$$

Ans: $135639 < \mu < 157745$

2. A random sample of 20 fuses subjected to overload has mean time for blow of 10.63 minutes with s.d. of 2.48 mt. What can we assert with 95% confidence about the maximum

error if we use $\bar{x} = 10.63$ mts as a point estimate of true average it takes such fuses for blow when subjected to overload.

$$\text{Ans: } E = t_{\alpha/2} \frac{\sigma}{\sqrt{n}} = 2.093 \frac{(2.48)}{\sqrt{20}} = 1.16 \text{ mt}$$

3. Construct a 99% confidence interval for the true mean weight loss if 16 persons on diet control after one month had a mean weight loss of 3.42 kgs with s.d. of 0.68 kgs.

Hint: $n = 16$, $\bar{x} = 3.42$, $s = 0.68$,
 $t_{0.005} = 2.947$ for 15 dof

$$3.42 \pm 2.947 \frac{(0.68)}{\sqrt{16}}.$$

Ans: $2.92 < \mu < 3.92$

29.3 BAYESIAN ESTIMATION

Personal or subjective probability is the new concept introduced in Bayesian methods. Also, parameters are viewed as random variables in Bayesian methods.

To estimate the mean of a population, μ is treated as a random variable whose distribution is indicative of the “strong feelings” or assumption of a person about the possible value of μ . Let μ_0 and σ_0 be the mean and standard deviation of such a subjective “prior distribution”.

Bayesian Estimation

Combining the prior feelings about the possible values of μ with direct sample evidence, the “posterior” distribution of μ in Bayesian estimation is approximated by normal distribution with

$$\mu_1 = \frac{n\bar{x}\sigma_0^2 + \mu_0\sigma^2}{n\sigma_0^2 + \sigma^2} \quad \text{and}$$

$$\sigma_1 = \sqrt{\frac{\sigma^2\sigma_0^2}{n\sigma_0^2 + \sigma^2}}$$

Here μ_1 and σ_1 are known as the mean and standard deviation of the posterior distribution. In the computation of μ_1 and σ_1 , σ^2 is assumed to be *known*. When σ^2 is unknown, which is generally the case, σ^2 is replaced by sample variance s^2 provided $n \geq 30$ (large sample).

Bayesian interval for μ :

A $(1 - \alpha)100\%$ Bayesian interval for μ is given by

$$\mu_1 - Z_{\alpha/2}\sigma_1 < \mu < \mu_1 + Z_{\alpha/2}\sigma_1.$$

WORKED OUT EXAMPLES

Example: A professor’s feelings about the mean mark in the final examination in “probability” of a large group of students is expressed subjectively by normal distribution with $\mu_0 = 67.2$ and $\sigma_0 = 1.5$.

(a) If the mean mark lies in the interval (65.0, 70.0), determine the prior probability the professor should assign to the mean mark. (b) Find the posterior mean μ_1 and posterior s.d. σ_1 if the examination is conducted on a random sample of 40 students yielding mean 74.9 and s.d. 7.4. Use $s = 7.4$ as an estimate of σ . (c) Determine the posterior probability which he will thus assign to the mean mark being in the interval (65.0, 70.0), using results obtained in (b). (d) construct a 95% Bayesian interval for μ .

Solution:

a. Here $\mu_0 = 67.2$, $\sigma_0 = 1.5$, $n = 40$

standard variable corresponding to 65.0 is

$$Z_1 = \frac{65.0 - 67.2}{1.5} = -1.466,$$

Similarly,
$$Z_2 = \frac{70 - 67.2}{1.5} = 1.866$$

Let X be the mean mark obtained in the final examination.

$$\text{Prior probability} = P(65 < X < 70)$$

$$= P(-1.47 < Z < 1.87)$$

$$= 0.4292 + 0.4693 = 0.8985$$

Fig. 29.1

b. Here $\bar{x} = 74.9$, $\sigma = s = 7.4$

$$\begin{aligned} \text{posterior mean } \mu_1 &= \frac{n\bar{x}\sigma_0^2 + \mu_0\sigma^2}{n\sigma_0^2 + \sigma^2} \\ &= \frac{40(74.9)(1.5)^2 + (67.2)(7.4)^2}{40(1.5)^2 + (7.4)^2} = 71.987 \approx 72 \end{aligned}$$

posterior s.d.

$$\sigma_1 = \sqrt{\frac{\sigma^2\sigma_0^2}{n\sigma_0^2 + \sigma^2}} = \sqrt{\frac{(7.4)^2(1.5)^2}{40(1.5)^2 + (7.4)^2}} = 0.922568 \approx 0.923$$

c. Here $\mu_1 = 72$, $\sigma_1 = 0.923$.

29.6 — HIGHER ENGINEERING MATHEMATICS—VII

Standard variable corresponding to 650 is

$$Z_1 = \frac{65 - 72}{0.923} = -7.5839,$$

similarly, corresponding to 70.0 is

$$Z_2 = \frac{70 - 72}{0.923} = -2.16684$$

Posterior probability = $P(65 < X < 70)$

$$\begin{aligned} &= P(-7.584 < Z < -2.167) \\ &= 0.5 - 0.4850 = 0.0150 \end{aligned}$$

Fig. 29.2

d. 95% Bayesian interval limits are

$$\mu_1 \pm Z_{\alpha/2}\sigma_1 = 71.987 \pm (1.96)(0.922568)$$

Thus the Bayesian interval is

$$(70.17876, 72.909568).$$

EXERCISE

1. Calculate μ_1, σ_1 for the posterior distribution if the random sample size is 80, $\bar{x} = 18.85$, $s = 5.55$ using s for s.d. of population σ .

Ans: $\mu_1 = 18.77, \sigma_1 = 0.60$

2. An insurance agent feelings about the average monthly commission of insurance policies may be described by means of normal distribution with $\mu_0 = \text{Rs. } 3800$ and $\sigma_0 = \text{Rs. } 260$. (a) What probability is the agent thus assigning to the true average monthly commission being in the interval of Rs. 3,500 to Rs. 4000. (b) How does the probability in part (a) is affected if the mean commission is Rs. 3702 with s.d. Rs. 390 for 9 months? Use $s = 390$ as an estimate of σ .

Hint: $P(3500 < X < 4000) = P(-1.154 < Z < 0.77) = 0.3749 + 0.2794$.

Ans: a. 0.6543

Hint: $\bar{x} = 3702, s = \sigma = 390, n = 9, \mu_0 = 3800, \sigma_0 = 260$

$$\mu_1 = \frac{\bar{n}\bar{x}\sigma_0^2 + \mu_0\sigma^2}{n\sigma_0^2 + \sigma^2} = 3721.6 \approx 3722,$$

$$\sigma_1 = \sqrt{\frac{\sigma^2\sigma_0^2}{n\sigma_0^2 + \sigma^2}} = 116.3 \approx 116$$

$$\begin{aligned} P(3500 < X < 4000) &= \\ P(-1.91 < Z < 2.40) &= 0.4719 + \\ 0.4918 &= 0.9637 \end{aligned}$$

Ans: b. 0.9637

3. The mean mark in mathematics in common entrance test will vary from year to year. If this variation of the mean mark is expressed subjectively by a normal distribution with mean $\mu_0 = 72$ and variance $\sigma_0^2 = 5.76$. (a) What probability can we assign to the actual mean mark being somewhere between 71.8 and 73.4 for the next year's test. (b) construct a 95% Bayesian interval for μ if the test is conducted for a random sample of 100 students from the next incoming class yielding a mean mark of 70 with s.d. of 8. (c) What posterior probability should we assign to the event of part (a).

Hint: $P(71.8 < X < 73.4) = P(-0.083 < Z < 0.583) = 0.0319 + 0.2190 = 0.2509$

Ans: a. 0.2509

Hint: $n = 100, \bar{x} = 70, \sigma_0 = 2.4, \mu_0 = 72, \sigma = 8$, so

$$\mu_1 = 70.2, \sigma_1 = 0.7589$$

$$\text{C.I.: } \mu_1 \pm Z_{\alpha/2}(\sigma_1) = 70.2 \pm 1.96(0.7589)$$

Ans: b. $68.71 < \mu < 71.69$

Hint: $P(71.8 < X < 73.4) = P(2.105 < Z < 4.21) = 0.5 - 0.4821 = 0.0179$

$$\text{since } Z_1 = \frac{71.8 - 70.2}{0.76} = 2.105,$$

$$Z_2 = \frac{73.4 - 70.2}{0.76} = 4.2105$$

Ans: c. 0.0179

4. A producer of TV's believes from past experience that the mean length of life of TV's μ is a normal random variable with mean $\mu_0 = 800$ hours and standard deviation $\sigma_0 = 10$ hours. It is known that TV's have mean length of life that is approximately normally distributed with a standard deviation of 100 hours. Construct a 95% Bayesian interval for μ if a random sample of 25 TV's has an average life of 780 hours.

Hint: $\mu_1 = \frac{(25)(780)(10)^2 + (800)(100)^2}{25(10)^2 + (100)^2} = 796$

$$\sigma_1 = \sqrt{\frac{(10)^2(100)^2}{25(10)^2 + (100)^2}} = \sqrt{80},$$

B.I.: $780 \pm 1.96 \left(\frac{100}{\sqrt{25}} \right)$

Here $Z_{\alpha/2} = 1.96$, $n = 25$, $\sigma = 100$,

$$\sigma_0 = 10, \bar{x} = 780.$$

Ans: $740.8 < \mu < 819.2$

29.4 TEST OF HYPOTHESIS

The principal objective of statistical inference is to draw inferences (or generalize) about the population on the basis of data collected by sampling from the population. Statistical inference consists of two major areas, estimation and tests of hypothesis. Estimation was discussed in Sections 29.1, 29.2 and 29.3. In tests of hypothesis, a postulate or conjecture or statement about a parameter of the population is tested for its validity or truthfulness.

Statistical decisions

Statistical decisions are decisions or conclusions about the population parameters on the basis of a random sample from the population.

Statistical Hypothesis

It is an assumption or conjecture or guess about the parameter(s) of population distribution(s). The statistical hypothesis is established before hand and may or may not be true. When more than one population is considered, statistical hypothesis consists of relationship between the parameters of the populations.

Null Hypothesis

It is (N.H.) denoted by H_0 is the statistical hypothesis which is to be actually tested for acceptance or rejection. N.H. is the hypothesis which is tested for possible rejection under the assumption that it is true (R.A. Fisher).

Alternative Hypothesis

(A.H.) denoted by H_1 , is any hypothesis other than the null hypothesis. Neyman originated the concept of alternative hypothesis.

Test of Hypothesis

Test of hypothesis or test of significance or rules of decision is a procedure to decide whether to accept or reject the (null) hypothesis. This test determines whether observed samples differ significantly from expected results. Acceptance of hypothesis merely indicates that the data do not give sufficient evidence to refute the hypothesis. Whereas, rejection is a firm conclusion where the sample evidence refutes it.

When N.H. is accepted, result is said to be non-significant i.e., observed differences are due to 'chance' caused by the process of sampling. When N.H. is rejected (i.e., A.H. is accepted) the result is said to be significant. Thus test of hypothesis decides whether a statement concerning a parameter is true or false instead of estimating the value of the parameter. Since the test is based on sample observations, the decision of acceptance or rejection of the null hypothesis is always subjected to some error i.e., some amount of risk.

Types of errors in test of hypothesis:

| | Accept H_0 | Reject H_0 |
|----------------|------------------|------------------|
| H_0 is true | correct decision | Type I error |
| H_0 is false | Type II error | correct decision |

Type I error involves rejection of null hypothesis when it should be accepted (as true).

Type II error involves acceptance of the null hypothesis when it is false and should be rejected.

Level of significance

(L.O.S.) of a test denoted by α is the probability of committing type I error. Thus L.O.S. measures the amount of risk or error associated in taking decisions. It is customary to fix α before sample information is collected and to choose (take) generally α as 0.05 or 0.01. L.O.S. $\alpha = 0.01$ is used for high precision and $\alpha = 0.05$ for moderate precision. L.O.S. is also expressed as percentage. Thus L.O.S. $\alpha = 5\%$ means there are 5 chances in 100 that N.H. is rejected when it is true or one is 95% confident that a right decision is made. L.O.S. is also known as the **size of the test**. Thus α = probability of committing type I error = P (reject H_0/H_0) = α and β = prob (type II error) = P (accept H_0/H_1) = β .

Power of the test is computed as $1 - \beta$.

Note 1: When the size of the sample is increased, the probability of committing both types of errors I and II i.e., α and β can be reduced simultaneously.

Note 2: α and β are known as producer's risk and consumer's risk respectively.

Note 3: When both α and β are small, the test procedure is good one giving good chance of making the correct decision.

Simple Hypothesis

It is a statistical hypothesis which completely specifies an exact parameter. Null hypothesis is always a simple hypothesis stated as an equality specifying an exact value of the parameter (includes any value not stated by A.H.).

Examples:

1. N.H. = $H_0 : \mu = \mu_0$
i.e., population mean equals to a specified constant μ_0 .
2. N.H. = $H_0 : \mu_1 - \mu_2 = \delta$
i.e., the difference between the sample means equals to a constant δ .

Composite Hypothesis

It is stated in terms of several possible values i.e., by an inequality.

Alternative Hypothesis

It is a composite hypothesis involving statements expressed as inequalities such as $<$, $>$ or $\neq$.

Examples:

1. A.H.: $H_1; \mu > \mu_0$
2. A.H.: $H_1 : \mu < \mu_0$
3. A.H.: $H_1 : \mu \neq \mu_0$

Critical Region (C.R.)

In any test of hypothesis, a test statistic S^* , calculated from the sample data, is used to accept or reject the null hypothesis of the test. Consider the area under the probability curve of the sampling distribution of the test statistic S^* which follows some known (given) distribution. This area under the probability curve is divided into to dichotomous regions, namely the region of rejection (significant region or critical region) where N.H. is rejected, and the region of acceptance (non-significant region or non-critical region) where N.H. is accepted. Thus **critical region** is the region of rejection of N.H. The area of the critical region equals to the level of significance α . Note that C.R. always lies on the tail (s) of the distribution. Depending on the nature of A.H., C.R. may lie on one side or both sides of the tails (s).

Critical value(s) or significant value(s)

It is (are) the value of the test statistic S^* (for given level of significance α) which divides (or separates) the area under the probability curve into critical (or rejection) region and non-critical (or acceptance) region.

One tailed test (O.T.T.) and two tailed test (T.T.T.)

Right one tailed test (R.O.T.T.): When the alternative hypothesis (A.H.): H_1 is of the greater than type i.e., $H_1 : \mu > \mu_0$ or $H_1 : \sigma_1^2 > \sigma_2^2$ etc., then the entire critical region of area α lies on the right side tail of the probability density curve as shown shaded in the Fig. 29.3. In such case, the test of hypothesis (T.O.H.) is known as **right one tailed test**.

Fig. 29.3

Left one tailed test (L.O.T.T.)

When the A.H.: H_1 is of the less than type i.e., $H_1: \mu_1 < \mu_0$ or $H_1: \sigma_1^2 < \sigma_2^2$ etc. then the entire C.R. of area α lies on the left side tail of the curve as shown in Fig. 29.4.

Fig. 29.4

Two tailed test (T.T.T.)

If A.H. is of the not equals type i.e., $H_1: \mu_1 \neq \mu_2$ or $H_1: \sigma_1 \neq \sigma_2$ etc. then the C.R. lies on both sides of the right and left tails of the curve such that the C.R. of area $\frac{\alpha}{2}$ lies on the right tail and C.R. of area $\frac{\alpha}{2}$ lies on the left tail, as shown in Fig. 29.5.

Fig. 29.5

Thus the test of hypothesis or test of significance or rule of decision consists of the following six steps.

1. Formulate N.H.: H_0 .
2. Formulate A.H.: H_1 .
3. Choose L.O.S.: α .
4. C.R.: is determined by the critical value S_{α}^* and the kind of A.H. (based on which the test is R.O.T.T. or L.O.T.T. or T.T.T.).

5. Compute the test statistic S^* using the sample data.
6. Decision: Accept or reject N.H. depending on the relation between S^* and S_{α}^* .

P-Value

In tests of hypothesis, preselection of a significance level α does not account for values of test statistics that are “close” to the critical region. Thus a test statistic value that is non-significant say for $\alpha = 0.05$ may become significant for $\alpha = 0.01$. In applied statistics, P -value approach is designed to give the user an alternative (in terms of probability) to a mere “reject” or “do not reject” conclusion.

P-Value is the lowest level (of significance) at which the observed value of the test statistic is significant.

In the significance testing by P -Value approach, α is not pre-determined but the conclusion is based on the size of the P -Value which is computed using the value of test statistic.

29.5 TEST OF HYPOTHESIS CONCERNING SINGLE POPULATION MEAN μ : (WITH KNOWN VARIANCE σ^2 : LARGE SAMPLE)

Let μ and σ^2 be the mean and variance of a population from which a random sample of size n is drawn. Let $\bar{x}$ be the mean of the sample. Then for large samples ($n \geq 30$), from central theorem it follows that the sampling distribution of $\bar{x}$ is approximately normally distributed with mean $\mu_{\bar{x}} = \mu$ and $\sigma_{\bar{x}}^2 = \frac{\sigma^2}{n}$.

The test statistic for single mean with known variance is $Z = \frac{\bar{x} - \mu_0}{\sigma/\sqrt{n}}$.

To test whether the population mean μ equals to a specified constant μ_0 or not, formulate the test of hypothesis as follows:

1. N.H.: $\mu = \mu_0$.
2. A.H.: $\mu \neq \mu_0$.
3. L.O.S.: α .
4. C.R.: Since the A.H. is a not equal to type, a T.T.T. is considered. For given α , critical values

29.10 — HIGHER ENGINEERING MATHEMATICS—VII

$-Z_{\alpha/2}$ and $+Z_{\alpha/2}$ are determined from normal table since normal distribution is assumed. For example, for $\alpha = 5\%$ or 0.05 from normal table $-Z_{0.025} = -1.96$ and $Z_{0.025} = 1.96$. Thus the critical region consists of the two shaded regions in Fig. 29.6 i.e., reject N.H.: H_0 if $Z < -Z_{\alpha/2}$ or $Z > Z_{\alpha/2}$.

Fig. 29.6

5. Compute the test statistic Z , denoted by Z_{cal} or simply Z by

$$Z = \frac{\bar{x} - \mu_0}{\sigma/\sqrt{n}}$$

Here $\bar{x}$, the mean of the sample of size n , is calculated from the sample data.

6. Conclusion: Reject H_0 if Z_{cal} or Z falls in the critical region i.e., observed sample statistic is probably significant or highly significant at α level. Otherwise accept H_0 (if $-Z_{\alpha/2} < Z < Z_{\alpha/2}$).

Note 1: Suppose the A.H. is $H_1 : \mu > \mu_0$. Then the critical region is given by $Z > Z_{\alpha}$ since we consider a right one tail test is this case, i.e., reject H_0 if $Z > Z_{\alpha}$ otherwise accept H_0 (if $Z < Z_{\alpha}$) (see Fig. 29.7).

Note 2: If A.H. is $H_1 : \mu < \mu_0$ then consider a left one tail test with C.R. given by $Z < -Z_{\alpha}$ as shown in Fig. 29.8, i.e., reject H_0 is $Z < -Z_{\alpha}$ otherwise accept H_0 (if $Z > -Z_{\alpha}$).

Note 3: Reference table of critical values for a given L.O.S. α for T.T.T., R.O.T.T. and L.O.T.T.

Fig. 29.7

Fig. 29.8

| $\alpha\%$
α | 15% | 10% | 5% | 4% | 1% | .5% | .2% |
|--|---------------|-----------------|---------------|---------------|---------------|---------------|---------------|
| $-Z_{\alpha/2}$ and
and
for T.T.T. | -1.44
1.44 | -1.645
1.645 | -1.96
1.96 | -2.06
2.06 | -2.58
2.58 | -2.81
2.81 | -3.08
3.08 |
| $-Z_{\alpha}$ for
L.O.T.T. | -1.04 | -1.28 | -1.645 | -2.6 | -2.33 | -2.58 | -2.88 |
| Z_{α} for
R.O.T.T. | 1.04 | 1.28 | 1.645 | 2.6 | 2.33 | 2.58 | 2.88 |

Note 4: For large sample $n \geq 30$, even if σ is unknown, σ can be replaced by sample variances (which can be computed from sample information).

WORKED OUT EXAMPLES

Test of hypothesis: For one mean

Example 1: The length of life X of certain computers is approximately normally distributed with mean

800 hours and standard deviation 40 hours. If a random sample of 30 computers has an average life of 788 hours, test the null hypothesis that $\mu = 800$ hours against the alternative that $\mu \neq 800$ hours at (a) 0.5% (b) 1% (c) 4% (d) 5% (e) 10% (f) 15% level of significance.

Solution:

Case a:

1. Null hypothesis: $\mu = 800$ hours
2. Alternate hypothesis: $\mu \neq 800$ hours
3. α level of significance = .5% = .005 (case (a))
4. Critical region: since alternate hypothesis is $\neq$ type, the test is two tailed and the critical region is

Fig. 29.9

5. Calculation of statistic:

Here $\bar{x}$ = mean of the sample = 788

n = sample size = 30

standard deviation $\sigma = 40$,

$$\text{so } Z = \frac{\bar{x} - \mu_0}{\sigma / \sqrt{n}} = \frac{788 - 800}{40 / \sqrt{30}} = -1.643$$

6. Decision: Accept the null hypothesis H_0 since

$$Z = -1.643 > -2.81 = Z_{\alpha/2} = Z_{0.0025}$$

Case b: α = level of significance = 1% = 0.01
critical region

$$-2.58 < Z < 2.58$$

Decision: Accept H_0 since

$$Z = -1.643 > -2.58 = Z_{\alpha/2} = Z_{0.005} \text{ (Fig. 29.10)}$$

Case c: $\alpha = 4\% = 0.04$, C.R.: $-2.06 < Z < 2.06$.
Accept H_0 since $Z = -1.643 > -2.06$ (Fig. 29.11)

Case d: $\alpha = 5\% = 0.05$, C.R.: $-1.96 < Z < 1.96$.
Accept H_0 since $Z = -1.643 > -1.96$ (Fig. 29.12)

Fig. 29.10

Fig. 29.11

Fig. 29.12

Case e: $\alpha = 10\% = 0.10$, C.R.: $-1.645 < Z < 1.645$.
Accept H_0 since $Z = -1.643 > -1.645$

Fig. 29.13

Case f: $\alpha = 15\% = 0.15$, C.R.: $-1.44 < Z < 1.44$.
Reject H_0 since $Z = -1.643 < -1.44$

Fig. 29.14

Test is significant.

Example 2: Mice with an average lifespan of 32 months will live up to 40 months when fed by a certain

29.12 — HIGHER ENGINEERING MATHEMATICS—VII

nutritious food. If 64 mice fed on this diet have an average lifespan of 38 months and standard deviation of 5.8 months, is there any reason to believe that average lifespan is less than 40 months.

Solution: Let μ = average lifespan of mice fed with nutritious food. Use 0.01 level of significance

1. N.H.: $H_0 : \mu = 40$ months
2. A.H.: $H_1 : \mu < 40$
3. L.O.S.: $\alpha = 0.01$
(Left one-tail test)

Fig. 29.15

4. C.R.: $Z < -Z_{\alpha} = -Z_{0.01} = -2.33$
5. Computation: Here $\bar{x} = 38$, $\sigma = 5.8$, $n = 64$

$$Z = \frac{38 - 40}{5.8/\sqrt{64}} = -2.76$$

6. Decision: Reject H_0 ,
since $Z = -2.76 < -2.33 = -Z_{\alpha} = -Z_{0.01}$
i.e., yes, there is reason to believe that the average lifespan of mice with nutritious food is less than 40 months.

Example 3: A machine runs on an average of 125 hours/year. A random sample of 49 machines has an annual average use of 126.9 hours with standard deviation 8.4 hours. Does this suggest to believe that machines are used on the average more than 125 hours annually at 0.05 level of significance?

Solution: μ = average number of hours a machine runs in an year.

1. $H_0 : \mu = 125$ hours/year
2. $H_1 : \mu > 125$
3. L.O.S.: $\alpha = 0.05$
4. C.R.: $Z > Z_{\alpha} = Z_{0.05} = 1.64$
5. Calculation: $Z = \frac{\bar{x} - \mu}{\sigma/\sqrt{n}} = \frac{126.9 - 125}{8.4/\sqrt{49}} = 1.58$

Fig. 29.16

6. Decision: Accept H_0 since $Z = 1.58 < 1.64 = Z_{0.05}$ i.e., can not believe that machine works more than 125 hours in an year.

EXERCISE

Test of hypothesis: For one mean

1. A company claims that the mean thermal efficiency of diesel engines produced by them is 32.3%. To test this claim, a random sample of 40 engines were examined which showed the mean thermal efficiency of 31.4% and s.d of 1.6%. Can the claim be accepted or not, at 0.01 L.O.S.?

Hint: $Z = \frac{\bar{x} - \mu_0}{\sigma/\sqrt{n}} = \frac{31.4 - 32.3}{1.6/\sqrt{40}} = -3.56 < -2.81 = Z_{\alpha} = Z_{0.01}$

Ans: Reject N.H.: $H_0 : \mu_0 = 32.3$ from a T.T.T. against A.H.: $H_1 : \mu_0 \neq 32.3$

2. It has previously been recorded that the average depth of ocean at a particular region is 67.4 fathoms. Is there reason to believe this at 0.01 L.O.S. if the readings at 40 random locations in that particular region showed a mean of 69.3 with s.d. of 5.4 fathoms?

Hint: $Z = \frac{69.3 - 67.4}{5.4/\sqrt{40}} = 2.23 < 2.58 = Z_{\alpha/2} = Z_{0.005}$

Ans: Accept $H_0 : \mu_0 = 67.4$ against A.H.: $H_1 : \mu_0 \neq 67.4$ by a T.T.T.

3. To determine whether the mean breaking strength of synthetic fibre produced by a certain company is 8 kg or not, a random sample of 50 fibres were tested yielding a mean breaking strength of 7.8 kg. If s.d. is 0.5 kg, test at 0.01 L.O.S.

Hint: $Z = \frac{7.8 - 8}{0.5/\sqrt{50}} = -2.83 > -2.575 = Z_{\alpha/2} = Z_{0.005}$

Ans: Reject $H_0 : \mu = 8$, accept A.H.: $H_1 : \mu \neq 8$ by a T.T.T.

4. Can it be concluded that the average lifespan of Indian is more than 70 years if a random sample of 100 Indians has an average lifespan of 71.8 years with a s.d. of 8.9 years.

Hint: $Z = \frac{71.8-70}{8.9/\sqrt{100}} = 2.02 > 1.645 =$

$Z_{\alpha} = Z_{0.05}$ by right O.T.T.

Ans: Yes, average lifespan is more than 70 years.

5. A company producing computers states that the mean lifetime of its computers is 1600 hours. Test this claim at 0.01 L.O.S. against the A.H.: $\mu < 1600$ hours if 100 computers produced by this company has mean lifetime of 1570 hours with s.d. of 120 h.

Hint: $Z = \frac{(1570-1600)}{120/\sqrt{100}} = -2.50 < -2.33 =$
 $Z_{0.01}$ by left O.T.T.

Ans: Reject H_0 i.e., claim is not tenable

6. A manufacturer of tyres guarantees that the average lifetime of its tyres is more than 28000 miles. If 40 tyres of this company tested, yields a mean lifetime of 27463 miles with s.d. of 1348 miles, can the guarantee be accepted at 0.01 L.O.S.?

Hint: $Z = \frac{27463-28000}{1348/\sqrt{40}} = -2.52 < -2.33 =$
 $Z_{0.01}$ by left O.T.T.

Ans: No, tyres run for < 28000 miles.

29.6 TEST OF HYPOTHESIS CONCERNING TWO MEANS

When variances σ_1 and σ_2 are known or large samples

Let $\bar{x}_1$ be the mean of a random sample of size n_1 drawn from a population with mean μ_1 and variance σ_1^2 . Let $\bar{x}_2$ be the mean of an independent random sample of size n_2 drawn from another population with mean μ_2 and variance σ_2^2 . To test the hypothesis for difference of means, consider the null hypothesis $\mu_1 - \mu_2 = \delta$ = given constant. So when $\delta = 0$, there is no difference between the means i.e., the two populations have the same means. If $\delta \neq 0$, the means of the two populations are different. In these cases, the test statistic will depend on the difference between the sample means $\bar{x}_1 - \bar{x}_2$ and is given by

$$Z = \frac{(\bar{x}_1 - \bar{x}_2) - \delta}{\sigma_{\bar{x}_1 - \bar{x}_2}}$$

Here it is assumed that both samples are drawn from normal populations with known variances.

Here Z follows standard normal distribution. If the two populations are infinite then the variance of the sampling distribution of the difference between the sample means is

$$\sigma_{\bar{x}_1 - \bar{x}_2}^2 = \frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}$$

Substituting we have the statistic for test concerning difference between two means as

$$Z = \frac{(\bar{x}_1 - \bar{x}_2) - \delta}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}}$$

Note: When the two variances σ_1^2 and σ_2^2 are unknown, they can be replaced by sample variances s_1^2 and s_2^2 provided both the samples are large ($n_1, n_2 \geq 30$). In this case the test statistic is

$$Z = \frac{(\bar{x}_1 - \bar{x}_2) - \delta}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

The critical regions for testing $\mu_1 - \mu_2 = \delta$ are:

1. A.H.: $\mu_1 - \mu_2 \neq \delta$, Reject H_0 if $Z < -Z_{\alpha/2}$ or $Z > Z_{\alpha/2}$
2. A.H.: $\mu_1 - \mu_2 > \delta$, Reject H_0 if $Z > Z_{\alpha}$
3. A.H.: $\mu_1 - \mu_2 < \delta$, Reject H_0 if $Z < -Z_{\alpha}$.

The A.H. 2 and 3 are used to determine whether one product (population) is better than (superior to) the other product.

WORKED OUT EXAMPLES

Example 1: In a random sample of 100 tube lights produced by company A, the mean lifetime (mlt) of tube light is 1190 hours with standard deviation of 90 hours. Also in a random sample of 75 tube lights from company B the mean lifetime is 1230 hours with standard deviation of 120 hours. Is there a difference between the mean lifetimes of the two brands of tube lights at a significance level of (a) 0.05 (b) 0.01?

29.14 — HIGHER ENGINEERING MATHEMATICS—VII

Solution: Let X_A , X_B denote the lifetime (in hours) of tube lights produced by company A and B respectively. It is given that the mean lifetime of tube lights of company A is $\bar{X}_A = 1190$, standard deviation for tube lights of A is $s_A = 90$. Similarly $\bar{X}_B = 1230$, $s_B = 120$, n_A = sample size of tube lights from A = 100, n_B = sample size from B = 75

1. Null hypothesis: $H_0 : \mu_1 - \mu_2 = \delta = 0$ i.e., no difference.
2. Alternate hypothesis: $H_1 : \mu_1 - \mu_2 \neq 0$ i.e., there is difference.
3. L.O.S.: α : (a) 0.05 (b) 0.01.
4. Critical region: two tailed test.

If

a. $-1.96 < Z < 1.96$ Accept N.H.

Fig. 29.17

b. $-2.57 < Z < 2.57$ Accept N.H.

Fig. 29.18

5. Computation: $\mu_{\bar{X}_A - \bar{X}_B} = \mu_{\bar{X}_A} - \mu_{\bar{X}_B} = \mu_A - \mu_B = 0$

$$\begin{aligned}\sigma_{\bar{X}_A - \bar{X}_B} &= \sqrt{\sigma_{\bar{X}_A}^2 + \sigma_{\bar{X}_B}^2} = \sqrt{\frac{s_A^2}{n_A} + \frac{s_B^2}{n_B}} \\ &= \sqrt{\frac{(90)^2}{100} + \frac{(120)^2}{75}} = 16.5227\end{aligned}$$

Test statistic:

$$Z = \frac{(\bar{X}_A - \bar{X}_B) - (\mu_A - \mu_B)}{\sigma_{\bar{X}_A - \bar{X}_B}} = \frac{1190 - 1230}{16.5227} = -2.421$$

6. Decision:

a. For $\alpha = 0.05$

Reject N.H. since $Z = -2.421 < -1.96 = Z_{\alpha/2} = Z_{0.025}$ i.e., yes, there is difference between the mean lifetimes of the tube lights produced by A and B.

b. For $\alpha = 0.01$

Accept N.H. since $Z = -2.421$ lies in the acceptable region $-2.57 < Z < 2.57$ i.e., no, there is no difference between $\bar{X}_A$ and $\bar{X}_B$.

Example 2: To test the effects a new pesticide on rice production, a farm land was divided into 60 units of equal areas, all portions having identical qualities as to soil, exposure to sunlight etc. The new pesticide is applied to 30 units while old pesticide to the remaining 30. Is there reason to believe that the new pesticide is better than the old pesticide if the mean number of kgs of rice harvested / unit using new pesticide (N.P.) is 496.31 with s.d. of 17.18 kgs while for old pesticide (O.P.) is 485.41 kgs and 14.73 kgs. Test at a level of significance (a) $\alpha = 0.05$ (b) 0.01.

Solution: Let the subscripts N and O denote respectively the quantities related the new pesticide and old pesticide.

1. N.H.: $H_0 : \mu_N - \mu_O = \delta = 0$ i.e., no difference.
2. A.H.: $H_1 : \mu_N - \mu_O = \delta > 0$ i.e., new pesticide is superior to (better than) old pesticide.
3. L.O.S.: (a) $\alpha = 0.05$ (b) 0.01.
4. Critical region: Right one tailed test.

Case a: $\alpha = 0.05$

Fig. 29.19

Accept N.H. if $Z < Z_{\alpha} = Z_{0.05} = 1.64$

Case b: $\alpha = 0.01$

Accept N.H. if $Z < Z_{\alpha} = Z_{0.01} = 2.33$

Fig. 29.20

5. Computation: Given data is

$$\bar{X}_N = 496.31, \bar{X}_0 = 485.41, s_N = 17.18, s_0 = 14.73, n_N = 30, n_0 = 30$$

Test statistic is

$$Z = \frac{(\bar{X}_N - \bar{X}_0) - (\mu_N - \mu_0)}{\sigma_{\bar{X}_N - \bar{X}_0}} = \frac{(\bar{X}_N - \bar{X}_0) - 0}{\sqrt{\frac{(s_N)^2}{n_N} + \frac{(s_0)^2}{n_0}}}$$

$$= \frac{(496.31 - 485.41) - 0}{\sqrt{\frac{(17.18)^2}{30} + \frac{(14.73)^2}{30}}} = 2.63814$$

6. Decision

Case a: $\alpha = 0.05$

Reject N.H. since $Z = 2.638 > Z_\alpha = Z_{0.05} = 1.64$ i.e., accept A.H. or new pesticide is superior to old pesticide.

Case b: $\alpha = 0.01$

Reject N.H. since $Z = 2.638 > Z_\alpha = Z_{0.01} = 2.33$ i.e., Accept A.H. or new pesticide is better than the old pesticide.

EXERCISE

1. A random sample of 40 'geyers' produced by company A have a mean lifetime (mlt) of 647 hours of continuous use with a s.d. of 27 hours, while a sample 40 produced by another company B have mlt of 638 hours with s.d. 31 hours. Does this substantiate the claim of company A that their 'geyers' are superior to those produced by company B at (a) 0.05 (b) 0.01 L.O.S.

Hint: N.H.: $\mu_A = \mu_B = 0$, A.H.: $\mu_A - \mu_B > 0$, reject N.H. if $Z > 1.645$.

$$Z_{\text{cal}} = \frac{(647 - 638) - 0}{\sqrt{\frac{(27)^2}{40} + \frac{(31)^2}{40}}} = 1.38, \text{ accept N.H.}$$

Ans: a. No, there is no difference between 'geyers' produced by the two companies A and B.

b. Accept N.H. since $1.38 < Z_\alpha = 2.33$

2. Test at 0.05 L.O.S. a manufacturer's claim that the mean tensile strength (mts) of a thread A exceeds the mts of thread B by at least 12 kgs. if 50 pieces of each type of thread are tested under similar conditions yielding the following data:

| | sample size | mts
(kgs) | s.d.
(kgs) |
|--------|-------------|--------------|---------------|
| Type A | 50 | 86.7 | 6.28 |
| Type B | 50 | 77.8 | 5.61 |

Hint: $H_0: \mu_A - \mu_B \geq 12$, $H_1: \mu_A - \mu_B < 12$, reject H_0 if $Z < Z_\alpha = -1.64$

$$Z = \frac{(86.7 - 77.8) - 12}{\sqrt{\frac{(6.28)^2}{50} + \frac{(5.61)^2}{50}}} = -2.60, \text{ reject } H_0,$$

Accept $\mu_1 - \mu_2 < 12$.

Ans: Claim not tenable.

3. Test the N.H.: $\mu_A - \mu_B = 0$ against the A.H.: $\mu_A - \mu_B \neq 0$ at 0.01 L.O.S. for the following data:

| | sample size | mts
(kgs) | s.d.
(kgs) |
|--------|-------------|--------------|---------------|
| Type A | 40 | 247.3 | 15.2 |
| Type B | 30 | 254.1 | 18.7 |

$$\text{Hint: } Z = \frac{(247.3 - 254.1) - 0}{\sqrt{\frac{(15.2)^2}{40} + \frac{(18.7)^2}{30}}} = -1.62866,$$

Acceptable region: $-2.58 < Z < 2.58$,
Accept N.H.

Ans: Accept N.H. i.e., no difference between type A and B

4. If random sample data show that 42 men earn on the average $\bar{x}_1 = 744.85$ with s.d. $s_1 = 397.7$ while 32 women earn on the average $\bar{x}_2 = 516.78$ with s.d. $s_2 = 162.523$, test at 0.05 level of significance whether the average

29.16 — HIGHER ENGINEERING MATHEMATICS—VII

income for men and women is same or not.

Hint: $H_0 : \mu_1 = \mu_2, H_1 : \mu_1 \neq \mu_2,$

$$Z = \frac{(744.85 - 516.78) - 0}{\sqrt{\frac{158165.43}{42} + \frac{26413.61}{32}}} = 3.36$$

Since $Z = 3.36 > 1.96 = Z_{\alpha} = Z_{0.05}$, Reject N.H. H_0 .

Ans: Not same.

5. A company claims that alloying reduces resistance of electric wire by more than 0.050 ohm. To test this claim samples of standard wire and alloyed wire are tested yielding the following results:

| Type of wire | sample size | mean resistance (ohms) | s.d. (ohms) |
|--------------|-------------|------------------------|-------------|
| Standard | 32 | 0.136 | 0.004 |
| Alloyed | 32 | 0.083 | 0.005 |

Can the claim be substantiated at 0.05 L.O.S.

Hint: $H_0 : \mu_1 - \mu_2 = 0.05, H_1 : \mu_1 - \mu_2 > 0.05, Z_{\alpha} = Z_{0.05} = 1.645$

$$Z = \frac{(0.136 - 0.083) - (0.05)}{\sqrt{\frac{(0.004)^2}{32} + \frac{(0.005)^2}{32}}} = 2.65,$$

Reject N.H. since $Z = 2.65 > 1.645 = Z_{0.05}$

Ans: Data substantiate the claim.

6. To test the claim that men are taller than women, a survey was conducted resulting in the following data:

| Gender | sample size | mean height (cm) | s.d. (cm) |
|--------|-------------|------------------|-----------|
| Men | 1600 | 172 | 6.3 |
| Women | 6400 | 170 | 6.4 |

Is the claim tenable at 0.01 L.O.S.

Hint: $H_0 : \mu_1 = \mu_2, H_1 : \mu_1 > \mu_2,$

$$Z = \frac{172 - 170}{\sqrt{\frac{(6.3)^2}{1600} + \frac{(6.4)^2}{6400}}} = 11.32$$

Reject H_0 since $Z = 11.32 > 2.33 = Z_{\alpha} = Z_{0.01}$.

Ans: Yes, men are taller than women.

7. Test the claim that teen-age boys are heavier than teen-age girls given the following infor-

mation:

| Gender | sample size | mean weight (kgs) | s.d. (kgs) |
|--------|-------------|-------------------|------------|
| Boys | 50 | 68.2 | 2.5 |
| Girls | 50 | 67.5 | 2.8 |

Use L.O.S. (a) 0.05 (b) 0.01

$$\text{Hint: } Z = \frac{\bar{X}_1 - \bar{X}_2}{\sigma_{\bar{X}_1 - \bar{X}_2}} = \frac{68.2 - 67.5}{0.53} = 1.32,$$

$$\sigma_{\bar{X}_1 - \bar{X}_2} = \sqrt{\frac{(2.5)^2}{50} + \frac{(2.8)^2}{50}} = 0.53$$

Ans: a. Accept N.H. i.e., no difference between mean weights.

b. Reject N.H. i.e., boys are heavier than girls.

29.7 TEST FOR ONE MEAN (SMALL SAMPLE: *t*-DISTRIBUTION)

For “expensive” populations such as satellites, aeroplanes, nuclear reactors, super computers, etc. the investigation of characteristics of large samples ($n \geq 30$) is uneconomical, impracticable and time consuming. In all such cases, the size of the sample, drawn is small (i.e., $n < 30$). For σ unknown and for small sample size, the test statistic cannot be used. Then the decision criterion is based on the *t*-distribution with $\nu = n - 1$ degrees of freedom. Thus the test statistic for small sample test (with σ unknown) concerning one mean is

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}}$$

This is also known as “one-sample *t*-test”. So the test procedure for small samples is similar to the procedure for large samples except that ‘*t*’ values are used in place of *Z* values and σ is replaced by *s*. For example, when A.H. is $\mu \neq \mu_0$ then the C.R. is $t < -t_{\alpha/2}$ or $t > t_{\alpha/2}$ etc.

WORKED OUT EXAMPLES

Examples: An ambulance service company claims that on an average it takes 20 minutes between a call for an ambulance and the patient’s arrival at the

hospital. If in 6 calls the time taken (between a call and arrival at hospital) are 27, 18, 26, 15, 20, 32. Can the company's claim be accepted?

Solution: Here $n = 6$. Let X be the time taken between a call and patient's arrival at hospital. From given data $\bar{X}$ = average time taken

$$\bar{X} = \frac{27 + 18 + 26 + 15 + 20 + 32}{6} = \frac{138}{6} = 23$$

standard deviation: $s = \sqrt{\frac{\sum (X_i - \bar{X})^2}{n-1}}$

$$s^2 = \frac{(27-23)^2 + (18-23)^2 + (26-23)^2 + (15-23)^2 + (20-23)^2 + (32-23)^2}{6-1}$$

$$s^2 = 40.8, s = 6.38748$$

1. N.H.: $X = 20$ minutes

2. A.H.: $X > 20$

3. L.O.S.: $\alpha = 0.10$

4. Critical region:

Reject N.H. if $t > t_\alpha = 1.476$ where $t_{0.10}$ with $v = n - 1 = 6 - 1 = 5$ degrees of freedom.

5. Calculation: $t = \frac{\bar{X} - \mu}{s/\sqrt{n}} = \frac{23 - 20}{6.39/\sqrt{6}} = 1.15$

Fig. 29.21

6. Decision: Accept H_0 since $t = 1.15 < 1.476 = t_{0.1}$ with 5 dof i.e., accept the claim of the company.

EXERCISE

- Mean lifetime (mlt) of computers manufactured by a company is 1120 hours with standard deviation of 125 hours. (a) Test the hypothesis that mean lifetime of computers has not changed if a sample of 8 computers has a mlt of 1070 hours (b) Is there decrease in mlt? Use (i) 0.05 (ii) 0.01 L.O.S.

Hint: N.H.: $\mu = 1120$, A.H.: $\mu \neq 1120$,

$$t = \frac{1070 - 1120}{125/\sqrt{8}} = -1.1313, t_{0.005} \text{ with 7 dof is } \pm 3.499, t_{0.025} \text{ with 7 dof is } \pm 2.365:$$

Accept H_0 in both cases.

Ans: a. Two-tailed test indicates that there is no reason at either level to believe that mlt has changed.

Hint: A.H.: $\mu < 1120$ (i) $t_{0.05}$ with 7 dof is -1.895 (ii) $t_{0.01}$ with 7 dof is -2.998 .

b. One-tail test indicates no decrease in mlt at either of the L.O.S.

- Producer of 'gutkha', claims that the nicotine content in his 'gutkha' on the average is 1.83 mg. Can this claim be accepted if a random sample of 8 'gutkhas' of this type have the nicotine contents of 2.0, 1.7, 2.1, 1.9, 2.2, 2.1, 2.0, 1.6 mg?

Hint: $\bar{x} = \frac{15.6}{8} = 1.95$, $s = \frac{\sqrt{0.3}}{7} = 0.20702$,

$$t = \frac{1.95 - 1.83}{0.207/\sqrt{8}} = 1.6395, t_\alpha = t_{0.05} \text{ with 7 dof is } 1.895.$$

N.H.: $\mu = 1.83$, A.H.: $\mu > 1.83$

Ans: Yes, the producer's claim can be accepted with 95% confidence.

- In 1950 in India the mean life expectancy was 50 years. If the life expectancies from a random sample of 11 persons are 58.2, 56.6, 54.2, 50.4, 44.2, 61.9, 57.5, 53.4, 49.7, 55.4, 57.0, does it confirm the expected view.

Hint: $H_0: \mu = 50$, $H_1: \mu \neq 50$, $\bar{x} = \frac{598.5}{11} = 54.41$, $s = 4.859$, $t = 3.01$, reject H_0 since $t = 3.01 > 2.228 = t_{0.0025}$ with 10 dof.

Ans: No, the life expectancy is more than 50 years.

- An auditor claims that he takes on an average 10.5 days to file income tax returns (I.T. returns). Can this claim be accepted if a random sample shows that he took 13, 19, 15, 10, 12, 11, 14, 18 days to file I.T. returns? Use (a) 0.01 (b) 0.05 L.O.S.

Hint: N.H.: $\mu = 10.5$, A.H.: $\mu > 10.5$,

$$\bar{x} = \frac{112}{8} = 14, s = \sqrt{\frac{72}{7}} = 3.207,$$

29.18 — HIGHER ENGINEERING MATHEMATICS—VII

$t = \frac{14-10.5}{3.207/\sqrt{8}} = 3.0869$, (a) $t_{0.01}$ with 7 dof is 2.998 (b) $t_{0.05}$ with 7 dof is 1.895.

Ans: Reject the claim, i.e., it takes more than 10.5 days to file I.T. returns.

5. If 5 pieces of certain ribbon selected at random have mean breaking strength of 169.5 pounds with s.d. of 5.7, do they confirm to the specification mean breaking strength of 180 pounds.

Hint: $H_0: \mu = 180$, $H_1: \mu < 180$,
L.O.S.: $\alpha = 0.01$, $t = -4.12$,

$t_\alpha = t_{0.01}$ with 4 dof is -3747 , so reject N.H.

Ans: They do not confirm to specification i.e., mbs is below.

6. In a random sample of 10 bolts produced by a machine the mean length of bolt is 0.53 mm and standard deviation 0.03 mm. Can we claim from this that the machine is in proper working order if in the past it produced bolts of length 0.50 mm? Use (a) 0.05 (b) 0.01 L.O.S.

Hint: $H_0: \mu = 0.50$, $H_1: \mu \neq 0.50$,

$$t = \frac{\bar{x} - \mu}{s} \sqrt{n-1} = \frac{0.53-0.50}{0.03} \sqrt{10-1} = 3.0$$

Acceptable region $-2.26 < t < 2.26$

Ans: a. At 0.05 L.O.S., by a T.T.T., reject H_0 .

b. At 0.01 L.O.S., by T.T.T., accept H_0

Acceptable region $-3.25 < t < 3.25$.

29.8 SMALL-SAMPLE TEST CONCERNING DIFFERENCE BETWEEN TWO MEANS

Suppose the two sample sizes n_1, n_2 or both are small ($n < 30$) and two samples are drawn from two normal populations with population variances σ_1^2 and σ_2^2 unknown but equal (i.e., $\sigma_1 = \sigma_2 = \sigma$). Then the pooling variance σ^2 is given by

$$\begin{aligned} \sigma^2 &= \frac{\sum (x_{i1} - \bar{x}_1)^2 + \sum (x_{i2} - \bar{x}_2)^2}{n_1 + n_2 - 2} \\ &= \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2} \end{aligned}$$

where $\bar{x}_1, s_1^2$ and $\bar{x}_2, s_2^2$ are the mean and variance of two samples of size n_1 and n_2 respectively. In a

test concerning the difference between the means for small samples, the t -test statistic is

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - \delta}{\sigma_{\bar{x}_1 - \bar{x}_2}}$$

with $n_1 + n_2 - 2$ degrees of freedom. This test is also known as two-sample pooled t -test. Rewriting

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - \delta}{\sqrt{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}} \sqrt{\frac{n_1 n_2 (n_1 + n_2 - 2)}{n_1 + n_2}}$$

with $n_1 + n_2 - 2$ dof.

The critical regions with this t -distribution can be obtained in a similar way. For example when A.H. is $\mu_1 - \mu_2 \neq \delta$, then the critical region (Reject H_0) is

$$t < -t_{\alpha/2, n_1 + n_2 - 2} \quad \text{or} \quad t > t_{\alpha/2, n_1 + n_2 - 2}.$$

Note 1: The critical values are given when $n_1 + n_2 - 2 \geq 30$ (although n_1 and n_2 are small).

Note 2: The two-sample t -test can not be used if $\sigma_1 \neq \sigma_2$.

Note 3: The two-sample t -test can not be used for “before and after” kind of data, where the data is naturally paired. In other words the samples must be “independent” for two sample t -test.

WORKED OUT EXAMPLES

Example 1: In a mathematics examination 9 students of class A and 6 students of class B obtained the following marks. Test at 0.01 level of significance whether the performance in mathematics is same or not for the two classes A and B. Assume that the samples are drawn from normal populations having same variance.

| | | | | | | | | | |
|---|----|----|----|----|----|----|----|----|----|
| A | 44 | 71 | 63 | 59 | 68 | 46 | 69 | 54 | 48 |
| B | 52 | 70 | 41 | 62 | 36 | 50 | | | |

Solution: Let X_A and X_B be the marks obtained in mathematics of class A and class B. Then from the given data $\bar{X}_A = \frac{\sum x_i}{n_1} = \frac{522}{9} = 58$, $\bar{X}_B = \frac{311}{6} = 51.83$

$$s_A^2 = \frac{\sum (X_i - \bar{X})^2}{n_1 - 1} = \frac{872}{8} = 109, s_A = 10.44,$$

$$s_B^2 = \frac{804.8334}{5}, \quad s_B = 12.687$$

Here n_A = sample size from (population) class A = 9

n_B = sample size from (population) class B = 6

1. N.H.: $\mu_1 - \mu_2 = 0$ i.e., no difference in performance.
2. A.H.: $\mu_1 - \mu_2 \neq 0$ i.e., there is difference.
3. L.O.S.: $\alpha = 0.01$.
4. Critical region: Two-tailed test. Reject N.H. if $t < -t_{\alpha/2}$ or $t > t_{\alpha/2}$ where $t_{\alpha/2} = t_{0.005}$ with $n_1 + n_2 - 2 = 9 + 6 - 2 = 13$ degrees of freedom. From table, $t_{0.005}$ is 3.012.

5. Computation: Test statistic

$$t = \frac{(\bar{X}_A - \bar{X}_B) - (\mu_1 - \mu_2)}{\sqrt{(n_A - 1)s_A^2 + (n_B - 1)s_B^2}} \sqrt{\frac{n_A n_B (n_A + n_B - 2)}{n_A + n_B}}$$

$$t = \frac{(58 - 51.83) - 0}{\sqrt{(9-1)(109) + (6-1)(160.96)}} \sqrt{\frac{(9)(6)(13)}{9+6}} = 1.030.$$

6. Decision: Accept N.H. since

$$t = 1.03 < 3.012 = t_{\alpha/2} = t_{0.005}$$

i.e., there is no difference between the two classes A and B in performance in mathematics examination.

Example 2: Under quality improvement programme some teachers are trained by instruction methodology A and some by methodology B. In a random sample of size 10, taken from a large group of teachers exposed to each of these two methods, the following marks are obtained in an appropriate achievement test

Method A 65 69 73 71 75 66 71 68 68 74

Method B 78 69 72 77 84 70 73 77 75 65

Assuming that populations sampled are approximately normally distributed having same variance, test the claim that method B is more effective at 0.05 level of significance.

Solution: Let subscripts A and B denote data pertaining to methodology A and B respectively. Then from the given data, $n_A = n_B = 10$,

$\bar{X}_A$ = average marks obtained in appropriate achievement test by teachers trained under methodology A is $\frac{700}{10} = 70$. Similarly, $\bar{X}_B = \frac{740}{10} = 74$

$$s_A^2 = \frac{102}{9} = 11.33, \quad s_A = 3.366,$$

$$s_B^2 = \frac{262}{9} = 29.11, \quad s_B = 5.3954$$

1. N.H.: $H_0 : \mu_1 - \mu_2 = 0$ i.e., no difference in teaching methodologies
2. A.H.: $H_1 : \mu_1 - \mu_2 < 0$ i.e., method B is more effective (superior) than method A
3. L.O.S.: $\alpha = 0.05$
4. Critical region (left one tailed test)

Reject H_0 if $t < -t_{\alpha} = -t_{0.05}$ with $n_A + n_B - 2 = 10 + 10 - 2 = 18$ degrees of freedom. From table $t_{0.05} = -1.734$

5. Computation

$$t = \frac{(\bar{X}_A - \bar{X}_B) - (\mu_1 - \mu_2)}{\sqrt{(n_A - 1)s_A^2 + (n_B - 1)s_B^2}} \sqrt{\frac{n_A n_B (n_A + n_B - 2)}{n_A + n_B}}$$

$$= \frac{(70 - 74) - 0}{\sqrt{9(11.33) + 9(29.11)}} \sqrt{\frac{(10)(10)(18)}{10 + 10}} = -1.989$$

6. Decision: Reject N.H. since $t = -1.989 < -1.734 = t_{0.05}$ i.e., accept the claim that method B is more effective (better) than the method A.

Example 3: Out of a random sample of 9 mice, suffering with a disease, 5 mice were treated with a new serum while the remaining were not treated. From the time of commencement of experiment, the following are the survival times:

| | | | | | |
|--------------|-----|-----|-----|-----|-----|
| Treatment | 2.1 | 5.3 | 1.4 | 4.6 | 0.9 |
| No treatment | 1.9 | 0.5 | 2.8 | 3.1 | |

Test whether the serum treatment is effective in curing the disease at 0.05 L.O.S., assuming that the two distributions are normally distributed with equal variances.

Solution: Let μ_T and μ_{NT} be the mean survival times of the mice treated and not treated with serum respectively.

1. N.H.: $H_0 : \mu_T - \mu_{NT} = 0$ i.e., not effective

29.20 — HIGHER ENGINEERING MATHEMATICS—VII

2. A.H.: $H_1 : \mu_T - \mu_{NT} > 0$ i.e., serum is effective
3. L.O.S.: $\alpha = 0.05$
4. Critical region: Reject N.H. if $z > t_{0.95,7} = 1.90$ since the dof is $\nu = n_T + n_{NT} - 2 = 5 + 4 - 2 = 7$.
5. Computation: $n_T = 5, \bar{X}_T = \frac{14.3}{5} = 2.86$

$$s_T^2 = \frac{15.532}{4} = 3.883, s_T = 1.9705,$$

$$n_{NT} = 4, \bar{X}_{NT} = \frac{8.3}{4} = 2.075,$$

$$s_{NT}^2 = \frac{4.0875}{3} = 1.3625,$$

$$s_{NT} = 1.16726,$$

$$S_p^2 = \frac{(n_T - 1)s_T^2 + (n_{NT} - 1)s_{NT}^2}{n_T + n_{NT} - 2} =$$

$$S_p^2 = \frac{(5 - 1)(1.9705)^2 + (4 - 1)(1.16726)^2}{5 + 4 - 2}$$

$$= 2.802, S_p = 1.674$$

$$t = \frac{(2.86 - 2.075) - 0}{1.674 \left(\frac{1}{5} + \frac{1}{4} \right)} = 0.6990 \approx 0.7$$

6. Decision: Accept N.H. since $t = 0.7 < 1.9 = t_{0.95,7}$ i.e., serum treatment is not effective.

EXERCISE

1. Random samples of specimens of coal from two mines A and B are drawn and their heat-producing capacity (in millions of calories/ton) were measured yielding the following results:

Mine A: 8350, 8070, 8340, 8130, 8260

Mine B: 7900, 8140, 7920, 7840, 7890, 7950

Is there significant difference between the means of these two samples at 0.01 L.O.S.

Hint: N.H.: $\mu_1 - \mu_2 = 0$, A.H.: $\mu_1 - \mu_2 \neq 0$, $t_{0.005}$ with $5 + 6 - 2 = 9$ dof is 3.250

Accept if $-3.250 < t < 3.250$, $\bar{x}_1 = \frac{41150}{5} = 8230$, $\bar{x}_2 = \frac{47640}{6} = 7940$

$$s_1^2 = \frac{63000}{4} = 15750, s_2^2 = \frac{54600}{5} = 10920,$$

$$t = \frac{8230 - 7940}{\sqrt{63000 + 54600}} \sqrt{\frac{5.6.9}{11}} = 4.19$$

Reject N.H. since $t = 4.19 > t_{0.005} = 3.250$.

Ans. Yes, there is significant difference.

2. To test the claim that substrate concentration (S.C.) causes an increase in the mean velocity (M.V.) of a chemical reaction by more than 0.5 m/l/30 minutes a study is conducted resulting in the following data:

| Reaction with S.C. of | No. of runs | Mean velocity | Sample s.d. |
|-----------------------|-------------|---------------|-------------|
| 1.5 moles/litre | 15 | 7.5 | 1.5 |
| 2.0 moles/litre | 12 | 8.8 | 1.2 |

Is the claim tenable at 0.01 L.O.S. assuming that the populations are normally distributed with equal variances.

Hint: $H_0 : \mu_1 - \mu_2 = \delta = 0.5$, $H_1 : \mu_1 - \mu_2 > \delta = 0.5$, $t_{0.01,25} = 2.485$

$$S_p^2 = \frac{14(1.5)^2 + 11(1.2)^2}{15 + 12 - 2} = 1.8936,$$

$$t = \frac{(8.8 - 7.5) - (0.5)}{1.376 \sqrt{\frac{1}{15} + \frac{1}{12}}} = 1.50$$

Reject N.H. since $t = 1.50 < 2.48$ (Right O.T.T.)

Ans. No, claim not tenable.

3. A study is conducted to determine whether the wear of material A exceeds that of B by more than 2 units. If test of 12 pieces of material A yielded a mean wear of 85 units and s.d. of 4 while test of 10 pieces of material B yielded a mean of 81 and s.d. 5, what conclusion can be drawn at 0.05 L.O.S. Assume that populations are approximately normally distributed with equal variances.

Hint: $H_0 : \mu_1 - \mu_2 = 2$, $H_1 : \mu_1 - \mu_2 > 2$, $t_{0.05}$ with 20 dof is 1.725

$$S_p^2 = \frac{11(16) + 9(25)}{12 + 10 - 2} = 20.052,$$

$$t = \frac{(85 - 81) - 2}{4.478 \sqrt{\frac{1}{12} + \frac{1}{10}}} = 1.04$$

Accept H_0 since $t = 1.04 < 1.725 = t_{0.05, 20}$.

Ans. Wear of A does not exceed that of B by 2 units.

4. To determine whether vegetarian and non-vegetarian diets effects significantly on increase in weight a study was conducted yielding the following data of gain in weight.

Vegetarian: 34, 24, 14, 32, 25, 32, 30, 24, 30, 31, 35, 25

Non-vegetarian: 22, 10, 47, 31, 44, 34, 22, 40, 30, 32, 35, 18, 21, 35, 29

Can we claim that the two diets differ pertaining to weight gain, assuming that samples are drawn from normal populations with same variance.

Hint: $\bar{X}_V = \frac{336}{12} = 28, n_V = 12, \bar{X}_{NV} = \frac{450}{15} = 30, n_{NV} = 15$

$$S^2 = 71.6, t = \frac{\bar{X}_V - \bar{X}_{NV}}{\sqrt{S^2 \left(\frac{1}{n_V} + \frac{1}{n_{NV}} \right)}} = \frac{28 - 30}{\sqrt{71.6 \left(\frac{1}{12} + \frac{1}{15} \right)}} = -0.609$$

Accept N.H.: $\mu_V = \mu_{NV}$ against A.H.: $\mu_V \neq \mu_{NV}$ at 0.05 L.O.S.

Since $-0.609 > -2.06$ and $t_{0.05}$ at $12 + 15 - 2 = 25$ dof is 2.06

Ans. Vegetarian and non-vegetarian diets do not differ significantly as far as their effect on increase in weight.

5. In a study on the influence of habitation, the intelligent quotients (IQs) of 16 students from urban area was found to have a mean of 107 and s.d. of 10, while the IQs of 14 students from a rural area showed a mean of 112 and s.d. 8. Determine whether the IQs differ significantly at (a) 0.01 (b) 0.05 levels.

Hint:

$$S_p^2 = \frac{n_1 s_1^2 + n_2 s_2^2}{n_1 + n_2 - 2} = \frac{16(10)^2 + 14(8)^2}{16 + 14 - 2} = 89.1136$$

$$t = \frac{112 - 107}{9.44 \sqrt{\frac{1}{16} + \frac{1}{14}}} = 1.45$$

- a. Accept $H_0 : \mu_U = \mu_R$, Acceptable region $(-2.76, 2.76)$

- b. Accept H_0 , since 1.45 lies in the acceptable region $(-2.05, 2.05)$

Ans. No, habitation has influence on IQs.

6. To test the claim that application of pesticide increases production of rice, a study was conducted as follows. Out of 24 plots of equal areas, equal soil conditions, same exposure to sunlight, 12 plots were treated with pesticides while the remaining 12 plots were left untreated. The mean increase in rice production was 4.8 kgs and s.d. of 0.40 kgs for treated plots and 5.1 kgs mean and 0.36 s.d. for untreated plots. Is there significant increase in rice production due to pesticide application at (a) 0.01 (b) 0.05 L.O.S.

Hint:

$$S^2 = \frac{12(0.40)^2 + 12(0.36)^2}{12 + 12 - 2} = 0.157609$$

$$t = \frac{5.1 - 4.8}{0.397 \sqrt{\frac{1}{12} + \frac{1}{12}}} = 1.85$$

$t_{0.99}$ at 22 dof, right O.T.T. is 2.51

$t_{0.95}$ at 22 dof, right O.T.T. is 1.72

Ans. (a) Accept $H_0 : \mu_1 = \mu_2$ (b) Reject H_0 , significant.

29.9 PAIRED-SAMPLE t-TEST

Paired observations arise in a very special experimental situation where each homogeneous experimental unit receives both population conditions. As a result, each experimental unit has a pair of observations, one for each population. Thus the paired observations are on the same unit or matching units.

Examples: To test the effectiveness of “insulin” some 10 diabetic patients sugar level in blood is measured “before” and “after” the insulin is injected. Here the individual diabetic patient is the experimental unit and the two populations are blood sugar level “before” and “after” the insulin is injected.

So for each observation is one sample, there is a corresponding observation in the other sample pertaining to the same character. Thus the two samples

29.22 — HIGHER ENGINEERING MATHEMATICS—VII

are *not* independent. Paired t -test is applied for n paired observations (which are dependent) by taking the (signed) differences $d_1, d_2, \dots, d_n$ of the paired data. To test whether the differences d form a random sample from a population with $\mu_D = d_O$ use large sample test (on Page 766) or one-sample t -test (on Page 773) when sample is small (the one sample t -test in this case is known as the paired-sample t -test). The test statistic is

$$\frac{\bar{d} - \mu_d}{S_d/\sqrt{n}}$$

with $\nu = n - 1$ dof and $\bar{d}$ and S_d^2 are the mean and variance of the differences $d_1, d_2, \dots, d_n$.

13, 7, -1, 5, 3, 2, -1, 0, 6, 1, 4, 3, 2, 6, 12, 4

$$\bar{x} = \text{mean of differences of sampled data} = \frac{66}{16} = 4.125$$

$$s^2 = \frac{247.73}{15} = 16.516, s = 4.064$$

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}} = \frac{4.125 - 0}{4.064/\sqrt{16}} = 4.06$$

6. Decision: Reject N.H. since $t = 4.06 > 2.602 = t_{0.01}$ i.e., yoga is useful in weight reduction.

EXERCISE

1. Use paired sample test at 0.05 level of significance to test from the following data whether

| | | | | | | | | | | | |
|--------|----------|-------|-------|------|-------|-------|------|-------|------|-------|-------|
| Weight | Scale I | 11.23 | 14.36 | 8.33 | 10.50 | 23.42 | 9.15 | 13.47 | 6.47 | 12.40 | 19.38 |
| in gms | Scale II | 11.27 | 14.41 | 8.35 | 10.52 | 23.41 | 9.17 | 13.52 | 6.46 | 12.45 | 19.35 |

WORKED OUT EXAMPLES

Examples: In a study of usefulness of yoga in weight reduction, a random sample of 16 persons undergoing yoga were examined of their weight before (without) and after (with) yoga with the following results:

| | | | | | | | | | | | | | | | | |
|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Weight before | 209 | 178 | 169 | 212 | 180 | 192 | 158 | 180 | 170 | 153 | 183 | 165 | 201 | 179 | 243 | 144 |
| Weight after | 196 | 171 | 170 | 207 | 177 | 190 | 159 | 180 | 164 | 152 | 179 | 162 | 199 | 173 | 231 | 140 |

Test whether yoga is useful in weight reduction at 0.01 level of significance.

Solution: Let μ be the mean of population of differences,

1. N.H.: $\mu = 0$ i.e., not useful.
2. A.H.: $\mu > 0$ i.e., yoga is useful in weight reduction.
3. L.O.S.: $\alpha = 0.01$.
4. Critical region: Right one tailed test.
Reject N.H. if $t > t_{0.01}$ with $16 - 1 = 15$ degrees of freedom. From table $t_{0.01} = 2.602$.
5. Calculation: differences d_i 's are

the differences of the means of the weights obtained by two different scales (weighting machines) is significant.

Hint: $\bar{x} = -\frac{0.2}{10} = -0.02$, $s = 0.028674$,
 $n = 10$, $t = \frac{-0.02-0}{0.028/\sqrt{10}} = -2.21$, $t_\alpha = t_{0.05}$ with 9 dof is 1.833.

Ans. No significant difference in the two scales.

2. The average weekly losses of man-hours due to strikes in an institute before and after a disciplinary program was implemented are as follows:

| | | | | | | | | | | |
|--------|----|----|----|-----|----|----|----|----|----|----|
| Before | 45 | 73 | 46 | 124 | 33 | 57 | 83 | 34 | 26 | 17 |
| After | 36 | 60 | 44 | 119 | 35 | 51 | 77 | 29 | 24 | 11 |

Is there reason to believe that the disciplinary program is effective at 0.05 level of significance?

Hint: $\bar{x} = 5.2$, $s = 4.08$, $n = 10$, $t = 4.03$, $t_{0.05}$ with 9 dof is 1.833.

Ans. Yes, program is effective.

3. The pulsality index (P.I.) of 11 patients before and after contracting a disease are given below. Test at 0.05 level of significance whether there is a significant increase of the mean of P.I. values.

| | | | | | | | | | | | |
|--------|-----|------|------|------|------|------|------|------|------|------|------|
| Before | 0.4 | 0.45 | 0.44 | 0.54 | 0.48 | 0.62 | 0.48 | 0.60 | 0.45 | 0.46 | 0.35 |
| After | 0.5 | 0.60 | 0.57 | 0.65 | 0.63 | 0.78 | 0.63 | 0.80 | 0.69 | 0.62 | 0.68 |

Hint: $\bar{x} = \frac{188}{11} = 0.171$, $s = 0.065$, $n = 11$, $t = 8.72$, $t_{0.05}$ with 10 dof is 1.812.

Ans. Yes, there is significant increase in P.I. values.

4. The following data gives the amount of androgen present in blood of 15 deers before and 30 minutes after a certain drug is injected to them.

| | | | | | | | | | | | | | | | |
|--------|------|------|------|------|------|-------|-------|-------|------|------|-------|------|-------|-------|-------|
| Before | 2.76 | 5.18 | 2.68 | 3.05 | 4.10 | 7.05 | 6.60 | 4.79 | 7.39 | 7.30 | 11.78 | 3.9 | 26 | 67.48 | 17.04 |
| After | 7.02 | 3.1 | 5.44 | 3.99 | 5.21 | 10.26 | 13.91 | 18.53 | 7.91 | 4.85 | 11.1 | 3.74 | 94.03 | 94.03 | 41.7 |

Test at 0.05 L.O.S. whether there is significant change in the concentration levels of androgen in blood.

Hint: $\bar{x} = 9.848$, $s = 18.474$, $t = 2.06$, critical region: $t < -2.145$ and $t > 2.145$ (with 14 dof).

Ans. Yes, there is difference in mean circulating levels of androgen in the blood of deer.

5. The blood pressure (B.P.) of 5 women before and after intake of a certain drug are given below:

| | | | | | |
|--------|-----|-----|-----|-----|-----|
| Before | 110 | 120 | 125 | 132 | 125 |
| After | 120 | 118 | 125 | 136 | 121 |

Test at 0.01 L.O.S. whether there is significant change in B.P.

Hint: $\bar{x} = \frac{10}{5} = 2$, $s = 5.477$, $t = 0.817$, $t_{0.01}$ with 4 dof is 3.747.

Ans. No significant change in B.P.

6. Marks obtained in mathematics by 11 students before and after intensive coaching are given below:

| | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|
| Before | 24 | 17 | 18 | 20 | 19 | 23 | 16 | 18 | 21 | 20 | 19 |
| After | 24 | 20 | 22 | 20 | 17 | 24 | 20 | 20 | 18 | 19 | 22 |

Test at 0.05 L.O.S. whether the intensive

coaching is useful?

Hint: $\bar{x} = -1$, $s = 2.296$, $t = -1.38$, $t_{0.05}$ with 10 dof is 1.812.

Ans. Not useful.

29.10 TEST OF HYPOTHESIS: ONE PROPORTION: SMALL SAMPLES

The quality control engineer wants to know the proportion of defective products (items) in his industry, a university the percentage of first classes and a

electronic component manufacturer the probability that a component works for a certain period and so on. In these cases, the observations on various items or objects are classified into two mutually exclusive (dichotomus) classes (forming a binomial population).

Let X , the number of successes be a binomial random variable. Let p be the parameter of the binomial distribution. Then the test of hypothesis concerning one proportion for *small samples* is as follows:

1. N.H.: $H_0 : p = p_0$ i.e., a proportion (percentage or probability) equals some given constant p_0 .
2. A.H.: $H_1 : p \neq p_0$ (or $p < p_0$ or $p > p_0$).
3. L.O.S.: α
4. Test statistic: Binomial variable X with $p = p_0$.
5. Computation: Let x be the number of successes in a sample of size n .

Compute p -value:

a. A.H.: $p \neq p_0$:

$$P = 2P(X \leq x \text{ when } p = p_0) \text{ if } x < np_0.$$

$$P = 2P(X \geq x \text{ when } p = p_0) \text{ if } x > np_0$$

b. A.H.: $p < p_0$: $P = P(X \leq x \text{ when } p = p_0)$

c. A.H.: $p > p_0$: $P = P(X \geq x \text{ when } p = p_0)$

6. Decision: Reject N.H.: H_0 if $P \leq \alpha$.

WORKED OUT EXAMPLES

Example 1: If 6 out of 20 cigarette smokers randomly chosen preferred ‘charminar’ cigarettes, test the claim at 0.05 L.O.S., that 20% of the smokers prefer ‘charminar’.

Solution:

1. N.H.: H_0 : Proportion of smokers preferring ‘charminar’ brand = $p = 0.2$.
2. A.H.: H_1 : $p \neq 0.2$.
3. L.O.S.: $\alpha = 0.05$.
4. Test statistic: Let X be the discrete binomial random variable which is the number of ‘charminar’ smokers with $p = 0.2$ and $n = 20$.
5. Computations: $X = 6$, $np_0 = (20)(0.2) = 4$.
Since $X = 6 > np_0 = 4$

$$\begin{aligned} P &= 2 [\text{probability that } X \geq 6 \text{ when } p = 0.2] \\ &= 2P(x \geq 6 \text{ with } p = 0.2) \\ &= 2 \left[1 - \sum_{x=0}^5 b(X; 20, 0.2) \right] \\ &= 2[1 - 0.8042] = 2(0.1958) = 0.3916. \end{aligned}$$

Since $P = 0.3916 > 0.05$, accept H_0 i.e., $p = 0.2$.

Example 2: Past experience shows that 40% of Indian youth favored ‘cricket’. If in a random sample of 15 Indian youth, 8 favoured cricket, is there reason to believe that the proportion of Indian youth favoring cricket today has increased. Use 0.05 L.O.S.

Solution: Let X be discrete random variable: number of Indian youth favouring cricket.

1. H_0 : $p = 0.4$
2. H_1 : $p > 0.4$
3. $\alpha : 0.05$
4. Binomial variable X with $p = 0.4$, $n = 15$.
5. Computation: $X = 8$, $np_0 = 15(0.4) = 6$
 $\therefore 8 = X > np_0 = 6$.

$$P = P(X \geq 8 \text{ when } p = 0.4) = 1 - P(X \leq 7)$$

$$= 1 - \sum_{X=0}^7 b(X; 15, 0.4)$$

$$P = 1 - 0.7869 = 0.2131 > 0.05.$$

6. Conclusion: Accept N.H.: $p = 0.4$ i.e., no, there is no increase in the proportion of Indian youth favouring cricket.

EXERCISE

1. To test the claim of a flat builder that mosquito nets were installed in 70% of the flats, a random survey was conducted and found that 8 out of 15 flats had mosquito nets. Is the claim valid at 0.10 L.O.S.

Hint:

$$\begin{aligned} P &= 2P(X \leq 8 \text{ when } p = 0.7) = 2 \sum_{x=0}^8 b(x; 15, 0.7) \\ &= 2(0.1311) = 0.2622, x = 8 < 10.5 = np_0 \\ &= (15)(0.7) \end{aligned}$$

Ans. Accept H_0 , claim of the builder is valid since $P = 0.2622 > 0.10$ by a T.T.T.

2. Test the N.H.: that a coin is fair at 0.03 L.O.S. against an A.H. that heads occur less than 50% of the time if 5 heads occur when it is tossed 20 times.

Ans. Reject N.H., i.e., coin is unpair (unbalanced) since $P = P(X \leq 5, p = 0.5) = \sum_{x=0}^5 b(x; 20, 0.5) = 0.0207 < 0.03$.

3. If 9 out of 20 ‘pizza’ eaters like the native variety over the Italian, can the claim that 40% of ‘pizza’ eaters like native variety is tenable?

Hint: $P = 0.4044$ (use O.T.T.)

Ans. Accept the claim (i.e., claim is not refuted).

29.11 TEST OF HYPOTHESIS: ONE PROPORTION: LARGE SAMPLE

Assume that sample size n is large. Then the binomial distribution can be approximated by normal distribution with the parameters mean $\mu = np_0$ and variance

$\sigma^2 = np_0q_0$. The test statistic for testing $p = p_0$ is given by

$$z = \frac{x - np_0}{\sqrt{np_0q_0}}$$

where x is the number of successes in a sample of size n and $q_0 = 1 - p_0$. This statistic can also be written as

$$z = \frac{P - p}{\sqrt{pq/n}}$$

where $P = \frac{x}{n}$ = proportion of successes in the sample, p = actual population proportion of successes. As usual, the critical regions are

- $z < -z_{\alpha/2}$ or $z > z_{\alpha/2}$ for A.H.: $p \neq p_0$
- $z > z_{\alpha}$ for A.H.: $p > p_0$
- $z < -z_{\alpha}$ for A.H.: $p < p_0$

WORKED OUT EXAMPLES

Example 1: If in a random sample of 600 cars making a right turn at a certain traffic junction 157 drove into the wrong lane, test whether actually 30% of all drivers make this mistake or not at this given junction. Use (a) 0.05 (b) 0.01 L.O.S.

Solution: Let X be discrete random variable denoting the number of cars driving into the wrong lane at a junction.

- N.H.: $H_0 : p = 0.3$
- A.H.: $H_1 : p \neq 0.3$
- L.O.S.: (a) $\alpha = 0.05$
(b) $\alpha = 0.01$
- Acceptable region: $\left\{ \begin{array}{l} \text{a) } -1.96 < Z < 1.96 \\ \text{b) } -2.57 < Z < 2.57 \end{array} \right\}$
- Computation: $\mu = np = (600)(0.3) = 180$,

$$\sigma = \sqrt{npq} = \sqrt{600(0.3)(0.7)} = \sqrt{126} = 11.225$$

$$157 \text{ in standard variable is } \frac{157-180}{11.225} = -2.0489$$

- Conclusion:
 - since $-2.0489 < -1.96$, reject N.H.
 - since $-2.0489 > -2.57$, accept N.H.

Example 2: Test the claim of a manufacturer that 95% of his 'stabilizers' conform to ISI specifications if out of a random sample of 200 stabilizers produced by this manufacturer 18 were faulty. Use (a) 0.01 (b) 0.05 L.O.S.

Solution: Let p = probability that the stabilizers are of ISI standard i.e., good

- N.H.: $H_0 : p = 0.95$
- A.H.: $H_1 : p < 0.95$
- L.O.S. (a) $\alpha = 0.01$ (b) 0.05
critical region (a) $z < -2.33$ (b) $z < -1.645$
- If H_0 is true, $\mu = np = (200)\left(\frac{95}{100}\right) = 190$,
 $\sigma = \sqrt{npq} = \sqrt{200 \cdot \frac{95}{100} \cdot \frac{5}{100}} = 3.082$
- Computation: $200 - 18 = 182$ in standard unit is
 $\frac{182-190}{3.082} = -2.5957$
- Conclusion:
 - since $z = -2.5957 < -2.33$, reject N.H.
 - since $z = -2.5957 < -1.645$, reject N.H.
 i.e., reject the claim of the manufacturer at both levels using left O.T.T.

EXERCISE

- If in a random sample of 200 persons suffering with 'headache' 160 persons got cured by a drug, can we accept the claim of the manufacturer that his drug cures 90% of the sufferers. Use 0.01 L.O.S.
Hint: $\mu = np = (200)(0.9) = 180$,
 $\sigma = \sqrt{npq} = \sqrt{200(0.9)(0.1)} = 4.23$
- Ans. Reject N.H., claim is not tenable since $z = \frac{160-180}{4.23} = -4.73 < -2.33 = z_{\alpha} = z_{0.01}$ by a left O.T.T.
- A student answers by guess 32 questions correctly in an examination with 50 true or false questions. Are the results significant at (a) 0.05 L.O.S. (b) 0.01 L.O.S.
Hint: $\mu = np = (50)(0.5) = 25$,
 $\sigma = \sqrt{50(0.5)10.5} = \sqrt{12.5} = 3.54$

29.26 — HIGHER ENGINEERING MATHEMATICS—VII

N.H.: $p = 0.5$, student is guessing i.e., results are due to chance, A.H.: $p > 0.5$

Ans. a. Reject N.H. since $z = \frac{32-25}{3.54} = 1.98 > 1.645 = z_{0.05}$ by a right O.T.T.

b. Accept N.H. since $z = \frac{32-25}{3.54} = 1.98 < 2.33 = z_{\alpha} = z_{0.01}$, by a right O.T.T.

3. If a random sample of 120 tractors produced by a company 47 are defective, is the claim, by the company that at most 30% of the tractors are defective, tenable. Use 0.05 L.O.S.

Hint: N.H.: $p = 0.3$, A.H.: $p > 0.3$

Ans. Reject N.H., claim not tenable (valid) since $z = \frac{47-120(0.3)}{\sqrt{12(0.3)(0.7)}} = 2.191 > 1.645 = z_{0.05}$ by a right O.T.T.

4. In a sample of 90 university professors 28 own a computer. Can we conclude at 0.05 L.O.S. that at most $\frac{1}{4}$ of the professors own a computer?

Ans. Accept N.H.: $p = \frac{1}{4}$ against $H_1 : p > \frac{1}{4}$ since $z = \frac{28-(90)(0.25)}{\sqrt{90(0.25)(0.75)}} = 1.3388 < 1.645 = z_{0.05}$ by right O.T.T.

5. It is observed that 174 out of a random sample of 200 truck drivers on highway during night are drunk. Is it valid to state that at least 90% of the truck drivers are drunk. Use 0.05 L.O.S.

Ans. Accept N.H.: $p = 0.9$ against A.H.: $p < 0.9$ since $z = \frac{174-(200)(0.9)}{\sqrt{200(0.9)(0.1)}} = -1.41 > -1.645 = z_{0.05}$ by a left O.T.T.

6. A hospital claims that at least 40% of the patients admitted are for 'emergency' ward. Is there reason to believe this claim if the records shows that only 49 of 150 patients are for 'emergency' ward. Use 0.01 L.O.S.

Ans. Accept N.H.: $p = 0.4$ against $p < 0.4$ since $z = \frac{49-(150)(0.4)}{\sqrt{150(0.4)(0.6)}} = -1.833 > -2.33 = z_{0.01}$ by a left O.T.T.

29.12 TEST OF HYPOTHESIS: TWO PROPORTIONS

Suppose there are two distinct populations A and B. Let each item (member) of these two populations belongs to two mutually exclusive classes depend-

ing on whether the item has (possess) an attribute c (success) or not (failure).

| | Classes having | | Total |
|--------------------------|--------------------------|-------------------------|-------|
| | attribute c
(success) | without c
(failures) | |
| Sample from population A | x_1 | $n_1 - x_1$ | n_1 |
| Sample from population B | x_2 | $n_2 - x_2$ | n_2 |
| Total | $x_1 + x_2$ | $n_1 + n_2 - x_1 - x_2$ | |

Let x_1 and x_2 be the number of items having (possessing) attribute c (successes), in random samples of sizes n_1 and n_2 drawn from the two populations A and B respectively. Then $p_1 = \frac{x_1}{n_1}$ and $p_2 = \frac{x_2}{n_2}$ are the sample proportions. Let P_1 and P_2 be population proportions of populations A and B respectively. To determine whether the proportion of items having attribute c (success) is same in the both the populations, test the null hypothesis.

$$H_0 : P_1 = P_2$$

or

$$H_1 : P_1 - P_2 = 0$$

i.e., there is "no difference" between the two population proportions, against the A.H.: $P_1 \neq P_2$ or A.H.: $P_1 > P_2$ or A.H.: $P_1 < P_2$. For large samples (when both $n_1, n_2 \geq 30$), p_1 and p_2 are asymptotically normally distributed and therefore the sampling distribution of differences in proportions ($p_1 - p_2$) will be approximately normally distributed with mean

$$\mu_{p_1-p_2} = 0 \text{ and } \sigma_{p_1-p_2} = \sqrt{\hat{p}(1-\hat{p})\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}.$$

Here an unbiased pooled estimate of the population proportion $\hat{p}$ is

$$\hat{p} = \frac{n_1 p_1 + n_2 p_2}{n_1 + n_2} = \frac{x_1 + x_2}{n_1 + n_2}$$

obtained by pooling the data from both the samples. Thus the z -value for testing $p_1 = p_2$ is

$$z = \frac{p_1 - p_2}{\sigma_{p_1-p_2}} = \frac{\frac{x_1}{n_1} - \frac{x_2}{n_2}}{\sqrt{\hat{p}(1-\hat{p})\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}}$$

Using the critical points of the standard normal curve, the critical regions are determined as before depending on the appropriate alternative hypothesis.

Test of Hypothesis: Difference Between Proportions

Suppose the difference between two population proportions equals to some constant δ . Then the test of hypothesis consists of

N.H.: $H_0: P_1 - P_2 = \delta$

A.H.: $H_1: P_1 - P_2 \neq \delta$ or $P_1 - P_2 > \delta$ or $P_1 - P_2 < \delta$ and the test statistic

$$z = \frac{\left(\frac{x_1}{n_1} - \frac{x_2}{n_2}\right) - \delta}{\sqrt{\frac{\frac{x_1}{n_1}\left(1 - \frac{x_1}{n_1}\right)}{n_1} + \frac{\frac{x_2}{n_2}\left(1 - \frac{x_2}{n_2}\right)}{n_2}}}$$

which for large samples is a random variable having the standard normal distribution.

WORKED OUT EXAMPLES

Test of hypothesis: Two proportions

Example 1: Out of two vending machines at a 'super bazar', the first machine fails to work 13 times in 250 trials and second machine fails to work 7 times in 250 trials. Test at 0.05 L.O.S. whether the difference between the corresponding sample proportions is significant.

Solution:

1. N.H.: $H_0: p_1 = p_2$ i.e., no difference
2. A.H.: $H_1: p_1 \neq p_2$ i.e., there is difference
3. L.O.S.: $\alpha = 0.05$
4. Critical region: Reject H_0 if $z < -z_{\alpha/2} = -1.96$ or if $z > z_{\alpha/2} = 1.96$
5. Computations: $x_1 = 237, x_2 = 243, n_1 = 250, n_2 = 250$

$$\hat{p} = \frac{x_1 + x_2}{n_1 + n_2} = \frac{237 + 243}{250 + 250} = \frac{24}{25}$$

$$z = \frac{\frac{\frac{x_1}{n_1} - \frac{x_2}{n_2}}{\sqrt{\hat{p}(1 - \hat{p})\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}}}$$

$$= \frac{\frac{237}{250} - \frac{243}{250}}{\sqrt{\frac{24}{25}\left(1 - \frac{24}{25}\right)\left(\frac{1}{250} + \frac{1}{250}\right)}} = -1.3698$$

6. Decision: Since $z = -1.3698$ lies between -1.96 and 1.96 accept H_0 i.e., there is no significant difference between the two vending machines.

Example 2: If 57 out of 150 patients suffering with certain disease are cured by allopathy and 33 out of 100 patients with same disease are cured by homeopathy, is there reason to believe that allopathy is better than homeopathy at 0.05 L.O.S.

Solution: Let p_1 and p_2 be proportion of patients cured by allopathy and homeopathy respectively.

1. N.H.: $H_0: p_1 = p_2$ i.e., no difference
2. A.H.: $H_1: p_1 > p_2$ i.e., allopathy is superior to homeopathy
3. L.O.S.: $\alpha = 0.05$
4. Criterion: Reject N.H. if $z > 1.645$ by a right O.T.T.
5. Calculations: $n_1 = 150, x_1 = 57, n_2 = 100, x_2 = 33$

$$\hat{p} = \frac{x_1 + x_2}{n_1 + n_2} = \frac{57 + 33}{150 + 100} = \frac{9}{25} = 0.36$$

$$z = \frac{\frac{\frac{x_1}{n_1} - \frac{x_2}{n_2}}{\sqrt{\hat{p}(1 - \hat{p})\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}}}{= \frac{\frac{57}{150} - \frac{33}{100}}{\sqrt{(0.36)(0.64)\left(\frac{1}{150} + \frac{1}{100}\right)}} = 0.807 \simeq 0.81$$

6. Decision: N.H. can not be rejected or accept N.H. since

$$z = 0.81 < 1.645 = z_{\alpha} = Z_{0.05}$$

i.e., there do not appear to be any significant difference at 0.05 level between the two treatments of allopathy and homeopathy.

Test of hypothesis: Difference between proportions

Example 3: A question in a true-false quiz is considered to be smart if it discriminates between intelligent person (IP) and average person (AP). Suppose 205 of 250 IP's and 137 of 250 AP's answer a quiz question correctly. Test at 0.01 L.O.S. whether for the given question, the proportion of correct answers can be expected to be at least 15% higher among IP's than among the AP's.

Solution: Let p_1 and p_2 be the proportion of correct answers by IP's and AP's respectively. Then

1. N.H.: $p_1 - p_2 = \delta$
2. A.H.: $p_1 - p_2 > \delta = \frac{15}{100} = 0.15$
3. L.O.S.: $\alpha = 0.01$
4. CR: Reject H_0 if $z > z_\alpha = 2.33$
5. Calculation:

$$z = \frac{\left(\frac{x_1}{n_1} - \frac{x_2}{n_2}\right) - \delta}{\sqrt{\frac{\frac{x_1}{n_1}\left(1 - \frac{x_1}{n_1}\right)}{n_1} + \frac{\frac{x_2}{n_2}\left(1 - \frac{x_2}{n_2}\right)}{n_2}}} = \frac{\left(\frac{205}{250} - \frac{137}{250}\right) - \frac{15}{100}}{\sqrt{\frac{(.82)(.18)}{250} + \frac{(.548)(.452)}{250}}} = 3.068$$

6. Decision: Reject H_0 since $z = 3.068 > 2.33 = z_\alpha$ i.e., yes, the proportion of correct answers by IP is 15% more than those by AP's.

EXERCISE

Test of hypothesis: Two proportions

1. A study of TV viewers was conducted to find the opinion about the mega serial 'Ramayana'. If 56% of a sample of 300 viewers from south and 48% of 200 viewers from north preferred the serial, test the claim at 0.05 L.O.S. that (a) there is a difference of opinion between south and north (b) 'Ramayana' is preferred in the south.

Hint: $z = \frac{0.560 - 0.480}{0.0456} = 1.75,$

$$\hat{p} = \frac{n_1 p_1 + n_2 p_2}{n_1 + n_2} = \frac{(300)(0.56) + (200)(.48)}{300 + 200},$$

$$\hat{p} = 0.528, q = 1 - \hat{p} = 1 - .528 = .472,$$

$$\sigma_{p_1 - p_2} = \sqrt{pq \left(\frac{1}{n_1} + \frac{1}{n_2}\right)} = 0.0456$$

Ans. a. Accept N.H. i.e., no significant difference between north and south viewers since by a T.T.T., $z = 1.75$ lies in $(-1.96, 1.96)$.

b. Reject N.H. i.e., 'Ramayana' is preferred in the south since $z = 1.75 > 1.645$ by right O.T.T.

2. In a survey of A.C. machines produced by company A it was found that 19 machines were defective in a random sample of 200 while for company B 5 were defective out of 100. At 0.05 L.O.S. is there reason to believe that (a) there is significant difference in performance of A.C. machines between the two companies A and B (b) products of B are superior to products of A.

Hint: $\hat{p} = \frac{n_1 p_1 + n_2 p_2}{n_1 + n_2} = \frac{200(.905) + 100(.95)}{200 + 100} = 0.92,$

$$q = 1 - \hat{p} = 1 - .92 = 0.08,$$

$$\sigma_{p_1 - p_2} = \sqrt{pq \left(\frac{1}{n_1} + \frac{1}{n_2}\right)} = 0.033,$$

$$z = \frac{p_1 - p_2}{\sigma_{p_1 - p_2}} = \frac{.905 - .95}{0.033} = -1.363636.$$

Ans. a. Accept N.H. i.e., no difference between performance of A.C. machines since $z = -1.363636$ lies in acceptable region $(-1.90, 1.90)$.

b. Accept N.H. i.e., B is not superior (better) in an A, by a left O.T.T. $z_\alpha = z_{0.05} = -1.645$.

3. In a random sample of 200 parents from urban areas 120, while 240 of 500 parents from rural areas preferred 'private' professional colleges, can we conclude that parents from urban areas prefer 'private' colleges at 0.025 L.O.S.

Hint: $\hat{p}_1 = \frac{120}{200} = 0.6, \hat{p}_2 = \frac{240}{500} = 0.48,$

$$\hat{p} = \frac{x_1 + x_2}{n_1 + n_2} = \frac{120 + 240}{200 + 500} = 0.51,$$

$$z = \frac{0.6 - 0.48}{\sqrt{(0.51)(0.49)\left(\frac{1}{200} + \frac{1}{500}\right)}} = 2.9.$$

Ans. Reject N.H. i.e., urban parents prefer 'private' colleges since $z = 2.97 > z_\alpha = z_{0.025} = 1.96$.

4. If 48 out of 400 persons in rural area possessed 'cell' phones while 120 out 500 in urban area can it be accepted that the proportion of 'cell' phones in the rural and urban area is same or not. Use 5% L.O.S.

$$\text{Hint: } p_1 = \frac{48}{400} = \frac{3}{25}, p_2 = \frac{120}{500} = \frac{6}{25}, \hat{p} = \frac{168}{900} \\ = \frac{14}{75}, z = \frac{\left| \frac{3}{25} - \frac{6}{25} \right|}{\sqrt{\frac{14}{75} \cdot \frac{61}{75} \cdot \left(\frac{1}{400} + \frac{1}{500} \right)}} = 4.8$$

Ans. Reject H_0 since $z = 4.8 > 1.96 = z_\alpha$ by a T.T.T. with $\alpha = 0.05$.

Test of hypothesis: Difference between proportions

5. In a study of the effect of drugs on 'cancer', two groups of 80 such patients were considered. One group was treated with allopathic drug while the other group with homeopathic drug. It was observed that 23 in the first group and 41 in the second group were cured. At 0.05 L.O.S. test whether the true percentage of patients cured is at least 8% less for those who were treated by homeopathic drug?

Hint: $p_1 = \text{Allopathy}, p_2 = \text{Homeopathy}$,
N.H.: $p_1 - p_2 = \delta = 0.08$ A.H.: $p_1 - p_2 >$

$$0.08, z = \frac{\left(\frac{57}{80} - \frac{39}{80} \right) - \frac{8}{100}}{\sqrt{\frac{(57)(43)}{80} + \frac{(39)(61)}{80}}} = 1.92358.$$

Reject H_0 since $z = 1.92358 > 1.645 = z_\alpha = z_{0.05}$ by right O.T.T.

Ans. Reject H_0 i.e., allopathy drug is more effective or proportion of patients cured by homeopathy is at least 8% less than those treated by allopathy drug.

29.13 TEST OF HYPOTHESIS FOR SEVERAL PROPORTIONS

Consider k binomial populations with parameters $p_1, p_2, \dots, p_k$. To test whether the population proportions of these k populations are all equal, consider the N.H.: $p_1 = p_2 = \dots = p_k$, against A.H.: these proportions are not all equal. Now draw k independent random samples of sizes $n_1, n_2, \dots, n_k$ one from each of the k populations. Let $x_1, x_2, \dots, x_k$ denote the number of items possessing the attribute (i.e.,

success)

| | Sample 1 | Sample 2 | ... | Sample k | Total |
|---------|-------------|-------------|-----|-------------|---------|
| Success | x_1 | x_2 | ... | x_k | x |
| Failure | $n_1 - x_1$ | $n_2 - x_2$ | ... | $n_k - x_k$ | $n - x$ |
| Total | n_1 | n_2 | ... | n_k | n |

Here x and n denote the total number of successes and total number of trials for all samples combined. The expected cell frequencies e_{ij} are calculated by

$$e_{1j} = \frac{n_j \cdot x}{n} \\ e_{2j} = \frac{n_j(n - x)}{n}$$

Test statistic concerning difference among proportions is given by $\chi^2 = \sum_{i=1}^2 \sum_{j=1}^k \frac{(o_{ij} - e_{ij})^2}{e_{ij}}$.

Reject N.H. if $\chi^2 > \chi_\alpha^2$ with $(k - 1)$ dof.

WORKED OUT EXAMPLES

Example: Test whether there is significant difference at 0.05 level in the quality of teaching among four engineering colleges A, B, C, D of a technological university if the number of failures are 26, 23, 15, 32 respectively. Assume that each college has a strength of 200 students.

Solution: Let p_1, p_2, p_3, p_4 be the proportion of students who passed (successful) from the A, B, C, D engineering colleges respectively.

1. N.H.: $H_0 : p_1 = p_2 = p_3 = p_4$, i.e., no difference
2. A.H.: $H_1 : p_1, p_2, p_3, p_4$ are not all equal i.e., there is difference in quality of teaching.
3. L.O.S.: $\alpha = 0.05$
4. Criterion: Reject N.H. if $\chi^2 > \chi_{0.05}^2$ with $k - 1 = 4 - 1 = 3$ dof. From table, $\chi_{0.05}^2$ with 3 dof is 7.815.

29.30 — HIGHER ENGINEERING MATHEMATICS—VII

5. Computation:

| Engineering Colleges | | | | | |
|----------------------|-----|-----|-----|-----|-------|
| | A | B | C | D | Total |
| Success | 174 | 177 | 185 | 168 | 704 |
| Failure | 26 | 23 | 15 | 12 | 76 |
| Total | 200 | 200 | 200 | 200 | 800 |

Grand Total

$$e_{ij} = n_j \frac{x_i}{n}, e_{2j} = n_j \frac{(n-x)}{n} \text{ so}$$

$$e_{11} = 704 \left(\frac{200}{800} \right) = 176 = e_{12} = e_{13} = e_{14}$$

$$e_{21} = 200 - 176 = 24 = e_{22} = e_{23} = e_{24}$$

$$\begin{aligned} \chi^2 &= \sum_{i=1}^2 \sum_{j=1}^4 (o_{ij} - e_{ij})^2 / e_{ij} \\ &= \frac{(176 - 174)^2}{176} + \frac{(177 - 176)^2}{176} + \dots + \frac{(32 - 24)^2}{24} \\ &= \frac{4}{176} + \frac{1}{176} + \frac{81}{176} + \frac{64}{176} + \frac{4}{24} + \frac{1}{24} + \frac{81}{24} + \frac{64}{24} \\ &= 7.10 \end{aligned}$$

6. Decision:

$$\text{Accept } H_0 \text{ since } \chi^2 = 7.10 < \chi_{0.05}^2 = 7.815$$

EXERCISE

1. A study was conducted to estimate the proportion of wives who regularly watch TV 'serials' yielding the following data:

| | PG wives | Graduate wives | Illiterate wives | Total |
|--------------|----------|----------------|------------------|-------|
| Watch | 52 | 31 | 37 | 120 |
| Do not watch | 148 | 119 | 113 | 380 |
| Total | 200 | 150 | 150 | 500 |

Is there reason to believe at 0.05 L.O.S. that there is no difference among the true proportions of wives with different educational background who watch TV 'serials'.

Hint: $e_{11} = 48, e_{12} = 36, e_{13} = 36, e_{21} = 152, e_{22} = 114, e_{23} = 114, \chi^2 = 1.3888 < 5.991 = \chi_{0.05}^2$ with $3 - 1 = 2$ dof.

Ans. Accept N.H. i.e., no difference or wives watch TV serials irrespective of their level of literacy.

2. Three cough syrups A, B, C were used on patients with cough with the following results:

| Cough syrup | | | | |
|-------------|-----|----|-----|-------|
| | A | B | C | Total |
| Cured | 41 | 27 | 22 | 90 |
| Not cured | 79 | 53 | 78 | 210 |
| Totals | 120 | 80 | 100 | 300 |

Can we conclude whether there is significant (at 0.05 level) difference among the proportion of patients cured by the three brands A, B, C?

Hint: $e_{11} = 36, e_{12} = 24, e_{13} = 30, e_{21} = 84, e_{22} = 56, e_{23} = 70$

- Ans.* There is no difference among the three brand A, B, C in curing cough i.e., their effect is same, or accept N.H. since $\chi^2 = 4.575 < 5.991 = \chi_{0.05}^2$ with $3 - 1 = 2$ dof.
3. A survey was conducted to determine whether three categories of employees prefer pension scheme or not resulting the table given below

| | Teaching | Non-teaching | Administrative | Totals |
|-----------------|----------|--------------|----------------|--------|
| For pension | 67 | 84 | 109 | 260 |
| Against pension | 33 | 66 | 41 | 140 |
| Totals | 100 | 150 | 150 | 400 |

At 0.01 L.O.S. test whether the proportions of employees favouring pension scheme are same.

Hint: $e_{11} = 65, e_{12} = 67.5, e_{13} = 97.5, e_{21} = 35, e_{22} = 52.5, e_{23} = 52.5$.

- Ans.* Reject N.H., i.e., not same since $\chi^2 = 9.392 > 9.21 = \chi_{0.01}^2$ with $3 - 1 = 2$ dof.
4. If a can containing 500 dry fruits is selected at random from each of three different companies A, B, C of mixed dry fruits and there are 345, 313 and 359 cashew nuts respectively in each of the cans, can we conclude at 0.01 L.O.S. that the mixed dry fruits of three companies contain equal proportions of cashew nuts.

Hint: $e_{11} = 339, e_{12} = 339, e_{13} = 339, e_{21} = 161 = e_{22} = e_{23}$.

Ans. Reject N.H. i.e., proportions of cashew nuts are different since $\chi^2 = 10.187 > \chi_{0.01}^2$ with $3 - 1 = 2$ dof = 9.392.

29.14 ANALYSIS OF $r \times c$ TABLES (CONTINGENCY TABLES)

A **manifold classification** is a classification in which attributes are divided into more than two classes (categories). Suppose attribute A is divided into r classes $A_1, A_2, \dots, A_r$ and another attribute B is divided into c classes $B_1, B_2, \dots, B_c$. Then the various cell frequencies can be expressed in the form of a table known as $r \times c$ manifold contingency table where A_i is the number of items possessing the attribute A_i with $i = 1, 2, \dots, r$ and B_j is the number of items having attribute B_j with $j = 1, 2, \dots, c$ and o_{ij} known as observed frequencies denotes the number of items possessing both the attributes A_i and B_j (with $i = 1, 2, \dots, r$, and $j = 1, 2, \dots, c$). Here the total frequency $N = \sum_{i=1}^r A_i = \sum_{j=1}^c B_j$.

| | B | | | | | | |
|----------------|-----------------|-----------------|-----|-----------------|-----|-----------------|---|
| A | B ₁ | B ₂ | ... | B _j | ... | B _c | Row Total |
| A ₁ | O ₁₁ | O ₁₂ | | O _{1j} | | O _{1c} | RT1 |
| A ₂ | O ₂₁ | O ₂₂ | | O _{2j} | | O _{2c} | RT2 |
| ⋮ | | | | | | | |
| A _i | O _{i1} | O _{i2} | | O _{ij} | | O _{ic} | RTi |
| ⋮ | | | | | | | |
| A _r | O _{r1} | O _{r2} | | O _{rj} | | O _{rc} | RTr |
| Column | | | | | | | |
| total | CT ₁ | CT ₂ | | CT _j | | CT _c | $N = \sum_{i=1}^r A_i = \sum_{j=1}^c B_j$ |

Here RT and CT denotes row totals and column totals respectively also known as marginal frequencies.

Thus $r \times c$ table is expressed in matrix form with r rows and c columns containing mn cells with cell frequencies O_{ij} . These tables arise in essentially two kinds of problems.

Test for independence (TFI)

In this problem ‘ c ’ samples from one population with each item are classified with respect to two (usually qualitative) attributes. The row totals and column totals are *not fixed, but random*. Only the grand total N is fixed. The null hypothesis consist of testing whether the two attributes are independent. Then

$$p_{ij} = (\text{prob of getting value belonging to } i\text{th row}) \times (\text{prob of getting a value belonging to } j\text{th column})$$

The alternative hypothesis is that the two attributes are not independent (i.e., dependent).

Test for homogeneity (TFH)

In this problem samples from several (c) populations are considered with each trial permitting more than two possible outcomes. Here both the marginal frequencies i.e., row totals and column totals are *fixed beforehand*. To test whether an attribute is common to all the populations i.e., to determine whether the c populations are “homogeneous” with respect to an attribute, consider the null hypothesis

$$\text{N.H.: } p_{i1} = p_{i2} = \dots = p_{ic}$$

for $i = 1, 2, \dots, r$ i.e., probability of obtaining an observation in the r th row is the *same* for each column i.e., $\sum_{i=1}^r p_{ij} = 1$ for each column.

The alternate hypothesis is p 's are not all equal for at least one row (i.e., non homogeneous).

In either of the problems the **expected cell frequencies** denoted by e_{ij} are calculated by

$$e_{ij} = \frac{(\text{total observed frequencies in the } j\text{th column}) \times (\text{total observed frequencies in the } i\text{th row})}{(\text{total of all cell frequencies})}$$

$$\text{i.e., } e_{ij} = \frac{(\text{column total}) \times (\text{row total})}{\text{grand total}}$$

Statistic for analysis of $r \times c$ tables is

$$\chi^2 = \sum_{i=1}^r \sum_{j=1}^c \frac{(O_{ij} - e_{ij})^2}{e_{ij}}$$

with $(r - 1)(c - 1)$ dof.

Reject N.H. if the calculated value of test statistic χ_{cal}^2 or simply χ^2 exceeds χ_{α}^2 with $(r - 1)(c - 1)$ dof.

i.e.,

Reject N.H. if $\chi^2 > \chi_{\alpha}^2$

WORKED OUT EXAMPLES

Test for independence (categorical data)

Examples: Test the hypothesis at 0.05 L.O.S. that the presence or absence of hypertension (HT) is independent of smoking habits from the following experimental data on 180 persons

| | Non smokers | Moderate smokers | Heavy smokers |
|-------|-------------|------------------|---------------|
| HT | 21 | 36 | 30 |
| No HT | 48 | 26 | 19 |

Solution:

1. N.H.: H_0 : Hypertension and smoking habits are independent.
2. A.H.: H_1 : Hypertension and smoking habits are not independent.
3. L.O.S.: $\alpha = 0.05$.
4. Criterion: Reject N.H. if $\chi^2 > \chi_{0.05}^2$ with $\nu = (r - 1)(c - 1) = (2 - 1)(3 - 1) = 2$ dof.
From table $\chi_{0.05}^2 = 5.991$
5. Computations:

| | NS | MS | HS | Total |
|-------|-------------------------|-------------------------|-------------------------|-------|
| HT | 21 <small>33.35</small> | 36 <small>29.97</small> | 30 <small>23.68</small> | 87 |
| No HT | 48 <small>35.65</small> | 26 <small>32.03</small> | 19 <small>25.32</small> | 93 |
| Total | 69 | 62 | 49 | 180 |

Grand total

$$e_{11} = 69 \left(\frac{87}{180} \right) = 33.35, \quad e_{12} = 62 \left(\frac{87}{180} \right) = 29.97, \quad e_{21} = 35.65, \quad e_{22} = 32.03 \text{ etc.}$$

$$\chi^2 = \frac{(21-33.35)^2}{33.35} + \frac{(36-29.97)^2}{29.97} + \dots + \frac{(19-25.32)^2}{25.32} = 14.4644$$

6. Conclusion: Reject N.H. since $\chi^2 = 14.46 > 5.99 = \chi_{0.05}^2$ i.e., Hypertension and smoking habits are dependent (i.e., not independent).

EXERCISE

Test for independence

1. A study was conducted to determine whether physical handicapness (P.H.) affects the performance of worker's in an industry with the following results:

| | Performance | | | |
|-------------|-------------|--------------|------------------|-------|
| | Good | Satisfactory | Not satisfactory | Total |
| Blind | 21 | 64 | 17 | 102 |
| Deaf | 16 | 49 | 14 | 79 |
| No handicap | 29 | 93 | 28 | 150 |
| Total | 66 | 206 | 59 | 331 |

Test the claim that handicaps have no effect on performance at 0.05 L.O.S.

Hint: $e_{11} = 20.34, e_{12} = 63.5, e_{13} = 18.18, e_{21} = 15.75, e_{22} = 49.17, e_{23} = 14.08, e_{31} = 29.90, e_{32} = 93.35, e_{33} = 26.74$

$$\chi^2 = .19472 \approx .195 < 9.488 = \chi_{0.05}^2 \quad \text{with } (3 - 1)(3 - 1) = 4 \text{ dof.}$$

Ans. Accept N.H. i.e., Handicaps have no effect on performance or performance and handicaps are independent.

2. The following 'police' records shows the type of crime in four regions of a country.

| | Type of crime | | | | |
|--------|------------------|--------|------|----------|-------|
| Region | Physical assault | Murder | Rape | Homicide | Total |
| East | 162 | 118 | 451 | 18 | 749 |
| West | 310 | 196 | 996 | 25 | 1527 |
| North | 258 | 193 | 458 | 10 | 919 |
| South | 280 | 175 | 390 | 19 | 864 |
| Total | 1010 | 682 | 2295 | 72 | 4059 |

Determine whether the incidence of crime depended on the region. Use 0.01 L.O.S.

Hint: $e_{11} = 186.37, e_{12} = 125.85, e_{13} = 423.49, e_{14} = 13.29, e_{21} = 379.96, e_{22} = 256.57, e_{23} = 863.38, e_{24} = 27.09,$

$$e_{31} = 228.68, \quad e_{32} = 154.41, \quad e_{33} = 519.6, \\ e_{34} = 16.30, \quad e_{41} = 215, \quad e_{42} = 145.17, \\ e_{43} = 488.51, \quad e_{44} = 15.33$$

Ans. Reject N.H. i.e., incidence of crime depends on the region since $\chi^2 = 124.5 > 21.666 = \chi_{0.00}^2$ with $(4 - 1)(4 - 1) = 9$ dof

3. In order to determine whether 'efficiency' in job depends on the 'academic performance', 400 persons were examined yielding the following data:

| | | Academic performance | | | |
|------------|--------------|----------------------|------|--------------|-------|
| | | Excellent | Good | Satisfactory | Total |
| Efficiency | Excellent | 23 | 60 | 29 | 112 |
| | Good | 28 | 79 | 60 | 167 |
| | Satisfactory | 9 | 49 | 63 | 121 |
| | Total | 60 | 188 | 152 | 400 |

Hint: $e_{11} = 16.8, \quad e_{12} = 52.6, \quad e_{13} = 42.6, \\ e_{21} = 25.0, \quad e_{22} = 78.5, \quad e_{23} = 63.5, \quad e_{31} = 18.2, \quad e_{32} = 56.9, \quad e_{33} = 45.9$

Ans. Yes, there is dependence between 'efficiency' in job and academic performance since $\chi^2 = 20.34 > 13.277 = \chi_{0.01}^2$ with $(3 - 1)(3 - 1) = 4$ dof (Reject N.H.)

WORKED OUT EXAMPLES

Test for homogeneity

Examples: A study was conducted with parents 200 from north, 150 from south, 100 from east and 100 from west regions of India to determine the current attitudes about prayers in public schools. Test at 0.01 L.O.S. for homogeneity of attitudes of parents among the four regions concerning prayers in the public schools.

Solution:

1. N.H.: $p_1 = p_2 = p_3 = p_4$
2. A.H.: Not all P_i 's are equal
3. L.O.S.: 0.01.

4. Critical region: Reject N.H. H_0 if $\chi^2 > \chi_{0.01}^2$ with $v = (3 - 1)(4 - 1) = 6$ dof i.e., if $\chi^2 > 16.812$

5. Computation:

| Attitude of parents | Region | | | | Total |
|---------------------|------------|------------|------------|------------|-------|
| | North | South | East | West | |
| Favour | 65 (74.55) | 66 (55.90) | 40 (37.27) | 34 (37.27) | 205 |
| Oppose | 42 (53.45) | 30 (40.09) | 33 (26.72) | 42 (26.72) | 147 |
| No opinion | 93 (72) | 54 (54) | 27 (36) | 24 (36) | 198 |
| Total | 200 | 150 | 100 | 100 | 550 |

$$\chi^2 = \sum_{i=1}^3 \sum_{j=1}^4 \frac{(O_{ij} - e_{ij})^2}{e_{ij}} \\ = \frac{(65 - 74.55)^2}{74.55} + \dots + \frac{(24 - 36)^2}{36} \\ = 31.11636 \approx 31.17$$

6. Decision: Reject N.H. H_0 since $\chi^2 = 31.17 > 16.812 = \chi_{0.01}^2$ with 6 dof i.e., attitudes of parents about prayer are *not* homogeneous (not same).

EXERCISE

Test for homogeneity

1. In order to find out the opinion about "ragging" in professional colleges, a campus study was conducted with the following results.

| Ragging | Faculty | Students | Adminis-
tration | Total |
|-----------|---------|----------|---------------------|-------|
| For | 82 | 70 | 62 | 214 |
| Against | 93 | 62 | 67 | 222 |
| Undecided | 25 | 18 | 21 | 64 |
| Total | 200 | 150 | 150 | 500 |

Determine whether the three categories of persons are *homogeneous* w.r.t. their opinions pertaining to "ragging".

Hint: $e_{11} = 85.6, \quad e_{12} = 64.2, \quad e_{13} = 64.2, \\ e_{21} = 88.8, \quad e_{22} = 66.6, \quad e_{23} = 66.6, \quad e_{31} = 25.6, \quad e_{32} = 19.2, \quad e_{33} = 19.2$

Ans. Accept N.H.: homogeneous opinion since

29.34 — HIGHER ENGINEERING MATHEMATICS—VII

$\chi^2 = 1.53 < 9.488$ where $\chi^2_{0.05}$ with $\nu = (3 - 1)(3 - 1) = 4$ dof is 9.488.

2. To determine the effectiveness of drugs against “aids”, three types of medicines, allopathic, homeopathic and ayurvedic were tested on 50 persons with the following results.

| | Drug | | | Total |
|--------------|-----------|-------------|---------|-------|
| | Allopathy | Homeo-pathy | Ayurved | |
| No relief | 11 | 13 | 9 | 33 |
| Some relief | 32 | 28 | 27 | 87 |
| Total relief | 7 | 9 | 14 | 30 |
| Total | 50 | 50 | 50 | 150 |

Hint: $e_{11} = 11, e_{12} = 11, e_{13} = 11, e_{21} = 29, e_{22} = 29, e_{23} = 29, e_{31} = 10, e_{32} = 10, e_{33} = 10$.

Ans. Accept N.H. since $\chi^2 = 3.8100313 < 9.488 = \chi^2_{0.05}$ with $\nu = (3 - 1)(3 - 1) = 4$ dof i.e., three drugs are equally effective or the drugs are homogeneous.

3. The following table shows the opinions of voters before and after a presidential election.

| | Before | After | Total |
|------------------|--------|-------|-------|
| For ruling party | 79 | 91 | 170 |
| For opposition | 84 | 66 | 150 |
| Undecided | 37 | 43 | 80 |
| Total | 200 | 200 | 400 |

Test the claim at 0.05 L.O.S. whether there has been a change of opinion of voters.

Hint: $e_{11} = e_{12} = 85, e_{21} = e_{22} = 75, e_{31} = e_{32} = 40$

Ans. No, there is no change in opinion of voters since $\chi^2 = 3.46 < 5.991 = \chi^2_{0.05}$ at $(3 - 1)(2 - 1) = 2$ dof (i.e., accept N.H.)

29.15 GOODNESS OF FIT TEST

To determine if a population follows a specified known theoretical distribution such as normal

distribution, binomial distribution or Poisson distribution, the χ^2 (chi-square) test is used to assertion how closely the actual distribution approximate the assumed theoretical distributions. This test, which is based on how good a fit is there between the observed frequencies (o_i from the sample) and the expected frequencies (e_i from the theoretical distribution) is known as “**goodness-of-fit-test**”. This test judges whether the sample is drawn from a certain hypothetical distribution i.e., whether the observed frequencies follow a postulated distribution or not.

The statistic χ^2 is a measure of the discrepancy existing between the observed and expected (or theoretical) frequencies.

$$\left. \begin{array}{l} \text{Statistic for test of} \\ \text{“goodness of fit”} \end{array} \right\} \chi^2 = \sum_{i=1}^k \frac{(o_i - e_i)^2}{e_i} \quad (1)$$

Here O_i and e_i are the observed and expected frequencies of the i th cell (or class interval), such that $\sum O_i = \sum e_i = N = \text{Total frequency}$.

k is the number of cells or class intervals, in the given frequency distribution.

Here χ^2 is a random variable which is very closely approximated with ν degrees of freedom.

Degrees of Freedom (dof) for χ^2 -Distribution

Let k be the number of terms in the formula (1) for χ^2 . Then the dof for χ^2 is:

- $\nu = k - 1$ if e_i can be calculated *without* having to estimate population parameters from sample statistics.
- $\nu = k - 1 - m$ if e_i can be calculated *only by* estimating m number of population parameters from sample statistics.

Examples:

- B.D.: p is the parameter, $m = 1$,
 $\nu = k - 1 - m = k - 1 - 1 = k - 2$
- P.D.: λ is the parameter, $m = 1$, $\nu = k - 2$
- N.D.: μ, σ are two parameters, $m = 2$,
 $\nu = k - 1 - 2 = k - 3$

Test for Goodness-of-Fit

1. N.H.: good-fit exists between the theoretical distribution and given data (of observed frequencies).
2. N.H.: no good fit.
3. L.O.S.: α (prescribed).
4. Critical region: Reject N.H. if $\chi^2 > \chi_\alpha^2$ with ν dof, i.e., theoretical distribution is a poor fit.
5. Compute χ^2 from (1).
6. Decision: Accept N.H. if $\chi^2 < \chi_\alpha^2$ i.e., the theoretical distribution is a good fit to the data.

Solution: Mean of the given frequency distribution is

$$\lambda = \frac{0 \times 52 + 1 \times 151 + 2 \times 130 + 3 \times 102 + 4 \times 45 + 5 \times 12 + 6 \times 5 + 7 \times 1 + 8 \times 2}{52 + 151 + 130 + 102 + 45 + 12 + 5 + 1 + 2}$$

$$\lambda = \frac{1010}{500} = 2.02$$

The Poisson distribution that fits to the data with this parameter $\lambda = 2.02$ is

$$P(x, \lambda) = \frac{e^{-\lambda} \lambda^x}{x!} = \frac{e^{-2.02} (2.02)^x}{x!} \quad x = 0, 1, 2, \dots, 8$$

| | | | | | | | | | |
|---------------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| $x:$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| $P(x)$ | 0.1326 | 0.26796 | 0.2706 | 0.1822 | 0.092 | 0.037 | 0.0125 | 0.0036 | 0.00091 |
| Expected frequency | 66.32 | 133.94 | 135.32 | 91.116 | 46.01 | 18.5896 | 6.25 | 1.806 | 0.456 |
| $\approx$ | $\approx$ | $\approx$ | $\approx$ | $\approx$ | $\approx$ | $\approx$ | $\approx$ | $\approx$ | $\approx$ |
| $= 500 \times P(x)$ | 66 | 134 | 135 | 91 | 46 | 19 | 6 | 2 | 0 |

Note 1: If $\chi^2 = 0$ then O_i and e_i agree exactly.

Note 2: when $\chi^2 > 0$.

- χ^2 small: O_i are close to e_i , indicating “good” fit.
- χ^2 large: O_i differ considerably from e_i indicating “poor” fit.

Conditions for Validity of χ^2 -Test

1. Sample size n should be large (i.e., $n \geq 50$).
2. If individual frequencies O_i (or e_i) are small say $O_i < 10$ then combine neighbouring frequencies so that combined frequency O_i (or e_i) is ≥ 10 .
3. The number of classes k should be neither too small nor too large. In general $4 \leq k \leq 16$.

WORKED OUT EXAMPLES

Example 1: Test for goodness of fit of a poisson distribution at 0.05 L.O.S. to the following frequency distribution:

| | | | | | | | | | |
|---------------------------------------|----|-----|-----|-----|----|----|---|---|---|
| Number of patients arriving/hour: (x) | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Frequency | 52 | 151 | 130 | 102 | 45 | 12 | 5 | 1 | 2 |

1. N.H.: H_0 : R.V. x has Poisson distribution with $\lambda = 2.02$
2. A.H.: H_1 : R.V. does *not* have P.D.
3. L.O.S. $\alpha = 0.05$
4. Critical region: Reject N.H. if $\chi^2 > 14.067$ where $\chi_{0.05}^2$ with $k - 1 - m = 9 - 1 - 1 = 9 - 2 = 7$ dof is 14.067 (since only one parameter λ is needed to calculate expected frequencies)
5. Calculation:

$$\begin{aligned} \chi^2 &= \sum_i \frac{(O_i - e_i)^2}{e_i} \\ &= \frac{(52 - 66)^2}{66} + \frac{(151 - 134)^2}{134} + \frac{(130 - 135)^2}{135} \\ &\quad + \frac{(102 - 91)^2}{91} + \frac{(45 - 46)^2}{46} + \frac{(12 - 9)^2}{19} \\ &\quad + \frac{[(5 + 1 + 2) - (6 + 2 + 0)]^2}{8} \end{aligned}$$

$$\chi^2 = 9.2419$$

6. Decision: Accept N.H. i.e., Poisson distribution with $\lambda = 2.02$ is a good fit to the given frequency distribution since $\chi^2 = 9.2419 < 14.067 = \chi_{0.05}^2$ with 7 dof.

29.36 — HIGHER ENGINEERING MATHEMATICS—VII

Example 2: Use 0.05 L.O.S. to test that the following given data may be treated as a random sample from a normal population

| Class | Frequency |
|-----------|-----------|
| 5.0–8.9 | 3 |
| 9.0–12.9 | 10 |
| 13.0–16.9 | 14 |
| 17.0–20.9 | 25 |
| 21.0–24.9 | 17 |
| 25.0–28.9 | 9 |
| 29.0–32.9 | 2 |
| Total | 80 |

Solution: A.M. = $\bar{x}$ = 18.85, σ = s.d. = 5.5.
The normal distribution with these two parameters is given below:

| X | $z = \frac{\bar{x} - X}{\sigma}$ | Area under | Probability of | Expected frequency |
|-------|----------------------------------|------------|----------------|--------------------|
| Class | $= \frac{X - 18.85}{5.5}$ | N.C. | a class | = probx 80 |
| 4.95 | -2.52 | .4941 | 0.03 | 2.4 |
| 8.95 | -1.8 | .4641 | .1064 | 8.512 |
| 12.95 | -1.072 | .3577 | .221 | 17.67 |
| 16.95 | -0.345 | .1368 | .285 | 22.8 |
| 20.95 | 0.3818 | .1480 | .216 | 17.304 |
| 24.95 | 1.109 | .3643 | .105 | 8.4 |
| 28.95 | 1.836 | .4693 | | |
| 32.95 | 2.563 | .4948 | .0255 | 2.04 |

$$\begin{aligned}\chi^2 &= \frac{(3 - 2.4)^2}{2.4} + \frac{(10 - 8.5)^2}{8.5} + \frac{(14 - 17.7)^2}{17.7} \\ &+ \frac{(25 - 22.8)^2}{22.8} + \frac{(17 - 17.3)^2}{17.3} + \frac{(9 - 8.4)^2}{8.4} \\ &+ \frac{(2 - 2.04)^2}{2.04} = 1.4524\end{aligned}$$

Cannot reject H_0 i.e., accept H_0 since $\chi^2 = 1.4524 < 9.488 = \chi_{0.05}^2$ with $k - 1 - 2 = 7 - 3 = 4$ dof (since 2 parameters $\bar{X}$, σ are needed).

EXERCISE

- Test for goodness of fit of a Poisson distribution at 0.01 L.O.S. to the following observed data

of e-mails received:

| No. of e-mails | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 |
|--------------------|---|----|----|----|----|----|----|----|----|---|----|----|----|----|
| Observed frequency | 3 | 15 | 47 | 76 | 68 | 74 | 46 | 39 | 15 | 9 | 5 | 2 | 0 | 1 |

Hint: $\lambda = \frac{1814}{400} = 4.535 \approx 4.6$

$e_0 = 4.0$, $e_1 = 18.4$, $e_2 = 42.8$, $e_3 = 65.2$,
 $e_4 = 74.8$, $e_5 = 69.2$, $e_6 = 52.8$, $e_7 = 34.8$,
 $e_8 = 20$, $e_9 = 10$, $e_{10} = 4.8$, $e_{11} = 2.0$, $e_{12} = 0.8$, $e_{13} = 0.4$

$$\begin{aligned}\chi^2 &= \frac{(18 - 22.4)^2}{22.4} + \frac{(47 - 42.8)^2}{42.8} + \dots \\ &+ \frac{(8 - 8.0)^2}{8.0} = 6.749.\end{aligned}$$

- Ans.** P.D. with $\lambda = 4.6$ provides a good fit since $\chi^2 = 6.749 < 16.919 = \chi_{0.01}^2$ with 9 dof.
- Test for goodness of fit of a uniform distribution to the following data obtained when a die is tossed 120 times.

| Face | 1 | 2 | 3 | 4 | 5 | 6 |
|----------|----|----|----|----|----|----|
| Observed | 20 | 22 | 17 | 18 | 19 | 24 |
| Expected | 20 | 20 | 20 | 20 | 20 | 20 |

Use 0.05 L.O.S.

Hint: $\chi^2 = \frac{(20-20)^2}{20} + \frac{(22-20)^2}{20} + \frac{(17-20)^2}{20} + \frac{(18-20)^2}{20} + \frac{(19-20)^2}{20} + \frac{(24-20)^2}{20} = 1.7.$

- Ans.** Uniform distribution is a good fit to the data. Accept N.H. that die is balanced since $\chi^2 = 1.7 < 11.070 = \chi_{0.05}^2$ with $6 - 1 = 5$ dof.
- Test for goodness of fit of normal distribution to the following frequency table:

| Class | 1.45–1.95 | 1.95–2.45 | 2.45–2.95 | 2.95–3.45 | 3.45–3.95 | 3.95–4.45 | 4.45–4.95 |
|-----------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| Frequency O_i | 2 | 1 | 4 | 15 | 10 | 5 | 3 |

Hint: $e_1 = 0.5 + 2.1 + 5.9 = 8.5$, $e_2 = 10.3$,
 $e_4 = 7.0 + 3.5 = 10.5$, $e_3 = 10.7$

$$\begin{aligned}\chi^2 &= \frac{(7 - 8.5)^2}{8.5} + \frac{(15 - 10.3)^2}{10.3} + \frac{(10 - 10.7)^2}{10.7} \\ &+ \frac{(8 - 10.5)^2}{10.5} = 3.05.\end{aligned}$$

Ans. Normal distribution with $\bar{x} = 3.5$ and $\sigma = 0.7$ is a good fit since $\chi^2 = 3.05 < 7.815 = \chi_{0.05}^2$ for 3 dof (Here first three classes are clubbed to have 7 frequency and last two classes to have 8 frequency, so $k = 4$ classes $- 1 = 3$).

4. Test for goodness of fit of a binomial distribution to the data given below:

| | | | | | | | |
|-------|---|----|----|----|---|---|---|
| X_i | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
| O_i | 5 | 18 | 28 | 12 | 7 | 6 | 4 |

Hint: $\mu = 2.4 = 6p$, $p = 2.4$

e_i : 4 15 25 22 11 3 0

Clubbing: e_i 19 25 22 14

Ans. Reject N.H. i.e., B.D. is not a good fit since $\chi^2 = 6.39 > 5.99 = \chi_{0.05}^2$ with $4 - 2 = 2$ dof.

5. Test for goodness of fit of a Poisson distribution to the following data:

| | | | | | | |
|-------|-----|-----|----|---|---|---|
| X | 0 | 1 | 2 | 3 | 4 | 5 |
| O_i | 275 | 138 | 75 | 7 | 4 | 1 |

Hint: $\lambda = \frac{330}{500} = 0.66$, $e_1 = 258$, $e_2 = 171$, $e_3 = 56$, $e_4 = 12.4$, $e_5 = 2.05$, $e_6 = 0.25$,

$$\chi^2 = \frac{(275 - 258)^2}{258} + \frac{(138 - 171)^2}{171} + \frac{(75 - 56)^2}{56} + \frac{(12 - 15)^2}{15} = 14.534.$$

Ans. P.D. is not a good fit since $\chi^2 = 14.534 > 5.991 = \chi_{0.05}^2$ with 2 dof.

6. Test for goodness of fit of normal distribution to the following data:

| | | | | | | | |
|-----------|-------|---------|---------|---------|----------|-----------|-----------|
| Class | 0–100 | 100–250 | 250–500 | 500–750 | 750–1000 | 1000–1250 | 1250–1500 |
| Frequency | 7 | 9 | 19 | 12 | 8 | 5 | 4 |

Hint: $e_1 = 7.62$, $e_2 = 6.32$, $e_3 = 15.26$, $e_4 = 16.17$, $e_5 = 11.52$, $e_6 = 5.24$, $e_7 = 1.88$, club the last two classes.

Ans. Normal distribution with $\bar{X} = 541.8$ and $\sigma = 375.46$ is a good fit to the given data since $\chi^2 = 4.751 < 7.81 = \chi_{0.05}^2$ with $6 - 2 - 1 = 3$ dof.

29.16 ESTIMATION OF PROPORTIONS

Engineering problems dealing with proportions, percentages or probabilities are one and the same because a proportion multiplied by 100 is percentage and proportion with number of trials very large is interpreted as probability.

Examples: Percentage of engineering students getting first class, proportion of students gaining useful employment or the probability that a first class graduate is employed.

Sample proportion $= \frac{X}{n}$ where X is the number of times an event occurs in n trials.

Sample proportion is an unbiased estimator of the of true proportion, the binomial parameter p .

Large Sample Confidence Interval for p

When n is large, normal approximation is used for binomial distribution to construct confidence interval for p from the inequality

$$-z_{\alpha/2} < \frac{X - np}{\sqrt{np(1-p)}} < z_{\alpha/2}$$

by replacing $\frac{X}{n}$ by p . Thus the confidence interval for p , when n is large, is

$$\frac{x}{n} - z_{\alpha/2} \sqrt{\frac{\frac{x}{n}(1 - \frac{x}{n})}{n}} < p < \frac{x}{n} + z_{\alpha/2} \sqrt{\frac{\frac{x}{n}(1 - \frac{x}{n})}{n}}.$$

Maximum Error of Estimate

The magnitude of error committed in using sample proportion $\frac{x}{n}$ for true proportion p is given by the maximum error of estimate E , where

$$E = z_{\alpha/2} \sqrt{\frac{p(1-p)}{n}}$$

Sample size:

- a. when p is known, the sample size n is given by

$$n = p(1-p) \left[\frac{z_{\alpha/2}}{E} \right]^2$$

- b. when p is unknown, then

$$n = \frac{1}{4} \left[\frac{z_{\alpha/2}}{E} \right]^2.$$

One-sided Confidence Interval

For $p \rightarrow 0$ and $n \rightarrow \infty$, binomial distribution is approximated with Poisson distribution with $\lambda = np$ and instead of the usual confidence interval, one-sided confidence interval of the form

$$p < \frac{1}{2n} \chi_{\alpha}^2$$

is used. Here χ_{α}^2 is with $2(x + 1)$ degrees of freedom.

WORKED OUT EXAMPLES

Example 1: For an ABC insurance company, 84 insurance claims for “accident” cars out of a random sample of 200 such claims, claim amount exceeded Rs. 100000. Construct 95% confidence interval for the true proportion of insurance claims filed against the ABC company which exceeded Rs. 100000.

Solution: Here $n = 200$, $x = 84$, $z_{\alpha/2} = z_{0.025} = 1.96$ $(1 - \alpha)100\%$ confidence interval for the true proportion p of insurance claims for accident cars exceeding Rs. 100000 amount is

$$\frac{x}{n} - z_{\alpha/2} \sqrt{\frac{\frac{x}{n} (1 - \frac{x}{n})}{n}} < p < \frac{x}{n} + z_{\alpha/2} \sqrt{\frac{\frac{x}{n} (1 - \frac{x}{n})}{n}}$$

$$\text{i.e., } \frac{84}{200} \pm 1.96 \sqrt{\frac{\frac{84}{200} (1 - \frac{84}{200})}{200}}$$

or Confidence interval: $0.352 < p < 0.488$.

Example 2: Using the sample proportion as an estimate of the true proportion of insurance claims in the above example, find the maximum error of estimate with 99% confidence.

Solution:

$$\begin{aligned} \text{Maximum error} = E &= z_{\alpha/2} \sqrt{\frac{\frac{x}{n} (1 - \frac{x}{n})}{n}} \\ &= 2.575 \sqrt{\frac{\frac{84}{200} (1 - \frac{84}{200})}{200}} = 0.0898671. \end{aligned}$$

Example 3: To estimate the percentage of all “lorry” drivers exceeding 60 kmph speed on NH 5,

determine the size of the smallest sample required to be at least 99% confidence that the error of estimate (sample percentage) is at most 3.5%.

Solution: Here $E = 0.035$, $z_{\alpha/2} = z_{0.005} = 2.575$ when p is unknown, sample size $n = \frac{1}{4} \left[\frac{z_{\alpha/2}}{E} \right]^2$

$$n = \frac{1}{4} \left[\frac{2.575}{0.035} \right]^2 = 1353.1887 \approx 1353.$$

Example 4: If the percentage (of all drivers) p to be estimated in the above example is known and is at most 40%, how large a sample is required?

Solution: when p is known,

$$\text{sample size } n = p(1 - p) \left[\frac{z_{\alpha/2}}{E} \right]^2$$

Here $p = 0.4$, $E = 0.035$, $z_{\alpha/2} = 2.575$ so

$$n = (0.4)(1 - 0.4) \left[\frac{2.575}{0.035} \right]^2 = 1299.06 \approx 1299.$$

Example 5: Construct an upper 95% confidence limit for the probability that a rocket will explode upon ignition, if it is found that in a random sample of 4000 such rocket firings, 10 exploded upon ignition.

Solution: Here: $n = 4000$, $\chi_{\alpha}^2 = \chi_{0.05}$ with $2(10 + 1) = 22$ dof is 33.294. So

$$p < \frac{1}{2n} \chi_{\alpha}^2 = \frac{1}{2(4000)} \cdot (33.294) = 0.00416175.$$

EXERCISE

- Construct 95% confidence interval for the true proportion of computer literates if 36 out of 100 persons from rural areas are computer literates.

Ans. $0.266 < p < 0.454$

- Find maximum error estimate with 99% confidences using the sample proportion as an estimate of the true proportion of parents if 136 of 400 parents for “privatization” of education.

Ans. $E = 2.575 \sqrt{\frac{(.34)(.66)}{400}} = 0.061$

- Construct 99% confidence interval for the true proportion of road accidents, if in a random sample of 400 road accidents, 231 were due to lack of traffic ‘sense’.

Ans. C.I.: $\frac{231}{400} \pm 2.575 \sqrt{\frac{(.5775)(.4225)}{400}} =$
 (.5139, .64109)

4. Find maximum error with 95% confidence for the above Example 3 using the sample proportion to estimate the corresponding true proportion

Ans. M.E. = $1.96 \sqrt{\frac{(.5775)(.4225)}{400}} = 0.04840$

5. Construct 98% confidence interval for the probability that buyers are lured by 'discount sales' if it is found that 204 buyers out of random sample of 300 were lured by such 'discount sales'

Ans. C.I. = $\frac{204}{300} \pm 2.33 \sqrt{\frac{\frac{204}{300} \frac{96}{300}}{300}} = (.61725, .74275)$

6. Find the maximum error with sample proportion as an estimate of true proportion of ragging incidents if 69 out of a random sample of 120 professional colleges reported cases of ragging.

Ans. $E = 1.96 \sqrt{\frac{(.575)(.425)}{120}} = 0.0884491$

7. Determine the size of smallest sample required to estimate an unknown proportion of blind students to within a maximum error of 0.06 with at least 95% confidence.

Ans. $n = \frac{1}{4} \left[\frac{z_{\alpha/2}}{E} \right]^2 = \frac{1}{4} \left[\frac{1.96}{.06} \right]^2 = 266.77 \approx 267$

8. Given that the proportion of blind students to be estimated in the above Example 7 is at least 0.75 what should be the required sample size.

Ans. $n = p(1 - p) \left[\frac{z_{\alpha/2}}{E} \right]^2 =$
 $(0.75)(0.25) \left[\frac{1.96}{.06} \right]^2 = 200.08 \approx 200$

9. To estimate the true proportion of 'substandard' computers from a large consignment and to be at least 95% confident that the error is at most 0.04, what should be the size of the smallest sample required if (a) true proportion does not exceed 0.12 (b) if true proportion is not known

a. $p = 0.12, \quad n = (0.12)(0.88) \left[\frac{1.96}{.04} \right]^2 =$
 $253.55 \approx 254$

b. $n = \frac{1}{4} \left[\frac{1.96}{0.04} \right]^2 = 600.25 \approx 601$

10. In a study conducted for 500 days, only on 4 days it was recorded that 'lead' content in a famous river exceeded 200 mg/cm. Construct an upper 99% confidence limit for the probability that the 'lead' content in the river will exceed 200 mg/cm on any one day.

Ans. $p < \frac{1}{2n} \chi_{\alpha}^2 = \frac{1}{2(500)} \chi_{0.01}^2$ with $2(4 + 1)$ dof
 $= \frac{1}{1000} 34.805 = 0.034805.$

Chapter 30

Curve Fitting, Regression and Correlation Analysis

INTRODUCTION

Approximating curve is the graph of data obtained through measurement or observation. Curve fitting is the process of finding the "best fit" curve since different approximating curves can be obtained for the same data. Least squares method is the best curve fitting method and is easily implemented on computers than the other methods like method of moments, method of group averages, graphical method. We also consider curve fitting by a sum of exponentials, linear weighted and non-linear weighted least squares approximation.

In the univariate case, a single variable say the height of an Indian, is analyzed. Whereas in the bivariate case, two "numerical" variables are measured resulting in a pair of measurements for each member, say the height and weight of an Indian; the age and the blood pressure of a person; amount spent on advertising and volume of sales; intake of nutritious food and I.Q of a student etc. In the correlation analysis, one wish to find whether a (mathematical) relationship exists and measure the strength of such relationship. In the regression analysis, the exact nature and form of mathematical equation (of the relation) is obtained. While the correlation coefficient measures the "closeness", the "regression equation" is used for prediction (or estimation).

30.1 CURVE FITTING

It is the method of finding equation of a curve that approximates a given set of data. On the basis of this

mathematical equation, predictions can be made in many statistical investigations.

Relationship

Relationship (or association) between two (or more) variables may exist.

Examples: Blood pressure and age, rainfall and crop yield, volume of a cube and length of its side, consumption of food and weight gain, intake of drug and heart rate, height and weight, income and medical care, nutrition and I.Q.

Scatter Diagram

To find a mathematical relationship (equation) between say two variables X and Y , plot the set of given N paired observations of X and Y i.e., $(X_1, Y_1), (X_2, Y_2), \dots, (X_N, Y_N)$ in the XY -plane. The resulting set of points is known as a scatter diagram.

Approximating Curve

It is a smooth curve that approximates the given set of N data points plotted in the scatter diagram.

Collocational polynomial For unequally spaced X_i 's N coefficients $a_0, a_1, a_2, \dots, a_{N-1}$ in the collocational polynomial

$$Y(X) = a_0 + a_1 X + a_2 X^2 + \dots + a_{N-1} X^{N-1}$$

can be determined so that the given set of N data points $(X_1, Y_1), \dots, (X_N, Y_N)$ lies (collocates) on the curve (satisfies the above equation)

Lagrange's interpolation formula is used when X_i 's are equally spaced. Collocation becomes laborious when the number of data points N is large and the empirical or observed data contains errors (i.e., when X or Y or both are random variables). In such cases data may be approximated by some function $Y = f(x)$ containing few unknown parameters.

Best fitting curve by method of least squares Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_N, Y_N)$ be a given set of N data points. Let $d_i = Y_i - \hat{Y}_i$ denotes the difference between Y_i and the corresponding value

$$Y_i \text{ estimate} = Y_i \text{ est} = \hat{Y}_i = f(X_i)$$

determined from the curve $c: y = f(X)$ (Fig. 30.1). The d_i 's known as deviations, errors or residuals which may be positive or negative or zero. Then the Legendre's principle of least squares (L.S.) or least squares criteria states that, of all the curves approximating a given set of data points, the curve having the least or minimum sum of the squares of the deviations is the "best fitting" curve, i.e., $\sum_{i=1}^N d_i^2$ the residuals or error sum of squares, is minimum.

Such a curve is known as a least squares (L.S.) curve. Thus the least squares criteria is the measure "goodness of fit". If the curve is a straight line fitted according to least squares sense then it is known as least squares straight line; if it is a parabola, it is known as least squares parabola, etc.

Some standard approximating curves

1. $Y = a_0 + a_1 X$ straight line
2. $Y = a_0 + a_1 X + a_2 X^2$

Fig. 30.1

parabola or quadratic curve

3. $Y = a_0 + a_1 X + \dots + a_N X^N$
nth degree (polynomial) curve

4. $Y = AB^X$ exponential curve

5. $Y = AX^B$ geometric curve

6. $Y = \frac{1}{a_0 + a_1 X}$ hyperbola.

Curve Fitting by Least Squares

(i) Least squares straight line

For a given set of N data points $(X_1, Y_1), (X_2, Y_2), \dots, (X_N, Y_N)$, assume that the straight line

$$Y = a_0 + a_1 X = f(X) \quad (1)$$

fits to the data in the least squares sense.

To determine the two unknowns a_0 and a_1 in (1), use the L.S. criteria that $\sum d_i^2$ is minimum, i.e.,

$$\sum_{i=1}^N d_i^2 = \sum_{i=1}^N (Y_i - f(X_i))^2 = \sum_{i=1}^N (Y_i - a_0 - a_1 X_i)^2 \quad (2)$$

is minimum. Differentiating (2) partially w.r.t. a_0 and a_1 and equating to zero, we get

$$\begin{aligned} \frac{\partial \sum d_i^2}{\partial a_0} &= \frac{\partial}{\partial a_0} \left\{ \sum (Y_i - a_0 - a_1 X_i)^2 \right\} \\ &= 2 \sum (Y_i - a_0 - a_1 X_i)^{2-1} \cdot (-1) = 0 \end{aligned}$$

$$\text{or} \quad \sum (Y_i - a_0 - a_1 X_i) = 0$$

$$\text{i.e.,} \quad \sum_{i=1}^N Y_i = Na_0 + a_1 \sum_{i=1}^N X_i \quad (3)$$

Similarly,

$$\begin{aligned} \frac{\partial}{\partial a_1} \left(\sum d_i^2 \right) &= \frac{\partial}{\partial a_1} \left(\sum (Y_i - a_0 - a_1 X_i)^2 \right) \\ &= 2 \sum (Y_i - a_0 - a_1 X_i)^{2-1} \cdot (-X_i) = 0 \end{aligned}$$

$$\text{or} \quad \sum Y_i X_i = a_0 \sum X_i + a_1 \sum X_i^2 \quad (4)$$

Thus the two unknown parameters a_0, a_1 of (1) are determined from the two equations

$$\sum Y_i = Na_0 + a_1 \sum X_i \quad (3)$$

$$\sum X_i Y_i = a_0 \sum X_i + a_1 \sum X_i^2 \quad (4)$$

known as “**normal equations**”. In such a case Equation (1) represents a least squares straight line.

Note: Here and in the following normal equations, the summation is for $i = 1$ to n .

(ii) Least squares quadratic curve (parabola)

Assume that

$$Y = a_0 + a_1X + a_2X^2 \quad (5)$$

approximates the data according to L.S. principle. Then the unknown three parameters a_0, a_1, a_2 are determined from the following three normal equations obtained in a similar way as above.

$$\begin{aligned} \sum Y_i &= Na_0 + a_1 \sum X_i + a_2 \sum X_i^2 \\ \sum X_i Y_i &= a_0 \sum X_i + a_1 \sum X_i^2 + a_2 \sum X_i^3 \\ \sum X_i^2 Y_i &= a_0 \sum X_i^2 + a_1 \sum X_i^3 + a_2 \sum X_i^4. \end{aligned}$$

(iii) Nonlinear curves

Nonlinear curves (4), (5), (6) can be transformed to a linear curve straight line. For the exponential curve (4)

$$Y = AB^X$$

taking logarithm on both sides, we get

$$\ln Y = \ln A + X \ln B$$

or put $Y^* = \ln Y$, $\ln A = A^*$, $\ln B = B^*$, then

$$Y^* = A^* + BX$$

which is a straight line.

In a similar way by putting $Y = \frac{1}{Y^*}$ in (6), we get $Y^* = a_0 + a_1X$ which is linear and can be solved as in *i*.

Note: Normal equations of the n th degree Equation (3) can be obtained formally by multiplying (3) on both sides by $1, X, X^2, \dots, X^N$ and summing upto N terms. This results in $(N + 1)$ normal equations to determine the $(N + 1)$ unknown parameters $a_0, a_1, a_2, \dots, a_N$ of (3).

Linear interpolation (Extrapolation) is to find Y corresponding to a value of X included between two (or outside or exterior to the) given values of X .

Result 1: Show that least squares line always passes through the point $(\bar{X}, \bar{Y})$.

Solution: Let

$$Y = a_0 + a_1X \quad (1)$$

be the least square line (L.S.L.) of Y on X . Its normal equation is

$$\begin{aligned} \sum Y &= Na_0 + a_1 \sum X \\ \text{dividing by } N, \quad \frac{\sum Y}{N} &= a_0 + a_1 \frac{\sum X}{N} \\ \text{or} \quad \bar{Y} &= a_0 + a_1 \bar{X} \end{aligned} \quad (2)$$

i.e., L.S.L. passes through $(\bar{X}, \bar{Y})$.

Similarly, for

$$X = b_0 + b_1Y \quad (3)$$

dividing by N its normal equation, we get

$$\frac{\sum X}{N} = b_0 + b_1 \frac{\sum Y}{N} \quad \text{or} \quad \bar{X} = b_0 + b_1 \bar{Y} \quad (4)$$

So L.S.L passes through $(\bar{X}, \bar{Y})$.

Result 2: Prove that L.S.L. Y on X can be expressed as

$$y = \left(\frac{\sum xy}{\sum x^2} \right) x \quad (5)$$

where $x = X - \bar{X}$, $y = Y - \bar{Y}$.

Solution: Let L.S.L. be $Y = a_0 + a_1X$. Since it passes through $(\bar{X}, \bar{Y})$, $\bar{Y} = a_0 + a_1\bar{X}$. Subtracting

$$Y - \bar{Y} = a_1(X - \bar{X})$$

or $y = a_1x$

So it is enough to show that $a_1 = \frac{\sum xy}{\sum x^2}$
Solving the normal equations

$$\begin{aligned} \sum Y &= Na_0 + a_1 \sum X \\ \sum XY &= a_0 \sum X + a_1 \sum X^2, \\ \text{we get} \quad a_1 &= \frac{N \sum XY - \sum X \sum Y}{N \sum X^2 - (\sum X)^2} \end{aligned}$$

Substituting $X = x + \bar{X}$, $Y = y + \bar{Y}$

$$\begin{aligned} a_1 &= \frac{N \sum (x + \bar{X})(y + \bar{Y}) - \sum (x + \bar{X}) \sum (y + \bar{Y})}{N \sum (x + \bar{X})^2 - \left(\sum (x + \bar{X}) \right)^2} \\ &= \frac{N \sum (xy + x\bar{Y} + y\bar{X} + \bar{X}\bar{Y}) - \sum (x + \bar{X}) \sum (y + \bar{Y})}{N \sum (x^2 + \bar{X}^2 + 2x\bar{X}) - \left(\sum x + N\bar{X} \right)^2} \\ &= \frac{N \sum xy + N\bar{Y} \sum x + N\bar{X} \sum y + N^2 \bar{X}\bar{Y} - \left(\sum x + N\bar{X} \right) \left(\sum y + N\bar{Y} \right)}{N \sum x^2 + 2N\bar{X} \sum x + N^2 \bar{X}^2 - \left(\sum x + N\bar{X} \right)^2} \end{aligned}$$

Since $\sum x = \sum (X - \bar{X}) = 0$,

$$\sum y = \sum (Y - \bar{Y}) = 0$$

$$a_1 = \frac{N \sum xy + N^2 \bar{X}\bar{Y} - N^2 \bar{X}\bar{Y}}{N \sum x^2 + N^2 \bar{X}^2 - N^2 \bar{X}^2} = \frac{\sum xy}{\sum x^2} \quad (6)$$

Result 3: Similarly, L.S.L. of X on Y can be expressed as

$$x = \left(\frac{\sum xy}{\sum y^2} \right) y$$

Result 4: Solving the normal equations

$$a_0 = \frac{\sum X^2 \sum Y - \sum X \sum Y X}{N \sum X^2 - (\sum X)^2} \quad (7)$$

Introducing

$$S_{XX} = N \sum X^2 - \left(\sum X \right)^2$$

$$S_{YY} = N \sum Y^2 - \left(\sum Y \right)^2$$

$$S_{XY} = N \sum XY - \left(\sum X \right) \left(\sum Y \right)$$

we have

$$a_1 = \frac{N \sum XY - \sum X \sum Y}{N \sum X^2 - (\sum X)^2} = \frac{S_{XY}}{S_{XX}}$$

$$a_0 = \frac{\sum X^2 \sum Y - \sum X \sum XY}{S_{XX}}$$

or from $\bar{Y} = a_0 + a_1 \bar{X}$, we get

$$a_0 = \bar{Y} - a_1 \bar{X} \quad \text{where} \quad a_1 = \frac{S_{XY}}{S_{XX}}.$$

30.2 REGRESSION ANALYSIS

In regression analysis, the nature (or form) of actual relationship if it exists, between two (or more vari-

ables) is studied by determining the mathematical equation between the variables. It is mainly used to predict or estimate one (the dependent) variable (response) in terms of the other (independent) variable(s), (regressor(s)). It is also used in optimization, to determine the values of independent variable(s) for which the dependent variable attains maximum or minimum. Sir Francis Galton (1822–1911) used regression analysis to study, whether the offspring having either short or tall parents, revert (regress) back to average height of the general population.

Simple Regression

It establishes the relationship between two variables (one dependent variable and one independent variable). In **multiple regression** the number of variables is more than two (with one dependent variable and two or more independent variables).

Linear Regression

In linear regression, the relationship between the variables, is linear and is represented by a straight line, known as a regression line or the line of average relationship or prediction equation.

Regression Line of Y on X

Suppose in the study of relationship between two variables X and Y if Y is dependent on X then the simple linear relation

$$Y = a_0 + a_1 X$$

is known as regression line of Y on X . Similarly, if X depends on Y , then

$$X = b_0 + b_1 Y$$

is known as regression line of X on Y .

In multiple regression the equation is

$$Y = f(X_1, X_2, X_3, \dots, X_k)$$

In multiple linear regression, f is linear

$$\text{i.e., } Y = b_0 + b_1 X_1 + b_2 X_2 + \dots + b_k X_k$$

In multiple nonlinear regression, f is nonlinear, for example,

$$\text{i.e., } Y = b_0 + b_1 X_1 + b_2 X_2 + b_3 X_1 X_2 + b_4 X_1^2 + b_5 X_2^2.$$

30.3 INFERENCES BASED ON THE LEAST SQUARES ESTIMATION

Simple linear regression model consists of

$$Y = \alpha + \beta x + \epsilon$$

where α and β are unknown intercept and slope parameters respectively. Here ϵ , known as, random error or random disturbance is assumed to be normally distributed with mean $E(\epsilon) = 0$ and variance σ^2 . The quantity σ^2 is known as residual variance or error variance. To estimate the regression coefficients α and β , a regression line $\hat{Y} = a_0 + a_1x$ is fitted according to the principle of least squares. Here $\hat{Y}$ is the predicted or fitted or estimated value. The least square estimates of α and β , are a_0 and a_1 given by (6) and (7) in 27.1. The slope of regression line β is the change in mean of Y 's corresponding to a unit increase in x .

Result: Gauss-Markov theorem: The least squares estimates a_0 and a_1 for the actual regression coefficients α and β have the smallest variance and hence most reliable among all unbiased estimators.

Confidence Intervals

A $(1 - \alpha)100\%$ confidence interval for the parameter β is

$$a_1 - \frac{t_{\alpha/2} s_{\epsilon} \sqrt{n}}{\sqrt{S_{xx}}} < \beta < a_1 + \frac{t_{\alpha/2} s_{\epsilon} \sqrt{n}}{\sqrt{S_{xx}}}$$

where $t_{\alpha/2}$ is the value of the t -distribution with $n - 2$ degrees of freedom.

A $(1 - \alpha)100\%$ confidence interval for α is

$$\begin{aligned} a_0 - t_{\alpha/2} s_{\epsilon} \sqrt{\frac{S_{xx} + (n\bar{x})^2}{nS_{xx}}} &< \alpha \\ &< a_0 + t_{\alpha/2} s_{\epsilon} \sqrt{\frac{S_{xx} + (n\bar{x})^2}{nS_{xx}}} \end{aligned}$$

Here $s_{\epsilon}^2 = (\text{unbiased}) \text{ estimate of } \sigma^2$

$$= \frac{S_{xx} \cdot S_{yy} - (S_{xy})^2}{n(n-2)S_{xx}}$$

Testing of hypothesis Statistics for inferences about α and β .

For slope β :

$$t = \frac{a_1 - \beta}{s_{\epsilon}} \sqrt{\frac{S_{xx}}{n}}$$

For intercept α :

$$t = \frac{a_0 - \alpha}{s_{\epsilon}} \sqrt{\frac{nS_{xx}}{S_{xx} + (n\bar{x})^2}}$$

Here t distribution is of $n - 2$ degrees of freedom.

WORKED OUT EXAMPLES

Curve fitting: Least square straight line

Example 1: Find a least squares straight line for the following data:

| | | | | | | |
|----|---|---|---|---|---|---|
| X: | 1 | 2 | 3 | 4 | 5 | 6 |
| Y: | 6 | 4 | 3 | 5 | 4 | 2 |

and estimate (predict) Y at $X = 4$ and X at $Y = 4$.

| X | Y | X ² | Y ² | XY | |
|-------|----|----------------|----------------|-----|---|
| 1 | 6 | 1 | 36 | 6 | so $\sum X = 21$
$\sum Y = 24$
$\sum X^2 = 91$
$\sum Y^2 = 106$
$\sum XY = 75$
$N = 6$ |
| 2 | 4 | 4 | 16 | 8 | |
| 3 | 3 | 9 | 9 | 9 | |
| 4 | 5 | 16 | 25 | 20 | |
| 5 | 4 | 25 | 16 | 20 | |
| 6 | 2 | 36 | 4 | 12 | |
| Total | 21 | 24 | 91 | 106 | 75 |

Assume that the least squares straight line of Y on X is $Y = a_0 + a_1X$.

Its normal equations are

$$\begin{aligned} \sum Y &= Na_0 + a_1 \sum X \\ \sum XY &= a_0 \sum X + a_1 \sum X^2 \end{aligned}$$

Substituting the values

$$24 = 6a_0 + 21a_1$$

$$75 = 21a_0 + 91a_1$$

Solving $a_0 = 5.7999$, $a_1 = -0.51428571$

Thus the least square straight line Y on X is

$$Y = 5.7999 - 0.514X$$

$$Y_{\text{estimate}} = Y(\text{at } X = 4) = 5.7999 - 0.514(4) = 3.743$$

30.6 — HIGHER ENGINEERING MATHEMATICS—VII

Similarly, L.S.S.L. of X on Y is assumed to be

$$X = b_0 + b_1 Y$$

where b_0, b_1 are obtained as solutions of the normal equations

$$\sum X = Nb_0 + b_1 \sum Y$$

$$\sum XY = b_0 \sum Y + b_1 \sum Y^2$$

or $21 = 6b_0 + 24b_1$

$$75 = 24b_0 + 106b_1$$

Solving $b_0 = 7.1, b_1 = -0.9$ so

$$X = 7.1 - 0.94 Y$$

$$X_{\text{estimate}} = X \text{ (at } Y = 4) = 7.1 - 0.9(4) = 3.5.$$

Least squares parabola

Example 2: Fit a least squares quadratic curve to the following data

| | | | | |
|-----|-----|-----|-----|-----|
| X | 1 | 2 | 3 | 4 |
| Y | 1.7 | 1.8 | 2.3 | 3.2 |

Estimate $Y(2.4)$

Solution: Assume the L.S. quadratic curve (parabola) as

$$Y = a_0 + a_1 X + a_2 X^2$$

The normal equations are

$$\sum Y = Na_0 + a_1 \sum X + a_2 \sum X^2$$

$$\sum XY = a_0 \sum X + a_1 \sum X^2 + a_2 \sum X^3$$

$$\sum X^2 Y = a_0 \sum X^2 + a_1 \sum X^3 + a_2 \sum X^4$$

Here $N = 4$

| | X | Y | X^2 | XY | X^3 | X^4 | X^2Y |
|-------|-----|-----|-------|------|-------|-------|--------|
| | 1 | 1.7 | 1 | 1.7 | 1 | 1 | 1.7 |
| | 2 | 1.8 | 4 | 3.6 | 8 | 16 | 7.2 |
| | 3 | 2.3 | 9 | 6.9 | 27 | 81 | 20.7 |
| | 4 | 3.2 | 16 | 12.8 | 64 | 256 | 51.2 |
| Total | 10 | 9.0 | 30 | 25.0 | 100 | 354 | 80.8 |

Substituting these sums into normal equations, we have

$$9.0 = 4a_0 + 10a_1 + 30a_2$$

$$25 = 10a_0 + 30a_1 + 100a_2$$

$$80.8 = 30a_0 + 100a_1 + 354a_2$$

Solving $a_0 = 2, a_1 = -0.5, a_2 = 0.2$

Thus the required L.S. quadratic curve (parabola) is

$$Y(X) = 2 - 0.5X + 0.2X^2$$

$$\text{Estimate: } Y(2.4) = 2 - 0.5(2.4) + 0.2(2.4)^2 = 1.952$$

Inferences based on least square estimates

Example 3: Fit a least squares straight line (L.S.S.L.) to the following data:

$$X: \quad 2 \quad 7 \quad 9 \quad 1 \quad 5 \quad 12$$

$$Y: \quad 13 \quad 21 \quad 23 \quad 14 \quad 15 \quad 21$$

Solution: Here $n = 6, \sum X = 36, \sum Y = 107, \sum X^2 = 304, \sum Y^2 = 2001, \sum XY = 721, \bar{X} = \frac{36}{6} = 6, \bar{Y} = \frac{107}{6} = 17.833$

$$S_{xx} = n \sum_{i=1}^n x_i^2 - \left(\sum x_i \right)^2 = 6(304) - (36)^2 = 528$$

$$S_{yy} = n \sum_{i=1}^n y_i^2 - \left(\sum y_i \right)^2 = 6(2001) - (107)^2 = 557$$

$$S_{xy} = n \sum_{i=1}^n x_i y_i - \left(\sum x_i \right) \left(\sum y_i \right) = 6(721) - (36)(107) = 474$$

$$\text{Regression coefficient } b = \frac{S_{xy}}{S_{xx}} = \frac{474}{528} = 0.8977$$

$$\text{Intercept } a = \bar{Y} - b\bar{X} = (17.8333) - (0.8977)(6) = 12.447$$

$$\text{L.S.S.L: } Y = a + bX = 12.45 + 0.8977X.$$

Example 4: (a) For the above Example 3, find the standard error of estimate s_e . (b) Test for null hypothesis $\beta = 1.2$ against $\beta < 1.2$ at 0.05 level of significance.

Solution: a. The standard error of estimate

$$s_e^2 = \frac{S_{xx} \cdot S_{yy} - (S_{xy})^2}{n(n-2)S_{xx}} = \frac{(528)(557) - (474)^2}{6(6-4)(528)} = 5.47822$$

$$\text{so } s_e = 2.3405596 \approx 2.341$$

b. 1. Null hypothesis: $\beta = 1.2$

2. Alternate hypothesis: $\beta < 1.2$
3. Level of significance: $\alpha = 0.05$
4. Critical region: Left One-tailed test.

Reject N.H. if $t < -t_{\alpha} = -t_{0.05}$ with $n - 2$ degrees of freedom. From t -table $t_{0.05}$ with 4 D.O.F. is 2.132.

Thus reject N.H. if $t < -2.132$

$$\text{where } t = \frac{b - \beta}{s_{\epsilon}} \sqrt{\frac{S_{xx}}{n}}.$$

5. Computation: $n = 6$, $b = 0.8977$, $\beta = 1.2$,

$$s_{\epsilon} = 2.341, S_{xx} = 528 \quad \text{so}$$

$$t = \frac{0.8977 - 1.2}{2.341} \left(\sqrt{\frac{528}{6}} \right) = -1.21137.$$

6. Decision: Accept N.H. (i.e., can not reject N.H.) since $t = -1.21137 > t_{\alpha}$ with 4 D.O.F. $= -2.132$.

Example 5: Construct a 95% confidence interval for (a) α and (b) β , for the above Example 3.

Solution:

- a. 95% confidence limits for α are

$$\begin{aligned} a \pm t_{\alpha/2} s_{\epsilon} \sqrt{\frac{S_{xx} + (n\bar{x})^2}{nS_{xx}}} \\ = 12.45 \pm (2.776)(2.34) \sqrt{\frac{528 + ((6)(6))^2}{6(528)}} \\ = 12.45 \pm 4.93 \end{aligned}$$

Thus the 95% confidence interval for α is

$$(7.52, 17.379)$$

Here for $\alpha = 0.05$, $t_{\alpha/2} = t_{0.025} = 2.776$ from table.

- b. 95% confidence limits for β are

$$\begin{aligned} b \pm t_{\alpha/2} s_{\epsilon} \sqrt{\frac{n}{S_{xx}}} \\ = 0.8977 \pm (2.776)(2.34) \sqrt{\frac{6}{528}} \\ = 0.8977 \pm 0.6925 \end{aligned}$$

Thus the 95% confidence interval for β is

$$(0.205, 1.59).$$

EXERCISE

Inference based on the least squares estimators

1. a. Predict Y at $X = 5$ by fitting a least squares straight line to the following data:

| | | | | | | |
|-----|-----|-----|-----|-----|-----|-----|
| X | 2 | 4 | 6 | 8 | 10 | 12 |
| Y | 1.8 | 1.5 | 1.4 | 1.1 | 1.1 | 0.9 |

- b. Construct a 95% confidence interval for α .
- c. Test null hypothesis $\beta = -0.12$ against $\beta > -0.12$ at 0.01 level of significance.

Hint: $N = 6$, $\sum X = 42$, $\sum Y = 7.8$, $\sum X^2 = 364$, $\sum XY = 48.6$, $\sum Y^2 = 10.68$
 $S_{XX} = 420$, $S_{YY} = 3.24$, $S_{XY} = -36$, $s_{\epsilon} = 0.08017$.

- Ans.* a. $Y(X) = 1.9 - 0.086X$, $Y(5) = 1.47$
 b. confidence interval for α (1.6933, 2.1067)
 c. $t = 3.58$, reject null hypothesis
2. a. Estimate Y at $X = 25$ given that $N = 33$, $\sum X_i = 1104$, $\sum Y_i = 1124$, $\sum X_i Y_i = 41355$, $\sum X_i^2 = 41086$.
 - b. Determine a 95% confidence interval for α , β .
 - c. Test the hypothesis $\beta = 1.0$ against $\beta < 1.0$.
 - d. Test the hypothesis that $\alpha = 0$ against $\alpha \neq 0$ at 0.05 level of significance.

- Ans.* a. $Y = 3.8296 + 0.9036X$, $Y(25) = 26.4196$
 b. $0.8012 < \beta < 1.0061$,
 $0.2132 < \alpha < 7.4461$
 c. reject N.H. $\beta = 1.0$; $t = -1.92$.
 d. reject N.H. $\alpha = 0$; $t = 2.17$.

Hint: $S_{XX} = 4152.18$, $S_{XY} = 3752.09$,
 $s_{\epsilon} = 3.2295$.

3. a. Predict Y when $X = 210$ by fitting a L.S.S.L. to the given data:

| | | | | | | | | | | |
|-----|------|-----|-----|-----|-----|-----|------|------|------|------|
| X | 20 | 60 | 100 | 140 | 180 | 220 | 260 | 300 | 340 | 380 |
| Y | 0.18 | .37 | .35 | .78 | .56 | .75 | 1.18 | 1.36 | 1.17 | 1.65 |

- b. Determine 95% confidence interval for α and β .

- c. Test N.H. $\beta = 0$ against $\beta \neq 0$ at 0.05 level of significance.

Hint: $N = 10$, $\sum X = 2000$, $\sum X^2 = 532000$, $\sum Y = 8.35$, $\sum XY = 21754$

$$S_{XX} = 1320000, S_{YY} = 21.3745, \\ S_{XY} = 5054, S_e = 0.0253.$$

Ans. a. $Y = 0.069 + 0.0038X$, $Y(210) = 0.867$

$$\text{b. } -0.164 < \alpha < 0.302, \\ 0.00348 < \beta < 0.004119$$

c. reject N.H.: $\beta = 0$, ($t = 8.36 > 2.306$)

30.4 CURVILINEAR (OR NONLINEAR) REGRESSION

In simple curvilinear (or nonlinear) regression, the regression equation $y = f(x)$ is non linear. Polynomial, exponential, power, reciprocal functions are some examples of nonlinear functions.

Polynomial Regression

Let $Y = a_0 + a_1X + a_2X^2 + \dots + a_NX^N$

represent a polynomial in X of degree N .

For a given set of N pair of observations (X_i, Y_i) the unknowns $a_0, a_1, a_2, \dots, a_N$ are estimated by least square method by minimizing

$$d_i^2 = \sum_{i=1}^N \left[Y_i - (a_0 + a_1X_i + \dots + a_NX_i^N) \right]^2$$

This results in the following $(N + 1)$ normal equations for the determination of $(N + 1)$ unknowns $a_0, a_1, a_2, \dots, a_N$.

Normal equations

$$\sum Y_i = Na_0 + a_1 \sum X_i + a_2 \sum X_i^2 + \\ \dots + a_N \sum X_i^N$$

$$\sum X_i Y_i = a_0 \sum X_i + a_1 \sum X_i^2 + a_2 \sum X_i^3 + \\ \dots + a_N \sum X_i^{N+1}$$

$$\dots$$

$$\sum X_i^N Y_i = a_0 \sum X_i^N + a_1 \sum X_i^{N+1} + a_2 \sum X_i^{N+2}$$

$$+ \dots + a_N \sum X_i^{2N}$$

Some special cases of polynomial curve are:

- a. $N = 2$, parabola or quadratic curve

$$Y = a_0 + a_1X + a_2X^2$$

(generally used for relationship between the production of a crop and the quantity of fertilizer applied/unit area).

- b. $N = 3$, cubic curve

$$Y = a_0 + a_1X + a_2X^2 + a_3X^3$$

- c. $N = 4$, quartic curve

$$Y = a_0 + a_1X + a_2X^2 + a_3X^3.$$

Note: When the exact functional form $f(x)$ of the regression equation is not known, polynomial curve fitting is used.

The following simple curvilinear regression equations such as

- a. Exponential growth curve: $Y = AB^X$

- b. Exponential decay curve: $Y = AB^{-X}$

- c. Power (geometric) curve: $Y = AX^B$

- d. Reciprocal curve: $Y = \frac{1}{A+BX}$

can be transformed to simple linear regression equations by taking logarithms (or by substitution $Y = \frac{1}{Y^*}$ in case of (d)).

For example, taking logarithm $Y = AX^B$, we get

$$\ln Y = \ln A + B \ln X$$

putting $Y^* = \ln Y$, $X^* = \ln X$, $\ln A = A^*$, we have

$$Y^* = A^* + BX^*$$

which is linear X^* and Y^* .

WORKED OUT EXAMPLES

Curvilinear regression

Exponential curve

Example 1: Estimate the chlorine residual in a swimming pool 5 hours after it has been treated with

chemicals by fitting an exponential curve of the form $Y = AB^X$ to the following data:

| | | | | | | |
|-------------------------------------|-----|-----|-----|-----|-----|-----|
| No. of hours X | 2 | 4 | 6 | 8 | 10 | 12 |
| Chlorine residual parts/million Y | 1.8 | 1.5 | 1.4 | 1.1 | 1.1 | 0.9 |

Solution: Taking logarithm of the non-linear curve

$$Y = AB^X,$$

we get $\ln Y = \ln A + X \ln B$

Put $Y^* = \ln Y$, $\ln A = A^*$, $\ln B = B^*$

Then $Y^* = A^* + B^*X$

which is a linear equation in X . Its normal equations are

$$\begin{aligned}\sum Y^* &= NA^* + B^* \sum X \\ \sum XY^* &= A^* \sum X + B^* \sum X^2\end{aligned}$$

| X | Y | $Y^* = \ln Y$ | X^2 | XY^* |
|-------|-----|---------------|-------|----------|
| 2 | 1.8 | 0.5878 | 4 | 0.1756 |
| 4 | 1.5 | 0.4055 | 16 | 1.622 |
| 6 | 1.4 | 0.3365 | 36 | 2.019 |
| 8 | 1.1 | 0.0953 | 64 | 0.7264 |
| 10 | 1.1 | 0.0953 | 100 | 0.953 |
| 12 | 0.9 | -0.10536 | 144 | -1.26432 |
| Total | 42 | 1.415 | 364 | 5.26752 |

From the above table, $N = 6$, $\sum X = 42$, $\sum Y^* = 1.415$, $\sum X^2 = 364$, $\sum XY^* = 5.2675$. Thus the normal equation are

$$1.415 = 6A^* + 42B^*$$

$$5.268 = 42A^* + 364B^*$$

Solving $A^* = 0.3038$, $B^* = -0.02877$

or $A = 2.013$, $B = 0.936$.

The required least squares exponential curve is

$$Y = 2.013(0.936)^X$$

Prediction: chlorine content after 5 hours:

$$Y(X = 5) = 2.013(0.936)^5 = 1.4462 \text{ parts/million}$$

Geometric curve (power function)

Example 2: Fit a power function (geometric curve) of the form $Y = aX^b$ to the following data and estimate Y at $X = 12$:

| | | | | | |
|------------|----|----|-----|----|----|
| Price X | 20 | 16 | 10 | 11 | 14 |
| Demand Y | 22 | 41 | 120 | 89 | 56 |

Solution: Taking logarithm of the equation $Y = aX^b$, we get

$$\ln Y = \ln a + b \ln X$$

put $Y^* = \ln Y$, $A^* = \ln a$, $X^* = \ln X$, then

$$Y^* = A^* + bX^*$$

| X | Y | $X^* = \ln X$ | $Y^* = \ln Y$ | X^{*2} | X^*Y^* |
|-------|-----|---------------|---------------|----------|----------|
| 20 | 22 | 2.996 | 3.091 | 8.9760 | 9.2606 |
| 16 | 41 | 2.77 | 3.7135 | 7.6729 | 10.2864 |
| 10 | 120 | 2.30 | 4.7875 | 5.29 | 11.011 |
| 11 | 89 | 2.398 | 4.4886 | 5.7504 | 10.763 |
| 14 | 56 | 2.64 | 4.02535 | 6.9696 | 10.627 |
| Total | | 13.107 | 20.106 | 34.66 | 51.95 |

$$\text{So } 20.106 = 5A^* + 13.107b$$

$$51.95 = 13.107A^* + 34.66b$$

Solving $A^* = 10.254$, $a = 28491.416$, $b = -2.37948$
Thus the least squares geometric curve is

$$Y = 28491X^{-2.38}$$

Estimate: $Y(X=12) = 28491(12)^{-2.38} = 76.956 \approx 77$.

Reciprocal function

Example 3: Estimate Y at $X = 5$ by fitting a least squares curve of the form $Y = \frac{b}{X(X-a)}$ to the following data:

| | | | | | | | |
|-------|------|------|------|------|------|------|------|
| X : | 3.6 | 4.8 | 6.0 | 7.2 | 8.4 | 9.6 | 10.8 |
| Y : | 0.83 | 0.31 | 0.17 | 0.10 | 0.07 | 0.05 | 0.04 |

Solution: Rewriting the given equation

$$\frac{1}{Y} = -\frac{a}{b}X + \frac{1}{b}X^2$$

30.10 — HIGHER ENGINEERING MATHEMATICS—VII

Put $Y^* = \frac{1}{Y}$, $B^* = \frac{1}{b}$, $A^* = -\frac{a}{b}$
 so $Y^* = A^*X + B^*X^2 = a_2X + a_3X^2$
 where $a_2 = A^*$, $a_3 = B^*$.

The corresponding normal equations are

$$\begin{aligned}\sum Y^* &= a_2 \sum X + a_3 \sum X^2 \\ \sum XY^* &= a_2 \sum X^2 + a_3 \sum X^3 \\ \sum X^2Y^* &= a_2 \sum X^3 + a_3 \sum X^4\end{aligned}$$

Here $N = 7$, $\sum X = 50.4$, $\sum Y^* = 80$

$$\begin{aligned}\sum X^2 &= 403, \quad \sum X^3 = 3484, \quad \sum X^4 = 31758 \\ \sum XY^* &= 709, \quad \sum X^2Y^* = 7893\end{aligned}$$

So $709 = 403a_2 + 3484a_3$

$$7893 = 3484a_2 + 31758a_3$$

Solving $a_2 = -7.5472$, $a_3 = 1.0765$ or
 $a = 2.00562$, $b = 3.77396$

Required equation is

$$Y = \frac{3.774}{X(X-2)}$$

Now $Y(5) = 0.2516$.

EXERCISE

Parabola (quadratic curve)

1. Fit a least squares parabola to the following data:

$$\begin{array}{cccccc} X: & 0.0 & 0.2 & 0.4 & 0.7 & 0.9 & 1.0 \\ Y: & 1.016 & 0.768 & 0.648 & 0.401 & 0.272 & 0.193 \end{array}$$

Hint: $n = 6$, $\sum X = 3.2$, $\sum X^2 = 2.5$,
 $\sum X^3 = 2.144$, $\sum X^4 = 1.9234$,
 $\sum Y = 3.298$, $\sum XY = 1.1313$,
 $\sum X^2Y = 0.74421$.

Ans. $Y = 0.999 - 1.006X + 0.210X^2$

2. Find the quadratic equation that fits the following data by least squares method:

$$\begin{array}{cccccc} X: & 1 & 2 & 3 & 4 & 5 & 6 \\ Y: & 13235 & 11528 & 11600 & 12747 & 14940 & 18400 \end{array}$$

Hint: $n = 6$, $\sum X = 21$, $\sum X^2 = 91$,
 $\sum Y = 82450$, $\sum XY = 307179$,
 $\sum X^3 = 441$, $\sum X^4 = 2275$,
 $\sum X^2Y = 1403599$.

Ans. $Y = 11953 + 531.5X + 153.3X^2$

3. Fit a least squares curve of the form $Y = a_0 + a_2X^2$ for the following data:

$$\begin{array}{cccc} X: & 1 & 2.5 & 3.5 & 4.0 \\ Y: & 3.8 & 15.0 & 26.0 & 33.0 \end{array}$$

Hint: $n = 4$, $\sum X = 11$, $\sum Y = 77.8$,
 $\sum X^2 = 35.5$, $\sum X^4 = 446.125$,
 $\sum X^2Y = 944.05$.

Ans. $Y = 2.27 + 1.93X^2$

4. Using least squares method, fit a second degree polynomial. Estimate Y at $X = 6.5$

$$\begin{array}{cccccccccc} X: & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ Y: & 12.0 & 10.5 & 10.0 & 8.0 & 7.0 & 8.0 & 7.5 & 8.5 & 9.0 \end{array}$$

Hint: $n = 9$, $\sum X = 36$, $\sum X^2 = 204$,
 $\sum X^3 = 1296$, $\sum X^4 = 8772$, $\sum Y = 80.5$,
 $\sum XY = 299$, $\sum X^2Y = 1697$.

Ans. $y = 12.2 - 1.85X + 0.183X^3$, $Y(6.5) = 7.9$

Exponential curve

5. Fit an exponential curve of the form $Y = Ae^{BX}$ for the following data:

$$\begin{array}{cccc} X: & 1 & 2 & 3 & 4 \\ Y: & 7 & 11 & 17 & 27 \end{array}$$

Ans. $Y = 4.48e^{0.45X}$

6. Predict the mean radiation dose at an altitude of 3000 feet by fitting an exponential curve to the given data:

| Altitude x | 50 | 450 | 780 | 1200 | 4400 | 4800 | 5300 |
|-----------------------|----|-----|-----|------|------|------|------|
| Dose of radiation y | 28 | 30 | 32 | 36 | 51 | 58 | 69 |

Ans. $Y = 4.26737e^{1.000067X}$

(or $\ln Y = 1.4512 + 0.000067X$)

$Y(\text{at } X = 3000) = 44.9$

7. Estimate Y at $X = 7$ by fitting $Y = AB^X$ to the data below:

| | | | | | | | |
|-------------------------------------|----|----|----|----|-----|-----|-----|
| Number of
hours X | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
| No. of bacteria/
unit volume Y | 32 | 47 | 65 | 92 | 132 | 190 | 275 |

Ans. $Y = 32.14(1.427)^X$, $Y(7) = 387.3$

8. Fit an exponential curve by least squares

| | | | | | | | | |
|-------|------|------|------|------|------|------|------|------|
| X : | 1 | 2 | 5 | 10 | 20 | 30 | 40 | 50 |
| Y : | 98.2 | 91.7 | 81.3 | 64.0 | 36.4 | 32.6 | 17.1 | 11.3 |

Estimate Y when $X = 25$.

Ans. $Y = 100(0.96)^X$, $Y(25) = 33.9$

Geometric curve: $Y = AX^B$

9. Estimate γ by fitting the ideal gas law $PV^\gamma = c$ to the following data:

| | | | | | | |
|---|------|------|------|-------|-------|-------|
| Pressure P
(lb/in ²) (Y) | 16.6 | 39.7 | 78.5 | 115.5 | 195.3 | 546.1 |
| Volume V
(in ³) (X) | 50 | 30 | 20 | 15 | 10 | 5 |

Hint: $n = 6$, $\sum X = 7.352$, $\sum Y = 11.805$,
 $\sum X^2 = 9.63$, $\sum XY = 13.53$.

Ans. $\gamma = 1.504$, $c = 6476.33$

10. Fit a power function $Y = aX^b$ to the following data pertaining to demand for a product and its price charged at five different cities. Predict the demand when the price of the product is Rs. 12.

| | | | | | |
|----------------------------|----|----|-----|----|----|
| Price (Rs.) X | 20 | 16 | 10 | 11 | 14 |
| Demand
(1000 units) Y | 22 | 41 | 120 | 89 | 56 |

Ans. $a = 28491$, $b = -2.38$, $Y(12) = 76.9560$

11. Fit a geometric curve to the following data:

| | | | | |
|-------|---|---|---|---|
| X : | 1 | 2 | 4 | 6 |
| Y : | 6 | 4 | 2 | 2 |

Estimate $Y(2.5)$.

Hint: $n = 4$, $\sum X^* = \ln X = 3.87$,
 $\sum X^{*2} = 5.6$, $\sum Y^* = \ln Y = 4.56$,
 $\sum X^*Y^* = 3.16$.

Ans. $Y = 5.965X^{-0.672}$, $Y(2.5) = 3.2225$

12. Predict Y at $X = 3.75$ by fitting a power curve to the given data:

| | | | | | | |
|-------|------|------|------|------|------|------|
| X : | 1 | 2 | 3 | 4 | 5 | 6 |
| Y : | 2.98 | 4.26 | 5.21 | 6.10 | 6.80 | 7.50 |

Hint: $n = 6$, $\sum X^* = \sum \ln X = 2.8574$,
 $\sum Y^* = \sum \ln Y = 4.3133$, $\sum X^{*2} = 1.7749$,
 $\sum X^*Y^* = 2.2671$.

Ans. $Y = 2.978X^{0.5143}$, $Y(3.75) = 5.8769$

Reciprocal function

13. Estimate Y at $X = 2.25$ by fitting an indifference curve of the form $XY = AX + B$ to the following data:

| | | | | |
|-------|---|-----|---|-----|
| X : | 1 | 2 | 3 | 4 |
| Y : | 3 | 1.5 | 6 | 7.5 |

Hint: $Y = A + \frac{B}{X}$, put $X^* = \frac{1}{X}$, then
 $Y = A + BX^*$.

Ans. $XY = 1.3X + 1.7$, $Y(2.25) = 4.625$.

30.5 CURVE FITTING BY A SUM OF EXPONENTIALS

For a given set of data points

$$(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n),$$

consider

$$\begin{aligned} f(x) &= \sum_{i=1}^n A_i e^{\lambda_i x} \\ &= A_1 e^{\lambda_1 x} + A_2 e^{\lambda_2 x} + \dots + A_n e^{\lambda_n x} \end{aligned} \quad (1)$$

be a sum of exponentials. The unknowns A_i and λ_i are determined since f in (1) satisfies the n th order differential equation

$$\frac{d^n y}{dx^n} + a_1 \frac{d^{n-1} y}{dx^{n-1}} + a_2 \frac{d^{n-2} y}{dx^{n-2}} + \dots + a_n y = 0 \quad (2)$$

30.12 — HIGHER ENGINEERING MATHEMATICS—VII

Here the coefficients $a_1, a_2 \dots a_n$ are unknown constants. Froberg (1965) suggested the derivatives $y^{(n)}, y^{(n-1)} \dots$ at n data points are evaluated numerically and then substituted in (2) thus obtaining a system of n linear equation for the n unknowns $a_1, a_2, \dots a_n$. The unknown constants $\lambda_1, \lambda_2, \dots \lambda_n$ are obtained as the roots of the algebraic equation

$$\lambda^n + a_1\lambda^{n-1} + a_2\lambda^{n-2} + \dots + a_n = 0$$

Using the averaging technique, the unknown constants $A_1, A_2 \dots A_n$ are calculated from (1) or using least squares method. However the disadvantage in this method is the calculation of higher order derivatives, involving round off errors, resulting in unreliable values.

The following procedure is a modification of an earlier method due to prony [see Clenshaw (1970)]. Let us assume that $f(x)$ is the sum of two exponentials i.e.,

$$y = f(x) = A_1e^{-\lambda_1x} + A_2e^{-\lambda_2x} \quad (3)$$

The data points y_i are given at $x = 0, h, 2h, 3h$ i.e., $x = ih$, for $i = 0, 1, 2, 3$ where $h =$ spacing constant.

Substituting the set of four data points $(x_0, y_0), (x_1, y_1), (x_2, y_2), (x_3, y_3)$ in (3), we get

$$y_i = f(x_i) = A_1e^{-\lambda_1(ih)} + A_2e^{-\lambda_2(ih)} \quad (4)$$

Introducing $\eta_j = e^{-\lambda_jh}$ for $j = 1, 2$, (5) we rewrite (4) as

$$y_i = A_1(e^{-\lambda_1h})^i + A_2(e^{-\lambda_2h})^i$$

$$y_i = A_1n_1^i + A_2n_2^i \quad \text{for } i = 0, 1, 2, 3 \quad (6)$$

Here n_1 and n_2 are real positive roots of the quadratic

$$1 + p_1\eta + p_2\eta^2 = 0 \quad (7)$$

From (6)

$$y_{i+1} = A_1\eta_1^{i+1} + A_2\eta_2^{i+1}$$

or

$$y_{i+1} = A_1\eta_1\eta_1^i + A_2\eta_2\eta_2^i \quad (8)$$

From (6)

$$y_{i+2} = A_1\eta_1^{i+2} + A_2\eta_2^{i+2}$$

or

$$y_{i+2} = A_1\eta_1^2\eta_1^i + A_2\eta_2^2\eta_2^i \quad (9)$$

Adding (6), (8), (9) we get

$$\begin{aligned} y_i + y_{i+1} \cdot p_1 + p_2 y_{i+2} &= (A_1n_1^i + A_2n_2^i) \\ &\quad + p_1(A_1n_1n_1^i + A_2n_2n_2^i) \\ &\quad + p_2(A_1n_1^2n_1^i + A_2n_2^2n_2^i) \\ &= A_1n_1^i(1 + p_1n_1 + p_2n_1^2) \\ &\quad + A_2n_2^i(1 + p_2n_2 + n_2^2p_2) \end{aligned}$$

since n_1 and n_2 are roots of (7), the R.H.S. above reduces to zero yielding

$$\boxed{y_i + y_{i+1} \cdot p_1 + p_2 y_{i+2} = 0} \quad (10)$$

For $i = 0, 1$, from (10), we have

$$y_0 + p_1y_1 + p_2y_2 = 0 \quad (11)$$

$$y_1 + p_2y_2 + p_2y_3 = 0 \quad (12)$$

Substituting the given data y_0, y_1, y_2, y_3 in (11) and (12) and solving we get p_1 and p_2 . With these values of p_1 and p_2 , the quadratic equation (7) yields the two roots n_1 and n_2 . From (5) we determine λ_j as

$$\lambda_j = -\frac{1}{h} \ln(n_j) \quad \text{for } j = 1, 2 \quad (13)$$

Now to determine A_1 and A_2 we substitute the values of y_i and n_1 and n_2 in (6).

For $i = 0, 1, 2, 3$, we have

$$A_1 + A_2 = y_0$$

$$A_1n_1 + A_2n_2 = y_1$$

$$A_1n_1^2 + A_2n_2^2 = y_2$$

$$A_1n_1^3 + A_2n_2^3 = y_3$$

Introducing

$$P = \begin{bmatrix} 1 & 1 \\ n_1 & n_2 \\ n_1^2 & n_2^2 \\ n_1^3 & n_2^3 \end{bmatrix}_{4 \times 2}, \quad B = \begin{bmatrix} y_0 \\ y_1 \\ y_2 \\ y_3 \end{bmatrix}_{4 \times 1}$$

and

$$A = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix}_{2 \times 1}$$

the above system of 4 linear equations in 2 unknowns can be written as

$$PA = B. \quad (14)$$

Now premultiplying (14) by P^T , this overdetermined system can be solved.

$$P^T P A = P^T B$$

or $CA = D$
 where $C_{2 \times 2} = P_{2 \times 4}^T P_{4 \times 2}$
 and

$$D_{2 \times 1} = P_{2 \times 4}^T B_{4 \times 1}$$

Now

$$A_{2 \times 1} = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} = C_{2 \times 2}^{-1} D_{2 \times 1} \quad (15)$$

Putting the values of A_1, A_2 from (15) and λ_1, λ_2 from (13) in (3), we get the required fit by sum of exponentials.

Another computational technique, due to Moore (1974, *Int. J. Num. meth. in Engg.*, Vol. 8, p. 271) is presented here. It gives reliable results but involves more (numerical integration) computation. Consider a function

$$y(x) = A_1 e^{\lambda_1 x} + A_2 e^{\lambda_2 x} \quad (16)$$

which is the sum of two exponentials. Function (16) satisfies the second order differential equation

$$\frac{d^2 y}{dx^2} = a_1 \frac{dy}{dx} + a_2 y \quad (17)$$

Here a_1, a_2 are unknown constants to be determined. Assuming 'a' as the initial value of x , integrate (17) from 'a' to x . Then

$$\frac{dy}{dx} - \frac{dy(a)}{dx} = a_1 y(x) - a_1 y(a) + a_2 \int_a^x y(x) dx$$

Integrating the above equation again from 'a' to x we get

$$\begin{aligned} y(x) - y(a) - y'(a) \cdot (x - a) &= a_1 \int_a^x y(x) dx \\ &\quad - a_1(x - a)y(a) \\ &\quad + a_2 \int_a^x \int_a^x y(x) dx \, dx \end{aligned} \quad (18)$$

Since

$$\int_a^x \int_a^x \cdots \int_a^x f(x) dx \cdots dx = \frac{1}{(n-1)!} \int_a^x (x-t)^{n-1} f(t) dt$$

equation (18) reduces to

$$\begin{aligned} y(x) - y(a) - (x - a)y'(a) &= a_1 \int_a^x y(x) dx \\ &\quad - a_1(x - a)y(a) \\ &\quad + a_2 \int_a^x (x - t)y(t) dt \end{aligned} \quad (19)$$

Choosing two data points x_1 and x_2 such that $a - x_1 = x_2 - a$, we obtain from (19)

$$\begin{aligned} y(x_1) - y(a) - (x_1 - a)y'(a) &= a_1 \int_a^{x_1} y(x) dx \\ &\quad - a_1(x_1 - a)y(a) \\ &\quad + a_2 \int_a^{x_1} (x_1 - t)y(t) dt \end{aligned}$$

and

$$\begin{aligned} y(x_2) - y(a) - (x_2 - a)y'(a) &= a_1 \int_a^{x_2} y(x) dx \\ &\quad - a_1(x_2 - a)y(a) \\ &\quad + a_2 \int_a^{x_2} (x_2 - t)y(t) dt \end{aligned}$$

Eliminating $y'(a)$ from the above two equations we get

$$\begin{aligned} y(x_1) + y(x_2) - 2y(a) &= a_1 \left[\int_a^{x_1} y(x) dx + \int_a^{x_2} y(x) dx \right] \\ &\quad + a_2 \left[\int_a^{x_1} (x_1 - t)y(t) dt \right. \\ &\quad \left. + \int_a^{x_2} (x_2 - t)y(t) dt \right] \end{aligned} \quad (20)$$

For a choice of two pairs of (x_1, x_2) , equation (20) yields two linear equations in a_1 and a_2 , which are solved for a_1 and a_2 . The values of λ_1 and λ_2 are obtained from $\lambda^2 = a_1 \lambda + a_2$. Finally the values of A_1 and A_2 are obtained by the method of least squares.

WORKED OUT EXAMPLES

Example 1: Fit a curve by a sum of exponentials to the following data

30.14 — HIGHER ENGINEERING MATHEMATICS—VII

| | | | | |
|------|-------|-------|-------|-------|
| $x:$ | 0 | 0.1 | 0.2 | 0.3 |
| $y:$ | 1.175 | 1.336 | 1.510 | 1.693 |

Solution: Assume that

$$y = f(x) = A_1 e^{-\lambda_1 x} + A_2 e^{-\lambda_2 x} \quad (1)$$

be a sum of two exponentials. We should determine the four unknown constants A_1 , A_2 , λ_1 , λ_2 by fitting the given data to (1). Here the data x_i is evenly spaced. $x_i = x_0 + ih = 0 + ih = 0 + i(0.1)$ for $i = 0, 1, 2, 3$.

Here $h = 0.1$

Substituting the set of data points

$$(x_0 = 0, y_0 = 1.175), (x_1 = 0.1, y_1 = 1.336),$$

$$(x_2 = 0.2, y_2 = 1.510), (x_3 = 0.3, y_3 = 1.698),$$

in the equation (1), we get

$$y_i = f(x_i) = A_1 e^{-\lambda_1 x_i} + A_2 e^{-\lambda_2 x_i}$$

$$y_i = A_1 e^{-\lambda_1 ih} + A_2 e^{-\lambda_2 ih}$$

for $i = 0, 1, 2, 3$.

Put $n_s = e^{-\lambda_s h}$ for $s = 1, 2$

Then

$$y_i = A_1 n_1^i + A_2 n_2^i \quad \text{for } i = 0, 1, 2, 3.$$

Using

$$y_i + p_1 y_{i+1} + p_2 y_{i+2} = 0 \quad \text{for } i = 0, 1$$

we get

$$y_0 + p_1 y_1 + p_2 y_2 = 0$$

and

$$y_1 + p_1 y_2 + p_2 y_3 = 0$$

For the given data

$$1.175 + 1.336p_1 + 1.510p_2 = 0$$

and

$$1.336 + 1.510p_1 + 1.698p_2 = 0$$

solving $p_1 = -1.9193$, $p_2 = 0.91998$

substituting p_1 , p_2 in

$$1 + np_1 + n^2 p_2 = 0$$

we get

$$1 - 1.9193n + 0.92n^2 = 0$$

with roots $n_1 = 1.0762$, $n_2 = 1.01$. To determine A_1 and A_2 , use

$$y_i = A_1 n_1^i + A_2 n_2^i, i = 0, 1, 2, 3$$

thus

$$y_0 = A_1 + A_2$$

$$y_1 = A_1 n_1 + A_2 n_2$$

$$y_2 = A_1 n_1^2 + A_2 n_2^2$$

$$y_3 = A_1 n_1^3 + A_2 n_2^3$$

yielding

$$A_1 + A_2 = 1.75$$

$$1.076A_1 + 1.01A_2 = 1.336$$

$$1.1578A_1 + 1.02A_2 = 1.510$$

$$1.246A_1 + 1.03A_2 = 1.698$$

$$\text{or } PA = B$$

where

$$\begin{bmatrix} 1 & 1 \\ 1.076 & 1.01 \\ 1.1578 & 1.02 \\ 1.246 & 1.03 \end{bmatrix} \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} = \begin{bmatrix} 1.75 \\ 1.336 \\ 1.510 \\ 1.698 \end{bmatrix}$$

$$PA = B$$

This overdetermined system can be solved by pre-multiplying both sides by P^T .

$$P^T PA = P^T B$$

Here

$$C = P^T P = \begin{bmatrix} 1 & 1.076 & 1.578 & 1.246 \\ 1 & 1.01 & 1.02 & 1.03 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1.076 & 1.01 \\ 1.1578 & 1.02 \\ 1.246 & 1.03 \end{bmatrix}$$

$$C = \begin{bmatrix} 6.2 & 4.98 \\ 4.98 & 4.12 \end{bmatrix}$$

$$P^T B = \begin{bmatrix} 1 & 1.076 & 1.578 & 1.246 \\ 1 & 1.01 & 1.02 & 1.03 \end{bmatrix} \begin{bmatrix} 1.75 \\ 1.336 \\ 1.510 \\ 1.698 \end{bmatrix}$$

$$= \begin{bmatrix} 7.111 \\ 5.8135 \end{bmatrix}$$

From

$$CA = P^T B$$

$$A = C^{-1} P^T B$$

Now

$$C^{-1} = (1.345) \begin{bmatrix} 4.12 & -4.98 \\ -4.98 & 6.2 \end{bmatrix}$$

Then

$$A = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} = C^{-1}(P^T B)$$

$$= (1.345) \begin{bmatrix} 4.12 & -4.98 \\ -4.98 & 6.2 \end{bmatrix} \begin{bmatrix} 7.111 \\ 5.8135 \end{bmatrix}$$

$$\begin{bmatrix} A_1 \\ A_2 \end{bmatrix} = \begin{bmatrix} 0.4655 \\ 0.8486 \end{bmatrix}$$

Thus, $A_1 = 0.4655$, $A_2 = 0.8486$. Now

$$1.0762 = n_1 = e^{-\lambda_1(0.1)} \quad \text{or} \quad \lambda_1 = -0.3189$$

$$1.01 = n_2 = e^{-\lambda_2(0.1)} \quad \text{or} \quad \lambda_2 = -0.0995$$

Thus the required curve, which is a sum of exponentials, is

$$y = 0.4655e^{0.3189x} + 0.8486e^{0.0995x}$$

Example 2: Fit a function $y = f(x) = A_1e^{\lambda_1x} + A_2e^{\lambda_2x}$, a sum of exponentials to the following data using the Moore technique.

| | | | | | |
|------|-------|-------|-------|-------|------|
| $x:$ | 2 | 2.2 | 2.4 | 2.6 | 2.8 |
| $y:$ | 3.63 | 4.46 | 5.47 | 6.70 | 8.19 |
| $x:$ | 3.0 | 3.2 | 3.4 | 3.6 | |
| $y:$ | 10.02 | 12.25 | 14.97 | 18.29 | |

Solution: Choose $x_1 = 2.0$, $x_2 = 2.8$ such that $a - x_1 = x_2 - a$ i.e., $a - 2.0 = 2.8 - a \therefore a = 2.4$.

Using equation (20), we get

$$y(2) + y(2.8) - 2y(2.4) = a_1 \left[\int_{2.4}^2 y(x)dx + \int_{2.4}^{2.8} y(x)dx \right]$$

$$+ a_2 \left[\int_{2.4}^2 (2 - t)y(t)dt \right]$$

$$+ \left[\int_{2.4}^{2.8} (2.8 - t)y(t)dt \right]$$

The integrals on the RHS are evaluated using Simpson's $\frac{1}{3}$ rule, on two intervals with three points. For example:

$$I_1 = - \int_2^{2.4} y(x)dx = - \frac{0.2}{3} [3.63 + 4(4.46) + 5.47]$$

$$I_2 = \int_{2.4}^{2.8} y(x)dx = \frac{0.2}{3} [5.47 + 4(6.70) + 8.19]$$

$$I_3 = - \int_2^{2.4} (2 - t)y(t)dt$$

$$I_3 = - \frac{0.2}{3} [(2 - 2)3.63 + 4(2 - 2.2)4.46 + (2 - 2.4)5.47]$$

$$I_4 = \frac{0.2}{3} [(2.8 - 2.4)5.47 + 4(2.8 - 2.6)6.70 + (2.8 - 2.8)8.19]$$

etc.

After simplification this yields one equation for a_1 and a_2 as

$$0.88 = 0.90a_1 + 0.887a_2 \quad (1)$$

Similarly choosing $x_1 = 2.8$, $x_2 = 3.6$, we get from $a - x_1 = x_2 - a$, $a - 2.8 = 3.6 - a$ as $a = 3.2$. Substituting this data in (20), we get

$$y(2.8) + y(3.6) - 2y(3.2) = a_1 \left[\int_{3.2}^{2.8} y(x)dx + \int_{3.2}^{3.6} y(x)dx \right]$$

$$+ a_2 \left[\int_{3.2}^{2.8} (2.8 - t)y(t)dt \right]$$

$$+ \left[\int_{3.2}^{3.6} (3.6 - t)y(t)dt \right]$$

After evaluation of R.H.S. integrals using Simpson's $\frac{1}{3}$ rule we get second equation for a_1 and a_2 as

$$1.98 = 0.6733a_1 + 1.986133a_2 \quad (2)$$

solving (1) and (2), we get

$$a_1 = 0.0071115, a_2 = 0.999324$$

substituting a_1, a_2 in $\lambda^2 - a_1\lambda - a_2 = 0$, we get

$$\lambda^2 + 0.007\lambda - 0.9993 = 0$$

whose roots are $\lambda_1 = -1.0031$ and $\lambda_2 = 0.99615$.

The equation takes the form

$$y = A_1e^{-1.0031x} + A_2e^{0.99615x}$$

$$= A_1e^{-x} + A_2e^{0.99x}$$

The values of A_1 and A_2 are determined by method of least squares by solving the two normal equations.

30.16 — HIGHER ENGINEERING MATHEMATICS—VII

$$A_1 \sum_{k=1}^9 e^{-2x_k} + A_2 \sum_{k=1}^9 e^{-0.01x_k} = \sum_{k=1}^9 y_k \cdot e^{-x_k}$$

and

$$A_1 \sum_{k=1}^9 e^{-0.01x_k} + A_2 \sum_{k=1}^9 e^{1.98x_k} = \sum_{k=1}^9 y_k \cdot e^{0.99x_k}$$

The values of $A_1 = -0.51$, $A_2 = 0.4999$, thus the required function is

$$y = f(x) = -0.51e^{-x} + 0.499e^x$$

Note that the given data is obtained by taking the exact function $y = \sin hx$ whose values are rounded off to two decimal places.

EXERCISE

1. Fit a curve by a sum of exponentials,

$$y = A_1 e^{-\lambda_1 x} + A_2 e^{-\lambda_2 x}$$

| | | | | |
|----|-------|-------|-------|-------|
| x: | 0 | 0.2 | 0.4 | 0.6 |
| y: | 2.513 | 1.123 | 0.534 | 0.272 |

Ans. $p_1 = -4.1307$, $p_2 = 3.9809$,

$$n_1 = 0.6529, n_2 = 0.3848,$$

$$A_1 = 0.5810, A_2 = 1.9322, \lambda_1 = 2.1316, \lambda_2 = -4.7712$$

$$y = 0.5810e^{-2.1316x} + 1.9322e^{4.7712x}$$

Exact function:

$$f(x) = 0.0951e^{-x} - 0.8607e^{-3x} + 1.5576e^{-5x}$$

$$P = \begin{bmatrix} 1 & 1 \\ 0.6529 & 0.3848 \\ 0.4263 & 0.1481 \\ 0.2783 & 0.0570 \end{bmatrix}, P^T P = \begin{bmatrix} 1.6855 & 1.3302 \\ 1.3302 & 1.1732 \end{bmatrix}$$

2. Fit $y = f(x) = A_1 e^{\lambda_1 x} + A_2 e^{\lambda_2 x} + A_3 e^{\lambda_3 x}$ to the following data.

| | | | | | | |
|----|--------|--------|--------|--------|--------|--------|
| x: | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 | 1.5 |
| y: | -1.543 | -1.668 | -1.811 | -1.971 | -2.151 | -2.352 |
| x: | 1.6 | 1.7 | 1.8 | 1.9 | 2.0 | |
| y: | -2.578 | -2.828 | -3.108 | -3.418 | -3.762 | |

Ans. $A_1 = \frac{1}{2}$, $A_2 = -\frac{1}{2}$, $A_3 = -\frac{1}{2}$, $\lambda_1 = 1$, $\lambda_2 = -1$, $\lambda_3 = -1$

3. Fit a function of the form $y = A_1 e^{\lambda_1 x} + A_2 e^{\lambda_2 x}$ to the following data:

| | | | | | |
|----|------|------|------|------|------|
| x: | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 |
| y: | 1.54 | 1.67 | 1.81 | 1.97 | 2.15 |
| x: | 1.5 | 1.6 | 1.7 | 1.8 | |
| y: | 2.35 | 2.58 | 2.83 | 3.11 | |

Ans. $A_1 = 0.499$, $A_2 = 0.491$, $\lambda_1 = 0.988$, $\lambda_2 = -0.96$
 $y = 0.499e^{0.988x} + 0.491e^{-0.96x}$

Exact function: $y = \cos hx$; with $A_1 = A_2 = \frac{1}{2}$ and $\lambda_1 = 1.0$ and $\lambda_2 = -1.0$

Hint. Solve $1.81a_1 + 2.180a_2 = 2.10$ and $2.88a_1 + 3.104a_2 = 3.00$ to get $a_1 = 0.03204$, $a_2 = 0.9364$. Solving $\lambda^2 = a_1\lambda + a_2$ gives λ_1 and λ_2 .

30.6 LINEAR WEIGHTED LEAST SQUARES APPROXIMATION

Data are generally not exact. They are subject to measurement errors (known as noise in signal processing). Modeling of data aims at condensing and summarizing a given set of observations (data) by fitting it to a model, a “merit function” that depends on adjustable parameters. The parameters of the model are then adjusted to achieve a minimum in the merit function, yielding “best-fit” parameters. Least squares fitting is a maximum likelihood estimation of the fitted parameters if the measurement errors are independent and normally distributed with constant standard deviation. The least squares principle is to minimize the sum of the squares of the errors. For a given set of data, it gives a unique solution.

For discrete data $(x_0, y_0), (x_1, y_1), \dots, (x_N, y_N)$, weights w_i are positive numbers prescribed according to the relative accuracy of the data points. When a discrete data point (x^*, y^*) is more reliable (or accurate) than the other data, a larger weight is assigned to (x^*, y^*) . If all the data points have the same accuracy then equal weights are assigned i.e., $w_i = 1$ for $i = 1$ to N .

For continuous (data) function, an integrable function $w(x)$ is called a *weight function* on $[a, b]$ of $w(x) \geq 0$ for $x \in [a, b]$. The purpose of a weight

function is to assign varying degrees of importance to approximations on certain portions of the interval.

Example 1: Weight function $w(x) = (1 - x^2)^{-\frac{1}{2}}$ assigns more emphasis when $|x|$ is near one and less emphasis near the center of the interval $(-1, 1)$.

General weighted least squares approximation:

Suppose the function $y = f(x)$ is known only at $(N + 1)$ tabulated points $(x_0, y_0), (x_1, y_1), \dots, (x_N, y_N)$ in the form a discrete data, with weights $w_1, w_2, \dots, w_N$; respectively.

$$\begin{array}{cccccc} x: & x_0 & x_1 & x_2 & \dots & x_N \\ y & y_0 & y_1 & y_2 & \dots & y_N \\ w: & w_0 & w_1 & w_2 & \dots & w_N \end{array}$$

Then the function $f(x)$ can be approximated by a function of the form

$$p(x) = a_0\phi_0(x) + a_1\phi_1(x) + \dots + a_m\phi_m(x) \quad (1)$$

where the set of functions $\{\phi_0, \phi_1, \dots, \phi_m\}$ are linearly independent. These functions $\phi_i(x)$ are known as “basis” or “coordinate” functions, can be wildly non-linear functions of x , usually chosen as $\phi_i(x) = x^i$ for $i = 0, 2, \dots, m$. The function $p(x)$ is said to be the weighted least squares approximation of $f(x)$ if the $(m + 1)$ unknown coefficients $a_0, a_1, \dots, a_m$ in (1) are determined such that the error of approximation

$$E(a_0, a_1, \dots, a_m) = \sum_{k=0}^N w_k \left[f(x_k) - \sum_{i=0}^m a_i \phi_i(x_k) \right]^2 \quad (2)$$

is minimum. The necessary conditions for the numbers $a_0, a_1, a_2, \dots, a_m$ to minimize E are

$$\frac{\partial E}{\partial a_j} = 0 \quad \text{for } j = 0, 1, 2, \dots, m$$

Differentiating (2) partially wrt a_j , we get $(m + 1)$ linear equations in $(m + 1)$ unknown $a_0, a_1, \dots, a_m$, known as *normal equations* given by

$$\sum_{k=0}^N w_k \left[f(x_k) - \sum_{i=0}^m a_i \phi_i(x_k) \right]^2 \phi_j(x_k) \quad (3)$$

for $j = 0, 1, 2, \dots, m$. When the function $f(x)$ is known continuous function on $[a, b]$ then the nor-

mal equations take the form

$$\int_a^b w(x) \left[f(x) - \sum_{i=0}^m a_i \phi_i(x) \right] \phi_j(x) dx = 0$$

for $j = 0, 1, \dots, m$ (4)

Discrete (Data) Case

Suppose

$$P_1(x) = a_0 + a_1x \quad (5)$$

be the linear weighted least squares straightened line fitted to the following discrete data

$$\begin{array}{cccccc} x: & x_0 & x_1 & x_2 & \dots & x_N \\ y: & y_0 & y_1 & y_2 & \dots & y_N \\ w: & w_0 & w_1 & w_2 & \dots & w_N \end{array}$$

In (1) we have taken $m = 1$ and $\phi_1(x) = x$. Then normal equations (3) reduce to

$$\begin{aligned} a_0 \sum_{i=0}^N w_i + a_1 \sum_{i=0}^N w_i x_i &= \sum_{i=0}^N w_i y_i & (6) \\ a_0 \sum_{i=0}^N w_i x_i + a_1 \sum_{i=0}^N w_i x_i^2 &= \sum_{i=0}^N w_i x_i y_i & (7) \end{aligned}$$

Solving (6) and (7) we get a_0 and a_1 which when substituted in (5) gives the required linear weighted least squares approximation.

Continuous Function (Case)

Suppose $f(x)$ is a known continuous function defined on the interval $[a, b]$, then the normal equations (4) reduce to

$$\begin{aligned} a_0 \int_a^b w(x) dx + a_1 \int_a^b x \cdot w(x) dx &= \int_a^b w(x) y(x) dx & (8) \\ a_0 \int_a^b x w(x) dx + a_1 \int_a^b x^2 w(x) dx &= \int_a^b x w(x) y(x) dx & (9) \end{aligned}$$

Solving (8) and (9), we get a_0 and a_1 . Substituting these values in $y = a_0 + a_1x$ we get the linear weighted least squares approximation in the continuous case.

WORKED OUT EXAMPLES

Linear Weighted Least Squares Approximation

Example 1: (Discrete Data) Fit a linear weighted least squares straight line to the following data

| | | | | | |
|------|----|---|----|---|----|
| $x:$ | -2 | 0 | 2 | 4 | 6 |
| $y:$ | 1 | 3 | 6 | 8 | 13 |
| $w:$ | 2 | 5 | 10 | 1 | 4 |

Solution: Let $y = a_0 + a_1x$ be the LS line. Then the normal equations are

$$a_0 \sum_{i=1}^5 w_i + a_1 \sum_{i=1}^5 w_i x_i = \sum_{i=1}^5 w_i y_i$$

and

$$a_0 \sum w_i x_i + a_1 \sum w_i x_i^2 = \sum w_i x_i y_i$$

| x | y | w | wx | wx^2 | wy | wxy |
|----------|-----|-----|------|--------|------|-------|
| -2 | 1 | 2 | -4 | 8 | 2 | -4 |
| 0 | 3 | 5 | 0 | 0 | 15 | 0 |
| 2 | 6 | 10 | 20 | 40 | 60 | 120 |
| 4 | 8 | 1 | 4 | 16 | 8 | 32 |
| 6 | 13 | 4 | 24 | 144 | 52 | 312 |
| Σ | | 22 | 44 | 208 | 137 | 460 |

Thus $N = 5$, $\sum_{i=1}^5 w_i = 22$, $\sum w_i x_i = 44$,
 $\sum w_i x_i^2 = 208$, $\sum w_i y_i = 137$, $\sum w_i x_i y_i = 460$.
 The two normal equations are

$$\begin{aligned} 22a_0 + 44a_1 &= 137 \\ 44a_0 + 208a_1 &= 460 \end{aligned}$$

Solving $a_1 = 1.55$, $a_0 = 3.127$. Thus the linear weighted least squares straight line fit to the given data is

$$y = 3.127 + 1.55x$$

At $x = 1$, $y(1) = 4.677$

Note: Linear (non-weighted) least squares line for the above data (with weights $w_1 = w_2 = w_3 = w_4 = w_5 = 1$) is

$$y = 3.30 + 1.45x$$

and $y(1) = 4.75$.

Example 2: (Continuous function) Fit a linear weighted least squares straight line to the function: $f(x) = \frac{1}{x}$ on $[1, 3]$ with $w(x) = 1$.

Solution: Let $y = a_0 + a_1x$ be the L.S. straight line. The normal equations are

$$a_0 \int_1^3 dx + a_1 \int_1^3 x dx = \int_1^3 \frac{1}{x} dx$$

$$a_0 \int_1^3 x dx + a_1 \int_1^3 x^2 dx = \int_1^3 x \cdot \frac{1}{x} dx$$

or

$$2a_0 + 4a_1 = \ln 3$$

$$4a_0 + \frac{26}{3}a_1 = 2$$

Solving $a_1 = -0.2959$, $a_0 = 1.140$. The required linear LS line is

$$y = 1.140 - 0.2958x$$

At $x = 2$, $y(2) = 0.5484$. At $x = 2$, $f(x) = \frac{1}{x}$, $f(\frac{1}{2}) = 0.50$.

EXERCISE

Linear Weighted Least Squares Approximation (Discrete Data)

Fit a linear weighted least squares straight line $y = a + bx$ for the following data with the appropriate given weights.

| | | | | | | |
|----|-------|----|----|---|---|---|
| 1. | $x :$ | -2 | -1 | 0 | 1 | 2 |
| | $y :$ | 1 | 2 | 3 | 3 | 4 |
| | $w :$ | 1 | 2 | 3 | 4 | 5 |

Ans. $y = 2.63 + 0.657x$, $y(\frac{1}{2}) = 2.9585$. Without weights i.e., $w_1 = w_2 = w_3 = w_4 = w_5 = 1$, $y = y\frac{1}{2}$

Hint: $\sum w_i = 15$, $\sum w_i x_i = 10$, $\sum w_i x_i^2 = 30$, $\sum w_i y_i = 46$, $\sum w_i x_i y_i = 46$

| | | | | | | |
|----|-------|-----|-----|-----|-----|------|
| 2. | $x :$ | -4 | -2 | 0 | 2 | 4 |
| | $y :$ | 1.2 | 2.8 | 6.2 | 7.8 | 13.2 |
| | $w :$ | 2 | 3 | 5 | 3 | 2 |

Ans. $y = 6.1 + 1.43x$, $y(1) = 7.53$. Without weights i.e., $w_1 = w_2 = w_3 = w_4 = w_5 = 1$, $y = y(1)$

Hint: $\sum w_i = 15$, $\sum w_i x_i = 0$, $\sum w_i y_i = 91.6$, $\sum w_i x_i^2 = 88$, $\sum w_i x_i y_i = 126$

$$\begin{array}{lcl} 3. & x : & 0 \quad 1 \quad 3 \quad 6 \quad 8 \\ & y : & 1 \quad 3 \quad 2 \quad 5 \quad 4 \\ & w : & 1 \quad 2 \quad 10 \quad 2 \quad 1 \end{array}$$

Ans. $y = 1.2 + 0.42x$

Hint: $\sum w_i = 16$, $\sum w_i x_i = 52$, $\sum w_i y_i = 41$, $\sum w_i x_i^2 = 228$, $\sum w_i x_i y_i = 158$

$$\begin{array}{lcl} 4. & x : & 0 \quad 2 \quad 5 \quad 7 \\ & y : & -1 \quad 5 \quad 12 \quad 20 \\ & w : & 1 \quad 1 \quad 10 \quad 1 \end{array}$$

Ans. $y = -1.349345 + 2.73799x$, $y(5) = 12.34061$

Hint: $\sum w_i = 13$, $\sum w_i x_i = 59$, $\sum w_i x_i^2 = 303$, $\sum w_i y_i = 144$, $\sum w_i x_i y_i = 750$. Without weights i.e., $w_1 = w_2 = w_3 = w_4 = 1$,

$$\begin{aligned} y &= -1.0334 + 2.6222x \\ y(5) &= 13.3449 \end{aligned}$$

$$\begin{array}{lcl} 5. & x : & 0 \quad 2 \quad 5 \quad 7 \\ & y : & -1 \quad 5 \quad 12 \quad 20 \\ & w : & 1 \quad 1 \quad 100 \quad 1 \end{array}$$

Ans. $y = -1.41258 + 2.6905x$, $y(5) = 12.0402$

Hint: $\sum w_i = 103$, $\sum w_i x_i = 509$, $\sum w_i x_i y_i = 6150$, $\sum w_i x_i^2 = 2553$, $\sum w_i y_i = 1224$. Without weights $y = -1.0334 + 2.622x$, $y(5) = 13.3449$.

Linear Weighted Least Squares Approximation (Continuous Function)

Fit a least squares approximation of degree one to $f(x)$ in $[a, b]$

1. $f(x) = x^2 - 2x + 3$, $[0, 1]$

Ans. $-x + 2.8333$

2. $f(x) = x^3 - 1$, $[0, 2]$

Ans. $3.6x - 2.6$

3. $f(x) = e^{-x}$, $[0, 1]$

Ans. $e^{-1}[6(e-3)x + 2(4-e)]$

4. $f(x) = \cos \pi x$, $[0, 1]$

Ans. $-2.4317x + 1.2159$

5. $f(x) = \ln x$, $[1, 2]$

Ans. $0.68223x - 0.63706$

30.7 NON-LINEAR WEIGHTED LEAST SQUARES APPROXIMATION

Given a set of $(N + 1)$ data points, we can fit a non linear m th degree polynomial of the form.

$$y = a_0 + a_1x + a_2x^2 + \dots + a_mx^m \quad (10)$$

by minimizing the error function.

$$E(a_0, a_1, \dots, a_m) = \sum w_i [y_i - (a_0 + a_1x_i + \dots + a_mx_i^m)]^2 \quad (11)$$

The necessary conditions for minimization of (11) gives the following $(m + 1)$ normal equations.

$$\begin{aligned} a_0 \sum_{i=0}^N w_i + a_1 \sum_i x_i w_i + \dots + a_m \sum_i x_i^m w_i &= \sum_i y_i w_i. \\ a_0 \sum_i x_i w_i + a_1 \sum_i x_i^2 w_i + \dots &+ a_m \sum_i x_i^{m+1} w_i = \sum_i x_i y_i w_i \quad (12) \end{aligned}$$

$$\begin{aligned} a_0 \sum_i x_i^m w_i + a_1 \sum_i x_i^{m+1} w_i + \dots &+ a_m \sum_i x_i^{2m} w_i = \sum_i x_i^m y_i w_i. \end{aligned}$$

If x_i are distinct data points and when $m < (N + 1)$, then the above set of $(m + 1)$ equations for the $(m + 1)$ unknowns $a_0, a_1, \dots, a_m$ has *unique* solution.

Discret case

Suppose $y = a_0 + a_1x + a_2x^2$ is the non linear weighted least squares approximation to a given discrete set of $(N + 1)$ data points. Then normal equations (12) take the form.

$$\begin{aligned} a_0 \sum_i w_i + a_1 \sum_i x_i w_i + a_2 \sum_i x_i^2 w_i &= \sum_i y_i w_i \quad (13) \\ a_0 \sum_i x_i w_i + a_1 \sum_i x_i^2 w_i + a_2 \sum_i x_i^3 w_i &= \sum_i x_i y_i w_i \quad (14) \\ a_0 \sum_i x_i^2 w_i + a_1 \sum_i x_i^3 w_i + a_2 \sum_i x_i^4 w_i &= \sum_i x_i^2 y_i w_i \quad (15) \end{aligned}$$

30.20 — HIGHER ENGINEERING MATHEMATICS—VII

The best fit parameters a_0, a_1, a_2 are obtained by solving the above three equations (13), (14) and (15).

Continuous function (case)

When $f(x)$ is a continuous function defined on the interval $[a, b]$ with a weight function $w(x)$, then the non-linear weighted least squares approximation is to minimize

$$E(a_0, a_1, \dots, a_m) = \int_a^b w(x)[y(x) - (a_0 + a_1x + \dots + a_mx^m)]^2 dx \quad (16)$$

Differentiating (16) partially w.r.t. the parameters $a_0, a_1, \dots, a_m$ we get the following $(m + 1)$ normal equations

$$\begin{aligned} a_0 \int_a^b w(x) dx + a_1 \int_a^b xw(x) dx + \dots \\ + a_m \int_a^b x^m w(x) dx &= \int_a^b y(x)w(x) dx. \\ a_0 \int_a^b xw(x) dx + a_1 \int_a^b x^2 w(x) dx + \dots \\ + a_m \int_a^b x^{m+1} w(x) dx &= \int_a^b xy(x)w(x) dx. \\ a_0 \int_a^b x^m w(x) dx + a_1 \int_a^b x^{m+1} w(x) dx + \dots + \\ + \int_a^b x^{2m} w(x) dx &= \int_a^b x^m y(x)w(x) dx. \end{aligned}$$

When we consider a second degree polynomial of the form

$$y = a_0 + a_1x + a_2x^2$$

then the above normal equations take the form:

$$\begin{aligned} a_0 \int_a^b w(x) dx + a_1 \int_a^b xw(x) dx + \\ + a_2 \int_a^b x^2 w(x) dx &= \int_a^b w(x) \cdot y(x) dx \quad (17) \end{aligned}$$

$$\begin{aligned} a_0 \int_a^b xw(x) dx + a_1 \int_a^b x^2 w(x) dx + \\ + a_2 \int_a^b x^3 w(x) dx &= \int_a^b xy(x)w(x) dx. \quad (18) \end{aligned}$$

$$\begin{aligned} a_0 \int_a^b x^2 w(x) dx + a_1 \int_a^b x^3 w(x) dx + \\ + a_2 \int_a^b x^4 w(x) dx &= \int_a^b x^2 y(x)w(x) dx. \quad (19) \end{aligned}$$

Solving (17), (18) and (19) for a_0, a_1, a_2 gives the required non-linear weighted least squares approximation.

WORKED OUT EXAMPLES

Discrete (function) data

Example 1: Fit a non-linear weighted least squares (parabola) second degree polynomial $y = a_0 + a_1x + a_2x^2$ to the following data.

| | | | | |
|------|----|----|----|----|
| $x:$ | -3 | -1 | 1 | 3 |
| $y:$ | 15 | 5 | 1 | 5 |
| $w:$ | 2 | 5 | 10 | 20 |

Solution: The normal equations are

$$a_0 \sum_{i=1}^4 w_i + a_1 \sum w_i x_i + a_2 \sum w_i x_i^2 = \sum w_i y_i$$

$$a_0 \sum w_i x_i + a_1 \sum w_i x_i^2 + a_2 \sum w_i x_i^3 = \sum w_i x_i y_i$$

$$a_0 \sum w_i x_i^2 + a_1 \sum w_i x_i^3 + a_2 \sum w_i x_i^4 = \sum w_i x_i^2 y_i$$

The data is shown in the following table

$$N = 4, \sum w_i = 37, \sum w_i x_i = 59,$$

$$\sum x_i^2 w_i = 78, \sum w_i x_i^3 = 491, \sum w_i x_i^4 = 1797,$$

$$\sum w_i y_i = 165, \sum w_i x_i y_i = 195, \sum w_i x_i^2 y_i = 1205$$

| x | y | w | wx | wx^2 | wx^3 | wx^4 | wy | wxy | wx^2y |
|-----|-----|-----|------|--------|--------|--------|------|-------|---------|
| -3 | 15 | 2 | -6 | 18 | -54 | 162 | 30 | -90 | 270 |
| -1 | 5 | 5 | -5 | 5 | -5 | 5 | 25 | -25 | 25 |
| 1 | 1 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 |
| 3 | 5 | 20 | 60 | 45 | 540 | 1620 | 100 | 300 | 900 |
| 0 | 26 | 37 | 59 | 78 | 491 | 1797 | 165 | 195 | 1205 |

Thus the three normal equations are

$$\begin{aligned} 37a_0 + 59a_1 + 78a_2 &= 165 \\ 59a_0 + 78a_1 + 491a_2 &= 195 \\ 78a_0 + 491a_1 + 1797a_2 &= 1205 \end{aligned}$$

solving $a_0 = 0.38, a_1 = 2.65, a_2 = -0.07$

Thus the non-linear weighted least squares quadratic fit is

$$y = 0.38 + 2.65x - 0.07x^2$$

with $y(1) = 2.96$.

The corresponding least squares parabola fit (without weights i.e., $w_1 = w_2 = w_3 = w_4 = 1$) is

$$y = 2.125 - 1.70x + 0.875x^2$$

with $y(1) = 1.3$.

Note: See example II in exercise with different weights.

EXERCISE

Discrete (function) data

1. Fit a non-linear weighted least squares (parabola) second degree polynomial $y = a_0 + a_1x + a_2x^2$ to the following data.

| | | | | | | |
|----|------|----|----|----|---|----|
| I. | $x:$ | -2 | -1 | 0 | 1 | 2 |
| | $y:$ | 15 | 1 | 1 | 3 | 19 |
| | $w:$ | 1 | 3 | 10 | 3 | 1 |

Ans. $y = 0.1166 + x + 3.85x^2, y(0.5) = 1.5791$

Hint: $N = 5, \sum w_i = 18, \sum w_i x_i = 0, \sum w_i x_i^2 = 14, \sum w_i x_i^3 = 0, \sum w_i x_i^4 = 38, \sum w_i y_i = 56, \sum w_i x_i y_i = 14, \sum w_i x_i^2 y_i = 148$

Note: (Non-weighted) corresponding LS parabola for the above data (with weights $w_1 = w_2 = w_3 = w_4 = w_5 = 1$) is

$$y = -1.057 + x + 4.43x^2$$

$$y(0.5) = 1.0505$$

| | | | | | |
|-----|------|----|----|----|---|
| II. | $x:$ | -3 | -1 | 1 | 3 |
| | $y:$ | 15 | 5 | 1 | 5 |
| | $w:$ | 1 | 2 | 10 | 5 |

Ans. $y = 1.91 - 1.72x + 0.91x^2, y(1) = 1.1$

Hint: $N = 4, \sum w_i = 18, \sum w_i x_i = 20, \sum w_i x_i^2 = 66, \sum w_i x_i^3 = 116, \sum w_i x_i^4 = 498, \sum w_i y_i = 60, \sum w_i x_i y_i = 30, \sum w_i x_i^2 y_i = 380$

WORKED OUT EXAMPLES

Continuous function

Examples: Fit a non-linear weighted least squares (parabola) second degree polynomial $y = a_0 + a_1x + a_2x^2$ to the function $y(x) = e^x$ on the interval $[0, 1]$ with respect to the weight function $w(x) = x$.

Solution: The three normal equations are

$$\begin{aligned} a_0 \int_a^b w(x)dx + a_1 \int_a^b x w(x)dx + \\ + a_2 \int_a^b x^2 w(x)dx = \int_a^b w(x)y(x)dx. \quad (1) \end{aligned}$$

$$\begin{aligned} a_0 \int_a^b x w(x)dx + a_1 \int_a^b x^2 w(x)dx + \\ + a_2 \int_a^b x^3 w(x)dx = \int_a^b x w(x)y(x)dx. \quad (2) \end{aligned}$$

$$\begin{aligned} a_0 \int_a^b x^2 w(x)dx + a_1 \int_a^b x^3 w(x)dx + \\ + a_2 \int_a^b x^4 w(x)dx = \int_a^b x^2 w(x)y(x)dx. \quad (3) \end{aligned}$$

Here $a = 0, b = 1, w(x) = x, y(x) = e^x$.

So the normal equations are

$$\begin{aligned} a_0 \int_0^1 x dx + a_1 \int_0^1 x^2 dx + a_2 \int_0^1 x^3 dx &= \int_0^1 x e^x dx \\ a_0 \int_0^1 x^2 dx + a_1 \int_0^1 x^3 dx + a_2 \int_0^1 x^4 dx &= \int_0^1 x^2 e^x dx \\ a_0 \int_0^1 x^3 dx + a_1 \int_0^1 x^4 dx + a_2 \int_0^1 x^5 dx &= \int_0^1 x^3 e^x dx \end{aligned}$$

After integration, we get

$$\frac{a_0}{2} + \frac{a_1}{3} + \frac{a_2}{4} = 1$$

$$\frac{a_0}{3} + \frac{a_1}{4} + \frac{a_2}{5} = e - 2$$

30.22 — HIGHER ENGINEERING MATHEMATICS—VII

$$\frac{a_0}{4} + \frac{a_1}{5} + \frac{a_2}{6} = 6 - 2e$$

or

$$6a_0 + 4a_1 + 3a_2 = 12$$

$$20a_0 + 15a_1 + 12a_2 = 60(e - 2)$$

$$15a_0 + 12a_1 + 10a_2 = 60(6 - 2e).$$

Solving $a_0 = (1632 - 600e)$, $a_1 = 2340e - 6360$, $a_2 = 5220 - 1920e$.

Thus the required non-linear weighted least squares parabola fit to e^x with weight function x on $[0, 1]$ is

$$y(x) = (1632 - 600e) + (2340e - 6360)x + (5220 - 1920e)x^2$$

$$\text{At } x = \frac{1}{2}, xy(x) = \frac{1}{2}y\left(\frac{1}{2}\right) = \frac{1.6452}{2} = 0.8226$$

$$\text{At } x = \frac{1}{2}, xe^x = \frac{1}{2}e^{\frac{1}{2}} = 0.82436.$$

EXERCISE

Fit a non-linear weighted least squares (parabola) second degree polynomial $y = a_0 + a_1x + a_2x^2$ to the function $f(x)$ on the interval $[a, b]$ w.r.t. the weight function $w(x)$.

$$1. f(x) = e^x, [0, 1], w(x) = 1.$$

$$\text{Ans. } y = (39e - 105) + (588 - 216e)x + (210e - 570)x^2$$

$$y\left(\frac{1}{2}\right) = 1.64838, e^{\frac{1}{2}} = 1.64872$$

Hint: Normal equations are

$$6a_0 + 3a_1 + 2a_2 = 6(e - 1)$$

$$6a_0 + 4a_1 + 3a_2 = 12$$

$$20a_0 + 15a_1 + 12a_2 = 60(e - 2)$$

$$2. f(x) = \cos x, \left[0, \frac{\pi}{2}\right], w(x) = 1$$

$$\text{Ans. } \cos x = \left(\frac{6}{\pi} + \frac{144}{\pi^2} - \frac{480}{\pi^3}\right)$$

$$+ \left(-\frac{96}{\pi^2} + \frac{5760}{\pi^4} - \frac{1536}{\pi^3}\right)x$$

$$+ \left(-\frac{11520}{\pi^5} + \frac{2880}{\pi^4} + \frac{240}{\pi^3}\right)x^2$$

$$\text{At } x = \frac{\pi}{4}, \cos\left(\frac{\pi}{4}\right) = -\frac{3}{\pi} - \frac{60}{\pi^2} + \frac{240}{\pi^3} = 0.70616$$

Hint: Normal equations are

$$12a_0 + 3a_1\pi + a_2\pi^2 = \frac{24}{\pi}$$

$$8a_0 + \frac{8}{3}a_1\pi + a_2\pi^2 = \frac{32(\pi - 2)}{\pi^2}$$

$$\frac{20}{3}a_0 + \frac{5}{2}a_1\pi + a_2\pi = \frac{40(\pi^2 - 8)}{\pi^3}$$

$$3. f(x) = \sin(x), \left[0, \frac{\pi}{2}\right], w(x) = 1,$$

$$\begin{aligned} \text{Ans. } \sin x &= \left(\frac{18}{\pi} + \frac{96}{\pi^2} - \frac{480}{\pi^3}\right) \\ &+ \left(-\frac{144}{\pi^2} - \frac{1344}{\pi^3} + \frac{5760}{\pi^4}\right)x \\ &+ \left(\frac{240}{\pi^3} + \frac{2880}{\pi^4} - \frac{11520}{\pi^5}\right)x^2 \end{aligned}$$

$$\text{At } x = \frac{\pi}{4}; \sin\left(\frac{\pi}{4}\right) = -\frac{3}{\pi} - \frac{60}{\pi^2} + \frac{240}{\pi^3} = 0.70616$$

Hint: Normal equations are

$$12a_0\pi + 3a_1\pi^2 + a_2\pi^3 = 24$$

$$8a_0\pi^2 + \frac{8}{3}a_1\pi^3 + a_2\pi^4 = 64$$

$$\frac{20}{3}a_0\pi^3 + \frac{5}{2}a_1\pi^4 + a_2\pi^5 = 320\left(\frac{\pi}{2} - 1\right)$$

$$4. f(x) = \sin \pi x, [0, 1], w(x) = 1$$

$$\text{Ans. } P_2(x) = -0.050465 + 4.12251x - 4.12251x^2$$

Hint: Normal equations

$$a_0 + \frac{a_1}{2} + \frac{a_2}{3} = \frac{2}{\pi}, \frac{a_0}{2} + \frac{a_1}{3} + \frac{a_2}{4} = \frac{1}{\pi}$$

$$\frac{a_0}{3} + \frac{a_1}{4} + \frac{a_2}{5} = \frac{(\pi^2 - 4)}{\pi^3}$$

$$\begin{aligned} a_0 &= (12\pi^2 - 120)/\pi^3, a_1 = -a_2 \\ &= (720 - 60\pi^2)/\pi^3. \end{aligned}$$

30.8 MULTIPLE REGRESSION

It is known in agriculture that, the crop yield (Y) not only depends on the amount of rainfall (X_1) but also on the amount of fertilizer (X_2) applied, pesticides

(X_3) used, quality of seeds (X_4), quality of soil (X_5), etc. Thus in multiple regression, the dependent variable Y is a function of more than one independent variables, i.e.,

$$Y = f(X_1, X_2, X_3, \dots, X_k).$$

In **multiple nonlinear regression**, f is nonlinear. In **multiple linear regression** f is linear i.e., $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k$. Response surface analysis deals with statistical methods of prediction and optimization.

Linear Multiple Regression

Suppose Y depends on two independent variables X_1 and X_2 , i.e.,

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 \quad (1)$$

Fig. 30.2

Then the linear multiple regression problem is to fit the regression plane given by Equation (1) to a given set of N triples (X_{1i}, X_{2i}, Y_i) (Fig. 30.2). To estimate the coefficient $\beta_0, \beta_1, \beta_2$, apply the least squares method to minimize

$$\sum_{i=1}^N \left\{ Y_i - (b_0 + b_1 X_{1i} + b_2 X_{2i}) \right\}^2.$$

This results in three normal equations given by

$$\begin{aligned} \sum_{i=1}^N Y_i &= N b_0 + b_1 \sum_{i=1}^N X_{1i} + b_2 \sum_{i=1}^N X_{2i} \\ \sum_{i=1}^N X_{1i} Y_i &= b_0 \sum_{i=1}^N X_{1i} + b_1 \sum_{i=1}^N X_{1i}^2 + b_2 \sum_{i=1}^N X_{1i} X_{2i} \\ \sum_{i=1}^N X_{2i} Y_i &= b_0 \sum_{i=1}^N X_{2i} + b_1 \sum_{i=1}^N X_{1i} X_{2i} + b_2 \sum_{i=1}^N X_{2i}^2 \end{aligned}$$

Here b_0, b_1, b_2 are the least squares estimates of $\beta_0, \beta_1, \beta_2$.

Note: By introducing $\bar{X}_1 = \frac{\sum X_{1i}}{N}$, $\bar{X}_2 = \frac{\sum X_{2i}}{N}$, $\bar{Y} = \frac{\sum Y_i}{N}$, $\bar{Y}_i = Y_i - \bar{Y}$, $\bar{X}_{1i} = X_{1i} - \bar{X}_1$, $\bar{X}_{2i} = X_{2i} - \bar{X}_2$, the above three normal equations reduces to 2 normal equations

$$\begin{aligned} \sum \bar{X}_{1i} \bar{Y}_i &= b_1 \sum (\bar{X}_{1i})^2 + b_2 \sum \bar{X}_{1i} \bar{X}_{2i} \\ \sum \bar{X}_{2i} \bar{Y}_i &= b_1 \sum \bar{X}_{1i} \bar{X}_{2i} + b_2 \sum (\bar{X}_{2i})^2. \end{aligned}$$

Linear multiple regression in k -independent variables: The above analysis can be generalized to fit $N(k+1)$ tuples ($X_{1i}, X_{2i}, X_{3i}, \dots, X_{ki}$) (with i varying from 1 to N) to the equation

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k.$$

The $(k+1)$ normal equations are

$$\begin{aligned} \sum_{i=1}^N Y_i &= N b_0 + b_1 \sum_{i=1}^N X_{1i} + b_2 \sum_{i=1}^N X_{2i} \\ &\quad + \dots + b_k \sum_{i=1}^N X_{ki} \\ \sum_{i=1}^N X_{1i} Y_i &= b_0 \sum_{i=1}^N X_{1i} + b_1 \sum_{i=1}^N X_{1i}^2 + b_2 \sum_{i=1}^N X_{1i} X_{2i} \\ &\quad + \dots + b_k \sum_{i=1}^N X_{1i} X_{ki} \\ &\dots \dots \dots \\ \sum_{i=1}^N X_{ki} Y_i &= b_0 \sum_{i=1}^N X_{ki} X_{1i} + b_1 \sum_{i=1}^N X_{ki} X_{2i} \\ &\quad + \dots + b_k \sum_{i=1}^N X_{ki}^2. \end{aligned}$$

WORKED OUT EXAMPLES

Examples: Fit a regression plane to estimate $\beta_0, \beta_1, \beta_2$ to the following data of a transport company on the weights of 6 shipments, the distances they were moved and the damage of the goods that was incurred. Estimate the damage when a shipment of 3700 kg is moved to a distance of 260 km.

30.24 — HIGHER ENGINEERING MATHEMATICS—VII

| | | | | | | |
|----------------------------|-----|-----|-----|-----|-----|-----|
| Weight x_1
(1000 kg) | 4.0 | 3.0 | 1.6 | 1.2 | 3.4 | 4.8 |
| Distance x_2
(100 km) | 1.5 | 2.2 | 1.0 | 2.0 | 0.8 | 1.6 |
| Damage y
(Rs.) | 160 | 112 | 69 | 90 | 123 | 186 |

Solution: Let the dependent variable damage be y , the two independent variables be weight x_1 and distance x_2 . Thus assume the equation of the regression plane as

$$y = b_0 + b_1x_1 + b_2x_2$$

where b_0, b_1, b_2 are the estimates of $\beta_0, \beta_1, \beta_2$. The three normal equations are

$$\sum_{i=1}^6 y_i = nb_0 + b_1 \sum_{i=1}^6 x_{1i} + b_2 \sum_{i=1}^6 x_{2i}$$

$$\sum x_{1i}y_i = b_0 \sum x_{1i} + b_1 \sum x_{1i}^2 + b_2 \sum x_{1i}x_{2i}$$

$$\sum x_{2i}y_i = b_0 \sum x_{2i} + b_1 \sum x_{1i}x_{2i} + b_2 \sum x_{2i}^2.$$

Here $n = 6$. Substitute the data from the following table, in the normal equations:

| | x_1 weight
(1,000 kg) | x_2 distance
(100 km) | y damage
(Rs.) | x_1^2 | x_2^2 | x_1x_2 | x_1y | x_2y |
|-------|----------------------------|----------------------------|---------------------|---------|---------|----------|--------|--------|
| | 4.0 | 1.5 | 160 | 16 | 2.25 | 6.0 | 640 | 240 |
| | 3.0 | 2.2 | 112 | 9 | 4.84 | 6.6 | 336 | 246.4 |
| | 1.6 | 1.0 | 69 | 2.56 | 1.0 | 1.6 | 110.4 | 69 |
| | 1.2 | 2.0 | 90 | 1.44 | 4.0 | 2.4 | 108 | 180 |
| | 3.4 | 0.8 | 123 | 11.56 | 0.64 | 2.72 | 418.2 | 98.4 |
| | 4.8 | 1.6 | 186 | 23.04 | 2.56 | 7.68 | 892.8 | 297.6 |
| Total | 18 | 9.1 | 740 | 63.6 | 15.29 | 27 | 250.54 | 1131.4 |

$$n = 6, \sum x_{1i} = 18, \sum x_{2i} = 9.1, \sum y_i = 740, \\ \sum x_{1i}^2 = 63.6, \sum x_{2i}^2 = 15.29, \sum x_{1i}x_{2i} = 27, \\ \sum x_{1i}y_i = 250.54, \sum x_{2i}y_i = 1131.4.$$

$$\text{So } 740 = 6b_0 + 18b_1 + 9.1b_2$$

$$250.54 = 18b_0 + 63.6b_1 + 27b_2$$

$$1131.4 = 9.1b_0 + 27b_1 + 15.29b_2$$

Solving we get $b_0 = 14.56$, $b_1 = 30.109$, $b_2 = 12.16$. Thus the required regression plane is

$$y = 14.56 + 30.109x_1 + 12.16x_2$$

Estimate: For a weight of 3700 kg ($x_1 = 3.7$) and for a distance of 260 km ($x_2 = 2.6$), the damage incurred in rupees is

$$y(x_1 = 3.7, x_2 = 2.6) = 14.56 + 30.109(3.7) + 12.16(2.6) \\ = \text{Rs. } 714.5798 \approx \text{Rs. } 715.$$

EXERCISE

1. Estimate Y for given $X_1 = 12$ and $X_2 = 10$ by fitting a regression plane to the following data:

| | | | | | | | | | | | |
|-------|------|------|------|------|------|------|------|------|------|------|------|
| Y | 412 | 226 | 292 | 323 | 233 | 368 | 239 | 382 | 218 | 222 | 214 |
| X_1 | 28.7 | 13.4 | 14.6 | 18.0 | 12.1 | 23.4 | 12.6 | 30.2 | 11.6 | 12.0 | 12.4 |
| X_2 | 21.5 | 11.7 | 12.9 | 14.8 | 11.0 | 19.2 | 11.4 | 22.6 | 10.8 | 10.2 | 10.1 |

$$\text{Hint: } n = 11, \sum Y_i = 3129, \sum_{i=1}^{11} X_{1i} = 189.0,$$

$$\sum X_{2i} = 156.2, \sum X_{1i}^2 = 3737.50, \sum X_{2i}^2 = 2437.64, \sum X_{1i}X_{2i} = 3010.03, \\ \sum X_{1i}Y_i = 58754.7, \sum X_{2i}Y_i = 47816.$$

$$\text{Ans. } Y = 40.96 - 6.30X_1 + 24.77X_2, \\ Y(12, 10) = 213.06$$

2. Find Y when $X_1 = 10$ and $X_2 = 6$ from the least squares regression equation of Y on X_1 and X_2 for the following data:

| | | | | | | |
|-------|----|----|----|----|----|----|
| Y | 90 | 72 | 54 | 42 | 30 | 12 |
| X_1 | 3 | 5 | 6 | 8 | 12 | 14 |
| X_2 | 16 | 10 | 7 | 4 | 3 | 2 |

Hint: $n = 6$, $\sum Y_i = 300$, $\sum X_{1i} = 48$,
 $\sum X_{2i} = 42$, $\sum X_{1i} X_{2i} = 236$, $\sum X_{1i}^2 = 474$,
 $\sum X_{2i}^2 = 434$, $\sum X_{1i} Y_i = 1818$,
 $\sum X_{2i} Y_i = 2820$.

Ans. $Y = 61.40 - 3.65X_1 + 2.54X_2$,
 $Y(10, 6) = 40.14 \approx 40$

3. Determine the equation of the regression plane connecting x_1 , x_2 and y . Estimate y at $x_1 = 1.8$, $x_2 = 112$.

| | | | | | | | | | | |
|-----------------------------------|-----|-----|-----|-----|------|-----|-----|-----|-----|------|
| Diffusion time
(hours) x_1 | 1.5 | 2.5 | 0.5 | 1.2 | 2.6 | 0.3 | 2.4 | 2.0 | 0.7 | 1.6 |
| Sheet-resistance
Ohms-cm x_2 | 66 | 87 | 69 | 141 | 93 | 105 | 111 | 78 | 66 | 123 |
| Current gain y | 5.3 | 7.8 | 7.4 | 9.8 | 10.8 | 9.1 | 8.1 | 7.2 | 6.5 | 12.6 |

Hint: $n = 10$, $\sum x_{1i} = 15.3$, $\sum x_{2i} = 939$,
 $\sum y_i = 84.6$, $\sum x_{1i}^2 = 29.85$, $\sum x_{2i}^2 = 94131$,
 $\sum x_{1i} x_{2i} = 1458.9$, $\sum x_{1i} y_i = 132.27$,
 $\sum x_{2i} y_i = 8320.2$.

Ans. $y = 2.27 + 0.22x_1 + 0.062x_2$,
 $y(1.8, 112) = 9.61$

4. Fit a regression plane of y on x_1 and x_2 given
 $\sum (\bar{x}_{1i})^2 = 38.4$, $\sum (\bar{x}_{2i})^2 = 3.4$, $\sum \bar{x}_{1i} \bar{y}_i = 29.76$, $\sum \bar{x}_{2i} \bar{y}_i = 8.94$, $\sum \bar{x}_{1i} \bar{x}_{2i} = 9.6$ where
 $\bar{y}_i = y_i - \bar{y}$, $\bar{x}_{1i} = x_{1i} - \bar{x}_1$, $\bar{x}_{2i} = x_{2i} - \bar{x}_2$
are the deviation of the data from their respective means, $\bar{y} = 55.2$, $\bar{x}_1 = 20.1$, $\bar{x}_2 = 6.4$

Hint: Solve only two normal equations (see Page 808).

Ans. $y = 37.56 + 0.4x_1 + 1.5x_2$

5. Fit a multiple linear regression equation to the following data and predict wear (y) when oil viscosity (x_1) is 30 and load (x_2) is 1400.

| | | | | | | |
|------------------------|-----|------|------|------|------|------|
| Wear y | 193 | 230 | 172 | 91 | 113 | 125 |
| Oil
viscosity x_1 | 1.6 | 15.5 | 22.0 | 43.0 | 33.0 | 40.0 |
| Load x_2 | 851 | 816 | 1058 | 1201 | 1357 | 1115 |

Hint: $n = 6$, $\sum y_i = 924$, $\sum x_{1i} = 155.1$,
 $\sum x_{2i} = 6398$, $\sum x_{1i} x_{2i} = 178309.6$,
 $\sum x_{1i}^2 = 5264.81$, $\sum x_{2i}^2 = 7036496$,
 $\sum x_{1i} y_i = 20299.8$, $\sum x_{2i} y_i = 935906$.

Ans. $y = 350.9943 - 1.2702x_1 - 0.1539x_2$,
 $y(x_1 = 30, x_2 = 1400) = 97.4283$.

30.9 CORRELATION ANALYSIS

In correlation analysis, the degree (or strength) of relationship between two variables, say X and Y , is measured by a single number r called a correlation coefficient formed by Karl Pearson in 1896. Here both X and Y are assumed to be random variables unlike the regression analysis where the dependent variable Y is assumed to be a random variable and the regressor (independent) variable x to be a physical or scientific or mathematical variable but not a random variable. Besides Pearsonian correlation, the other types of correlation include rank correlation, biserial correlation, intraclass correlation.

Examples:

- Volume of a cube $V = L^3$, perfectly correlated.
- Rainfall and crop yield, correlated.
- Two coins being tossed simultaneously, uncorrelated.

Types of Correlation

By plotting a given set of n pairs of random variables (X_i, Y_i) , for $i = 1, 2, 3, \dots, n$, as a scatter diagram, the correlation is said to be

Positive or direct if Y increases as X increases.

Negative or inverse if Y decreases as X increases.

Linear if all the n points lie near a straight line.

Non-linear if the points lie on some non-linear curve.

Examples:

- Income and expenditure: positively correlated.
- Age and IQ: negatively correlated.

Fig. 30.3

Simple

The correlation between two variables is said to be simple correlation.

Multiple

The correlation between more than two variables is known as multiple correlation. If $r = \pm 1$, there is a perfect positive (or negative) correlation. If $r = 0$ there is no (linear) correlation; but a nonlinear correlation may exist. Similarly, a high correlation due

to a third (lurking) variables is known as a spurious correlation (refer Fig. 30.3).

Example: Poverty and crime are highly correlated but the spurious correlation is due to the lurking variable illiteracy.

Standard error of estimate

Y on X is denoted by $S_{Y,X}$ is defined as

$$S_{Y,X} = \sqrt{\frac{\sum (Y - Y_{\text{est}})^2}{N}}$$

where Y_{est} is the estimated or predicted value of Y from the least squares regression line $Y = a_0 + a_1 X$. Similarly, the standard error of estimate X on Y is

$$S_{X,Y} = \sqrt{\frac{\sum (X - X_{\text{est}})^2}{N}}$$

In general, $S_{Y,X} \neq S_{X,Y}$.

Result: $\sum (Y - \bar{Y})^2 = \sum (Y - Y_{\text{est}})^2 + \sum (Y_{\text{est}} - \bar{Y})^2$, i.e., Total variation = unexplained variation + explained variation.

Coefficient of determination

$$= r^2 = \frac{\text{Explained variation}}{\text{Unexplained variation}}$$

Coefficient of correlation

$$= r = \pm \sqrt{\frac{\text{Explained variation}}{\text{Unexplained variation}}}$$

$$\text{i.e., } r = \pm \sqrt{\frac{\sum (Y_{\text{est}} - \bar{Y})^2}{\sum (Y - \bar{Y})^2}}$$

The +ve and -ve signs correspond to positive and negative correlation respectively.

Properties of r

- r lies in the interval $[-1, 1]$, i.e., $-1 \leq r \leq 1$.
- r is independent of origin.
- r is independent of (scale of measurements) unit.

Karl Pearson product-moment formula or simply sample correlation coefficient for the linear correlation coefficient r :

From the least squares regression line of Y on X

$$\hat{Y} = Y_{\text{est}} = a_0 + a_1 X$$

Put $y_{\text{est}} = Y_{\text{est}} - \bar{Y}$, $x = X - \bar{X}$, $y = Y - \bar{Y}$ then

$$y_{\text{est}} = a_1 x = \frac{\sum xy}{\sum x^2} x.$$

We know that

$$\begin{aligned} r^2 &= \frac{\sum y_{\text{est}}^2}{\sum y^2} = \frac{\sum a_1^2 x^2}{\sum y^2} = a_1^2 \frac{\sum x^2}{\sum y^2} \\ &= \left(\frac{\sum xy}{\sum x^2} \right)^2 \frac{\sum x^2}{\sum y^2} = \frac{(\sum xy)^2}{\sum x^2 \sum y^2}. \end{aligned}$$

Therefore

$$r = \pm \frac{\sum xy}{\sqrt{\sum x^2 \sum y^2}}.$$

The $\pm$ sign can be omitted without any loss of generality since y_{est} increases (decreases) as x increases (decreases).

Thus the coefficient of linear correlation is

$$r = \frac{\sum xy}{\sqrt{\sum x^2 \sum y^2}}$$

Introducing covariance S_{XY} of X and Y by

$$S_{XY} = \frac{\sum xy}{N}$$

and s.d. of X and Y by

$$S_X = \sqrt{\frac{\sum x^2}{N}}, \quad S_Y = \sqrt{\frac{\sum y^2}{N}}.$$

we can write

$$r = \frac{S_{XY}}{S_X S_Y}.$$

Computational Formula

$$r = \frac{N \sum XY - \sum X \sum Y}{\sqrt{\left[N \sum X^2 - \left(\sum X \right)^2 \right] \left[N \sum Y^2 - \left(\sum Y \right)^2 \right]}}$$

Regression lines and the linear correlation coefficient:

The least squares regression line Y on X

$$Y = a_0 + a_1 X$$

can be written as

$$y = \left(\frac{\sum xy}{\sum x^2} \right) x$$

where $y = Y - \bar{Y}$, $x = X - \bar{X}$.

$$\text{Since } r = \frac{\sum xy}{\sqrt{\sum x^2 \sum y^2}}$$

$$\text{so } \frac{\sum xy}{\sum x^2} = \frac{r \sqrt{\sum x^2 \sum y^2}}{\sum x^2} = r \sqrt{\frac{\sum y^2}{\sum x^2}} = r \frac{S_Y}{S_X}.$$

$$\text{Thus } y = a_1 x = \left(\frac{\sum xy}{\sum x^2} \right) x = r \frac{S_Y}{S_X} x.$$

In a similar way, we get

$$x = r \frac{S_X}{S_Y} y.$$

Result: Show that the coefficient of correlation r is the geometric mean between the regression coefficients.

Solution: Let $Y = a_0 + a_1 X$ and $X = b_0 + b_1 Y$ be the least squares regression lines, with a_1 and b_1 as regression coefficients. We know that $a_1 = \frac{r S_Y}{S_X}$ and $b_1 = r \frac{S_X}{S_Y}$.

$$\text{So } a_1 b_1 = \left(r \frac{S_Y}{S_X} \right) \left(r \frac{S_X}{S_Y} \right) = r^2$$

$$\text{or } r = \sqrt{a_1 b_1}.$$

Test of Hypothesis for Correlation Coefficient

Let $\rho = \pm \sqrt{1 - \frac{\sigma_z^2}{\sigma_z^2}}$ denote the population correlation coefficient where $\sigma_z^2 = \frac{1}{n-3}$, n is number of pairs of observations. The Fisher Z transformation is defined by

$$Z = \frac{1}{2} \ln \frac{1+r}{1-r} = 1.1513 \log_{10} \left(\frac{1+r}{1-r} \right).$$

Here the statistic Z is a value of random variable approximately normally distributed with mean $\mu_Z = \frac{1}{2} \ln \frac{1+\rho}{1-\rho}$ and variance $\sigma_Z^2 = \frac{1}{n-3}$.

30.28 — HIGHER ENGINEERING MATHEMATICS—VII

Statistic for inference about $\rho (\neq 0)$

$$z = \frac{Z - \mu_Z}{\left(\frac{1}{\sqrt{n-3}}\right)} = \frac{\sqrt{n-3}}{2} \ln \left\{ \frac{(1+r)(1-\rho)}{(1-r)(1+\rho)} \right\}$$

Test of hypothesis for no correlation: $\rho = 0$

$$z = \sqrt{n-3} \quad Z = \frac{\sqrt{n-3}}{2} \ln \left(\frac{1+r}{1-r} \right)$$

values of Z are tabulated (A21) for various values of $r = 0$ to 0.99 .

Note: When r is negative, read Z corresponding to $-r$ and then take $-Z$.

WORKED OUT EXAMPLES

Correlation:

Example 1: (a) Estimate (predict) the blood pressure (B.P.) of a woman of age 45 years from the following data which shows the ages X and systolic B.P. Y of 12 women. (b) Are the two variables ages X and B.P. Y correlated?

| | | | | | | | | | | | | |
|--------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Age (X) | 56 | 42 | 72 | 36 | 63 | 47 | 55 | 49 | 38 | 42 | 68 | 60 |
| B.P. (Y) | 147 | 125 | 160 | 118 | 149 | 128 | 150 | 145 | 115 | 140 | 152 | 155 |

Solution: **a.** To estimate B.P., determine the prediction equation which is the least squares regression equation of Y on X . Assume it to be $Y = a_0 + a_1 X$. Its normal equations are

$$\begin{aligned} \sum Y &= N a_0 + a_1 \sum X \\ \sum XY &= a_0 \sum X + a_1 \sum X^2 \end{aligned}$$

From the given data, $\sum X = 628$; $\sum Y = 1684$;
 $\sum X^2 = 34416$; $\sum Y^2 = 238822$;
 $\sum XY = 89894$; $N = 12$.
 Substituting

$$1684 = 12a_0 + 628a_1$$

$$89894 = 628a_0 + 34416a_1$$

Solving $a_0 = 80.77738$, $a_1 = 1.138005$.

so the prediction equation is $Y = 80.777 + 1.138X$. The B.P. of a woman with age $X = 45$ is obtained as

$$Y(45) = 80.777 + 1.138(45) = 131.987225 \approx 132.$$

b. To find the association between age and B.P., determine the correlation coefficient r by

$$\begin{aligned} r &= \frac{N \sum XY - \sum X \sum Y}{\sqrt{[N \sum X^2 - (\sum X)^2][N \sum Y^2 - (\sum Y)^2]}} \\ &= \frac{12(89894) - (628)(1684)}{\sqrt{[(12)(34416) - (628)^2][(12)(238822) - (1684)^2]}} \\ &= 0.8961 \end{aligned}$$

Age X and B.P. Y are strongly positively correlated.

Example 2: Test the hypothesis that there is no linear association among two variables x , air velocity cm/sec, and y , evaporation coefficient mm²/sec of a burning fuel droplets in an impulse engine, with $n = 10$ and $r = 0.9515$.

Solution:

1. Null hypothesis $\rho = 0$
2. Alternate hypothesis $\rho \neq 0$

3. Level of significance: $\alpha = 0.05$

4. Critical region: (two tailed test)

Reject null hypothesis if

$$Z > Z_{\alpha/2} = 1.96 \quad \text{or} \quad Z < -Z_{\alpha/2} = -1.96$$

5. Calculation: For $r = 0.95$ from table

$$Z^* = \frac{1}{2} \ln \left(\frac{1+r}{1-r} \right) = 1.832$$

$$\text{so } Z = \sqrt{n-3} Z^* = \sqrt{10-3}(1.832) = 4.847$$

6. Decision: Reject N.H. since $Z = 4.847 > Z_{\alpha/2} = 1.96$, i.e., there is linear relation between x and y .

Example 3: In a certain paired data $n = 18$ and $r = 0.44$, test the N.H. $\rho = 0.30$ against $\rho > 0.30$ at 0.01 level of significance.

Solution:

1. Null hypothesis: $\rho = 0.30$
2. Alternate hypothesis: $\rho > 0.30$
3. Level of significance: $\alpha = 0.01$
4. Critical region: (Right one tailed test)

Reject null hypothesis if $Z > 2.33$

5. Calculation: For $r = 0.44$, from table A21

$$Z^* = \frac{1}{2} \ln \left(\frac{r+1}{r-1} \right) = 0.472$$

$$\text{so } Z = \sqrt{n-3} Z^* = \sqrt{18-3}(0.472) = 1.828$$

6. Decision: Accept the null hypothesis since

$$Z = 1.828 < Z_{\alpha} = 2.33$$

Example 4: Determine 95% confidence limits and the confidence intervals for a correlation coefficient which is computed to be 0.60 from a sample of 28.

Solution: $r = 0.60, n = 28, \alpha = 0.05$

Confidence limits (C.L.) for μ_Z are $Z \pm 1.96\sigma_Z$ where $Z = 0.693$ from table A21 (for $r = 0.60$) and

$$\sigma_Z = \frac{1}{\sqrt{n-3}} = \frac{1}{\sqrt{28-3}} = \frac{1}{5} = 0.2. \text{ Thus}$$

μ_Z has class limits as

$$0.693 - 1.96(0.2), 0.693 + 1.96(0.2)$$

i.e., confidence interval for μ_Z is:
(0.3011516, 1.0851516).

If $0.30115 = \mu_Z = 1.1513 \ln \left(\frac{1+\rho}{1-\rho} \right)$ then

$$\rho = \frac{.826}{2.826} = 0.29236$$

If $1.0851 = \mu_Z = 1.1513 \ln \left(\frac{1+\rho}{1-\rho} \right)$ then

$$\rho = \frac{7.7608}{9.7608} = 0.7951.$$

Thus the confidence limits for ρ are 0.29236, 0.7951 and the confidence interval is (0.29236, 0.7951).

**Least squares regression lines,
standard error estimate**

Example 5: For the following data determine
(a) least squares regression line of y on x (b) $y(3)$
(c) least squares regression line of x on y (d) $x(4)$

(e) S_{yx} (f) S_{xy} (g) total variation in y (h) unexplained variation in y (i) explained variation in y .

| | | | | | | | | | | |
|-----|---|---|---|----|---|---|----|---|---|---|
| x | 6 | 5 | 8 | 8 | 7 | 6 | 10 | 4 | 9 | 7 |
| y | 8 | 7 | 7 | 10 | 5 | 8 | 10 | 6 | 8 | 6 |

Solution:

| x | y | x^2 | y^2 | xy | |
|-------|-----|-------|-------|------|--|
| 6 | 8 | 36 | 64 | 48 | so $\sum x = 70$
$\sum y = 75$
$\sum x^2 = 520$
$\sum y^2 = 587$
$\sum xy = 540$
$N = 10$ |
| 5 | 7 | 25 | 49 | 35 | |
| 8 | 7 | 64 | 49 | 56 | |
| 8 | 10 | 64 | 100 | 80 | |
| 7 | 5 | 49 | 25 | 35 | |
| 6 | 8 | 36 | 64 | 48 | |
| 10 | 10 | 100 | 100 | 100 | |
| 4 | 6 | 16 | 36 | 24 | |
| 9 | 8 | 81 | 64 | 72 | |
| 7 | 6 | 49 | 36 | 42 | |
| Total | 70 | 75 | 520 | 587 | 540 |

- a. Assume that the required L.S.R.L. of y on x is

$$y = a_0 + a_1 x$$

whose normal equations are

$$\begin{aligned} \sum y &= N a_0 + a_1 \sum x \\ \sum xy &= a_0 \sum x + a_1 \sum x^2 \end{aligned}$$

Substituting

$$75 = 10 a_0 + 70 a_1$$

$$540 = 70 a_1 + 520 a_1$$

Solving $a_1 = 0.5, a_0 = 4$.

So L.S.R.L. of y on x is

$$y = 4 + 0.5x \quad (1)$$

- b. $y(3) = 4 + 0.5(13) = 4 + 1.5 = 5.5$

- c. Assume that L.S.R.L. of x on y is

$$x = b_0 + b_1 y$$

with normal equations

$$\begin{aligned} \sum x &= N b_0 + b_1 \sum y \\ \sum xy &= b_0 \sum y + b_1 \sum y^2 \end{aligned}$$

30.30 — HIGHER ENGINEERING MATHEMATICS—VII

or $70 = 10b_0 + 75b_1$

$540 = 75b_0 + 587b_1$

Solving

$b_1 = 0.612, b_0 = 2.41$

So L.S.R.L. of x on y is

$x = 2.41 + 0.612y$ (2)

Now

$$S_{xy} = \sqrt{\frac{\sum(x - x_{\text{est}})^2}{N}} = 1.44278647 \approx 1.443$$

g, h, i. $\bar{y} = \frac{\sum y}{N} = \frac{75}{10} = 7.5.$

Total variation = unexplained variation + explained variation.

$$\sum(y - \bar{y})^2 = \sum(y - y_{\text{est}})^2 + \sum(y_{\text{est}} - \bar{y})^2 \quad (3)$$

| | | | | | | | | | | | |
|--------------------------------|------|------|------|------|------|------|------|------|------|------|-------|
| $(y_{\text{est}} - \bar{y})$ | 0.5 | -1 | 0.5 | 0.5 | 0 | -0.5 | 1.5 | -1.5 | 1 | 0 | Total |
| $(y_{\text{est}} - \bar{y})^2$ | 0.25 | 1 | 0.25 | 0.25 | 0 | 0.25 | 2.25 | 2.25 | 1 | 0 | 7.50 |
| $(y - \bar{y})$ | 0.5 | -0.5 | -0.5 | 2.5 | -2.5 | 0.5 | 2.5 | -1.5 | 0.5 | -1.5 | |
| $(y - \bar{y})^2$ | 0.25 | 0.25 | 0.25 | 6.25 | 6.25 | 0.25 | 6.25 | 2.25 | 0.25 | 2.25 | 24.50 |

d. $x(4) = 2.41 + 0.612(4) = 4.858$

e. From (1), estimated value of $y = y_{\text{est}} = 4 + 0.5x$

| x | y | y_{est} | $y - y_{\text{est}}$ | $(y - y_{\text{est}})^2$ |
|-------|-----|------------------|----------------------|--------------------------|
| 6 | 8 | 7 | 1 | 1 |
| 5 | 7 | 6.5 | 0.5 | 0.25 |
| 8 | 7 | 8 | -1 | 1 |
| 8 | 10 | 8 | 2 | 4 |
| 7 | 5 | 7.5 | -2.5 | 6.25 |
| 6 | 8 | 7 | 1 | 1 |
| 10 | 10 | 9 | 1 | 1 |
| 4 | 6 | 6 | 0 | 0 |
| 9 | 8 | 8.5 | -0.5 | 0.25 |
| 7 | 6 | 7.5 | -1.5 | 2.25 |
| Total | | | | 17.0 |

Now $S_{yx} = \sqrt{\frac{\sum(y - y_{\text{est}})^2}{N}} = \sqrt{\frac{17.0}{10}} = 1.30384$

f. From (2) $x_{\text{est}} = 2.41 + 0.612y$

| y | x | x_{est} | $x - x_{\text{est}}$ | $(x - x_{\text{est}})^2$ |
|-------|-----|------------------|----------------------|--------------------------|
| 8 | 6 | 7.306 | -1.306 | 1.705636 |
| 7 | 5 | 6.694 | -1.694 | 2.869636 |
| 7 | 8 | 6.694 | 1.306 | 1.705636 |
| 10 | 8 | 8.53 | -0.53 | 0.2809 |
| 5 | 7 | 5.47 | 1.53 | 2.3409 |
| 8 | 6 | 7.306 | -1.306 | 1.705636 |
| 10 | 10 | 8.53 | 1.47 | 2.1609 |
| 6 | 4 | 6.082 | -2.082 | 4.334724 |
| 8 | 9 | 7.306 | 1.694 | 2.869636 |
| 6 | 7 | 6.082 | 0.918 | 0.842724 |
| Total | | | | 20.816328 |

Total variation = $\sum(y - \bar{y})^2 = 24.50.$

Explained variation = $\sum(y_{\text{est}} - \bar{y})^2 = 7.50.$

From (3) unexplained variation = $\sum(y - y_{\text{est}})^2 = 24.50 - 7.50 = 17.$

Example 6: Calculate the coefficient of correlation r for the above data in 4 ways.

Solution:

a.
$$r = \pm \sqrt{\frac{\text{explained variation}}{\text{total variation}}} = \pm \sqrt{\frac{7.50}{24.50}} = 0.55328335.$$

b. Correlation coefficient is the geometric mean between the regression coefficients, i.e.,

$$r = \sqrt{b_{xy} \cdot b_{yx}}$$

From Equation (1) the regression coefficient of y on x is $b_{xy} = 0.5$. Similarly, regression coefficient of x on y is $b_{yx} = 0.612$

Now $r = \sqrt{(0.5)(0.612)} = 0.553172667.$

c. By product-moment formula

$$r = \frac{N \sum xy - \sum x \sum y}{\sqrt{[N \sum x^2 - (\sum x)^2][N \sum y^2 - (\sum y)^2]}}$$

$$r = \frac{10(540) - (70)(75)}{\sqrt{[10(520) - (70)^2][10(587) - (75)^2]}} = \frac{150}{\sqrt{73500}} = 0.55328$$

d. By formula

$$r = \frac{\sigma_x^2 + \sigma_y^2 - \sigma_{x-y}^2}{2\sigma_x\sigma_y}$$

where $\sigma_x^2, \sigma_y^2, \sigma_{x-y}^2$ are variances of $x, y, x - y$ respectively.

We know that

$$\text{variance} = \frac{\sum d^2}{N} - \left(\frac{\sum d}{N}\right)^2$$

Where d is the deviation of data from an assumed (class mark) origin.

| x | y | $X =$
$x-10$ | $Y =$
$y-10$ | X^2 | Y^2 | $y-x$ | $(x-y)^2$ | |
|-------|-----|-----------------|-----------------|-------|-------|-------|-----------|----|
| 6 | 8 | -4 | -2 | 16 | 4 | 2 | 4 | |
| 5 | 7 | -5 | -3 | 25 | 9 | 2 | 4 | |
| 8 | 7 | -2 | -3 | 4 | 9 | -1 | 1 | |
| 8 | 10 | -2 | 0 | 4 | 0 | 2 | 4 | |
| 7 | 5 | -3 | -5 | 9 | 25 | -2 | 4 | |
| 6 | 8 | -4 | -2 | 16 | 4 | 2 | 4 | |
| 10 | 10 | 0 | 0 | 0 | 0 | 0 | 0 | |
| 4 | 6 | -6 | -4 | 36 | 16 | 2 | 4 | |
| 9 | 8 | -1 | -2 | 1 | 4 | -1 | 1 | |
| 7 | 6 | -3 | -4 | 9 | 16 | -1 | 1 | |
| Total | 70 | 75 | -30 | -25 | 120 | 87 | 5 | 27 |

Now

$$\sigma_x^2 = \frac{\sum X^2}{N} - \left(\frac{\sum X}{N}\right)^2 = \frac{120}{10} - \left(\frac{-30}{10}\right)^2 = 12 - 9 = 3$$

$$\sigma_y^2 = \frac{\sum Y^2}{N} - \left(\frac{\sum Y}{N}\right)^2 = \frac{87}{10} - \left(\frac{-25}{10}\right)^2 = 2.45$$

$$\sigma_{x-y}^2 = \frac{\sum (x - y)^2}{N} - \left(\frac{\sum (x - y)}{N}\right)^2 = \frac{27}{10} - \left(\frac{5}{10}\right)^2 = 2.45$$

By formula

$$r = \frac{\sigma_x^2 + \sigma_y^2 - \sigma_{x-y}^2}{2\sigma_x\sigma_y} = \frac{3 + 2.45 - 2.45}{2\sqrt{3}\sqrt{2.45}} = 0.55328335.$$

Example 7: Calculate (a) the standard error estimate of y (b) the standard error estimate of x for the above data in Example 6.

Solution: a. Standard error estimate of y

$$= S_y = \sigma_y \sqrt{(1 - r^2)} = \sqrt{2.45} \sqrt{1 - (0.55328335)^2}$$

$$S_y = 1.086089.$$

Similarly, standard error estimate of x

$$S_x = \sigma_x \sqrt{(1 - r^2)} = 3 \sqrt{1 - (0.55328335)^2} = 2.081630.$$

Example 8: From 10 pairs of observations for x and y the following data is obtained: $n = 10, \sum x = 66, \sum y = 69, \sum x^2 = 476, \sum y^2 = 521, \sum xy = 485$. It was later found that two pairs of (correct) values

| | | | | |
|-----|-----|-----------------------------------|-----|-----|
| x | y | | x | y |
| 4 | 6 | were (erroneously) copied down as | 2 | 3. |
| 9 | 8 | | 7 | 5 |

Calculate the correct value of the coefficient of correlation.

Solution: In order to get the correct data, subtract the incorrect values and add the corresponding correct values.

$$\text{Thus } \sum x = 66 - 2 - 7 + 4 + 9 = 70,$$

$$\sum y = 69 - 3 - 5 + 6 + 8 = 75,$$

$$\sum x^2 = 476 - 4 - 49 + 16 + 81 = 520,$$

$$\sum y^2 = 521 - 9 - 25 + 36 + 64 = 587,$$

$$\sum xy = 485 - 6 - 35 + 24 + 72 = 540.$$

Hence

$$r = \frac{N \sum xy - (\sum x)(\sum y)}{\sqrt{[N \sum x^2 - (\sum x)^2][N \sum y^2 - (\sum y)^2]}} = \frac{10(540) - (70)(75)}{\sqrt{[10(520) - (70)^2][10(587) - (75)^2]}} = 0.55328.$$

EXERCISE

1. Calculate correlation coefficient r for the following data:

X : 63, 50, 55, 65, 55, 70, 64, 70, 58, 68, 52, 60

30.32 — HIGHER ENGINEERING MATHEMATICS—VII

$Y: 87, 74, 76, 90, 85, 87, 92, 98, 82, 91, 77, 78$

Hint: $N = 12, \sum X = 730, \sum Y = 1017,$
 $\sum X^2 = 44932, \sum Y^2 = 86801,$
 $\sum XY = 62352.$

Ans. $r = 0.86$

2. Compute r for the data given below:

$X: 1 \quad 2 \quad 3 \quad 4 \quad 5 \quad 6$

$Y: 6 \quad 4 \quad 3 \quad 5 \quad 4 \quad 2$

Hint: $N = 6, \sum X = 21, \sum Y = 24,$
 $\sum X^2 = 91, \sum Y^2 = 106, \sum XY = 75.$

Ans. $r = -0.68$

3. Determine r for the following data:

$X: 50 \quad 60 \quad 70 \quad 90 \quad 100$

$Y: 65 \quad 51 \quad 40 \quad 26 \quad 8$

Ans. $r = -0.99$

4. Determine the least squares regression line of
 (a) y on x and (b) x on y (c) Find r using the
 regression coefficients. (d) Find $y(8)$ (e) Find
 $x(16).$

$x: 12 \quad 10 \quad 14 \quad 11 \quad 12 \quad 9$

$y: 18 \quad 17 \quad 23 \quad 19 \quad 20 \quad 15$

Ans. a. $y = 1.913 + 1.478x$

b. $x = 0.60714y$

c. $r = \sqrt{(1.478)(0.60714)} = 0.947287$
 ≈ 0.95

d. $y(8) = 13.737$

e. $x(16) = 9.71424$

5. Use $r = \frac{\sigma_x^2 + \sigma_y^2 - \sigma_{x-y}^2}{2\sigma_x\sigma_y}$ to find r for the following
 data:

$x: 21 \quad 23 \quad 30 \quad 54 \quad 57 \quad 58 \quad 72 \quad 78 \quad 87 \quad 90$

$y: 60 \quad 71 \quad 72 \quad 83 \quad 110 \quad 84 \quad 100 \quad 92 \quad 113 \quad 135$

Hint: $\sigma_x^2 = 584.6, \sigma_y^2 = 468.8,$
 $\sigma_{x-y}^2 = 134.6.$

Ans. $r = 0.876$

6. In a paired data for x, y with $N = 25, \sum x =$
 $127, \sum y = 100, \sum x^2 = 760, \sum y^2 = 449,$
 $\sum xy = 500,$ it was found later that two pairs

of correct values

$x \mid y$ $x \mid y$
 $8 \mid 12$ were (erroneously) copied down as $8 \mid 14.$
 $6 \mid 8$ $8 \mid 6$

Determine the correlation coefficient for the
 correct data.

Hint: $\sum x = 127 + 8 + 6 - 8 - 8 = 125,$
 $\sum y = 100 + 12 + 8 - 14 - 6 = 100$
 $\sum x^2 = 760 + 64 + 36 - 64 - 64 = 732,$
 $\sum y^2 = 449 + 144 + 64 - 39 - 196 = 425$
 $\sum xy = 500 + 96 + 48 - 48 - 112 = 484.$

Ans. -0.30984

7. For $n = 10$ and $r = 0.732$ test the null hypoth-
 esis $\rho = 0$ against alternate hypothesis $\rho \neq 0$
 at the 0.05 level of significance.

Ans. $Z = \sqrt{10-3}(0.933) = 2.47 > 1.96,$ Reject
 N.H.

8. Construct a 95% confidence interval for the
 population correlation coefficient ρ given
 $r = 0.70$ and $n = 30.$

Ans. $0.867 \pm \frac{1.96}{\sqrt{30-3}}$ i.e., $(0.490 < \mu_Z < 1.244)$ so
 $(0.45 < \rho < 0.85)$

9. At 0.05 level of significance, test the null
 hypothesis $\rho = 0.9$ against the alternative
 $\rho > 0.9,$ for $n = 29, r = 0.9435.$

Ans. $Z = \frac{\sqrt{26}}{2} \ln \left[\frac{(1+0.9435)(0.1)}{(1-0.9435)(1.9)} \right] = 1.51 < 1.645,$
 accept N.H.

30.10 RANK CORRELATION or SPEARMAN'S CORRELATION

Although data is measured numeric (quantitative) in
 several cases the data turns out to be non-numeric
 (qualitative).

Examples:

a. Appearance: beautiful, ugly.

b. Efficiency: excellent, good, average, bad.

c. Temperament: wild, composed, dosile.

In such cases, the data is ranked according to that par-

ticular character instead of taking numeric measurements on them, and therefore the usual Pearsonian correlation coefficient can not be calculated. Instead Charles Edward Spearman (1906) a psychologist developed a nonparametric counterpart of the conventional correlation coefficient as follows:

For a given set of n paired observations (X_i, Y_i) , for $i = 1$ to n ; ranks $1, 2, \dots, n$ are assigned to the X observations in order of magnitude and similarly to the Y observations. Then these ranks are substituted for the actual numerical values. The correlation coefficient calculated in this manner is called the “**rank correlation coefficient or Spearman’s correlation coefficient**” and is given by

$$r_{\text{rank}} = r_s = 1 - \frac{6 \sum_{i=1}^n d_i^2}{n(n^2 - 1)}$$

Here d_i = difference between ranks assigned to X_i and Y_i ; n = number of pairs of data.

Note 1: If there are ties among either X or Y observations, substitute for each of the tied observations, the mean of the ranks that they jointly occupy.

Note 2: r_s lies between -1 and 1 .

WORKED OUT EXAMPLES

Example: Determine rank correlation for the following data which shows the marks obtained in two quizzes in mathematics:

| | | | | | | | | | | |
|---------------------------|---|---|---|----|---|---|----|---|---|---|
| Marks in 1st quiz (X) | 6 | 5 | 8 | 8 | 7 | 6 | 10 | 4 | 9 | 7 |
| Marks in 2nd quiz (Y) | 8 | 7 | 7 | 10 | 5 | 8 | 10 | 6 | 8 | 6 |

Solution: Assigning ranks to the data of X , we get

X : 4, 5, 6, 6, 7, 7, 8, 8, 9, 10

Rank: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

or: 1, 2, 3.5, 3.5, 5.5, 5.5, 7.5, 7.5, 9, 10

Similarly, Y : 5, 6, 6, 7, 7, 8, 8, 8, 10, 10

Rank: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

or: 1, 2.5, 2.5, 4.5, 4.5, 7, 7, 7, 9.5, 9.5

Data assigned with ranks is

| | | | | | | | | | | |
|-------|-------|------|-----|-----|-------|-------|------|------|---|-----|
| X | 3.5 | 2 | 7.5 | 7.5 | 5.5 | 3.5 | 10 | 1 | 9 | 5.5 |
| Y | 7 | 4.5 | 4.5 | 9.5 | 1 | 7 | 9.5 | 2.5 | 7 | 2.5 |
| D | -3.5 | -2.5 | 3 | -2 | 4.5 | -3.5 | 0.5 | -1.5 | 2 | 3 |
| D^2 | 12.25 | 6.25 | 9 | 4 | 20.25 | 12.25 | 0.25 | 2.25 | 4 | 9 |

$$\begin{aligned} \text{Rank correlation} &= 1 - \frac{6 \sum D^2}{N(N^2 - 1)} = 1 - \frac{6(79.5)}{10(99)} \\ &= 1 - .4818181 = 0.5181818. \end{aligned}$$

EXERCISE

Rank correlation

Find the rank correlation for the following data:

1.

| | | | | | | | | | | | | |
|-------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| X : | 56 | 42 | 72 | 36 | 63 | 47 | 55 | 49 | 38 | 42 | 68 | 60 |
| Y : | 147 | 125 | 160 | 118 | 149 | 128 | 150 | 145 | 115 | 140 | 152 | 155 |

$$\text{Ans. } r_{\text{rank}} = \frac{1 - 6(19.5)}{12(143)} = 0.931818$$

2.

| | | | | | | |
|-------|----|----|----|---|---|----|
| X : | 2 | 4 | 5 | 6 | 8 | 11 |
| Y : | 18 | 12 | 10 | 8 | 7 | 5 |

$$\text{Ans. } r_{\text{rank}} = 1 - \frac{6(70)}{6(35)} = -1$$

3.

| | | | | | | | | | | |
|-------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| X : | 14 | 17 | 28 | 17 | 16 | 13 | 24 | 25 | 18 | 31 |
| Y : | 0.9 | 1.1 | 1.6 | 1.3 | 1.0 | 0.8 | 1.5 | 1.4 | 1.2 | 2.0 |

$$\text{Ans. } r_{\text{rank}} = 1 - \frac{6(5.50)}{(10)(99)} = 0.967$$

4.

| | | | | | | | | | | |
|-------|------|------|------|------|------|------|------|------|------|------|
| X : | 11.1 | 10.3 | 12.0 | 15.1 | 13.7 | 18.5 | 17.3 | 14.2 | 14.8 | 15.3 |
| Y : | 10.9 | 14.2 | 13.8 | 21.5 | 13.2 | 21.1 | 16.4 | 19.3 | 17.4 | 19.0 |

$$\text{Ans. } r_s = 0.697$$

5. Two judges gave the following ranks to 11 girls in a beauty contest:

| | | | | | | | | | | | |
|---------|---|---|---|---|---|----|----|----|----|----|----|
| Girl | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
| Judge A | 3 | 4 | 1 | 2 | 5 | 10 | 11 | 7 | 9 | 8 | 6 |
| Judge B | 2 | 4 | 3 | 1 | 7 | 9 | 6 | 11 | 10 | 5 | 8 |

$$\text{Ans. } r_s = 1 - \frac{6(66)}{11(120)} = 0.70$$

6. Rank by Judge

| | | | | | | | | | | |
|-------|---|---|---|----|---|----|---|----|---|---|
| A : | 1 | 6 | 5 | 10 | 3 | 2 | 4 | 9 | 7 | 8 |
| B : | 3 | 5 | 8 | 4 | 7 | 10 | 2 | 1 | 6 | 9 |
| C : | 6 | 4 | 9 | 8 | 1 | 2 | 3 | 10 | 5 | 7 |

Hint: $\sum d_1^2 = 200$, $\sum d_2^2 = 60$,

$$\sum d_3^2 = 214, n = 10.$$

30.34 — HIGHER ENGINEERING MATHEMATICS—VII

Ans. $r(A, B) = -\frac{7}{33}$, $r(A, C) = \frac{7}{11}$, $r(B, C) = -\frac{49}{65}$,
Judges A and C have nearest common approach (judgement) since $r(A, C)$ is maximum.

30.8 CORRELATION FOR BIVARIATE FREQUENCY DISTRIBUTION

When the data is very large, it is arranged into a bivariate frequency table (or bivariate frequency distribution) as follows:

| | | Class intervals for X | | | |
|-----------------------|---------------------|-----------------------|----------|---------------------|--------|
| Class intervals for Y | Y \ X | $X_{L_1} - X_{U_1}$ | $\dots$ | $X_{L_k} - X_{U_k}$ | Totals |
| | $Y_{L_1} - Y_{U_1}$ | f_{11} | $\dots$ | f_{1k} | |
| | $\vdots$ | $\vdots$ | f_{ij} | $\vdots$ | |
| | $Y_{L_m} - Y_{U_m}$ | f_{m1} | $\dots$ | f_{mk} | |
| | Totals | | | | N |

cell frequency.

$$N = \text{Total frequency} = \sum_{j=1}^k \sum_{i=1}^m f_{ij}$$

Let

X_i be the mid value (class mark) of the i th X class

Y_j be the mid value of the j th Y class.

$$\text{Put } U_X = \frac{X - A}{C_1}, \quad U_Y = \frac{Y - B}{C_2}$$

where C_1 = class size of X intervals

C_2 = class size of Y intervals

A = Assumed class mark for X-classes

B = Assumed class mark for Y-classes.

f_X : marginal frequencies of X (column sums of f_{ij} 's)

f_Y : marginal frequencies of Y (row sums of f_{ij} 's).

Note that $\sum f_X = \sum f_Y = N$.

fU_XU_Y is denoted by a number in corner of each cell as $\square$.

CORRELATION TABLE

| | | Mid value X | X_1 | $\dots$ | X_k | | | | |
|--|----------|-------------|---------|---------|-------|---------------------------|---------------|-----------------|---|
| Mid value Y | Y | U_X | $\dots$ | | | f_Y | f_YU_Y | $f_YU_Y^2$ | Sum of corner (boxed) numbers in each row |
| | | U_Y | $\dots$ | | | | | | |
| Y_1 | $\vdots$ | $\vdots$ | | | | | | | |
| Y_m | | | | | | | | | |
| f_X | | | | | | $N = \sum f_X = \sum f_Y$ | $\sum f_YU_Y$ | $\sum f_YU_Y^2$ | $\sum fU_XU_Y$ |
| f_XU_X | | | | | | $\sum f_XU_X$ | | | |
| $f_XU_X^2$ | | | | | | $\sum f_XU_X^2$ | | | |
| Sum of corner (boxed) numbers in each column | | | | | | $\sum fU_XU_Y$ | | | |

CHECK

Assume that

X is grouped into k classes

Y is grouped into m classes

f_{ij} or simply f is the cell frequency of the i th X-class interval and j th Y-class interval.

X_{L_1}, X_{U_1} denotes the lower and upper limits of the 1st class, Y_{L_m}, Y_{U_m} denotes the lower and upper limits of the m th class etc. Blank cell denotes zero

The bivariate frequency table is rewritten as (see Page 30.36)

Now the correlation coefficient takes the form as

$$r = \frac{N \sum fU_XU_Y - (\sum f_XU_X)(\sum f_YU_Y)}{\sqrt{[N \sum f_XU_X^2 - (\sum f_XU_X)^2][N \sum f_YU_Y^2 - (\sum f_YU_Y)^2]}}$$

Note:

1. U_X, U_Y turns out to be 0, $\pm 1, \pm 2, \pm 3, \dots$

2. In general, $C_1 = C_2$.

3. Check: total frequency $N = \sum f_X = \sum f_Y$.

4. Check: $\sum f U_X U_Y = \sum f U_Y U_X$ obtained from row sums and column sums.

WORKED OUT EXAMPLES

Correlation for bivariate frequency distribution

Example 1: The following table shows the bivariate frequency distribution of marks obtained by 25 students in mathematics X and computer science Y . Determine the coefficient of correlation r . Test the null hypothesis $\rho = 0$ against the alternative hypothesis $\rho \neq 0$ at 0.05 level of significance. Determine whether there is a relationship between marks in the two subjects.

| Marks in mathematics: X | | | | | |
|---------------------------|-------|-------|-------|-------|-------|
| | 21–25 | 26–30 | 31–35 | 36–40 | 41–45 |
| Marks in C. S.: Y | 21–25 | 1 | | | |
| | 26–30 | | 3 | 1 | |
| | 31–35 | | 2 | 5 | 2 |
| | 36–40 | | | 1 | 4 |
| | 41–45 | | | 1 | 3 |
| | 46–50 | | | | 1 |

Solution: Here $N = \text{total frequency} = 25$. From the bivariate correlation table (overleaf on Page 821), we get $\sum f_X U_X = 6$, $\sum f_Y U_Y = 11$, $\sum f_X U_X^2 = 26$, $\sum f_Y U_Y^2 = 39$, $\sum f U_X U_Y = 25$. We know that the correlation coefficient for a bivariate frequency distribution is given by

$$r = \frac{N \sum f U_X U_Y - (\sum f_X U_X)(\sum f_Y U_Y)}{\sqrt{[N \sum f_X U_X^2 - (\sum f_X U_X)^2][N \sum f_Y U_Y^2 - (\sum f_Y U_Y)^2]}}$$

$$= \frac{(25)(25) - (6)(11)}{\sqrt{[(25)(26) - (6)^2][(25)(39) - (11)^2]}} = 0.7719669.$$

Test of hypothesis:

1. $H_0: \rho = 0$ Null hypothesis
2. $H_1: \rho \neq 0$ Alternative hypothesis
3. $\alpha = 0.05$ Level of significance
4. Critical region: Reject the null hypothesis if $Z < -1.96$ or $Z > 1.96$, where

$$Z = \sqrt{n-3} Z^*.$$

5. Computation: The value of Z^* corresponding to $r = 0.772$ is $Z^* = \frac{1}{2} \ln \frac{1+r}{1-r} = \frac{1}{2} \ln \frac{1+0.772}{1-0.772} = 1.020$
so $Z = \sqrt{n-3} Z^* = \sqrt{25-3}(1.020) = 4.80889 \approx 4.81$
6. Decision: Reject the null hypothesis of “no linear association” because $Z = 4.81 > 1.96$. So conclude that there is a relationship between the marks obtained in the subjects mathematics and computer science.

Example 2: Test the null hypothesis $\rho = 0.9$ against the alternative that $\rho > 0.9$ at 0.05 level of signification for the above data with $r = 0.772$.

Solution:

1. $H_0: \rho = 0.9$
2. $H_1: \rho > 0.9$
3. $\alpha: 0.05$
4. Critical region: $Z > 1.645$
5. Calculation:

$$Z = \frac{\sqrt{n-3}}{2} \ln \left\{ \frac{(1+r)(1-\rho_0)}{(1-r)(1+\rho_0)} \right\}$$

$$Z = \frac{\sqrt{25-3}}{2} \ln \left[\frac{(1+0.772)(0.1)}{(1-0.772)(1.9)} \right] = -2.14$$

6. Decision: Since $Z = -2.14 < Z_{\alpha} = 1.645$ accept null hypothesis i.e., there is some evidence that correlation coefficient does not exceed 0.9.

EXERCISE

Find the correlation coefficient for the following bivariate frequency distribution:

| | | X | | | | |
|-----|---------|-------|-------|-------|-------|-------|
| | | 59–62 | 63–66 | 67–70 | 71–74 | 75–78 |
| Y | 90–109 | 2 | 1 | | | |
| | 110–129 | 7 | 8 | 4 | 2 | |
| | 130–149 | 5 | 15 | 22 | 7 | 1 |
| | 150–169 | 2 | 12 | 63 | 19 | 5 |
| | 170–189 | | 7 | 28 | 32 | 12 |
| | 190–209 | | 2 | 10 | 20 | 7 |
| | 210–229 | | | 1 | 4 | 2 |

BIVARIATE CORRELATION TABLE

| X | | 23 | 28 | 33 | 38 | 43 | f_Y | $f_Y U_Y$ | $f_Y U_Y^2$ | Sum of corner numbers in each row |
|--------------------------------------|-------|-------|----------|----------|----------|----------|----------------------------|---------------------|-----------------------|-----------------------------------|
| Y | U_Y | U_Y | -2 | -1 | 0 | 1 | | | | |
| 23 | -2 | 1 | <u>4</u> | | | | 1 | -2 | 4 | 4 |
| 28 | -1 | | 3 | <u>3</u> | 1 | <u>0</u> | 4 | -4 | 4 | 3 |

Ans. $r = -0.19$

Chapter 31

Joint Probability Distribution and Markov Chains

INTRODUCTION

So far in the univariate case, we restricted our attention to probability distribution of a single random variable. However, in problems in economics, biology or social sciences we will be interested in the study of statistical methods analyzing two or more (bivariate or multivariate) variables. In such cases the concept of joint probability distribution is required. Markov* chains, involving calculation of high power of matrices, are powerful tool for forecasting future events.

31.1 JOINT PROBABILITY DISTRIBUTION

Let S be a sample space associated with a random experiment ε . Let $X = X(s)$ and $Y = Y(s)$ be two random variables on the same sample space S . The two real valued functions $X(s)$ and $Y(s)$ each assign a real number to each outcome s of the sample space S , with respective image sets given by

$$X(s) = \{X(s_1), X(s_2), \dots, X(s_n)\} = \{X_1, X_2, \dots, X_n\}$$

$$\text{and } Y(s) = \{Y(s_1), Y(s_2), \dots, Y(s_m)\} = \{Y_1, Y_2, \dots, Y_m\}$$

Here the two random variables X and Y are discrete since the possible values of X and Y are finite (or countably infinite).

Example:

a. X : Age, Y : Blood pressure of a person.

b. X : Crop yield, Y : Rain fall in an area.

c. X : I.Q., Y : Nutrition of an individual.

Consider the product set

$$X(S) \times Y(S) = \{(x_1, y_1), (x_1, y_2), \dots, (x_n, y_m)\}.$$

Fig. 31.1

The joint probability distribution or joint distribution or probability mass function or joint probability function of two discrete random variables X and Y is a function $h(x, y)$ defined on the product set $X(s) \times Y(s)$ assigning probability to each of the ordered pairs (x_i, y_i) .

Thus $h(x_i, y_i) = P(X = x_i, Y = y_i)$ gives the probability for the simultaneous occurrences of the outcomes x_i and y_i . Further $h(x, y)$ satisfies the following:

$$1. h(x_i, y_j) \geq 0$$

$$2. \sum_{j=1}^m \sum_{i=1}^n h(x_i, y_j) = 1$$

The set of triplets $(x_i, y_j, h(x_i, y_j))$ for $i = 1$ to n , $j = 1$ to m , known as the probability distribution of

* Andrei Andrejevtich Markov (1856-1922), Russian mathematician

31.2 — HIGHER ENGINEERING MATHEMATICS—VII

the two random variables X, Y is in general represented in the form of a rectangular table as follows:

Joint Probability distribution

| $X \backslash Y$ | y_1 | y_2 | $\dots$ | y_m | Row sums |
|------------------|---------------|---------------|---------|---------------|----------|
| x_1 | $h(x_1, y_1)$ | $h(x_1, y_2)$ | $\dots$ | $h(x_1, y_m)$ | $f(x_1)$ |
| x_2 | $h(x_2, y_1)$ | $h(x_2, y_2)$ | $\dots$ | $h(x_2, y_m)$ | $f(x_2)$ |
| $\vdots$ | $\dots$ | $\dots$ | $\dots$ | $\dots$ | $\vdots$ |
| x_n | $h(x_n, y_1)$ | $h(x_n, y_2)$ | $\dots$ | $h(x_n, y_m)$ | $f(x_n)$ |
| Column sums | $g(y_1)$ | $g(y_2)$ | $\dots$ | $g(y_m)$ | |

Marginal Distributions

Marginal distribution $f(x)$ of X is the probability distribution of X alone; obtained by summing $h(x, y)$ over the values of Y . i.e.,

$$f(x_i) = \sum_{j=1}^m h(x_i, y_j)$$

or $f(x_i)$ is the row sum of the i th row entries. Similarly, marginal distribution $g(y)$ of Y is the probability distribution of Y alone, obtained by summing $h(x, y)$ over the values of X . i.e.,

$$g(y_j) = \sum_{i=1}^n h(x_i, y_j)$$

or $g(y_j)$ is the column sum of the j th column entries.

Conditional Probability Distributions

Conditional distribution of random variable Y given that $X = x$ is

$$h(y|x) = \frac{h(x, y)}{f(x)}, \quad \text{provided } f(x) > 0.$$

Similarly, the conditional distribution of X given that $Y = y$ is

$$h(x|y) = \frac{h(x, y)}{g(y)}, \quad \text{provided } g(y) > 0.$$

Thus

$$P(a < X < b | Y = y) = \sum_x h(x|y)$$

where the summation is for all values of X between a and b .

Statistical Independence

The random variables X and Y are said to be statistically independent or simply independent if

$$h(x, y) = f(x) \cdot g(y)$$

for all (x, y) i.e.,

$$\begin{aligned} h(x_i, y_j) &= P(X = x_i, Y = y_j) = P(X = x_i) \cdot P(Y = y_j) \\ &= f(x_i) \cdot g(y_j) \end{aligned}$$

for all $i = 1$ to n and $j = 1$ to m . In other words, when X and Y are independent, each entry $h(x_i, y_j)$ is obtained as the product of its marginal entries. The joint distribution of X and Y can be determined from their marginal distribution functions. However, in the case of dependent variables, the joint distribution can **not** be determined in this simple fashion.

Covariance

The covariance of X and Y , denoted by $\text{Cov}(x, y)$ is given by

$$\begin{aligned} \text{Cov}(X, Y) &= \sum_j \sum_i (x_i - \mu_X)(y_j - \mu_Y)h(x_i, y_j) \\ &= E((X - \mu_X)(Y - \mu_Y)) \\ &= \sum_j \sum_i x_i \cdot y_j \cdot h(x_i, y_j) - \mu_X \cdot \mu_Y \end{aligned}$$

$$\text{Cov}(X, Y) = E(XY) - \mu_X \mu_Y$$

Correlation

The correlation of X and Y is

$$\rho(X, Y) = \frac{\text{Cov}(X, Y)}{\sigma_X \sigma_Y}$$

The dimensionless number ρ satisfy the following properties:

- i. $\rho(X, Y) = \rho(Y, X)$ symmetry
- ii. $\rho(X, X) = 1$ perfectly correlated
 $\rho(X, -X) = -1$ negatively correlated
- iii. $-1 \leq \rho \leq 1$ $\begin{cases} -1 \text{ if } X = -aY, (a > 0) \\ 0 \text{ if } X \text{ and } Y \text{ are uncorrelated} \\ 1 \text{ if } X = aY, (a > 0) \end{cases}$
- iv. $\rho(aX + b, cY + d) = \rho(X, Y)$ if $a, c \neq 0$.

Result: If X and Y are independent, then

- a. $E(XY) = E(X)E(Y)$
- b. $\text{Var}(X + Y) = \text{Var}(X) + \text{Var}(Y)$
- c. $\text{Cov}(X, Y) = 0$

Proof:

$$\begin{aligned} \text{a. } E(XY) &= \sum_{i,j} x_i y_j h(x_i, y_j) = \sum_i x_i y_j f(x_i) g(y_j) \\ &= \sum_i x_i f(x_i) \sum_j y_j g(y_j) = E(X) \cdot E(Y) \end{aligned}$$

b. Var (X + Y)

$$\begin{aligned} &= \sum_{i,j} (x_i + y_j)^2 h(x_i, y_j) - \mu_{X+Y}^2 \\ &= \sum_i x_i^2 h(x_i, y_j) + 2 \sum_i x_i y_j h(x_i, y_j) \\ &\quad + \sum_{i,j} y_j^2 h(x_i, y_j) - (\mu_X + \mu_Y)^2 \\ &= \sum_i x_i^2 f(x_i) + 2 \sum_i x_i f(x_i) \cdot \sum_j y_j g(y_j) + \\ &\quad + \sum_j y_j^2 g(y_j) - \mu_X^2 - 2\mu_X \mu_Y - \mu_Y^2 \\ &= \left[\sum_i x_i^2 f(x_i) - \mu_X^2 \right] + \left[\sum_j y_j^2 g(y_j) - \mu_Y^2 \right] \\ &= \text{Var}(X) + \text{Var}(Y) \end{aligned}$$

$$\begin{aligned} \text{c. } \text{Cov}(X, Y) &= E(XY) = \mu_X \mu_Y \\ &= E(X)E(Y) - \mu_X \mu_Y \end{aligned}$$

$$\text{since } E(XY) = E(X)E(Y)$$

$$\text{Cov}(X, Y) = \mu_X \mu_Y - \mu_X \mu_Y = 0.$$

WORKED OUT EXAMPLES

Example 1: Find (a) marginal distributions $f(x)$ and $g(y)$, (b) $E(X)$ and $E(Y)$, (c) $\text{Cov}(X, Y)$, (d) σ_X, σ_Y and (e) $\rho(X, Y)$ for the following joint distribution, (f) Are X and Y independent random variables?

| $X \backslash Y$ | -4 | 2 | 7 |
|------------------|---------------|---------------|---------------|
| 1 | $\frac{1}{8}$ | $\frac{1}{4}$ | $\frac{1}{8}$ |
| 5 | $\frac{1}{4}$ | $\frac{1}{8}$ | $\frac{1}{8}$ |

Solution: (a) The marginal distribution $f(x)$ is obtained by row sums and $g(y)$ by column sums.

| $X \backslash Y$ | -4 | 2 | 7 | Row sums |
|------------------|---------------|---------------|---------------|---------------|
| 1 | $\frac{1}{8}$ | $\frac{1}{4}$ | $\frac{1}{8}$ | $\frac{1}{2}$ |
| 5 | $\frac{1}{4}$ | $\frac{1}{8}$ | $\frac{1}{8}$ | $\frac{1}{2}$ |
| Column sums | $\frac{3}{8}$ | $\frac{3}{8}$ | $\frac{1}{4}$ | CHECK 1 |

The marginal distribution $f(x)$:

| x_i : | 1 | 5 |
|------------|---------------|---------------|
| $f(x_i)$: | $\frac{1}{2}$ | $\frac{1}{2}$ |

The marginal distribution $g(y)$:

| y_i : | -4 | 2 | 7 |
|------------|---------------|---------------|---------------|
| $g(y_i)$: | $\frac{3}{8}$ | $\frac{3}{8}$ | $\frac{1}{4}$ |

$$\text{(b) } E(X) = \mu_X = \sum_{i=1}^2 x_i f(x_i) = 1 \cdot \frac{1}{2} + 5 \cdot \frac{1}{2} = \frac{6}{2} = 3$$

$$E(Y) = \mu_Y = \sum_{j=1}^3 y_j g(y_j)$$

$$E(Y) = -4 \cdot \frac{3}{8} + 2 \cdot \frac{3}{8} + 7 \cdot \frac{1}{4} = 1.$$

$$\text{(c) We know that } \text{Cov}(X, Y) = E(XY) - \mu_X \cdot \mu_Y.$$

Now

$$\begin{aligned} E(XY) &= \sum_{j=1}^3 \sum_{i=1}^2 x_i y_j h(x_i, y_j) \\ &= 1 \cdot (-4) \cdot \frac{1}{8} + 1 \cdot 2 \cdot \frac{1}{4} + 1 \cdot 7 \cdot \frac{1}{8} + \\ &\quad + 5 \cdot (-4) \cdot \frac{1}{4} + 5 \cdot 2 \cdot \frac{1}{8} + 5 \cdot 7 \cdot \frac{1}{8} \\ E(XY) &= \frac{3}{2} = 1.5. \end{aligned}$$

$$\text{So } \text{Cov}(X, Y) = E(XY) - \mu_X \cdot \mu_Y = 1.5 - 3 \cdot 1 = -1.5.$$

$$\text{(d) } \sigma_X^2 = \text{Var}(X) = E(X^2) - \mu_X^2 = 13 - 3^2 = 4, \sigma_X = 2$$

$$\left(\because E(X^2) = 1 \cdot \frac{1}{2} + 25 \cdot \frac{1}{2} = 13 \right)$$

$$\sigma_Y^2 = \text{Var}(Y) = E(Y^2) - \mu_Y^2 = 19.75 - 1 = 18.75, \sigma_Y = 4.33$$

$$\left(\because E(Y^2) = 16 \cdot \frac{3}{8} + 4 \cdot \frac{3}{8} + 49 \cdot \frac{1}{4} = 19.75 \right)$$

31.4 — HIGHER ENGINEERING MATHEMATICS—VII

$$\rho(X, Y) = \frac{\text{Cov}(X, Y)}{\sigma_X \cdot \sigma_Y} = \frac{-1.5}{2(4.33)} = -0.1732.$$

(e) Note that $P(X = 1, Y = -4) = \frac{1}{8}$ from table.

$P(X = 1) = \frac{1}{2}$, $P(Y = -4) = \frac{3}{8}$ from marginal distributions. Thus

$$\begin{aligned} P(X = 1, Y = -4) &= \frac{1}{8} \neq P(X = 1) \cdot P(Y = -4) \\ &= \frac{1}{2} \cdot \frac{3}{8} = \frac{3}{16} \end{aligned}$$

$\therefore X$ and Y are **not** independent.

Example 2: Find the joint distribution of X and Y , which are independent random variables with the following respective distributions:

| | | |
|------------|----|----|
| x_i : | 1 | 2 |
| $f(x_i)$: | .7 | .3 |

and

| | | | |
|------------|----|----|----|
| y_j : | -2 | 5 | 8 |
| $g(y_j)$: | .3 | .5 | .2 |

Show that $\text{Cov}(X, Y) = 0$.

Solution: Since X and Y are independent random variables,

$$h(x_i, y_j) = f(x_i)g(y_j).$$

Thus the entries of the joint distribution are the products of the marginal entries

| $X \backslash Y$ | -2 | 5 | 8 | Sum |
|------------------|-----|-----|-----|---------|
| 1 | .21 | .35 | .14 | .7 |
| 2 | .09 | .15 | .06 | .3 |
| Sum | .3 | .5 | .2 | CHECK 1 |

$$\begin{aligned} \text{Now } E(XY) &= 1 \cdot (-2)(.21) + 1 \cdot 5(.35) + 1 \cdot 8(.14) \\ &\quad + 2 \cdot (-2)(.09) + 2 \cdot 5(.15) + 2 \cdot 8(.06) = 4.55 \end{aligned}$$

$$\mu_X = 1(.7) + 2(.3) = 1.3,$$

$$\mu_Y = -2(.31) + 5(.5) + 8(.2) = 3.5$$

$$\begin{aligned} \text{So } \text{Cov}(X, Y) &= E(XY) - \mu_X \cdot \mu_Y \\ &= 4.55 - (1.3)(3.5) = 0. \end{aligned}$$

Example 3: Two cards are selected at a random from a box which contains five cards numbered 1, 1, 2, 2 and 3. Find the joint distribution of X and Y where X denotes the sum and Y , the maximum of the two numbers drawn. Also determine $\text{Cov}(X, Y)$ and $\rho(X, Y)$.

Solution: The possible pair of numbers are (1,1), (1,1), (1,2), (2,1), (1,2), (2,1), (1,3), (3,1), (2,2), (2,3), (3,2). Sum of two numbers are 2, 3, 4, 5 while maximum numbers are 1, 2, 3. Thus

Distribution of X is

| | | | | |
|------------|----------------------|----------------------|----------------------|----------------------|
| x_i : | 2 | 3 | 4 | 5 |
| $f(x_i)$: | $\frac{1}{10} = 0.1$ | $\frac{4}{10} = 0.4$ | $\frac{3}{10} = 0.3$ | $\frac{2}{10} = 0.2$ |

Distribution of Y is

| | | | |
|------------|----------------------|----------------------|----------------------|
| y_j : | 1 | 2 | 3 |
| $g(y_j)$: | $\frac{1}{10} = 0.1$ | $\frac{5}{10} = 0.5$ | $\frac{4}{10} = 0.4$ |

Joint distribution

| $X \backslash Y$ | 1 | 2 | 3 | Sum |
|------------------|----|----|----|---------|
| 2 | .1 | 0 | 0 | .1 |
| 3 | 0 | .4 | 0 | .4 |
| 4 | 0 | .1 | .2 | .3 |
| 5 | 0 | 0 | .2 | .2 |
| Sum | .1 | .5 | .4 | CHECK 1 |

$$\begin{aligned} \text{Cov}(X, Y) &= E(XY) - \mu_X \cdot \mu_Y = 8.8 - (3.6)(2.3) \\ &= 0.52 \neq 0. \end{aligned}$$

Therefore X, Y are **not** independent.

$$\sigma_X^2 = \text{Var}(X) = E(X^2) - \mu_X = 13.8 - (3.6)^2 = 0.84$$

$$(\because E(X^2) = .4 + 3.6 + 4.8 + 5 = 13.8)$$

$$\sigma_Y^2 = \text{Var}(Y) = E(Y^2) - \mu_Y = 5.7 - (2.3)^2 = 0.41$$

$$(\because E(Y^2) = .1 + 2 + 3.6 = 5.7)$$

$$\text{Thus } \sigma_X = 0.9165, \sigma_Y = 0.6403$$

$$\therefore \rho(X, Y) = \frac{\text{Cov}(XY)}{\sigma_X \sigma_Y} = \frac{0.52}{(0.9165)(0.6403)} = 0.886 \approx 0.9$$

Example 4: Evaluate the conditional distributions $h(x|1)$ for the following joint distribution. Show that X and Y are not independent

| $X \backslash Y$ | 1 | 2 | 3 |
|------------------|----------------|---------------|----------------|
| 1 | $\frac{1}{12}$ | $\frac{1}{6}$ | 0 |
| 2 | 0 | $\frac{1}{9}$ | $\frac{1}{5}$ |
| 3 | $\frac{1}{18}$ | $\frac{1}{4}$ | $\frac{2}{15}$ |

Solution: Adding rowwise and columnwise rewrite the joint distribution with the marginal distributions. Note that the entries of the above joint distribution are *not* obtained as the products of the marginal entries because it is not known whether X and Y are independent (In fact, it will be proved below that X and Y are dependent).

Explanation for the rowwise entries The number of pairs having the sum 2 and maximum number 1 is (1, 1) only. Thus $h(2, 1) = \frac{1}{10} = 0.1$. Also, there is no pair where the sum is 2 and maximum number is also 2. So this is an impossible event, therefore $h(2, 2) = 0$. The number of pairs whose sum is 3 and maximum number is 2 are (1, 2), (2, 1), (1, 2), (2, 1): four: $h(3, 2) = \frac{4}{10} = 0.4$, similarly, $h(4, 2) = \frac{1}{10}$ (only (2, 2)), $h(4, 3) = \frac{2}{10}$ (only {(1, 3) and (3, 1)}). Similarly, $h(5, 1) = 0$, $h(5, 2) = 0$, $h(5, 3) = \frac{2}{10} = 0.2$ {(2, 3) and (3, 2) are the two pairs}.

$$\mu_X = 2(.1) + 3(.4) + 4(.3) + 5(.2) = 3.6$$

$$\mu_Y = 1(.1) + 2(.5) + 3(.4) = 2.3$$

$$E(XY) = 2 \cdot 1 \cdot (.1) + 3 \cdot 2 \cdot (.4) + 4 \cdot 2 \cdot (.1) + 4 \cdot 3 \cdot (.2) + 5 \cdot 3 \cdot (.2) = 8.8$$

| $Y \backslash X$ | 1 | 2 | 3 | Row sum |
|------------------|-----------------|-----------------|----------------|-------------------|
| 1 | $\frac{1}{12}$ | $\frac{1}{6}$ | 0 | $\frac{1}{4}$ |
| 2 | 0 | $\frac{1}{9}$ | $\frac{1}{5}$ | $\frac{14}{45}$ |
| 3 | $\frac{1}{18}$ | $\frac{1}{4}$ | $\frac{2}{15}$ | $\frac{201}{540}$ |
| Column sum | $\frac{10}{72}$ | $\frac{19}{36}$ | $\frac{5}{15}$ | CHECK 1 |

$$\text{Conditional distribution } h(x|y) = \frac{h(x,y)}{g(y)}$$

$$\text{Now } h(x|1) = \frac{h(x,1)}{g(1)} = 4h(x, 1)$$

since from the table $g(1) = \frac{1}{4}$. So

$$h(1|1) = \frac{h(1,1)}{g(1)} = 4h(1, 1) = 4\left(\frac{1}{12}\right) = \frac{1}{3}$$

$$h(2|1) = 4h(2, 1) = 4 \cdot \frac{1}{6} = \frac{2}{3}$$

$$h(3|1) = 4h(3, 1) = 4 \cdot 0 = 0$$

Conditional distribution $h(x|1)$:

| x_i : | 1 | 2 | 3 |
|------------|---------------|---------------|---|
| $h(x 1)$: | $\frac{1}{3}$ | $\frac{2}{3}$ | 0 |

Dependence: From table

$$h(2, 3) = P(X = 2, Y = 3) = \frac{1}{4}.$$

From marginal distributions

$$P(X = 2) = f(2) = \frac{19}{36} \text{ and}$$

$$P(Y = 3) = g(3) = \frac{201}{540}. \text{ But}$$

$$h(2, 3) = P(X = 2, Y = 3) = \frac{1}{4} \neq \frac{19}{36} \cdot \frac{201}{540} = f(2)g(3) \\ = P(X = 2) \cdot P(Y = 3)$$

$\therefore X$ and Y are not independent.

EXERCISE

- Determine (a) marginal distributions of X and Y (b) $\text{Cov}(X, Y)$ (c) $\rho(X, Y)$, for the following joint distribution. (d) Determine whether X and Y are independent.

| $X \backslash Y$ | -3 | 2 | 4 |
|------------------|----|----|----|
| 1 | .1 | .2 | .2 |
| 3 | .3 | .1 | .1 |

Hint: $\mu_X = 2$, $\mu_Y = 0.6$, $E(XY) = 0$, $E(X^2) = 5$, $\sigma_X^2 = 1$, $E(Y^2) = 9.6$, $\sigma_Y^2 = 9.24$, $\sigma_Y = 3.0$ (d) $h(1, -3) = .1 \neq .2 = f(1)$, $g(-3) = (.5)(.4)$.

$$\text{Ans. (a)} \quad \begin{bmatrix} x_i & 1 & 3 \\ f(x_i) & .5 & .5 \end{bmatrix}, \quad \begin{bmatrix} y_j & -3 & 2 & 4 \\ g(y_j) & .4 & .3 & .3 \end{bmatrix};$$

- $\text{Cov}(X, Y) = -1.2$, (c) $\rho(X, Y) = -4$, (d) not independent

- If X and Y are independent random variables, find the joint distribution of X and Y with the

31.6 — HIGHER ENGINEERING MATHEMATICS—VII

following marginal distribution of X and Y .

| | | |
|----------|----|----|
| x_i | 1 | 2 |
| $f(x_i)$ | .6 | .4 |

,

| | | | |
|----------|----|----|----|
| y_j | 5 | 10 | 15 |
| $g(y_j)$ | .2 | .5 | .3 |

Hint: $h(x_i, y_j) = f(x_i)g(y_j)$.

Ans.

| $X \backslash Y$ | 5 | 10 | 15 | Row sums |
|------------------|-----|-----|-----|----------|
| 1 | .12 | .30 | .18 | .6 |
| 2 | .08 | .20 | .12 | .4 |
| Column sums | .2 | .5 | .3 | |

3. A fair coin is tossed three times. Let X denote 0 or 1 according as a head or a tail occurs on the first toss. Let Y denote the number of heads which occur. (a) Find the marginal distributions of X and Y , (b) Determine the joint distribution of X and Y and (c) $\text{Cov}(X, Y)$.

Hint:

$$S = \{H, T\} \times \{H, T\} \times \{H, T\} : 2^3 = 8 \text{ points}$$

$$= \{HHH, HHT, HTH, HTT, THH, THT, TTH, TTT\}, X(HHH) = 0, X(THH) = 1 \text{ etc.}, Y(HHH) = 3, Y(TTT) = 0 \text{ etc.}$$

(c) $\mu_X = \frac{1}{2}, \mu_Y = \frac{3}{2}, E(XY) = \frac{1}{2}$

Ans. (a)

| | | |
|----------|---------------|---------------|
| x_i | 0 | 1 |
| $f(x_i)$ | $\frac{1}{2}$ | $\frac{1}{2}$ |

,

| | | | | |

| y_j | 0 | 1 | 2 | 3 |
| $g(y_j)$ | $\frac{1}{8}$ | $\frac{3}{8}$ | $\frac{3}{8}$ | $\frac{1}{8}$ |

(b)

| $X \backslash Y$ | 0 | 1 | 2 | 3 | Sums |
|------------------|---------------|---------------|---------------|---------------|---------------|
| 0 | 0 | $\frac{1}{8}$ | $\frac{2}{8}$ | $\frac{1}{8}$ | $\frac{1}{2}$ |
| 1 | $\frac{1}{8}$ | $\frac{2}{8}$ | $\frac{1}{8}$ | 0 | $\frac{1}{2}$ |
| Sums | $\frac{1}{8}$ | $\frac{3}{8}$ | $\frac{3}{8}$ | $\frac{1}{8}$ | |

(c) $\text{Cov}(X, Y) = -\frac{1}{4}$

4. The joint distributions of two pairs of random variables X, Y and X^*, Y^* are given below. Find the marginal distributions of X, Y and X^*, Y^* , $\text{Cov}(X, Y)$, $\text{Cov}(X^*, Y^*)$, $\rho(X, Y)$, $\rho(X^*, Y^*)$. Comment.

Ans. Marginal distributions of X and X^* are same. Also, marginal distributions of Y and Y^* are

same.

| | | |
|----------|---------------|---------------|
| x_i | 1 | 3 |
| $f(x_i)$ | $\frac{1}{2}$ | $\frac{1}{2}$ |

,

| | | |
|----------|---------------|---------------|
| y_j | 4 | 10 |
| $g(y_j)$ | $\frac{1}{2}$ | $\frac{1}{2}$ |

$$\mu_X = \mu_{X^*} = 2, \mu_Y = \mu_{Y^*} = 7, \text{Cov}(X, Y) = 0, \text{Cov}(X^*, Y^*) = -3, \rho(X, Y) = 0, \rho(X^*, Y^*) = -\frac{3}{2 \cdot 7} = -\frac{3}{14} = -0.21428.$$

Comment: Although the marginal distributions are identical, covariances and correlations coefficients are different.

5. Given the joint distribution

| $Y \backslash X$ | 0 | 1 | 2 |
|------------------|----|----|----|
| 0 | .1 | .4 | .1 |
| 1 | .2 | .2 | 0 |

- (a) Determine the marginal distributions of X and Y , (b) Find the conditional probability distribution $h(x|y = 1)$, (c) Are X and Y independent?

Ans. (a)

| | | | |
|----------|----|----|----|
| x_i | 0 | 1 | 2 |
| $f(x_i)$ | .3 | .6 | .1 |

,

| | | |
|----------|----|----|
| y_j | 0 | 1 |
| $g(y_j)$ | .6 | .4 |

(b) $h(0|1) = \frac{h(0,1)}{g(1)} = \frac{.2}{.4} = .5, h(1|1) = .5, h(2|1) = 0;$

(c) Dependent, since $f(0, 1) = 0.2 \neq (.3)(.4) = f(0)g(1)$.

6. Find the marginal distributions of X and Y and find $P(Y = 3|X = 2)$ if the joint distribution is

| $Y \backslash X$ | 1 | 2 | 3 |
|------------------|------|------|------|
| 1 | 0.05 | 0.05 | 0.1 |
| 2 | 0.05 | 0.1 | 0.35 |
| 3 | 0 | 0.2 | 0.1 |

Ans.

| | | | |
|----------|-----|------|------|
| x_i | 1 | 2 | 3 |
| $f(x_i)$ | 0.1 | 0.35 | 0.55 |

,

| | | | |
|----------|-----|-----|-----|
| y_j | 1 | 2 | 3 |
| $g(y_j)$ | 0.2 | 0.5 | 0.3 |

$$P(Y = 3|X = 2) = \frac{0.2}{0.35} = 0.5714.$$

7. Two marbles are selected at random from a box containing 3 blue, 2 red and 3 green marbles. If X is the number of blue marbles and Y is the number of red marbles selected, find (a) joint

probability function $h(x, y)$, (b) $P[(X, Y) \in A]$ where A is the region $\{(x, y) | x + y \leq 1\}$, (c) the marginal distributions of X and Y .

Hint: (a) $h(x, y) = \binom{3}{x} \binom{2}{y} \binom{3}{2-x-y} / \binom{8}{2}$

(b) $x = 0, 1, 2; y = 0, 1, 2; 0 \leq x + y \leq 2$

$$\begin{aligned} P[(x, y) \in A] &= P(X + Y \leq 1) \\ &= h(0, 0) + h(0, 1) + h(1, 0) \\ &= \frac{3}{28} + \frac{3}{14} + \frac{9}{28} = \frac{9}{14}. \end{aligned}$$

| (c) $h(0, 1) = \frac{3}{14} \neq \frac{5}{14} \cdot \frac{3}{7} = f(0)g(1)$ | | | |

31.2 MARKOV CHAINS

Suppose a box A contains 5 red, 3 white and 8 black marbles while box B contains 3 red and 5 white marbles. A fair die is tossed and if 2 or 5 occurs a

marble is chosen from B otherwise from A . Further in box A , two red, one white and 4 black marbles are defective while in box B one red and 2 white marbles are defective. To determine the probability that a marble drawn at random is say a defective red marble, we have to conduct a sequence of experiments in which each experiment has a finite number of outcomes with given probabilities as shown in the tree diagram below (Fig. 31.2).

Fig. 31.2

The four experiments are: toss a die, choose a box, draw a marble and decide whether it is defective. Here probability of a defective red marble is $\frac{2}{3} \cdot \frac{5}{16} \cdot \frac{2}{5} + \frac{1}{3} \cdot \frac{3}{8} \cdot \frac{1}{3}$.

Stochastic Process (or Chance or Random Process)

It is a family of random variables $\{X(t) | t \in T\}$ defined on a common sample space S and indexed by the parameter t , which varies on an index set T .

The values assumed by the random variables $X(t)$ are called *states*, and the set of all possible values

from the *state space* of the process is denoted by I . If the state space is discrete, the stochastic process is known as a *chain*. In this case the state space is assumed to be $I = \{0, 1, 2, \dots\}$. Thus a (finite) stochastic process consists of a sequence of experiments in which each experiment has a finite number of outcomes with given probabilities.

Example: Jobs arrive at random points in time, queue for service and depart after service completion. If N_k denotes the number of jobs at the time of departure of the k th job (customer) then $\{N_k | k = 1, 2, \dots\}$ is a stochastic process.

A *Markov (memoryless)* process is a stochastic process whose entire past history is summarized in its current (present) state. i.e., the “*future*” is independent of its “*past*”.

Markov chain

It is a Markov process in which the state space I is discrete (finite or countably infinite). Thus a (*finite*) *Markov chain* is a finite stochastic process consisting of a sequence of trials whose outcomes say $x_1, x_2, \dots$ satisfy the following two conditions:

- Each outcome belongs to the state space $I = \{a_1, a_2, \dots, a_m\}$, which is the finite set of outcomes.
- The outcome of any trial depends at most upon the outcome of the immediately preceding trial and not upon any other previous outcomes. This Markov property can be stated as

$$P(X_n = i_n | X_0 = i_0, X_1 = i_1, \dots, X_{n-1} = i_{n-1}) \\ = P(X_n = i_n | X_{n-1} = i_{n-1}).$$

Now the system is said to be in state ‘ a_i ’ at time n or at the n th step if a_i is the outcome on the n th trial. Associated with each ordered pair of states (a_i, a_j) , the number p_{ij} gives the probability that system changes from i th state to j th state. In other words, p_{ij} is the probability that a_j occurs immediately after a_i occurs. The numbers p_{ij} are known as transition probabilities.

Transition matrix

P is square matrix of the transition probabilities p_{ij} :

$$P = \begin{matrix} & \begin{matrix} a_1 & a_2 & a_3 & \dots & a_m \end{matrix} \\ \begin{matrix} a_1 \\ a_2 \\ \vdots \\ a_m \end{matrix} & \begin{pmatrix} p_{11} & p_{12} & p_{13} & \dots & p_{1m} \\ p_{21} & p_{22} & p_{23} & \dots & p_{2m} \\ \dots & \dots & \dots & \dots & \dots \\ p_{m1} & p_{m2} & p_{m3} & \dots & p_{mm} \end{pmatrix} \end{matrix}.$$

The i th row of P namely $(p_{i1}, p_{i2}, \dots, p_{im})$ represents the probabilities of that system will change from a_i to $a_1, a_2, a_3, \dots, a_m$.

Probability vector

It is a vector $v = (v_1, v_2, \dots, v_n)$, if $v_i \geq 0$ for every i and $\sum_{i=1}^n v_i = 1$.

Note: A vector whose components are non-negative, but their sum is not one, can be converted into a probability vector by dividing each component by the sum of the components.

Stochastic matrix

P is a square matrix with each row being a probability vector. In other words, all the entries of P are non-negative and the sum of the entries of any row is one.

A vector v is said to be a **fixed vector** or a fixed point of a matrix A if $vA = v$ and $v \neq 0$.

Obviously if v is a fixed vector of A , so is kv since $(kv)A = k(vA) = k(v) = kv$.

Theorem 1: If $v = (v_1 v_2 v_3)$ is a probability vector

of a stochastic matrix $P = \begin{pmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{pmatrix}$ then vP is also a probability vector.

Proof:

$$vP = (v_1 v_2 v_3)_{1 \times 3} \begin{pmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{pmatrix}_{3 \times 3} \\ = (v_1 a_1 + v_2 a_2 + v_3 a_3, v_1 b_1 + v_2 b_2 \\ + v_3 b_3, v_1 c_1 + v_2 c_2 + v_3 c_3).$$

Since a_i, b_i, c_i, v_i are all non-negative for any i , the components of vP are all non-negative. Now the sum

of the components of vP is

$$\begin{aligned} & (v_1a_1 + v_2a_2 + v_3a_3) + (v_1b_1 + v_2b_2 + v_3b_3) \\ & \quad + (v_1c_1 + v_2c_2 + v_3c_3) \\ & = v_1(a_1 + b_1 + c_1) + v_2(a_2 + b_2 + c_2) + v_3(a_3 + b_3 + c_3) \\ & = v_1 \cdot 1 + v_2 \cdot 1 + v_3 \cdot 1 = v_1 + v_2 + v_3 = 1, \text{ since} \end{aligned}$$

P is a stochastic matrix and v is given probability vector.

General result: If $v = (v_1 v_2 v_3 \dots v_n)$ is a probability vector of a n square stochastic matrix P then vP is also a probability vector.

Theorem 2: If P and Q are stochastic matrices then their product PQ is also stochastic matrix. Thus P^n is stochastic matrix for all positive integer values of n .

Proof: The i th row of PQ is the product of i th row of P with matrix Q . Since P and Q are stochastic matrices, i th row of P is a probability vector and by previous Theorem 1, i th row of P with matrix Q is also a probability vector and hence PQ is a stochastic matrix. If $P = Q$, then $PQ = P^2$ is stochastic and in general P^n is stochastic for n positive integer.

Theorem 3: Let $t = (t_1 t_2 \dots t_m)$ be a vector and T be a square matrix whose rows are each the same vector t . Then $pT = t$, if $p = (p_1 p_2 \dots p_m)$ is a probability vector.

Proof:

$$\begin{aligned} pT &= (p_1 p_2 \dots p_m)_{1 \times m} \begin{pmatrix} t_1 & t_2 & t_3 & \dots & t_m \\ t_1 & t_2 & t_3 & \dots & t_m \\ \text{---} & \text{---} & \text{---} & \text{---} & \text{---} \\ t_1 & t_2 & t_3 & \dots & t_m \end{pmatrix}_{m \times m} \\ &= (t_1(p_1 + p_2 + \dots + p_m), t_2(p_1 + p_2 + \dots + p_m), \\ & \quad \dots, t_m(p_1 + p_2 + \dots + p_m)) \\ &= (t_1 \cdot 1, t_2 \cdot 1, \dots, t_m \cdot 1) = (t_1 t_2 \dots t_m) = t \end{aligned}$$

since p is a probability vector (then $\sum_{i=1}^m p_i = 1$).

Theorem 4: The transition matrix P of a Markov chain is a stochastic matrix.

Proof: All the entries of a transition matrix P are non negative because p_{ij} are probabilities. The sum of the elements $(p_{i1}, p_{i2}, \dots, p_{im})$ of any i th row is one, because they represent the probabilities of all the

possible outcomes of transition from state a_i to the states $a_1, a_2, \dots, a_i, \dots, a_m$. Thus each row of P is a probability vector. Therefore P is a stochastic matrix.

A Stochastic matrix P is said to be *regular* if all the entries of some power P^m are positive.

Theorem 5: Let P be a regular stochastic matrix. Then

- (a) P has a unique fixed probability vector t and the components of t are all positive.
- (b) The sequence $P, P^2, P^3 \dots$ of powers of P approaches the matrix T whose rows are each the fixed point t .
- (c) If p is any probability vector, then the sequence of vectors $pP, pP^2, pP^3, \dots$ approaches the fixed point t .

Note: Here matrix A approaches matrix B , means every entry of A approaches the corresponding entry of B .

Higher Transition Probabilities

One-step transition probabilities

The entry p_{ij} in the transition probability matrix P is the probability that the system moves from the state a_i to the state a_j in one step i.e., $a_i \rightarrow a_j$. The one-step transition probabilities in P can also be described by a directed graph known as state-transition diagram or simply transition diagram of the Markov chain. A node labelled i of the transition diagram represents state i of the Markov chain. A branch labeled p_{ij} from node i to j represents the conditional probability (or the one-step transition probabilities) defined by

$$p_{ij} = P(X_n = j \mid X_{n-1} = i)$$

n -step Transition Probabilities

The probability that a Markov chain will move from state i to state j in exactly n steps, is denoted by $p_{ij}(n)$ or $p_{ij}^{(n)}$ and is given by

$$p_{ij}^{(n)} = p_{ij}(n) = P(X_{m+n} = j \mid X_m = i)$$

i.e., $a_i \rightarrow a_{k_1} \rightarrow a_{k_2} \rightarrow \dots \rightarrow a_{k_{n-1}} \rightarrow a_j$.

Evaluation of n -step Transition Probability Matrix $P^{(n)}$ or $P(n)$

using Chapman-Kolmogorov equation

$$p_{ij}(m+n) = \sum_k p_{ik}(m)p_{kj}(n).$$

Let $P^{(n)}$ or $P(n)$ represent a matrix whose (i, j) th entry is $p_{ij}^{(n)}$ or $p_{ij}(n)$. Putting $m = 1$ and $n = n - 1$ in the above C-K equation, $P^{(n)}$ or $P(n)$ the n -step transition probabilities matrix can be written as

$$P^{(n)} = P(n) = P \cdot P(n-1) = P P P(n-2) = P^n.$$

Thus the matrix of n -step transition probabilities $P^{(n)}$ is obtained by multiplying the matrix of one step transition probabilities P by itself $n - 1$ times.

Theorem 6: If P is the transition matrix of a Markov chain, then the n -step transition matrix $P^{(n)}$ is equal to the n th power of P , i.e., $P^{(n)} = P^n$.

In other words, the problem of finding the n -step transition probabilities is reduced to one of forming powers of a given matrix.

Probability distribution of the system at some arbitrary time is denoted by the probability vector.

$$p = (p_1, p_2, p_i, \dots, p_m)$$

where p_i denotes the probability that the system is in state a_i . At time $t = 0$, when the process begins, the corresponding probability vector

$$p^{(0)} = (p_1^{(0)}, p_2^{(0)}, \dots, p_i^{(0)}, \dots, p_m^{(0)})$$

denotes the initial probability distribution. Similarly, the n th step probability distribution i.e., the distribution after the first n -steps is denoted by

$$p^{(n)} = (p_1^{(n)}, p_2^{(n)}, \dots, p_m^{(n)}).$$

Now the (marginal) pmf of the random variable X_n can be obtained from the n -step transition probabilities and the initial distribution as follows

$$p^{(n)} = p^{(0)} P^{(n)} = p^{(0)} P^n$$

Thus the probability distributions of a homogeneous Markov chain are completely determined from the one-step transition probability matrix P and the initial probability distribution $p^{(0)}$.

Theorem 7: The probability distribution of the system n -steps later is given by

$$p^{(n)} = p^{(0)} P^n$$

$$\text{i.e., } p^{(1)} = p^{(0)} P, p^{(2)} = p^{(1)} P = p^{(0)} P P = p^{(0)} P^2$$

$$p^{(3)} = p^{(2)} P = p^{(0)} P^2 P = p^{(0)} P^3 \quad \text{etc.}$$

Stationary Distribution of Regular Markov Chains

Theorem 7: Let P be a regular transition matrix of a Markov chain. Then in the long run, the probability that any state a_j occurs is approximately equal to the component t_j of the unique fixed probability vector t of P .

Proof: Suppose the Markov chain is regular, i.e., P is regular, then by Theorem 5, the sequence of n -step transition matrices P^n approaches the matrix T , whose rows are each the unique fixed probability vector t of P . Hence the probability $p_{ij}(n)$ that a_j occurs for sufficiently large n is independent of the original state a_i and it approaches the component t_j of t .

Stationary distribution

Stationary distribution of a Markov chain is the unique fixed probability vector t of the regular transition matrix P of the Markov chain because every sequence of probability distributions approaches t .

Absorbing States

A state a_i of a Markov chain is said to be an absorbing state if the system remains in the state a_i once it enters there, i.e., a state a_i is absorbing if $p_{ii} = 1$. Thus once a Markov chain enters such an absorbing state, it is destined there to remain forever. In other words the i th row in P has 1 at the main diagonal (i, i) position and zeros everywhere else.

Theorem 8: A stochastic matrix P is not regular if a 1 occurs in the principal main diagonal.

Proof: Suppose a_i is the absorbing state of the given Markov chain whose transition matrix is P . Then 1 occurs in the (i, i) position and the i th row

of P is of the form $(0, 0, \dots, 0, 1, 0, \dots, 0)$. When powers of P are calculated the i th row of P^n persists to contain $(0, 0, \dots, 1, 0, \dots, 0)$. Thus for $i \neq j$ (non diagonal elements), the n -step transition probability $p_{ij}^{(n)} = 0$ for any n . Thus every power of P contains some zero elements. Therefore P is not regular.

WORKED OUT EXAMPLES

Probability vector and stochastic matrix

Example 1: Which vectors are probability vectors

- (i) $(\frac{1}{4}, \frac{3}{2}, -\frac{1}{4}, \frac{1}{2})$ (ii) $(\frac{5}{2}, 0, \frac{8}{3}, \frac{1}{6}, \frac{1}{6})$
 (iii) $(\frac{1}{12}, \frac{1}{2}, \frac{1}{6}, 0, \frac{1}{4})$ (iv) $(3, 0, 2, 5, 3)$

Solution:

- (i) is not a probability vector because negative entry $(-\frac{1}{4})$
 (ii) is not because the sum of the components do not add up to 1
 (iii) is a probability vector because all the entries are non-negative and sum $\frac{1}{12} + \frac{1}{2} + \frac{1}{6} + \frac{1}{4} = \frac{12}{12} = 1$.
 (iv) Dividing by $3 + 0 + 2 + 5 + 3 = 13$, we get the probability vector $(\frac{3}{13}, 0, \frac{2}{13}, \frac{5}{13}, \frac{3}{13})$.

Example 2: Which matrices are stochastic

- (i) $\begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \end{pmatrix}$ (ii) $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ (iii) $\begin{pmatrix} 0 & 1 \\ \frac{1}{2} & \frac{1}{4} \end{pmatrix}$
 (iv) $\begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}$ (v) $\begin{pmatrix} 0 & 1 \\ -\frac{1}{2} & \frac{3}{2} \end{pmatrix}$.

Solution: (i), (iii), (v) are not stochastic because (i) is not square (iii) last row sum is not 1 (v) negative entry (ii) & (iv) are stochastic matrices: each row sum is one, entries non-negative.

Example 3: Which of the stochastic matrices are regular

$$\begin{aligned} \text{(i)} \quad A &= \begin{pmatrix} \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \\ 0 & 1 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix} & \text{(ii)} \quad B &= \begin{pmatrix} \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{4} & \frac{1}{4} & \frac{1}{2} \end{pmatrix} \\ \text{(iii)} \quad C &= \begin{pmatrix} 0 & 0 & 1 \\ \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 1 & 0 \end{pmatrix} \end{aligned}$$

Solution:

- (i) not regular since 1 lies on the main diagonal.

$$\text{(ii)} \quad B^2 = B \cdot B = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{3}{8} & \frac{3}{8} & \frac{1}{4} \end{pmatrix},$$

$$B^3 = B^2 B = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{7}{16} & \frac{7}{16} & \frac{1}{8} \end{pmatrix}$$

since entries b_{13}, b_{23} are zero, B is not regular

$$\text{(iii)} \quad C^2 = C \cdot C = \begin{pmatrix} 0 & 1 & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix},$$

$$C^3 = C \cdot C^2 = \begin{pmatrix} \frac{1}{2} & 0 & \frac{1}{2} \\ \frac{1}{4} & \frac{1}{2} & \frac{1}{4} \\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix}$$

$$C^4 = C^3 \cdot C = \begin{pmatrix} 0 & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{4} & \frac{1}{4} & \frac{1}{2} \\ \frac{1}{4} & \frac{1}{2} & \frac{1}{4} \end{pmatrix},$$

$$C_5 = \begin{pmatrix} \frac{1}{4} & \frac{1}{2} & \frac{1}{4} \\ \frac{1}{8} & \frac{1}{2} & \frac{3}{8} \\ \frac{1}{4} & \frac{1}{4} & \frac{1}{2} \end{pmatrix}.$$

Since all the entries of some power of C are positive, C is regular stochastic matrix.

Fixed probability vectors

Example 4: Show that $v = (b \ a)$ is fixed point of the stochastic matrix $P = \begin{pmatrix} 1-a & a \\ b & 1-b \end{pmatrix}$.

Solution: $vP = (b \ a) \begin{pmatrix} 1-a & a \\ b & 1-b \end{pmatrix} = (b-ab+ab \quad ba+a-b) = (b \ a) = v$.

Example 5:

(a) Find the unique fixed probability vector t of

$$P = \begin{pmatrix} 0 & \frac{3}{4} & \frac{1}{4} \\ \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

(b) What matrix does P^n approach?

(c) What vector does $(\frac{1}{4}, \frac{1}{4}, \frac{1}{2}) P^n$ approach?

Solution:

(a) Let $t = (x, y, z)$ be the fixed probability vector. By definition $x + y + z = 1$. So $t = (x, y, 1-x-y)$, t is said to be fixed vector, if $tP = t$

$$(x \ y \ 1-x-y) \begin{pmatrix} 0 & \frac{3}{4} & \frac{1}{4} \\ \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 1 & 0 \end{pmatrix} = (x \ y \ 1-x-y)$$

Solving

$$\frac{1}{2}y = x$$

$$\frac{3}{4}x + \frac{1}{2}y + 1-x-y = y$$

$$\frac{1}{4}x = 1-x-y$$

Solving $y = 2x, x = \frac{4}{13}, y = \frac{8}{13}, z = \frac{1}{13}$

Required fixed probability vector is

$$t = (x, y, z) = \left(\frac{4}{13}, \frac{8}{13}, \frac{1}{13} \right) \\ = (0.3077, 0.6154, 0.077)$$

(b) $P^2 = P \cdot P = \begin{pmatrix} \frac{3}{8} & \frac{5}{8} & 0 \\ \frac{1}{4} & \frac{5}{8} & \frac{1}{8} \\ \frac{1}{2} & \frac{1}{2} & 0 \end{pmatrix}$

$$P^3 = P^2 P = \begin{pmatrix} \frac{5}{16} & \frac{19}{32} & \frac{3}{32} \\ \frac{5}{16} & \frac{5}{8} & \frac{1}{16} \\ \frac{1}{4} & \frac{5}{8} & \frac{1}{8} \end{pmatrix}$$

$$P^4 = P^3 P = \begin{pmatrix} \frac{19}{64} & \frac{40}{64} & \frac{5}{64} \\ \frac{20}{64} & \frac{39}{64} & \frac{5}{64} \\ \frac{20}{64} & \frac{40}{64} & \frac{4}{64} \end{pmatrix}$$

$$P^5 = P^4 \cdot P = \frac{1}{64} \begin{pmatrix} 20 & \frac{196}{4} & \frac{19}{4} \\ 39 & \frac{79}{2} & 5 \\ 20 & 39 & 5 \end{pmatrix}$$

$$= \frac{1}{256} \begin{pmatrix} 80 & 196 & 19 \\ 78 & 158 & 20 \\ 80 & 156 & 20 \end{pmatrix} = \begin{pmatrix} 0.3125 & 0.7656 & 0.0742 \\ 0.304 & 0.61718 & 0.078 \\ 0.3125 & 0.61718 & 0.078 \end{pmatrix}$$

Thus $P^n \rightarrow T = \begin{pmatrix} t \\ t \\ t \end{pmatrix}$, where $t = (0.3077, 0.6154, 0.077)$

(c) $\begin{pmatrix} \frac{1}{4} & \frac{1}{4} & \frac{1}{2} \end{pmatrix} P^n = \begin{pmatrix} \frac{1}{4} & \frac{1}{4} & \frac{1}{2} \end{pmatrix} \begin{pmatrix} 0.3125 & 0.7656 & 0.0742 \\ 0.304 & 0.61718 & 0.078 \\ 0.3125 & 0.61718 & 0.078 \end{pmatrix} \\ = (0.310375, 0.654285, 0.07705) \approx t$

Finite stochastic process

Example 6: An urn A contains 5 red, 3 white and 8 green marbles while urn B contains 3 red and 5 white marbles (Fig. 31.3). A fair die is tossed; if 3

or 6 appears a marble is chosen from B otherwise from A . Find the probability that (a) a red marble is chosen (b) a white marble is chosen (c) a green marble is chosen.

Solution: p = probability that 3 or 6 appears in the toss of a die

$$p = \frac{1}{6} + \frac{1}{6} = \frac{2}{6} = \frac{1}{3}$$

$$q = 1 - p = \frac{2}{3}$$

Fig. 31.3

probability of a red marble chosen from urn $A = P(R/A) = \frac{5}{16}$, $P(\text{white from } A) = P(W/A) = \frac{3}{16}$, $P(G/A) = \frac{8}{16}$, probability of a red marble chosen from urn $B = P(R/B) = \frac{3}{8}$, $P(W/B) = \frac{5}{8}$.

Fig. 31.4

Here we perform a sequence of two experiments. First, toss a die and choose the box. Second, choose a marble from the (chosen) box.

(a) Probability that a red marble is chosen

$$= P(R) = P(A) \cdot P(R/A) + P(B) \cdot P(R/B)$$

$$= \frac{2}{3} \cdot \frac{5}{16} + \frac{1}{3} \cdot \frac{3}{8} = \frac{16}{48} = \frac{1}{3}$$

(b) $P(W) = P(A) \cdot P(W/A) + P(B) \cdot P(W/B)$

$$= \frac{2}{3} \cdot \frac{3}{16} + \frac{1}{3} \cdot \frac{5}{8} = \frac{16}{48} = \frac{1}{3}$$

(c) $P(G) = P(A)P(G/A) = \frac{2}{3} \cdot \frac{8}{16} = \frac{1}{3}$.

Transition matrix and transition diagram

Example 7: Figure 31.5 shows four compartments with door leading from one to another. A mouse in any compartment is equally likely to pass through each of the doors of the compartment. Find the transition matrix of the Markov chain. Draw the transition diagram.

Fig. 31.5

Solution: The 4 rooms are considered as four states say 1, 2, 3, 4. Since mouse is moving, it does not stay in the same room. From room 1 it can go to 4 or 2 with probability $\frac{1}{3}$ or $\frac{2}{3}$. It can not go from 1 to 3. Then the first row consists of 0, $\frac{2}{3}$, 0, $\frac{1}{3}$. Thus the transition matrix is

$$\begin{matrix} & \begin{matrix} 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \begin{pmatrix} 0 & \frac{2}{3} & 0 & \frac{1}{3} \\ \frac{2}{3} & 0 & \frac{1}{3} & 0 \\ 0 & \frac{1}{2} & 0 & \frac{1}{2} \\ \frac{1}{2} & 0 & \frac{1}{2} & 0 \end{pmatrix} \end{matrix}$$

Figure 31.6 gives the transition diagram:

Fig. 31.6

Fig. 31.7

Markov chain

Example 8: Every year, a man trades his car for a new car. If he has a Maruti, he trades it for an Ambassador. If he has an Ambassador, he trades it for a Santro. However, if he has a Santro, he is just as likely to trade it for a new Santro as to trade it for a Maruti or an Ambassador. In 2000 he bought his first car, which was a Santro.

- (i) Find the probability that he has
- 2002 Santro
 - 2002 Maruti
 - 2003 Ambassador
 - 2003 Santro
- (ii) In the long run, how often will he have a Santro.

Solution: (i) Define 3 states a_1, a_2, a_3 as follows a_1 : state of having Maruti car, a_2 : having Ambassador, a_3 : having Santro. Then the transition matrix is

$$P = \begin{matrix} & \begin{matrix} a_1 & a_2 & a_3 \end{matrix} \\ \begin{matrix} a_1 \\ a_2 \\ a_3 \end{matrix} & \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix} \end{matrix}$$

2000: Initial state $= P^{(0)} = (0, 0, 1)$ since he has Santro car in 2000 (his first purchase).

- (a) To reach 2002 year, (2-steps later) compute the

2-step transition matrix P^2

$$P^2 = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix} \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 1 \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\ \frac{1}{9} & \frac{4}{9} & \frac{4}{9} \end{pmatrix}$$

Then

$$p^{(2)} = p^{(0)} P^2 = (0 \quad 0 \quad 1) \begin{pmatrix} 0 & 0 & 1 \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\ \frac{1}{9} & \frac{4}{9} & \frac{4}{9} \end{pmatrix}$$

$$p^{(2)} = \left(\frac{1}{9} \quad \frac{4}{9} \quad \frac{4}{9} \right)$$

The probability that he has a Santro in the year 2002 is $p_3^{(2)} = \frac{4}{9}$.

- (b) Probability that he has a Maruti in 2002 is $p_1^{(2)} = \frac{1}{9}$.
- (c) To reach 2003: 3 steps later

$$p^{(3)} = p^{(2)} P = \left(\frac{1}{9} \quad \frac{4}{9} \quad \frac{4}{9} \right) \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix}$$

(or equivalently $p^{(3)} = p^{(0)} P^3$).

$$p^{(3)} = \left(\frac{4}{27} \quad \frac{7}{27} \quad \frac{16}{27} \right)$$

Probability that he has an Ambassador in 2003 is $p_2^{(3)} = \frac{7}{27}$.

(d) Probability that has a Santro in 2003 is

$$p_3^{(3)} = \frac{16}{27}.$$

(ii) To discover what happens in the long run, we must find a fixed probability vector t of P . Let $t = (x, y, 1 - x - y)$.

Then $tP = t$

$$(x \quad y \quad 1 - x - y) \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix} = (x \quad y \quad 1 - x - y)$$

or $1 - x - y = 3x$

$$3x + (1 - x - y) = 3y$$

$$3y + (1 - x - y) = 3(1 - x - y)$$

Solving $y = \frac{1}{3}, x = \frac{1}{6}, z = \frac{3}{6} = \frac{1}{2}$

Thus $t = \left(\frac{1}{6}, \frac{1}{3}, \frac{1}{2}\right)$

In the long run, he has a Santro 50% ($\frac{1}{2}$) of the time.

Example 9: Suppose an urn A contains 2 white marbles and urn B contains 4 red marbles. At each step of the process, a marble is selected at random from each urn and the two marbles selected are interchanged. Let X_n denote the number of red marbles in urn A after n interchanges.

- (i) Find the transition matrix P .
- (ii) What is the probability that there are 2 red marbles in urn A after 3 steps.
- (iii) In the long run, what is the probability that there are 2 red marbles in urn A .
- (iv) What is the stationary distribution of the system.

Solution: There are three states a_0, a_1 and a_2 as shown in Fig. 31.8 below:

Fig. 31.8

(i) Transition matrix

If the system is in the state a_0 , then a white marble from A and a red from B must be selected, so that the system will now move to state a_1 . Accordingly the first row of the transition matrix (T.M.) is $(0, 1, 0)$.

Now suppose the system is in a_1 . It can move to state a_0 , iff red from A and white from B with probability $\frac{1}{2} \cdot \frac{1}{4} = \frac{1}{8}$. Thus $p_{10} = \frac{1}{8}$. The system can move from a_1 to a_2 , iff white from A and red from B with probability $\frac{1}{2} \cdot \frac{3}{4} = \frac{3}{8}$ i.e., $p_{12} = \frac{3}{8}$, probability that system will remain in a_1 itself is $1 - \frac{1}{8} - \frac{3}{8} = \frac{1}{2}$. (Note: white from A and white from B with probability $\frac{1}{2} \cdot \frac{1}{4} = \frac{1}{8}$ or red from A and red from B with probability $\frac{1}{2} \cdot \frac{3}{4} = \frac{3}{8}$. Thus the probability that system will remain in state a_1 itself is $\frac{1}{8} + \frac{3}{8} = \frac{1}{2}$). Thus the 2nd row of T.M. is $(\frac{1}{8}, \frac{1}{2}, \frac{3}{8})$.

Finally, suppose the system is in state a_2 . Note that the system can never move from state a_2 to a_0 . However, it may remain in a_2 itself, if a red from A and red from B is chosen. In this case the probability is $\frac{1}{2} \cdot \frac{2}{4} = \frac{1}{2}$. Lastly, if a red from A and white from B is chosen, then system moves from a_2 to a_1 with probability $\frac{2}{4} = \frac{1}{2}$. Thus third row of the T.M. is $(0, \frac{1}{2}, \frac{1}{2})$. The Transition Matrix and transition diagram are shown in Fig. 31.9

Fig. 31.9

| | | | |
|-------|---------------|---------------|---------------|
| | a_0 | a_1 | a_2 |
| a_0 | 0 | 1 | 0 |
| a_1 | $\frac{1}{8}$ | $\frac{1}{2}$ | $\frac{3}{8}$ |
| a_2 | 0 | $\frac{1}{2}$ | $\frac{1}{2}$ |

31.16 — HIGHER ENGINEERING MATHEMATICS—VII

(ii) The system starts in state a_0 , so that $p^{(0)} = (1, 0, 0)$ is the initial state. Now

$$p^{(1)} = p^{(0)}P = (1 \ 0 \ 0) \begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{8} & \frac{1}{2} & \frac{3}{8} \\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix} = (0 \ 1 \ 0)$$

$$p^{(2)} = p^{(1)}P = (0 \ 1 \ 0) \begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{8} & \frac{1}{2} & \frac{3}{8} \\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix} = \left(\frac{1}{8} \ \frac{1}{2} \ \frac{3}{8}\right)$$

$$p^{(3)} = p^{(2)}P = \left(\frac{1}{8} \ \frac{1}{2} \ \frac{3}{8}\right) \begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{8} & \frac{1}{2} & \frac{3}{8} \\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix} = \left(\frac{1}{16} \ \frac{9}{16} \ \frac{6}{16}\right)$$

Probability that there are two red in A i.e., in state a_2 after three steps is $\frac{6}{16} = \frac{3}{8}$.

(iii) To study the system in the long run, we should find a unique fixed probability vector t of the transition matrix P . Let t be (x, y, z) or $(x, y, 1 - x - y)$.

Then

$$(x \ y \ z) \begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{8} & \frac{1}{2} & \frac{3}{8} \\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix} = (x \ y \ z)$$

$$\text{Solving} \quad \frac{1}{8}y = x \quad \text{or} \quad y = 8x$$

$$x + \frac{1}{2}y + \frac{1}{2}z = y \quad \text{or} \quad 2x - y + z = 0$$

$$\frac{3}{8}y + \frac{1}{2}z = z \quad \text{or} \quad 3y = 4z$$

$$\text{Now} \quad 3y = 4z = 4(1 - x - y)$$

$$7y = 4 - 4x \quad \text{or} \quad 56x + 4x = 4$$

$$\therefore \quad x = \frac{4}{60}, y = \frac{8}{15}, z = \frac{6}{15}$$

Therefore, the fixed vector

$$t = \left(\frac{1}{15} \ \frac{8}{15} \ \frac{6}{15}\right)$$

Hence the system in the long run stays in the state a_2 , 40% of the time ($\frac{6}{15} = \frac{2}{5}$) (i.e., there will be 2 red in A, 40% of the time).

(iv) The fixed unique probability vector $t = (\frac{1}{15}, \frac{8}{15}, \frac{6}{15})$ is the stationary distribution, since P^n approaches t , in the long run.

Markov chain with absorbing states:

Example 10: A player has Rs. 300. At each play of a game, he losses Rs. 100 with probability $\frac{3}{4}$ but wins Rs. 200 with probability $\frac{1}{4}$. He stops playing if he has lost his Rs. 300 or he has won at least Rs. 300.

- Determine the transition probability matrix of the Markov chain.
- Find the probability that there are at least 4 plays to the game.

Solution: (a) This is random walk with absorbing barriers at states 0 and 6. The transition probability matrix P is

$$P = \begin{matrix} & \begin{matrix} a_0 & a_1 & a_2 & a_3 & a_4 & a_5 & a_6 \end{matrix} \\ \begin{matrix} a_0 \\ a_1 \\ a_2 \\ a_3 \\ a_4 \\ a_5 \\ a_6 \end{matrix} & \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{3}{4} & 0 & 0 & \frac{1}{4} & 0 & 0 & 0 \\ 0 & \frac{3}{4} & 0 & 0 & \frac{1}{4} & 0 & 0 \\ 0 & 0 & \frac{3}{4} & 0 & 0 & \frac{1}{4} & 0 \\ 0 & 0 & 0 & \frac{3}{4} & 0 & 0 & \frac{1}{4} \\ 0 & 0 & 0 & 0 & \frac{3}{4} & 0 & \frac{1}{4} \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \end{matrix}$$

Explanation for the probability matrix P : There are seven states $a_0, a_1, a_2, a_3, a_4, a_5, a_6$ where a_i indicates the state that he has Rs. i hundreds (i.e., a_3 indicate he has Rs. 300, a_5 he has 500 etc.).

First row: If he is in state a_0 he has zero money (lost his initial amount of Rs. 300) and therefore he stops the game. Then he remains in that state forever. He does not play again. Thus the state a_0 is an absorbing state, no money (and he does not transit from this state to any other state).

Last row: Similarly if he has Rs. 600 (i.e., his original Rs. 300 and winning amount of Rs. 300) he stops the

game and remains in the state (he does not play). Thus the state a_6 is also an absorbing state, all money.

Second row: Suppose he has Rs. 100 i.e., he is in state a_1 . Then the probability that he will lose Rs. 100 is $\frac{3}{4}$ and therefore transfers to a_0 state (no money). But he can not transfer to states a_2, a_3, a_5, a_6 . But by winning Rs. 200 with probability $\frac{1}{4}$ he can have Rs. 300 (Rs. 100 original + Rs. 200 winning). Thus the probability of going from state a_1 to a_3 is $\frac{1}{4}$, and from a_1 to a_0 is $\frac{3}{4}$. Thus the probability vector (second row) is $(\frac{3}{4} \ 0 \ 0 \ \frac{1}{4} \ 0 \ 0)$.

Third row: Starting with Rs. 200 (a_2 state) he can lose Rs. 100 with probability $\frac{3}{4}$ thereby go to state a_1 or win Rs. 200 with probability $\frac{1}{4}$, thereby go to state a_4 . Thus third row $(0 \ \frac{3}{4} \ 0 \ 0 \ \frac{1}{4} \ 0)$. Similarly, other rows of P are obtained.

(b) The initial probability distribution is

$$p^{(0)} = (0 \ 0 \ 0 \ 1 \ 0 \ 0)$$

because he has started the game with an initial amount of Rs. 300 and is therefore in state a_3 . To find the probability that the game has at least 4 plays, we compute $p^{(4)}$, which gives the probability distribution of the system after 4 steps (i.e., 4 games). Now

$$p^{(1)} = p^{(0)}P =$$

$$= (0 \ 0 \ 0 \ 1 \ 0 \ 0) \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ \frac{3}{4} & 0 & 0 & \frac{1}{4} & 0 & 0 \\ 0 & \frac{3}{4} & 0 & 0 & \frac{1}{4} & 0 \\ 0 & 0 & \frac{3}{4} & 0 & 0 & \frac{1}{4} \\ 0 & 0 & 0 & \frac{3}{4} & 0 & \frac{1}{4} \\ 0 & 0 & 0 & 0 & \frac{3}{4} & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}$$

$$p^{(1)} = (0, 0, \frac{3}{4}, 0, 0, \frac{1}{4})$$

$$p^{(2)} = p^{(1)}P = (0, \frac{9}{16}, 0, 0, \frac{6}{16}, 0, \frac{1}{16})$$

$$p^{(3)} = p^{(2)}P = (\frac{27}{64}, 0, 0, \frac{27}{64}, 0, 0, \frac{10}{64})$$

$$p^{(4)} = p^{(3)}P = (\frac{27}{64}, 0, \frac{81}{256}, 0, 0, \frac{27}{256}, \frac{10}{64})$$

He plays 4 or more games, if after 4 steps he is not

in any one of the absorbing states a_0 or a_6 . Thus the probability that there at least 4 plays in the game is

$$0 + \frac{81}{256} + 0 + 0 + \frac{27}{256} = \frac{108}{256} = \frac{27}{64}.$$

EXERCISE

1. Which vectors are probability vectors (i) $(\frac{1}{2}, \frac{1}{3}, 0, -\frac{1}{5})$; (ii) $(3 \ 4 \ 5 \ 0)$; (iii) $(\frac{1}{4}, \frac{1}{2}, 0, \frac{1}{4})$.

Ans. (i) not (since negative component); (ii) not (since do not add upto 1); (iii) yes

2. Find a scalar multiple of each vector, which is a probability vector.

- (i) $(2, \frac{1}{2}, 0, \frac{1}{4}, \frac{3}{4}, 0, 1)$; (ii) $(\frac{1}{3}, 2, \frac{1}{2}, 0, \frac{1}{4}, \frac{2}{3})$; (iii) $(1 \ 2 \ 3 \ 4 \ 5 \ 6)$; (iv) $(\frac{1}{2}, \frac{2}{3}, 0, 2, \frac{5}{6})$.

Ans. (i) $\frac{4}{18}$; (ii) $\frac{12}{45}$; (iii) $\frac{1}{21}$. Then required probability vectors are $\frac{4}{18}(2, \frac{1}{2}, 0, \frac{1}{4}, \frac{3}{4}, 0, 1) = (\frac{8}{18}, \frac{2}{18}, 0, \frac{1}{18}, \frac{3}{18}, 0, \frac{4}{18})$; (iv) multiply 6 : $(3, 4, 0, 12, 5)$. Divide by $3 + 4 + 0 + 12 + 5 = 24$. Then probability vector $(\frac{3}{24} = \frac{1}{8}, \frac{4}{24} = \frac{1}{6}, 0, \frac{12}{24} = \frac{1}{2}, \frac{5}{24})$.

3. Which matrices are stochastic

- (a) $\begin{pmatrix} \frac{1}{3} & \frac{2}{3} & \frac{4}{3} \\ \frac{1}{2} & 1 & \frac{1}{2} \end{pmatrix}$ (b) $\begin{pmatrix} \frac{15}{16} & \frac{1}{16} \\ \frac{2}{3} & \frac{4}{3} \end{pmatrix}$
(c) $\begin{pmatrix} 1 & 0 \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}$ (d) $\begin{pmatrix} \frac{1}{2} & -\frac{1}{2} \\ \frac{1}{4} & \frac{3}{4} \end{pmatrix}$

Ans. (a) not (square); (b) not adding to 1; (c) yes; (d) No (negative entry)

4. Which of the following matrices are regular

- (a) $A = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ 0 & 1 \end{pmatrix}$ (b) $B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$;
(c) $C = \begin{pmatrix} \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \\ 0 & 1 & 0 \\ \frac{1}{2} & \frac{1}{2} & 0 \end{pmatrix}$ (d) $D = \begin{pmatrix} 0 & 0 & 1 \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \\ 0 & 1 & 0 \end{pmatrix}$

Ans. (a) Not regular, since 1 appears in the main diagonal.

(b) $B^2 = I$, $B^3 = B$, B is not regular, since 1 appears in the main diagonal

31.18 — HIGHER ENGINEERING MATHEMATICS—VII

(c) c not regular, 1 appears on diagonal

$$(d) D^2 = \begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{8} & \frac{5}{16} & \frac{9}{16} \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \end{pmatrix}, D^3 = \begin{pmatrix} \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \\ \frac{5}{32} & \frac{41}{64} & \frac{13}{64} \\ \frac{1}{8} & \frac{5}{16} & \frac{9}{16} \end{pmatrix}$$

D is regular since all the entries of D^3 are positive.

5. Find the unique fixed probability vector of each matrix

$$(a) A = \begin{pmatrix} \frac{2}{3} & \frac{1}{3} \\ \frac{2}{5} & \frac{3}{5} \end{pmatrix} \quad (b) B = \begin{pmatrix} \frac{1}{4} & \frac{3}{4} \\ \frac{5}{6} & \frac{1}{6} \end{pmatrix}$$

$$(c) C = \begin{pmatrix} 0.2 & 0.8 \\ 0.5 & 0.5 \end{pmatrix}$$

Ans. (a) $(\frac{6}{11}, \frac{5}{11})$; (b) $(\frac{10}{19}, \frac{9}{19})$; (c) $(\frac{5}{13}, \frac{8}{13})$.

6. Find the unique fixed probability vector of

$$(a) A = \begin{pmatrix} 0 & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{3} & \frac{2}{3} & 0 \\ 0 & 1 & 0 \end{pmatrix}, (b) B = \begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \end{pmatrix}$$

Ans. (a) $(\frac{2}{9}, \frac{6}{9}, \frac{1}{9})$ (b) $(\frac{5}{15}, \frac{6}{15}, \frac{4}{15})$

7. Given $P = \begin{pmatrix} 0 & 1 \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}$ (a) find a unique fixed probability vector; (b) what matrix does P^n approach; (c) what vector does $(\frac{1}{4} \ \frac{3}{4}) P^n$ approach.

Ans. (a) $(\frac{1}{3}, \frac{2}{3})$; (b) $P^5 = \begin{pmatrix} 0.31 & 0.69 \\ 0.34 & 0.66 \end{pmatrix} \rightarrow (0.33, 0.66)$; (c) $(\frac{43}{128}, \frac{85}{128}) \approx (\frac{1}{3}, \frac{2}{3})$

8. (a) Find the unique fixed probability vector t of

$$P = \begin{pmatrix} 0 & \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{2} & \frac{1}{4} & 0 & \frac{1}{4} \\ 0 & 0 & 0 & 1 \\ 0 & \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix}$$

(b) What matrix does P^n approach

(c) What vector does $(\frac{1}{4} \ 0 \ \frac{1}{2} \ \frac{1}{4}) P^n$ approach

(d) What vector does $(\frac{1}{2} \ 0 \ 0 \ \frac{1}{2}) P^n$ approach.

Hint: $t = (x, y, z, 1 - x - y - z)$, $y = 2x$, $x = 2z$, $y = 4z$

Ans. (a) $t = (\frac{2}{11}, \frac{4}{11}, \frac{1}{11}, \frac{4}{11}) = (0.1818, 0.3636, 0.0909, 0.3636)$

$$(b) P^5 = \frac{1}{1024} \begin{pmatrix} 196 & 546 & 136 & 540 \\ 306 & 569 & 100 & 766 \\ 240 & 440 & 96 & 592 \\ 200 & 436 & 80 & 552 \end{pmatrix} \sim t$$

(c) $\sim t$

(d) $\sim t$

9. Find the transition matrix

Fig. 31.10

Fig. 31.11

$$\text{Ans. (i)} \quad \begin{matrix} a_1 & a_2 \\ a_1 & \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{3} & \frac{2}{3} \end{pmatrix} \\ a_2 & \end{matrix}$$

$$\text{(ii)} \quad \begin{matrix} a_1 & a_2 & a_3 \\ a_1 & \begin{pmatrix} \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \end{pmatrix} \\ a_2 & \\ a_3 & \end{matrix}$$

10. For a Markov chain, the transition matrix

$$P = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{3}{4} & \frac{1}{4} \end{pmatrix} \text{ with initial distribution } p^{(0)} = \left(\frac{1}{4} \quad \frac{3}{4}\right). \text{ Find}$$

(a) $p_{21}^{(2)}$ (b) $p_{12}^{(2)}$

(c) $p^{(2)}$ (d) $p_1^{(2)}$

(e) the vector $p^{(0)} P^n$ approaches

(f) P^n approaches

Ans. $P^2 = \begin{pmatrix} \frac{5}{8} & \frac{3}{8} \\ \frac{9}{16} & \frac{7}{16} \end{pmatrix}$ (a) $p_{21}^{(2)} = \frac{9}{16}$ (b) $p_{12}^{(2)} = \frac{3}{8}$

(c) $p^{(2)} = p^{(0)} P^2 = \left(\frac{37}{64} \quad \frac{27}{64}\right)$ (d) $p_1^{(2)} = \frac{37}{64}$

(e) $p^{(0)} P^n$ approaches fixed vector $t = \left(\frac{3}{5} \quad \frac{2}{5}\right)$

(f) $P^n \rightarrow T = \begin{pmatrix} t \\ t \end{pmatrix} = \begin{pmatrix} \frac{3}{5} & \frac{2}{5} \\ \frac{3}{5} & \frac{2}{5} \end{pmatrix}$

11. A man's smoking habits are as follows. If he smokes filter cigarettes one week, he switches to nonfilter cigarettes the next week with probability 0.2. On the other hand if he smokes nonfilter cigarettes one week, there is a probability of 0.7 that he will smoke nonfilter cigarettes the next week as well. In the long run how often does he smoke filter cigarettes.

Ans. $P : \begin{matrix} & F & NF \\ F & \begin{pmatrix} 0.8 & 0.2 \end{pmatrix} \\ NF & \begin{pmatrix} 0.3 & 0.7 \end{pmatrix} \end{matrix}, t = \text{fixed} = (x, 1-x)$

$$x = \frac{3}{5}, \quad y = \frac{2}{5}, \quad t = \left(\frac{3}{5}, \frac{2}{5}\right)$$

Man smokes filter cigarettes 60% $\left(\frac{3}{5}\right)$ time in the long run.

12. A salesman's territory consists of 3 cities A, B and C. He never sells in the same city on successive days. If he sells in city A, then the next day he sells in city B. However if he sells in either B or C, then the next day he is twice as likely to sell in city A as in other city. In the long run, how often does he sell in

each of the cities.

$$\text{Ans. } P = \begin{matrix} & A & B & C \\ A & \begin{pmatrix} 0 & 1 & 0 \end{pmatrix} \\ B & \begin{pmatrix} \frac{2}{3} & 0 & \frac{1}{3} \end{pmatrix} \\ C & \begin{pmatrix} \frac{2}{3} & \frac{1}{3} & 0 \end{pmatrix} \end{matrix}, \quad \begin{matrix} \frac{2}{3}y + \frac{2}{3}z = z \\ x + \frac{1}{3}z = y \\ \frac{1}{3}y = z \end{matrix}$$

$t = \left(\frac{2}{5}, \frac{9}{20}, \frac{3}{20}\right)$. In the long run he sells 40% of time in city A, 45% in B, 15% of time in C.

13. There are 2 white marbles in box A and 3 red marbles in box B. At each step of the process a marble is selected from each box and the two marbles selected are interchanged. Let the state a_i of the system be the number i of red marbles in box A.

(a) Find the transition matrix P .

(b) What is the probability that there are 2 red marbles in box A after 3 steps

(c) In the long run, what is the probability that there are 2 red marbles in box A.

$$a_0 \quad a_1 \quad a_2$$

$$(a) P = \begin{matrix} & a_0 & a_1 & a_2 \\ a_0 & \begin{pmatrix} 0 & 1 & 0 \end{pmatrix} \\ a_1 & \begin{pmatrix} \frac{1}{6} & \frac{1}{2} & \frac{1}{3} \end{pmatrix} \\ a_2 & \begin{pmatrix} 0 & \frac{2}{3} & \frac{1}{3} \end{pmatrix} \end{matrix}$$

Initial distribution: $p^{(0)} = (1, 0, 0)$

$$p^{(1)} = p^{(0)} P = (0, 1, 0), \quad p^{(2)} = p^{(1)} P = \left(\frac{1}{6} \quad \frac{1}{2} \quad \frac{1}{3}\right),$$

$$p^{(3)} = p^{(2)} P = \left(\frac{1}{12} \quad \frac{23}{36} \quad \frac{5}{18}\right).$$

(b) Probability that there are 2 red marbles in box A after 3 steps is $\frac{5}{18}$.

(c) Fixed probability vector: $t = (0.1, 0.6, 0.3)$.

Ans. (c) In the long run, 30% of the time, there will be 2 red marbles in box A.

Finite stochastic process

14. Box A contains 3 red and 5 white marbles, Box B contains 2 red and 1 white marbles, Box C contains 2 red and 3 white marbles. One box is selected at random and a marble is drawn from the box. If the marble is red, what is the probability that it came from box A.

Hint: $P(A/R) = \frac{P(A \cap R)}{P(R)} = \frac{\frac{1}{8}}{\frac{173}{360}}$

Ans. $\frac{45}{173}$

15. Box A contains cards numbered 1 to 9. Box B contains cards numbered 1 to 5. One box is chosen at random and a card is drawn. If the card is even, another card from the same box is drawn, if odd the card is drawn from the other box. Find

- (a) the probability that both cards are even.
 (b) if both cards are even, find the probability that they came from box A.
 (c) what is the probability that both cards are odd?

Ans. (a) $\frac{1}{2} \cdot \frac{4}{9} \cdot \frac{3}{8} + \frac{1}{2} \cdot \frac{2}{5} \cdot \frac{1}{4} = \frac{1}{12} + \frac{1}{20} = \frac{2}{15}$

(b) $\frac{\frac{12}{15}}{\frac{5}{8}} = \frac{5}{8}$

(c) $\frac{1}{2} \cdot \frac{5}{9} \cdot \frac{3}{5} + \frac{1}{2} \cdot \frac{3}{5} \cdot \frac{5}{9} = \frac{1}{6} + \frac{1}{6} = \frac{1}{3}$.

16. A box contains 3 coins, two of them fair and one two-headed. A coin is selected at random and tossed twice. If head appears both times, what is the probability that the coin is two headed.

Ans. $\frac{\frac{1}{3} \cdot \frac{1}{2} \cdot \frac{1}{2}}{\frac{1}{3} \cdot \frac{1}{2} \cdot \frac{1}{2} + \frac{1}{3} \cdot \frac{1}{2} \cdot \frac{1}{2} + \frac{1}{3} \cdot 1 \cdot 1} = \frac{2}{3}$

Absorbing states

17. A player has Rs. 200. He bets Rs. 100 at a time and wins Rs. 100 with probability $\frac{1}{2}$. He stops playing if he loses the Rs. 200 or wins Rs. 400.

- (a) Find the probability that he has lost his money at the end of at most 5 days.
 (b) Determine the probability that the game lasts more than 7 plays.

Hint:

$$\begin{matrix} & a_0 & a_1 & a_2 & a_3 & a_4 & a_5 & a_6 \\ \begin{matrix} a_0 \\ a_1 \\ a_2 \\ a_3 \\ a_4 \\ a_5 \\ a_6 \end{matrix} & \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & \frac{1}{2} & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{2} & 0 & \frac{1}{2} & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{2} & 0 & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{2} & 0 & \frac{1}{8} \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \end{matrix}$$

$p^{(0)} = (0, 0, 1, 0, 0, 0, 0),$

$p^{(1)} = p^{(0)}P = \left(0, \frac{1}{2}, 0, \frac{1}{2}, 0, 0, 0\right)$

$p^{(2)} = p^{(1)}P = \left(\frac{1}{4}, 0, \frac{1}{2}, 0, \frac{1}{4}, 0, 0\right), p^{(5)} = p^{(4)}P$

$p^{(5)} = \left(\frac{3}{8}, \frac{5}{32}, 0, \frac{9}{32}, 0, \frac{1}{8}, \frac{1}{16}\right).$

$p^{(5)}$: probability that he has no money after 5 plays is $\frac{3}{8}$, $p^{(7)} = \left(\frac{29}{64}, \frac{7}{64}, 0, \frac{27}{128}, 0, \frac{13}{128}, \frac{1}{8}\right)$

Ans. (a) $\frac{3}{8}$ (b) $\frac{7}{64} + \frac{27}{128} + \frac{13}{128} = \frac{27}{64}$.

Numerical Analysis

INTRODUCTION

Using Mathematical Modeling, most of the problems in Engineering and Physical and Economical sciences can be formulated in terms of systems of linear or non-linear equations, ordinary or partial differential equations or integral equations. In majority of the cases, the solutions to these problems in analytical form are non-existent or difficult or not amenable for direct interpretation. In all such problems, Numerical Analysis provides approximate solutions, practical and amenable for analysis. Numerical analysis does not strive for exactness. Instead, it yields approximations with specified degree of accuracy. The early disadvantage of the several number of computations involved has been removed through high speed computation using computers, giving results which are accurate, reliable and fast. Numerical analysis is not only a science but also an 'art' because the choice of 'appropriate' procedure which 'best' suits to a given problem yields 'good' solutions.

In this chapter we consider the bisection, regula falsi and Newton-Raphson's methods of obtaining solutions of transcendental equations. For an unknown function $f(x)$ given at a set of tabulated values, interpolation is the process of obtaining a simpler function $\phi(x)$. We study Newton-Gregory finite differences formulae. Sterling and Bessel's central differences for equally spaced value of x . Lagrange's interpolation and inverse interpolation is used for arbitrarily spaced x . For tabulated func-

tions, the derivatives can be calculated using numerical differentiation. Numerical integration is useful even for integrals such as $\int \frac{\sin x}{x} dx$, $\int \sqrt{1+x^4} dx$, $\int_2^3 e^{-x^2} dx$ which can not be expressed in terms of elementary functions. We study trapezoidal, Simpson's $\frac{1}{3}$, $\frac{3}{8}$ rule, Weddle's and Boole's rules of integration. Quadratic and cubic splines which are powerful tools in piecewise-polynomial approximation are also considered.

32.1 ROOTS OF TRANSCENDENTAL EQUATIONS

An algebraic equation of degree n is

$$P(x) \equiv a_0 x^n + a_1 x^{n-1} + \dots + a_n = 0 \quad (1)$$

where the coefficients $a_0, a_1, \dots, a_n$ are real numbers and $a_0 \neq 0$. Here $n \geq 1$. Transcendental equations are non-algebraic equations involving transcendental functions such as exponential, logarithmic, trigonometric or hyperbolic functions. A general form of an algebraic or transcendental equation is

$$f(x) = 0 \quad (2)$$

where the function $f(x)$ is defined and continuous on an interval $a < x < b$.

Root

Any value ξ for which $f(\xi) = 0$ is known as the root or solution of the equation (2) or ξ is called the zero of the function $f(x)$. In the case of the algebraic Equation (1), the roots can be determined in analytical (literal) form when $n = 1, 2, 3, 4$ (i.e., for linear, quadratic, cubic and biquadratic equations). For $n \geq 5$ no such results exists for the roots of (1). Also from the fundamental theorem of algebra, (1) has exactly n roots, real or complex whereas the number and analytical form of roots of a transcendental equation are not known at all.

Example: $\sin x = 2$ has no real roots, $\sin x = \frac{1}{2}$ has infinite number of roots, while $\sin x = \frac{x}{2}$ has three real roots (see Fig. 32.9 on page 32.6).

Therefore only approximate solutions (roots) of an algebraic or transcendental Equation (2) are to be found by numerical methods consisting of (a) isolating the roots (b) and then improving the value of the approximate roots. Here it is assumed that the roots of (2) are isolated i.e., for any root ξ of (2) there exists an interval containing no other root except ξ .

Geometrically, the root of Equation (2) is the point where the graph (or curve) of $y = f(x)$ crosses the x -axis (i.e., $y = f(x) = 0$). Although the roots can be isolated by drawing the graphs of the curve, these graphical methods are cumbersome. The following theorem is very useful in isolating the roots of (2).

Theorem 1: If a continuous function $f(x)$ assumes values of opposite sign at the end points of an interval $[\alpha, \beta]$ i.e., $f(\alpha)f(\beta) < 0$, then the interval will contain at least one root of the equation $f(x) = 0$ i.e., there exists $\xi \in (\alpha, \beta)$ such that $f(\xi) = 0$.

Note 1: Root ξ will be unique (only one) in the interval (α, β) if $f'(x)$ has the same sign in the interval (α, β) (i.e., $f' > 0$ or $f' < 0$ in $\alpha < x < \beta$).

Note 2: For an n th degree algebraic Equation (1), we get $(n + 1)$ sign changes.

Note 3: Descartes's rule of sign: The number of positive roots of $f(x) = 0$ can not exceed the number of

Fig. 32.1

Fig. 32.2

Fig. 32.3

changes of sign in $f(x)$. Also the number of negative roots of $f(x)$ can not exceed the number of changes of sign in $f(-x)$.

Example: $f(x) = x^5 - 6x^2 - 4x + 5 = 0$.
 $f(x) : + - - + : 2$ changes of sign; no more than 2 positive roots.
 $f(-x) : - - + + : 1$ change of sign; no more than one negative root.

Bisection Method (or Halving Method or Bolzano Method)

Consider the equation

$$f(x) = 0 \quad (2)$$

in $[a, b]$. Assume that $f(a)f(b) < 0$. The bisection method isolates the root in $[a, b]$ by halving process, approximately dividing the given interval $[a, b]$ into two, four, eight etc. equal parts. Thus in order to find a root of (2) lying in the interval $[a, b]$, divide

the interval in half. If $f\left(\frac{a+b}{2}\right) = 0$, then $\xi = \frac{a+b}{2}$ is the required root. If $f\left(\frac{a+b}{2}\right) \neq 0$, then choose that half $\left[a, \frac{a+b}{2}\right]$ or $\left[\frac{a+b}{2}, b\right]$, at the end points of which $f(x)$ has opposite signs. The newly reduced interval $[a, b]$ is again bisected and the above process is repeated. Thus we get a sequence of nested intervals $[a_1, b_1], [a_2, b_2], \dots, [a_n, b_n]$ such that

$$f(a_n)f(b_n) < 0 \quad \text{for } n = 1, 2, \dots$$

and

$$b_n - a_n = \frac{1}{2^n}(b - a).$$

The required root $\xi = \frac{1}{2}(a_n + b_n)$.

Rugula-Falsi Method (or Method of False Position or Linear Interpolation or Method of Chords or Method of Proportional Parts)

This method is probably the oldest, faster method more generally applicable.

Fig. 32.4

To find root ξ of the equation $f(x) = 0$ in the interval $[a, b]$ assume that $f(a) < 0$ and $f(b) > 0$ so that $f(a) \cdot f(b) < 0$.

Geometrically, this method is equivalent to replacing the curve $y = f(x)$ by a chord that passes through the points $A(a, f(a))$ and $B(b, f(b))$. The equation of the chord AB is

$$\frac{x - a}{b - a} = \frac{y - f(a)}{f(b) - f(a)}$$

Fig. 32.5

If chord AB meets x -axis at $x = x_1$, then $y = 0$.

$$\frac{x_1 - a}{b - a} = \frac{0 - f(a)}{f(b) - f(a)} \quad \text{or}$$

$$x_1 = a - \frac{f(a)}{f(b) - f(a)}(b - a)$$

If $f(a) < 0$, then the end point b is fixed and the successive approximations

$$x_0 = a$$

$$x_{n+1} = x_n - \frac{f(x_n)}{f(b) - f(x_n)}(b - x_n),$$

(for $n = 0, 1, 2, 3, \dots$) form a bounded increasing monotonic sequence and

$$x_0 < x_1 < x_2 < \dots < x_n < x_{n+1} < \dots < \xi < b.$$

If $f(a) > 0$, end point a is fixed and successive approximations are

$$x_0 = b$$

$$x_{n+1} = x_n - \frac{f(x_n)}{f(x_n) - f(a)}(x_n - a)$$

and

$$a < \xi < \dots < x_{n+1} < x_n < \dots < x_1 < x_0.$$

Note 1: Fix the end point for which sign of f and f'' is same.

Note 2: Successive approximations x_n lie on the side of root ξ where sign of f is opposite to the sign of f'' .

Newton-Raphson Method (or Method of Tangents)

Newton's method is used to obtain a better (refined) approximation of a root using the earlier approximations obtained by bisection method or Regula-Falsi method. Geometrically, Newton's method is equivalent to replacing a small arc of the curve $y = f(x)$ by a tangent line drawn at a point of the curve. Draw a tangent to the curve at B_0 which meets x -axis at x_1 . Then draw a tangent at B_1 which meets x -axis at x_2 . Continuing this process, the root ξ is obtained.

Fig. 32.6

Suppose $\xi = x + h$ where h is a small quantity. Then applying Taylor's formula

$$0 = f(x + h) \approx f(x) + hf'(x)$$

or
$$h = -\frac{f(x)}{f'(x)}$$

Thus
$$\xi = x + h = x - \frac{f(x)}{f'(x)}.$$

In general,

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}, \quad n = 0, 1, 2, \dots$$

Note 1: A root ξ of equation $f(x) = 0$ can be computed to any degree of accuracy if a 'good' initial approximation x_0 is chosen for which

$$f(x_0)f''(x_0) > 0$$

i.e., choose the end point of the interval at which f and f'' have the same sign.

Note 2: Newton's method converge slow if f' is small (fails when $f' = 0$ because tangent in this case is parallel to x -axis and will never meet it).

WORKED OUT EXAMPLES

Example 1: Isolate the roots of the equation

$$x^3 - 4x + 1 = 0$$

Find all the roots using bisection method.

Solution: Here $f(x) = x^3 - 4x + 1$.

| | | | | | | | | | | |
|------------------|-----------|-------|------|------|-----|------|-----|------|------|----------|
| x : | $-\infty$ | -3 | -2 | -1 | 0 | 1 | 2 | 3 | 4 | ∞ |
| sign of $f(x)$: | $-$ | -14 | 1 | 4 | 1 | -2 | 1 | 16 | 49 | ∞ |

Since equation is cubic (degree three) and since there are 3 changes of signs, a unique (one) root lies in the three intervals $(-3, -2)$, $(0, 1)$, $(1, 2)$. Now consider the interval $(0, 1)$ and apply bisection method.

| x_i | $f(x_i)$ | new interval
(with signs) |
|---|-------------------------------|-------------------------------------|
| $x_1 = \frac{1+0}{2} = \frac{1}{2}$ | $f(x_1) = -8.75$ | $+$ $-$
(0, 0.5) |
| $x_2 = \frac{0+0.5}{2} = \frac{1}{4}$ | $f(x_2) = f(0.25) = 0.015625$ | $+$ $-$
(0.25, 0.5) |
| $x_3 = \frac{0.25+0.5}{2} = .375$ | $f(.375) = -0.357$ | $+$ $-$
(0.25, 0.375) |
| $x_4 = \frac{0.25+.375}{2} = .3125$ | $f(.3125) = -0.173$ | $+$ $-$
(.25, .3125) |
| $x_5 = \frac{0.25+.3125}{2} = .28125$ | $f(.28125) = -0.0792$ | $+$ $-$
(.25, .28125) |
| $x_6 = \frac{0.25+.28125}{2} = .265625$ | $f(.265625) = -0.0319$ | $+$ $-$
(.25, .265625) |
| $x_7 = \frac{0.25+.265625}{2} = .2578125$ | $f(.2578125) = -0.00817$ | $+$ $-$
(0.25, .2578125) |
| $x_8 = \frac{0.25+.2578125}{2} = .25390625$ | $f(.25390625) = 0.0100$ | $+$ $-$
(0.25390625, .2578125) |
| $x_9 = \frac{.25390625+.2578125}{2} = .255859375$ | $f(.255859375) = -0.00222$ | $+$ $-$
(.25390625, .255859375) |
| $x_{10} = \frac{.25390625+.255859375}{2} = .2549328125$ | $f(.2549328125) = 0.000743$ | $+$ $-$
(.25390625, .2549328125) |

The approximate root is

$$\xi = \frac{0.25390625 + 0.2546875}{2} = 0.254296875 \approx 0.2540$$

$$f(0.254296875) = -0.00074290925$$

By synthetic division

| | | | | |
|-------|---|-------|----------|-----------|
| 0.254 | 1 | 0 | -4 | 1 |
| | | 0.254 | 0.064516 | -0.99612 |
| | 1 | 0.254 | -3.93546 | 0.000387 |
| | | | | remainder |

Roots of the quadratic equation

$$x^2 + 0.254x - 3.93546 = 0$$

are $x = -2.11475 \approx -2.115$, $x = 1.86075 \approx 1.8608$.

Example 2: Using Regula-Falsi method, compute the real root of the equation $x^3 - 4x - 9 = 0$.

Solution: Here $f(x) = x^3 - 4x - 9$.

| | | | | |
|---------|----|-----|----|---|
| $x:$ | 0 | 1 | 2 | 3 |
| $f(x):$ | -9 | -12 | -9 | 6 |

By bisection method, $f\left(\frac{2+3}{2}\right) = f(2.5) = -3.375$ so a root of $f(x)$ lies in the interval $(2.5, 3)$. Here $f' = 3x^2 - 4$, $f'' = 6x$, $f''(3) = 18 > 0$, $f''(2.5) = 15 > 0$. Since sign of f and f'' is same at $x = 3$, fix the point $b = 3$ and since $f(a) = f(2.5) = -3.375 < 0$, use

$$x_{n+1} = x_n - \frac{f(x_n)}{f(b) - f(x_n)}(b - x_n)$$

$$x_{n+1} = x_n - \frac{f(x_n)}{6 - f(x_n)}(3 - x_n)$$

Then $x_0 = 2.5$, $f(x_0) = -3.375$, $n = 0$, then

$$x_1 = x_0 - \frac{f(x_0)(3 - x_0)}{6 - f(x_0)} = 2.5 + \frac{3.375}{6 + 3.375}(3 - 2.5)$$

$$x_1 = 2.5 + 0.18 = 2.68$$

At $x_1 = 2.68$, $f(2.68) = -0.471168$.

$$x_2 = 2.68 + \frac{0.471168}{6 + 0.471168}(3 - 2.68)$$

$$= 2.68 + 0.0232993$$

$$x_2 = 2.7033$$

At x_2 , $f(x_2) = f(2.7033) = -0.05794$

$$x_3 = 2.7033 + \frac{0.05794}{6 + 0.05794}(3 - 2.7033)$$

$$x_3 = 2.7033 + 0.0028377 = 2.706$$

$$f(2.706) = -0.009488$$

$$x_4 = 2.706 + \frac{0.009488}{6.009488}(3 - 2.706) = 2.70646$$

$$x_4 = 2.70650.$$

Example 3: Determine the root of $xe^x - 2 = 0$ by method of false position.

Solution: Here $f(x) = xe^x - 2$.

| | | | | | |
|---------|----|---------|---------|--------|-------|
| $x:$ | 0 | 0.5 | 0.8 | 0.9 | 1.0 |
| $f(x):$ | -2 | -1.1756 | -0.2196 | 0.2136 | 0.718 |

A root lies between 0.8 and 0.9. Now

$$f'(x) = e^x + xe^x, \quad f''(x) = 2e^x + xe^x$$

$$f''(0.8) = 6.2315, \quad f''(0.9) = 7.1328.$$

Since f and f'' have the same (positive) sign at $x = 0.9$, fix this point $b = 0.9$. Note that $f(0.8) < 0$.

$$x_{n+1} = x_n - \frac{f(x_n)}{f(0.9) - f(x_n)}(0.9 - x_n)$$

Take $n = 0$, $x_0 = 0.8$, $f(x_0) = f(0.8) = -0.2196$

$$x_1 = 0.8 + \frac{0.2196}{0.2136 + 0.2196}(0.9 - 0.8)$$

$$x_1 = 0.8 + 0.05069252 = 0.851$$

$$f(x_1) = f(0.851) = -0.00697$$

$$x_2 = 0.851 + \frac{0.00697}{0.2136 + 0.00697}(0.9 - 0.851)$$

$$x_2 = 0.851 + 0.0015484 = 0.85256$$

$$f(x_2) = -0.0001977$$

$$x_3 = 0.85256 + \frac{0.0001977}{0.2136 + 0.0001977}(0.9 - 0.85256)$$

$$x_3 = 0.85256 + 0.000043868 = 0.8526$$

$$f(x_3) = -0.0000239$$

$$x_4 = 0.8526 + \frac{0.0000239}{0.2136 + 0.0000239}(0.9 - 0.8526)$$

$$x_4 = 0.8526 + 0.0000053 = 0.8526$$

$\therefore$ Approximate root is 0.8526.

32.6 — HIGHER ENGINEERING MATHEMATICS—VIII

Example 4: Find the approximate value of the real root of the equation $2x - \log_{10}^x - 7 = 0$ by using Newton-Raphson method.

Solution: Here $f(x) = 2x - \log_{10}^x - 7$. Since log function is involved, x must be positive

| | | | | |
|----------|----|--------|---------|--------|
| x : | 1 | 2 | 3 | 4 |
| $f(x)$: | -5 | -3.301 | -1.4771 | 0.3979 |

Roots lies in between 3 and 4. Now

| | | | |
|----------|---------|---------|--------|
| x : | 3.5 | 3.7 | 3.8 |
| $f(x)$: | -0.5441 | -0.1682 | 0.0202 |

Here $f'(x) = 2 - \frac{\log_{10}^e}{x}$ and $f''(x) = \frac{\log_{10}^e}{x^2} = \frac{0.4343}{x^2}$. Since f and f'' have the same sign at $x = 3.8$, choose $x_0 = 3.8$. Then $f(x_0) = 0.0202$

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} = x_n - \frac{(2x_n - \log_{10} x_n - 7)}{\left(2 - \frac{\log_{10}^e}{x_n}\right)}$$

Take $n = 0$, $x_1 = 3.8 - \frac{0.0202}{1.88571} = 3.8 - 0.010712$

$x_1 = 3.7893$, $f(x_1) = 0.000041$, then

$$x_2 = 3.7893 - \frac{0.000041}{1.88538} = 3.7893 - 0.00002175$$

$x_2 = 3.789278 \approx 3.7893$ is the required root.

Example 5: Find a positive root of $x^4 - x = 10$ using Newton-Raphson's method.

Solution: Here $f(x) = x^4 - x - 10$.

| | | | |
|----------|-----|-----|---|
| x : | 0 | 1 | 2 |
| $f(x)$: | -10 | -10 | 4 |

A root lies between 1 and 2

| | | | | | | |
|----------|-----|---------|---------|---------|--------|---|
| x : | 1 | 1.5 | 1.75 | 1.8 | 1.9 | 2 |
| $f(x)$: | -10 | -6.4375 | -2.3711 | -1.3024 | 1.1321 | 4 |

Root lies between 1.8 and 1.9. Now

$$f'(x) = 4x^3 - 1. \text{ So}$$

$$x_{n+1} = x_n - \frac{x_n^4 - x_n - 10}{4x_n^3 - 1}.$$

Since both f and f'' have the same sign at $x = 1.9$, choose $x_0 = 1.9$ as the starting point. Now

$$x_1 = x_0 - \frac{x_0^4 - x_0 - 10}{4x_0^3 - 1}$$

$$= 1.9 - \frac{f(1.9)}{f'(1.9)} = 1.9 - \frac{1.1321}{26.436}$$

$$x_1 = 1.9 - 0.042824 = 1.8572$$

$$f(x_1) = 0.03972$$

$$x_2 = 1.8572 - \frac{0.03972}{24.623} = 1.8572 - 0.0016131$$

$$x_2 = 1.855586897$$

$$f(x_2) = +0.000058169.$$

So $x_2 = 1.855587$ is the required root.

EXERCISE

1. Using graphical method find an approximate roots of the transcendental equations:

- (a) $3x - \cos x - 1 = 0$; (b) $e^x - 3x = 0$; (c) $\sin x = 2$; (d) $\sin x = \frac{1}{2}$; (e) $\sin x = \frac{1}{2}x$.

Hint:

Fig. 32.7

Fig. 32.8

Fig. 32.9

Ans. (a) 0.6; (b) 0.619; (c) no root; (d) infinite number of roots; (e) $x = 30^\circ$

2. Obtain an approximate root using bisection method, for the following equations:

- (a) $x^4 - x - 10 = 0$; (b) $x^3 - x - 1 = 0$; (c) $x^4 - 4x - 9 = 0$; (d) $x^4 + 2x^3 - x - 1 = 0$.

Ans. (a) (1.85546875, 1.857421855) at 9th iteration; (b) $x_5 = 1.38125$; (c) $x_4 = 2.6875$; (d) $x_6: 0.867$

3. Isolate the roots of the equations:

(a) $x^3 - 6x + 2 = 0$; (b) $x + e^x = 0$.

Ans. a. $(-3, -1), (0, 1), (1, 3)$

b. $(-\infty, 1), (1, +\infty)$

4. Using Regula-Falsi method find an approximate root of the following equations:

(a) $x^3 - 4x + 1 = 0$; (b) $x^3 - 0.2x^2 - 0.2x - 1.2 = 0$; (c) $x^3 - 2x - 5 = 0$; (d) $xe^x - 3 = 0$; (e) $x \log_{10} x - 2 = 0$; (f) $xe^x - \cos x = 0$.

Ans. (a) 0.2541; (b) 1.198; (c) 2.094548; (d) 1.050; (e) 2.74065; (f) 0.5177

5. Using Newton-Raphson method, find an approximate root of the following equations:

(a) $(x - 1) \sin x - x = 1$; (b) $e^{-x} = \sin x$; (c) $x^3 - 25 = 0$; (d) $x^4 - x - 1 = 0$; (e) $x + e^x = 0$; (f) $3x^3 + 5x - 40 = 0$; (g) $x - e^{-x} = 0$; (h) $2 \sin x = x$; (i) $x^2 + 4 \sin x = 0$; (j) $x^3 - 3x - 5 = 0$; (k) $x^4 - 3x^2 + 75x - 10,000 = 0$.

Ans. (a) -0.42036 ; (b) 0.5885; (c) 2.924; (d) 1.22138; (e) -0.567 ; (f) 0.5635; (g) 0.5671; (h) 1.895494; (i) -1.9338 ; (j) 2.7984; (k) -10.261

6. Use Newton's method to find the smallest positive root of the equation $\tan x = x$.

Hint: Roots lies in $(\pi, \frac{3\pi}{2})$.

Ans. 4.49343

7. Find the real root of $x \log_{10} x = 1.2$ using Newton's iterative method.

Hint: Root lies in (2, 3).

Ans. 2.74065

8. Apply Newton-Raphson method to evaluate approximately $\sqrt{12}$.

Hint: Solve $x^2 - 12 = 0$, root lies in (3, 4).

Ans. 3.4641.

32.2 FINITE DIFFERENCES

Let $y = f(x)$ be a function and $\Delta x = h$ denote the increment in the independent variable x . Assume that

Δx , increment in the argument x (also known as *interval or spacing*) is fixed. i.e., $h = \text{constant}$. Then the first finite difference of the function y is defined

$$\Delta y \equiv \Delta f(x) = f(x + \Delta x) - f(x).$$

Similarly, finite differences of higher orders are defined as follows

$$\begin{aligned} \Delta^2 y &= \Delta(\Delta y) = \Delta(f(x + \Delta x) - f(x)) \\ &= \Delta(f(x + \Delta x)) - \Delta f(x) \\ &= [f(x + 2\Delta x) - f(x + \Delta x)] \\ &\quad - [f(x + \Delta x) - f(x)] \end{aligned}$$

$$\Delta^2 y = f(x + 2\Delta x) - 2f(x + \Delta x) + f(x).$$

In general,

$$\Delta^n y = \Delta(\Delta^{n-1} y), \quad \text{for } n = 2, 3, 4, \dots$$

Now consider the function $y = f(x)$ specified by tabular values $y_i = f(x_i)$ for a set of *equidistant* points x_i where $i = 0, 1, 2, \dots$ and $\Delta x_i = x_{i+1} - x_i = h = \text{constant}$. Thus the tabulated function consists of ordered pairs $(x_0, y_0), (x_1, y_1), (x_2, y_2), \dots, (x_k, y_k), \dots$. Here y_k 's are known as entries.

Forward differences

The first forward difference is denoted by Δy_k and defined as

$$\Delta y_k = y_{k+1} - y_k \quad (1)$$

Here the symbol Δ is the forward differences operator, having the following properties:

- (i) $\Delta c = 0$ (differences of a constant function are zero)
- (ii) $\Delta(cy_k) = c(\Delta y_k)$ where c is a constant
- (iii) $\Delta(u_k + v_k) = \Delta u_k + \Delta v_k$
- (iv) $\Delta(u_k v_k) = v_{k+1} \Delta u_k + u_k \Delta v_k$
- (v) $\Delta^m(\Delta^n y_k) = \Delta^{m+n} y_k$

where m and n are non-negative integers and $\Delta^0 y_k = y_k$ (by definition). Note that because of (ii) and (iii) Δ is a linear operator.

32.8 — HIGHER ENGINEERING MATHEMATICS—VIII

The higher order forward differences are similarly defined: The second order forward difference of y_k is

$$\Delta^2 y_k = \Delta(\Delta y_k) = \Delta y_{k+1} - \Delta y_k$$

In general,

$$\Delta^n y_k = \Delta(\Delta^{n-1} y_k) = \Delta^{n-1} y_{k+1} - \Delta^{n-1} y_k \quad (2)$$

defines the n th order forward differences. For example, $\Delta^3 y_k = \Delta^2 y_{k+1} - \Delta^2 y_k = (\Delta y_{k+2} - \Delta y_{k+1}) - (\Delta y_{k+1} - \Delta y_k) = y_{k+3} - 3y_{k+2} + 3y_{k+1} - y_k$.

From (1) $y_{k+1} = y_k + \Delta y_k = (1 + \Delta)y_k$

Similarly, $y_{k+2} = y_{k+1} + \Delta y_{k+1} = (1 + \Delta)y_{k+1}$

or $y_{k+2} = (1 + \Delta)(1 + \Delta)y_k = (1 + \Delta)^2 y_k$

Thus $y_{k+3} = (1 + \Delta)^3 y_k$

$$y_{k+n} = (1 + \Delta)^n y_k.$$

Expanding $(1 + \Delta)^n$ by binomial theorem

$$y_{k+n} = y_k + n_{c_1} \Delta y_k + n_{c_2} \Delta^2 y_k + \cdots + \Delta^n y_k.$$

Conversely, we have

$$\begin{aligned} \Delta^n y_k &= \left[(1 + \Delta) - 1 \right]^n y_k \\ &= (1 + \Delta)^n y_k - n_{c_1} (1 + \Delta)^{n-1} y_k + \\ &\quad + n_{c_2} (1 + \Delta)^{n-2} y_k - \cdots + (-1)^n y_k \\ \text{or } \Delta^n y_k &= y_{n+k} - n_{c_1} y_{n+k-1} \\ &\quad + n_{c_2} y_{n+k-2} + \cdots + (-1)^n y_k \end{aligned} \quad (3)$$

Thus any higher order forward differences can be expressed in terms of the successive values y_k 's of the function. For example,

$$\Delta^2 y_k = y_{k+2} - 2y_{k+1} + y_k$$

$$\Delta^3 y_k = y_{k+3} - 3y_{k+2} + 3y_{k+1} - y_k \quad \text{etc.}$$

Finite differences of various orders are conveniently arranged in the form of a forward (diagonal) differences table (Table 32.1).

In general, y_0 , the first entry is known as the leading terms, and Δy_0 , $\Delta^2 y_0$, $\Delta^3 y_0$, $\Delta^4 y_0$, $\Delta^5 y_0$, $\Delta^6 y_0$, $\Delta^7 y_0$ are known as the leading differences.

Table 32.1: Forward differences table

| x | y | Δy | $\Delta^2 y$ | $\Delta^3 y$ | $\Delta^4 y$ | $\Delta^5 y$ | $\Delta^6 y$ | $\Delta^7 y$ |
|-------|-------|--------------|----------------|----------------|----------------|----------------|----------------|----------------|
| x_0 | y_0 | Δy_0 | $\Delta^2 y_0$ | $\Delta^3 y_0$ | $\Delta^4 y_0$ | $\Delta^5 y_0$ | $\Delta^6 y_0$ | $\Delta^7 y_0$ |
| x_1 | y_1 | Δy_1 | $\Delta^2 y_1$ | $\Delta^3 y_1$ | $\Delta^4 y_1$ | $\Delta^5 y_1$ | $\Delta^6 y_1$ | $\Delta^7 y_1$ |
| x_2 | y_2 | Δy_2 | $\Delta^2 y_2$ | $\Delta^3 y_2$ | $\Delta^4 y_2$ | $\Delta^5 y_2$ | $\Delta^6 y_2$ | $\Delta^7 y_2$ |
| x_3 | y_3 | Δy_3 | $\Delta^2 y_3$ | $\Delta^3 y_3$ | $\Delta^4 y_3$ | $\Delta^5 y_3$ | $\Delta^6 y_3$ | $\Delta^7 y_3$ |
| x_4 | y_4 | Δy_4 | $\Delta^2 y_4$ | $\Delta^3 y_4$ | $\Delta^4 y_4$ | $\Delta^5 y_4$ | $\Delta^6 y_4$ | $\Delta^7 y_4$ |
| x_5 | y_5 | Δy_5 | $\Delta^2 y_5$ | $\Delta^3 y_5$ | $\Delta^4 y_5$ | $\Delta^5 y_5$ | $\Delta^6 y_5$ | $\Delta^7 y_5$ |
| x_6 | y_6 | Δy_6 | $\Delta^2 y_6$ | $\Delta^3 y_6$ | $\Delta^4 y_6$ | $\Delta^5 y_6$ | $\Delta^6 y_6$ | $\Delta^7 y_6$ |
| x_7 | y_7 | Δy_7 | $\Delta^2 y_7$ | $\Delta^3 y_7$ | $\Delta^4 y_7$ | $\Delta^5 y_7$ | $\Delta^6 y_7$ | $\Delta^7 y_7$ |

Differences of a Polynomial

Book Work: If $P_n(x) = a_0 x^n + a_1 x^{n-1} + \cdots + a_n$ is an n th degree polynomial, then prove that

$$\Delta^n P_n(x) = n! a_0 h^n = \text{constant} \quad (4)$$

where $\Delta x = h$.

Proof: Consider $\Delta P_n(x) = P_n(x + h) - P_n(x)$

$$\begin{aligned} &= [a_0(x + h)^n + a_1(x + h)^{n-1} + \cdots + a_n] - \\ &\quad - [a_0 x^n + a_1 x^{n-1} + \cdots + a_n] \\ &= a_0[(x + h)^n - x^n] + a_1[(x + h)^{n-1} - x^{n-1}] + \\ &\quad + \cdots + a_{n-1}[(x + h) - x]. \end{aligned}$$

Expanding by binomial theorem

$$(x + h)^n - x^n = x^n + nhx^{n-1} + n_{c_2} h^2 x^{n-2} + \cdots - x^n$$

Similar terms in the other brackets. Thus

$$Q_{n-1}(x) = \Delta P_n(x) = b_0 x^{n-1} + b_1 x^{n-2} + \cdots + b_{n-1}$$

which is a polynomial of $(n - 1)$ th degree. Here $b_0 = n h a_0$. Now

$$\Delta^2 P_n(x) = \Delta(\Delta P_n(x)) = Q_{n-1}(x + h) - Q_{n-1}(x).$$

Expanding by binomial theorem, observe that $\Delta^2 P_n(x)$ is a polynomial of degree $n - 2$:

$$\Delta^2 P_n(x) = c_0 x^{n-2} + c_1 x^{n-3} + \cdots + c_{n-2} \quad \text{where} \\ c_0 = (n-1)hb_0 = n(n-1)h^2 a_0.$$

Continuing in this manner successively, we get

$$\Delta^n P_n(x) = n!a_0 h^n = \text{constant}$$

Thus the n th order differences of a polynomial of n th degree are constant.

Corollary:

$$\Delta^s P_n(x) = 0 \quad \text{for } s > n \quad (5)$$

i.e., $(n+1)$ th order differences of a polynomial of n th degree are zero.

Converse: If the n th differences of a tabulated function are constant when the values of the independent variable (argument) are taken in arithmetic progression (i.e., at equal intervals apart), then the function is a polynomial of degree n .

Backward Differences

The first (order) backward difference is denoted by ∇ and defined as

$$\nabla y_k = y_k - y_{k-1} \quad (6)$$

Second (order) backward difference

$$\nabla^2 y_k = \nabla(\nabla y_k) = \nabla y_k - \nabla y_{k-1}$$

In general,

$$\nabla^n y_k = \nabla(\nabla^{n-1} y_k) = \nabla^{n-1} y_k - \nabla^{n-1} y_{k-1}.$$

Now $\nabla^3 y_k = \nabla^2 y_k - \nabla^2 y_{k-1}$

$$\begin{aligned} &= \nabla y_k - \nabla y_{k-1} - \nabla y_{k-1} + \nabla y_{k-2} \\ &= y_k - y_{k-1} - 2y_{k-1} + 2y_{k-2} + y_{k-2} - y_{k-3} \\ &= y_k - 3y_{k-1} + 3y_{k-2} - y_{k-3} \end{aligned}$$

In general,

$$\nabla^n y_k = \sum_{i=0}^n (-1)^i n_{ci} y_{k-i} \quad (7)$$

Here y_4 , the last entry, is the leading term and $\nabla y_4, \nabla^2 y_4, \nabla^3 y_4, \nabla^4 y_4$ are known as leading backward differences.

Table 32.2: Backward differences table

| x | y | ∇y | $\nabla^2 y$ | $\nabla^3 y$ | $\nabla^4 y$ |
|-------|-------|--------------|----------------|----------------|----------------|
| x_0 | y_0 | | | | |
| | | ∇y_1 | | | |
| x_1 | y_1 | | $\nabla^2 y_2$ | | |
| | | ∇y_2 | | $\nabla^3 y_3$ | |
| x_2 | y_2 | | $\nabla^2 y_3$ | | $\nabla^4 y_4$ |
| | | ∇y_3 | | $\nabla^3 y_4$ | |
| x_3 | y_3 | | $\nabla^2 y_4$ | | |
| | | ∇y_4 | | | |
| x_4 | y_4 | | | | |

Generalized Power or Factorial

The generalized n th power of a number x , denoted by $x^{[n]}$ or $[x]^n$, is defined as the product of n consecutive factors, the first of which is equal to x and each subsequent factor is h less than the preceding:

$$x^{[n]} = [x]^n = x \cdot (x-h) \cdot (x-2h) \cdots (x-(n-1)h) \quad (8)$$

Here h is some fixed constant $[x]^n$ is also known as a “factorial function”. Here $[x]^0 = x^{[0]} = 1$.

Corollary 1: For $h = 0$, the generalized power coincides with the ordinary power i.e., $x^{[n]} = [x]^n = x^n$.

Corollary 2: For $h = 1$, $[x]^n = x(x-1)(x-2) \cdots (x-n+1)$.

Differences of a Generalized Power

The first difference of the factorial function is

$$\begin{aligned} \Delta[x]^n &= [x+h]^n - [x]^n \\ &= \left\{ (x+h)(x)(x-h) \cdots (x-(n-2)h) \right\} - \\ &\quad - \left\{ x(x-h) \cdots (x-(n-1)h) \right\} \\ &= \left\{ x(x-h) \cdots (x-(n-2)h) \right\} \times \\ &\quad \times \left\{ x+h - (x-(n-1)h) \right\} \\ &= \left\{ x(x-h) \cdots (x-(n-2)h) \right\} nh = nh[x]^{n-1}. \end{aligned}$$

Thus $\Delta[x]^n = nh[x]^{n-1}$.

Now the second difference

$$\begin{aligned}\Delta^2[x]^n &= \Delta(\Delta[x]^n) = \Delta(nh[x]^{n-1}) \\ &= nh\Delta[x]^{n-1} = nh \cdot (n-1) \cdot h \cdot [x]^{n-2} \\ \Delta^2[x]^n &= n(n-1)h^2[x]^{n-2}.\end{aligned}$$

By mathematical induction

$$\Delta^k[x]^n = n(n-1) \cdots (n-(k-1))h^k[x]^{n-k} \quad (9)$$

where $k = 1, 2, 3, \dots, n$.

Corollary 1: For $k = n$, from (9), we have

$$\begin{aligned}\Delta^n[x]^n &= n(n-1)(n-2) \cdots 2 \cdot 1 \cdot h^n[x]^0 \\ \Delta^n[x]^n &= n!h^n = \text{constant} \quad (10)\end{aligned}$$

since $[x]^0 = 1$.

Corollary 2: For $k = n + 1$, from (9),

$$\Delta^{n+1}[x]^n = \Delta(\Delta^n[x]^n) = n!h^n - n!h^n = 0.$$

Thus

$$\Delta^s[x]^n = 0 \quad \text{when } s > n \quad (11)$$

Corollary 3: When $h = 1$, from (10), we have

$$\Delta^n[x]^n = n! \quad (12)$$

i.e., the result of *differencing* $[x]^n$ is analogous to that of *differentiating* x^n . In other words, the operator Δ is equivalent to the differential operator $D = \frac{d}{dx}$ i.e., $\Delta \equiv D$.

Corollary 4: Every polynomial of degree n can be expressed as a factorial polynomial of the same degree and vice versa.

WORKED OUT EXAMPLES

Example 1: Show that

$$\Delta(u_k v_k) = v_{k+1} \Delta u_k + u_k \Delta v_k.$$

Solution: $\Delta(u_k v_k) = u_{k+1} v_{k+1} - u_k v_k$. We know that $\Delta u_k = u_{k+1} - u_k$, $\Delta v_k = v_{k+1} - v_k$

$$\begin{aligned}\therefore u_{k+1} \cdot v_{k+1} &= (u_k + \Delta u_k)(v_k + \Delta v_k) \\ &= u_k v_k + u_k \Delta v_k + v_k \Delta u_k + \Delta u_k \Delta v_k.\end{aligned}$$

Thus

$$\begin{aligned}\Delta(u_k v_k) &= u_{k+1} \cdot v_{k+1} - u_k v_k \\ &= u_k \Delta v_k + \Delta u_k \{v_k + v_{k+1} - v_k\} \\ &= u_k \Delta v_k + v_{k+1} \Delta u_k.\end{aligned}$$

Note: $\Delta(u_k v_k) = v_k \Delta u_k + u_{k+1} \Delta v_k$ is true.

Example 2: Evaluate $\Delta^n(e^{3x+5})$.

Solution: $\Delta(e^{3x+5}) = e^{3(x+1)+5} - e^{3x+5}$
 $= e^{3x+5} (e^3 - 1)$. Now

$$\begin{aligned}\Delta^2(e^{3x+5}) &= \Delta(\Delta e^{3x+5}) = \Delta \left\{ (e^3 - 1)e^{3x+5} \right\} \\ &= (e^3 - 1)\Delta(e^{3x+5}), \text{ using the first result} \\ &= (e^3 - 1)(e^3 - 1)e^{3x+5} = (e^3 - 1)^2 e^{3x+5}.\end{aligned}$$

By induction $\Delta^n(e^{3x+5}) = (e^3 - 1)^n e^{3x+5}$.

Example 3: Evaluate $\Delta^2 \left\{ \frac{4x^2 - 25x + 31}{(x-1)(x-2)(x-3)} \right\}$.

Solution: Resolving into partial fractions

$$\begin{aligned}\Delta^2 \left(\frac{4x^2 - 25x + 31}{(x-1)(x-2)(x-3)} \right) &= \Delta^2 \left\{ \frac{5}{x-1} + \frac{3}{x-2} - \frac{4}{x-3} \right\} \\ &= \Delta \left[\Delta \left(\frac{5}{x-1} \right) + \Delta \left(\frac{3}{x-2} \right) + \Delta \left(\frac{-4}{x-3} \right) \right] \\ &= \Delta \left[5 \left(\frac{1}{x} - \frac{1}{x-1} \right) + 3 \left(\frac{1}{x-1} - \frac{1}{x-2} \right) \right. \\ &\quad \left. - 4 \left(\frac{1}{x-2} - \frac{1}{x-3} \right) \right] \\ &= 5 \left\{ \left(\frac{1}{x+1} - \frac{1}{x} \right) - \left(\frac{1}{x} - \frac{1}{x-1} \right) \right\} \\ &\quad + 3 \left\{ \left(\frac{1}{x} - \frac{1}{x-1} \right) - \left(\frac{1}{x-1} - \frac{1}{x-2} \right) \right\} \\ &\quad - 4 \left\{ \left(\frac{1}{x-1} - \frac{1}{x-2} \right) - \left(\frac{1}{x-2} - \frac{1}{x-3} \right) \right\} \\ &= \frac{5}{x+1} - \frac{7}{x} - \frac{5}{x-1} + \frac{11}{x-2} - \frac{4}{x-3}.\end{aligned}$$

Example 4: If $f(x) = x^3 + 5x - 7$, then form the table of backward differences for $x =$

−1, 0, 1, 2, 3, 4, 5. Continue the table to obtain $f(6)$.

Solution: For $x = -1, 0, 1, 2, 3, 4, 5$, the values of $f(x)$ are respectively −13, −7, −1, 11, 35, 77, 143. The backward differences table is

Table 32.3:

| i | x | $y = f(x)$ | ∇y | $\nabla^2 y$ | $\nabla^3 y$ | $\nabla^4 y$ | $\nabla^5 y$ | $\nabla^6 y$ |
|-----|-----|------------|------------|--------------|--------------|--------------|--------------|--------------|
| 0 | −1 | −13 | | | | | | |
| | | | 6 | | | | | |
| 1 | 0 | −7 | | 0 | | | | |
| | | | 6 | | 6 | | | |
| 2 | 1 | −1 | | 6 | | 0 | | |
| | | | 12 | | 6 | | 0 | |
| 3 | 2 | 11 | | 12 | | 0 | | 0 |
| | | | 24 | | 6 | | 0 | |
| 4 | 3 | 35 | | 18 | | 0 | | 0 |
| | | | 42 | | 6 | | 0 | |
| 5 | 4 | 77 | | 24 | | 6 | | 0 |
| | | | 66 | | 24 | | 6 | |
| 6 | 5 | 143 | | 96 | | 30 | | 6 |
| | | | | | | | | |
| 7 | | | | | | | | |

Values obtained by continuation at $f(6)$ are squared boxes.

Example 5: Construct the missing values in the following table

| | | | | | | |
|-------|---|----|----|----|----|----|
| $x :$ | 0 | 5 | 10 | 15 | 20 | 25 |
| $y :$ | 6 | 10 | — | 17 | — | 31 |

Solution: Name the missing values as y_2 and y_4 . Then the differences table is Table 32.4. Since only four entries y_0, y_1, y_3, y_5 are given, y can be represented by third degree polynomial. Consequently its fourth order differences are zero. Thus

$$\Delta^4 y_0 = y_4 + 6y_2 - 102 = 0 \quad \text{and}$$

$$\Delta^4 y_1 = 143 - 4y_4 - 4y_2 = 0$$

Solving $y_2 = 13.25, y_4 = 22.5$.

Generalized power (factorial function)

Example 6: Express $x^3 - 2x^2 + x - 1$ in generalized powers (or into factorial polynomial). Hence

Table 32.4:

| x | y | Δy | $\Delta^2 y$ | $\Delta^3 y$ | $\Delta^4 y$ |
|-----|-------|------------|------------------|-------------------|---------------------|
| 0 | 6 | | | | |
| | | 4 | | | |
| 5 | 10 | | $y_2 - 14$ | | |
| | | $y_2 - 10$ | | $41 - 3y_2$ | $y_4 + 6y_2 - 102$ |
| 10 | y_2 | | $27 - 2y_2$ | | |
| | | $17 - y_2$ | | $y_4 + 3y_2 - 61$ | |
| 15 | 17 | | $y_4 - 34 + y_2$ | | $143 - 4y_4 - 4y_2$ |
| | | $y_4 - 17$ | | $82 - 3y_4 - y_2$ | |
| 20 | y_4 | | $48 - 2y_4$ | | |
| | | $31 - y_4$ | | | |
| 25 | 31 | | | | |

show that $\Delta^4 f(x) = 0$.

Solution: Assume that

$$\begin{aligned} f(x) &= x^3 - 2x^2 + x - 1 = [x]^3 + B[x]^2 + C[x] + D \\ &= x(x-1)(x-2) + Bx(x-1) + cx + D. \end{aligned}$$

Put $x = 0$, then $-1 = D$

Put $x = 1$, then $C + D = -1 \therefore C = 0$

Put $x = 2$, then $2B + C + D = 1 \therefore B = 1$

Thus $f(x) = [x]^3 + [x]^2 - 1$

Since differencing of power function $[x]^r$ amounts differentiation of x^r , we have

$$\begin{aligned} \Delta f(x) &= \Delta[x]^3 + \Delta[x]^2 - \Delta[x]^0 \\ &= \frac{d}{dx} x^3 + \frac{d}{dx} x^2 - \frac{d}{dx} 1 = 3[x]^2 + 2[x] \end{aligned}$$

$$\Delta^2 f = 6[x] + 2$$

$$\Delta^3 f = 6 \quad \text{and} \quad \Delta^4 f(x) = 0.$$

Example 7: Obtain the function whose first difference is $2x^3 + 3x^2 - 5x + 4$.

Solution: Let $\Delta f(x) = 2x^3 + 3x^2 - 5x + 4$. Now like the above problem

$$2x^3 + 3x^2 - 5x + 4 = 2[x]^3 + B[x]^2 + C[x] + D$$

Solving $D = 4, C = 0, B = 9$. Thus

$$\Delta f(x) = 2[x]^3 + 9[x]^2 + 0 + 4$$

32.12 — HIGHER ENGINEERING MATHEMATICS—VIII

Integrating, $f(x) = \frac{2[x]^4}{4} + 9\frac{[x]^3}{3} + 4[x] + C$

$$f(x) = \frac{1}{2}x(x-1)(x-2)(x-3) + 3(x)(x-1)(x-2) + 4x + C$$

where C is constant of integration.

Example 8: Evaluate $\Delta^3[(1-x)(1-2x)(1-3x)]$.

Solution:

$$\begin{aligned}\Delta^3[(1-x)(1-2x)(1-3x)] \\ &= \Delta^3[(-1)(-2)(-3)x^3 + (11)x^2 + (-6)x + 1] \\ &= -6\Delta^3x^3 + 0 + 0 + 0 = -6 \cdot 3! = -6 \cdot 6 = -36 \\ &\therefore \Delta^n f(x) = a \cdot n!h^n.\end{aligned}$$

EXERCISE

1. Evaluate (a) $\Delta \tan^{-1} \left(\frac{n-1}{n} \right)$; (b) $\Delta^2 \cos 2x$; (c) $\Delta^n (e^{2x+3})$.

Ans. (a) $\tan^{-1} \frac{1}{2n^2}$; (b) $-4 \sin^2 h \cos(2x + 2h)$; (c) $(e^2 - 1)e^{2x+3}$

2. Evaluate

a. $\Delta^2 \left(\frac{5x+12}{x^2+5x+16} \right)$

b. $\Delta^2 \left(\frac{1}{(x^2)+5x+6} \right)$

with internal spacing $h = 1$.

Ans. (a) $\frac{2(5x+16)}{(x+2)(x+3)(x+4)(x+5)}$; (b) $\frac{-2}{(x+2)(x+3)(x+4)}$

3. Evaluate (a) $\Delta^{10}[(1-x)(1-2x^2)(1-3x^3) \times (1-4x^4)]$ if the interval of spacing is 2.

Hint: L.H.S. $= \Delta^{10}[(-1)(-2)(-3)(-4)x^{10} + \text{terms containing powers of } x \text{ less than } 10] = 24\Delta^{10}[x^{10}] + 0 + \dots + 0 = 24 \cdot 10!2^{10}$ since $\Delta^n f(x) = n!h^n$.

Ans. $24 \times 2^{10} \times 10!$

4. Show that $\Delta \left(\frac{u_k}{v_k} \right) = \frac{v_k \Delta u_k - u_k \Delta v_k}{v_k v_{k+1}}$.

Hint: $\Delta \left(\frac{u_k}{v_k} \right) = \frac{u_{k+1}}{v_{k+1}} - \frac{u_k}{v_k} = \frac{u_{k+1}v_k - u_kv_{k+1}}{v_kv_{k+1}}$

$$= \frac{(u_{k+1}v_k - u_kv_k + u_kv_k - u_kv_{k+1})}{(u_kv_{k+1})}$$

5. Express $f(x) = 2x^3 - 3x^2 + 3x - 10$ in generalized power (in factorial notation) and hence find $\Delta^3 y$.

Ans. $f(x) = 2[x]^3 + 3[x]^2 + 2[x] - 10, \Delta^3 y = 12$

6. Compute the missing values in the following table:

| | | | | | |
|-------|-----|----|-----|----|------|
| $x :$ | 45 | 50 | 55 | 60 | 65 |
| $y :$ | 3.0 | — | 2.0 | — | -2.4 |

Hint: Solve $\Delta^3 y_0 = 3y_1 + y_3 - 9 = 0, \Delta^3 y_1 = y_1 + 3y_2 - 3.6 = 0$

Ans. $y_1 = 2.925, y_3 = 0.225$

7. Represent $f(x) = x^4 - 12x^3 + 42x^2 - 30x + 9$ and its successive differences in generalized power.

Ans. $f(x) = [x]^4 - 6[x]^3 + 13[x]^2 + [x]^1 + 9, \Delta y = 4[x]^3 - 18[x]^2 + 26[x] + 1, \Delta^4 y = 24$.

8. Obtain the function whose first difference is $x^3 + 3x^2 + 5x + 12$.

Ans. $\frac{1}{4}[x]^4 + 2[x]^3 + \frac{9}{2}[x]^2 + 125[x]^1 + C$.

32.3 INTERPOLATION

To fix the height of dam across a river, an engineer utilizes a set of data of the form (x_i, y_i) where x_i denotes the year and y_i , the peak flood level across the river; to estimate the highest possible flood level in future. From the recorded data of (t_i, A_i) , time and altitude of a rocket, a physicist would like to estimate what was the altitude at a particular time $t_0 (\neq t_i)$. Thus most of the experimental or observed data is in the form a set of say $(n+1)$ ordered pairs $(x_0, y_0), (x_1, y_1), \dots, (x_n, y_n)$ which is the tabular form of an unknown function $y = f(x)$. The process of determining the value of y for an $x \in [x_0, x_n]$ is known as interpolation. Here $x_0, x_1, \dots, x_n$ are

called interpolation (or mesh) points. Note that x differs from the interpolation points. Thus interpolation is the “art of reading *between* the lines of a table.” In extrapolation value of y is determined for an $x \notin [x_0, x_n]$ i.e., for x outside the interval $[x_0, x_n]$. But generally interpolation includes extrapolation also.

The problem of interpolation is to construct a new (interpolating) function $F(x)$ which collocates (coincides) with the unknown function $f(x)$ at the tabulated $(n + 1)$ interpolation points

Fig. 32.10

i.e., $y_0 \equiv f(x_0) = F(x_0)$, $y_1 \equiv f(x_1) = F(x_1)$, ...

$y_n \equiv f(x_n) = F(x_n)$.

Geometrically, this means that graphs of $y = f(x)$ and $y = F(x)$ coincide at the $n + 1$ points. Since a unique straight line passes through two given points, a unique parabola through three given points, a unique polynomial $F(x)$ of degree n can be determined (passing) satisfying the given set of $(n + 1)$ points. In this case it is called a polynomial interpolation. Now from $y = F(x)$, y can be computed for a given x . This interpolating polynomial will be expressed in terms of finite differences in several forms leading to the Newton-Gregory forward, backward and central differences formulae of Gauss, Stirling, Bessel, Everett etc. Lagrange's interpolation and Newton's divided differences formulae are applicable for unequally spaced interpolation points x_i .

32.4 NEWTON-GREGORY FORWARD INTERPOLATION FORMULA

Suppose the values of $y_i = f(x_i)$ are given for equally spaced values of the independent variable (argument) $x_i = x_0 + ih$ for $i = 0, 1, 2, \dots, n$. Here h , known as the size of the interval or spacing, is constant. Assume that the n th degree interpolating polynomial is given by

$$F(x) = a_0 + a_1(x - x_0) + a_2(x - x_0)(x - x_1) + \dots + a_n(x - x_0)(x - x_1) \dots (x - x_{n-1}) \quad (1)$$

Using the $n + 1$ conditions, $y_i = F(x_i)$ for $i = 0, 1, 2, \dots, n$, we determine the $(n + 1)$ unknown coefficients $a_0, a_1, a_2, \dots, a_n$ in (1).

Putting $x = x_0$ in (1), we get

$$y_0 = F(x_0) = a_0 + 0 + \dots + 0 \quad \therefore a_0 = y_0$$

Putting $x = x_1$ in (1), we have

$$y_1 = F(x_1) = a_0 + a_1(x_1 - x_0)$$

But $a_0 = y_0$ and $x_1 - x_0 = h$

$$\therefore a_1 = \frac{y_1 - a_0}{x_1 - x_0} = \frac{y_1 - y_0}{h} = \frac{1}{h} \Delta y_0$$

Now with $x = x_2$ in (1), we get

$$y_2 = F(x_2) = a_0 + a_1(x_2 - x_0) + a_2(x_2 - x_0)(x_2 - x_1) \\ = a_0 + a_1 \cdot 2h + a_2 \cdot 2h \cdot h$$

$$\text{so } a_2 = \frac{y_2 - a_0 - 2h \cdot a_1}{2h^2} = \frac{y_2 - y_0 - 2h \frac{1}{h} \Delta y_0}{2h^2}$$

$$a_2 = \frac{y_2 - y_0 - 2(y_1 - y_0)}{2h^2} \\ = \frac{y_2 - 2y_1 + y_0}{2h^2} = \frac{1}{2h} \Delta^2 y_0.$$

Similarly, at $x = x_3$, we have

$$y_3 = F(x_3) = a_0 + a_1(x_3 - x_0) + a_2(x_3 - x_0)(x_3 - x_1) \\ + a_3(x_3 - x_0)(x_3 - x_1)(x_3 - x_2) \\ = a_0 + a_1 \cdot 3h + a_2 \cdot 3h \cdot 2h + a_3 \cdot 3h \cdot 2h \cdot h$$

$$\text{Solving } a_3 = \frac{y_3 - 3y_2 + 3y_1 - y_0}{3!h^3} = \frac{1}{3!h^3} \Delta^3 y_0.$$

32.14 — HIGHER ENGINEERING MATHEMATICS—VIII

This way, we get

$$a_4 = \frac{1}{4!h^4} \Delta^4 y_0, \quad a_5 = \frac{1}{5!h^5} \Delta^5 y_0 \quad \text{etc. and}$$

$$\boxed{a_n = \frac{1}{n!h^n} \Delta^n y_0} \quad (2)$$

Substituting these values of $a_0, a_1, \dots, a_n$ in (1), we get the Newton-Gregory forward interpolation formula (also known as *Newton's first interpolation formula*) as

$$\begin{aligned} y = F(x) = & y_0 + \frac{\Delta y_0}{h}(x - x_0) + \frac{\Delta^2 y_0}{2!h^2}(x - x_0)(x - x_1) + \\ & + \frac{\Delta^3 y_0}{3!h^3}(x - x_0)(x - x_1)(x - x_2) + \dots \\ & + \frac{\Delta^n y_0}{n!h^n}(x - x_0)(x - x_1)(x - x_2) \dots (x - x_{n-1}) \end{aligned} \quad (3)$$

Introducing $q = \frac{x - x_0}{h}$, the above formula (3) can be written in more convenient way.

$$\begin{aligned} \text{Now } \frac{x - x_1}{h} &= \frac{x - (x_0 + h)}{h} = \frac{x - x_0}{h} - 1 = q - 1, \\ \frac{x - x_2}{h} &= \frac{x - (x_0 + 2h)}{h} = \frac{x - x_0}{h} - 2 = q - 2 \text{ etc.} \\ \frac{x - x_{n-1}}{h} &= \frac{x - (x_0 + (n-1)h)}{h} \\ &= q - (n-1) = q - n + 1. \end{aligned}$$

Substituting these values, we have

$$\begin{aligned} F(x) = F(x_0 + hq) = g(q) = & y_0 + \Delta y_0 \cdot q + \\ & + \frac{\Delta^2 y_0}{2!} q(q-1) + \frac{\Delta^3 y_0}{3!} q(q-1)(q-2) + \dots \\ & + \frac{q(q-1) \dots (q-n+1)}{n!} \Delta^n y_0 \end{aligned} \quad (4)$$

Note that the coefficients of Δ 's are binomial coefficients. Since (4) involves only the "forward differences" $\Delta y_0, \Delta^2 y_0, \dots, \Delta^n y_0$, Newton-Gregory forward interpolation formula given by (4) is most often used to interpolate (and extrapolate) for values of y at the **beginning** of a set of tabular data. For $n = 1$ in (4), we get linear interpolation

$$P_1(x) = y_0 + q \Delta y_0.$$

For $n = 2$ in (4), we have parabolic interpolation

$$P_2(x) = y_0 + q \Delta y_0 + \frac{q(q-1)}{2} \Delta^2 y_0.$$

Newton-Gregory Backward Interpolation Gormula

It is mainly useful to interpolate near the **end** of the table. Assume the polynomial as

$$\begin{aligned} y = F(x) = & a_0 + a_1(x - x_n) + a_2(x - x_n)(x - x_{n-1}) + \\ & + a_3(x - x_n)(x - x_{n-1})(x - x_{n-2}) + \dots + \\ & + a_n(x - x_n)(x - x_{n-1}) \dots (x - x_1) \end{aligned} \quad (5)$$

We use $y_i = F(x_1)$ to determine $a_0, a_1, \dots, a_n$. Put $x = x_n$ in (5). Then

$$y_n = F(x_n) = a_0 + 0 \dots + 0 \quad \therefore a_0 = y_n.$$

When $x = x_{n-1}$ in (5), we get

$$y_{n-1} = F(x_{n-1}) = a_0 + a_1(x_{n-1} - x_n)$$

$$\text{or } a_1 = \frac{y_{n-1} - a_0}{x_{n-1} - x_n} = \frac{y_n - y_{n-1}}{x_n - x_{n-1}} = \frac{1}{h} \nabla y_n$$

For $x = x_{n-2}$ in (5), we have

$$\begin{aligned} y_{n-2} = F(x_{n-2}) = & a_0 + a_1(x_{n-2} - x_n) + \\ & + a_2(x_{n-2} - x_n)(x_{n-2} - x_{n-1}) \\ a_2 = & \frac{y_{n-2} - 2y_{n-1} + y_n}{2h^2} = \frac{1}{2h^2} \nabla^2 y_n. \end{aligned}$$

Similarly, we get

$$\boxed{a_n = \frac{1}{n!h^n} \nabla^n y_n}$$

Substituting these values of $a_0, a_1, \dots, a_n$ in (5), we get the Newton-Gregory backward interpolation formula (also known as *Newton's second interpolation formula*) as

$$\begin{aligned} y = F(x) = & y_n + \frac{(x - x_n)}{h} \nabla y_n + \\ & + \frac{(x - x_n)(x - x_{n-1})}{2!h^2} \nabla^2 y_n + \dots \\ & + \frac{(x - x_n)(x - x_{n-1}) \dots (x - x_1)}{n!h^n} \nabla^n y_n \end{aligned} \quad (6)$$

Introducing $q = \frac{x - x_n}{h}$ and noting that

$$\frac{x - x_{n-1}}{h} = q + 1, \quad \frac{x - x_{n-2}}{h} = q + 2, \dots$$

$$\frac{x - x_n}{h} = \frac{x - (x_n - (n-1)h)}{h} = q + n - 1,$$

$$y = F(x) = F(x_n + hq) = y_n + q\nabla y_n + \frac{q(q+1)}{2!}\nabla^2 y_n + \frac{q(q+1)(q+2)}{3!}\nabla^3 y_n + \dots + q(q+1)(q+2)\cdots(q+n-1)\cdot\frac{1}{n!}\nabla^n y_n \quad (7)$$

Generally (4) is used for forward interpolation and backward extrapolation and (7) is used for backward interpolation and forward extrapolation.

WORKED OUT EXAMPLES

Example 1: Compute (a) $y(9)$; (b) $y(7)$; (c) $y(17)$ and (d) $y(19)$ from the following data:

| | | | | | | |
|-------|----|----|------|----|------|------|
| $x :$ | 8 | 10 | 12 | 14 | 16 | 18 |
| $y :$ | 10 | 19 | 32.5 | 54 | 89.5 | 15.4 |

Solution: Since $x = 9$ and $x = 7$ are at the beginning of the table (data), use Newton-Gregory Forward Interpolation Formula (NGFIF) for interpolation at $x = 9$ and extrapolation at $x = 7$. Similarly, since $x = 17$ and $x = 19$ occur at the end of the data, use Newton-Gregory Backward Interpolation Formula (NGBIF) for interpolation at $x = 17$ and extrapolation at $x = 19$. Here interval size is $h = 2$ (points x_i are equidistant).

The finite differences table (from which both forward and backward differences can be read) is obtained below:

Table 32.5:

| i | x | y | Δy | $\Delta^2 y$ | $\Delta^3 y$ | $\Delta^4 y$ | $\Delta^5 y$ |
|-----|-----|------|------------|--------------|--------------|--------------|--------------|
| 0 | 8 | 10 | | | | | |
| 1 | 10 | 19 | 9 | | | | |
| | | | 4.5 | | | | |
| | | | 3.5 | | | | |
| 2 | 12 | 32.5 | 13.5 | 8 | | | |
| | | | 21.5 | 6 | | | |
| 3 | 14 | 54 | 35.5 | 14 | | | |
| | | | 29 | 15 | | | |
| 4 | 16 | 89.5 | 64.5 | | | | |
| 5 | 18 | 154 | | | | | |

Newton-Gregory forward interpolation formula is

$$y = y_0 + q\Delta y_0 + \frac{q(q-1)}{2!}\Delta^2 y_0 + \frac{q(q-1)(q-2)}{3!}\Delta^3 y_0 + \frac{q(q-1)(q-2)(q-3)}{4!}\Delta^4 y_0 + \frac{q(q-1)(q-2)(q-3)(q-4)}{5!}\Delta^5 y_0.$$

From the difference table, $y_0 = 10$, $\Delta y_0 = 9$, $\Delta^2 y_0 = 4.5$, $\Delta^3 y_0 = 3.5$, $\Delta^4 y_0 = 2.5$ and $\Delta^5 y_0 = 6.5$.

a. To interpolate at $x = 9$: $q = \frac{x-x_0}{h}$ so $q = \frac{9-8}{2} = \frac{1}{2}$.

Substituting the above data in the formula

$$\begin{aligned} y(9) &= 10 + \frac{1}{2}(9) + \frac{1}{2}\left(\frac{1}{2}-1\right)\frac{1}{2!}(4.5) \\ &\quad + \frac{\frac{1}{2}\left(\frac{1}{2}-1\right)\left(\frac{1}{2}-2\right)}{3!}(3.5) \\ &\quad + \frac{\frac{1}{2}\left(\frac{1}{2}-1\right)\left(\frac{1}{2}-2\right)\left(\frac{1}{2}-3\right)}{4!}(2.5) \\ &\quad + \frac{\frac{1}{2}\left(\frac{1}{2}-1\right)\left(\frac{1}{2}-2\right)\left(\frac{1}{2}-3\right)\left(\frac{1}{2}-4\right)}{5!}(6.5) \end{aligned}$$

$$y(9) = 14.455.$$

b. To extrapolate at $x = 7$: $q = \frac{7-8}{2} = -\frac{1}{2}$.

$$\begin{aligned} y(7) &= 10 - \frac{9}{2} + \left(\frac{1}{2}\right)\left(\frac{3}{2}\right)\frac{1}{2!}(4.5) \\ &\quad - \frac{1}{2}\left(\frac{3}{2}\right)\left(\frac{5}{2}\right)\frac{1}{3!}(3.5) \\ &\quad + \frac{1}{2}\left(\frac{3}{2}\right)\left(\frac{5}{2}\right)\left(\frac{7}{2}\right)\frac{1}{4!}(2.5) \\ &\quad - \frac{1}{2}\left(\frac{3}{2}\right)\left(\frac{5}{2}\right)\left(\frac{7}{2}\right)\left(\frac{9}{2}\right)\frac{1}{5!}(6.5) \end{aligned}$$

$$y(7) = 5.1777.$$

Newton-Gregory backward interpolation formula is

$$y = y_n + q\nabla y_n + \frac{q(q+1)}{2!}\nabla^2 y_n + \frac{q(q+1)(q+2)}{3!}\nabla^3 y_n + \dots$$

$$+ \frac{q(q+1)(q+2)(q+3)}{4!} \nabla^4 y_n +$$

$$+ \frac{q(q+1)(q+2)(q+3)(q+4)}{5!} \nabla^5 y_n.$$

From the difference table, $x_n = 18$, $y_n = 154$, $\nabla y_n = 64.5$, $\nabla^2 y_n = 29$, $\nabla^3 y_n = 15$, $\nabla^4 y_n = 9$, $\nabla^5 y_n = 6.5$.

c. To interpolate at $x = 17$, we have

$$q = \frac{x - x_n}{h} = \frac{17 - 18}{2} = -\frac{1}{2}$$

Substituting these values in the formula

$$y(17) = 154 + \left(-\frac{1}{2}\right)(64.5)$$

$$+ \left(-\frac{1}{2}\right)\left(-\frac{1}{2} + 1\right) \cdot \frac{1}{2!}(29)$$

$$+ \left(-\frac{1}{2}\right)\left(-\frac{1}{2} + 1\right)\left(-\frac{1}{2} + 2\right) \frac{1}{3!}15$$

$$+ \frac{\left(-\frac{1}{2}\right)\left(-\frac{1}{2} + 1\right)\left(-\frac{1}{2} + 2\right)\left(-\frac{1}{2} + 3\right)(9)}{4!}$$

$$+ \frac{\left(-\frac{1}{2}\right)\left(-\frac{1}{2} + 1\right)\left(-\frac{1}{2} + 2\right)\left(-\frac{1}{2} + 3\right)\left(-\frac{1}{2} + 4\right)(6.5)}{5!}$$

$$y(17) = 126.841.$$

d. To extrapolate at $x = 19$, take $q = \frac{19-18}{2} = \frac{1}{2}$.
Then

$$y(19) = 154 + \frac{1}{2}(64.5) + \frac{1}{2}\left(\frac{3}{2}\right) \frac{1}{2!}(29)$$

$$+ \frac{1}{2}\left(\frac{3}{2}\right)\left(\frac{5}{2}\right) \frac{1}{3!}(15)$$

$$+ \frac{1}{2}\left(\frac{3}{2}\right)\left(\frac{5}{2}\right)\left(\frac{7}{2}\right) \frac{1}{4!}(9)$$

$$+ \frac{1}{2}\left(\frac{3}{2}\right)\left(\frac{5}{2}\right)\left(\frac{7}{2}\right)\left(\frac{9}{2}\right) \frac{1}{5!}(6.5)$$

$$y(19) = 219.208.$$

Example 2: Fit a polynomial of degree three which takes the following values:

| | | | | |
|-------|---|----|----|-----|
| $x :$ | 3 | 4 | 5 | 6 |
| $y :$ | 6 | 24 | 60 | 120 |

Solution: The Newton-Gregory forward interpolating polynomial collocates (takes or geometrically passes through) the given set of points (x_0, y_0) , (x_1, y_1) , (x_2, y_2) , (x_3, y_3) and is given by

$$y = y_0 + q \Delta y_0 + \frac{q(q-1)}{2!} \Delta^2 y_0 + \frac{q(q-1)(q-2)}{3!} \Delta^3 y_0$$

Here $q = \frac{x-x_0}{h}$ and $h = 1$ (given).

The finite differences table is

Table 32.6:

| x | y | Δy | $\Delta^2 y$ | $\Delta^3 y$ |
|-----|-----|------------|--------------|--------------|
| 3 | 6 | | | |
| 4 | 24 | 18 | | |
| 5 | 60 | 36 | 18 | |
| 6 | 120 | 60 | 24 | 6 |

From the table, $x_0 = 3$, $y_0 = 6$, $\Delta y_0 = 18$, $\Delta^2 y_0 = 18$, $\Delta^3 y_0 = 6$, $q = \frac{x-x_0}{h} = \frac{x-3}{1} = x-3$

Substituting these values

$$y = 6 + (x-3)(18) + (x-3) \frac{(x-3-1)}{2!}(18)$$

$$+ (x-3)(x-3-1) \frac{(x-3-2)}{3!}(6)$$

$$= 6 + 18(x-3) + 9(x-3)(x-4)$$

$$+ (x-3)(x-4)(x-5)$$

$$y(x) = x^3 - 3x^2 + 2x$$

is the required cubic polynomial (which takes the given data for example, $y(3) = 3^3 - 3(3^2) + 2(3) = 6$ etc.).

Note: Using Newton's backward interpolating polynomial (using backward differences), we get the same cubic polynomial

$$y = y_n + q \nabla y_n + \frac{q(q+1)}{2!} \nabla^2 y_n$$

$$+ \frac{q(q+1)(q+2)}{3!} \nabla^3 y_n$$

$$= 120 + (x-6)60 + \frac{(x-6)(x-5)}{2!}(24)$$

$$+ \frac{(x-6)(x-5)(x-4)}{3!}6$$

$$y(x) = x^3 - 3x^2 + 2x.$$

EXERCISE

1. Using Newton's forward formula compute the pressure of the steam at temperature 142° from the following steam table:

Temperature: 140 150 160 170 180

Pressure: 3.685 4.854 6.302 8.076 10.225

Hint: Forward differences 1.169, 0.279, 0.047, 0.002.

Ans. 3.899

2. Using Newton's backward formula compute $f(43)$, $f(84)$ from the following table. Fit a polynomial

x : 40 50 60 70 80 90
 $f(x)$: 184 204 226 250 276 304

Hint: Backward differences: 28, 2, 0, 0, 0.

Ans. $f(43) = 190$, $f(84) = 287$; $f(x) = 84 + 2.9x - 0.01x^2$

3. Fit a cubic polynomial which takes the following values. Hence find $y(4)$.

x : 0 1 2 3
 y : 1 0 1 10

Ans. $x^3 - 2x^2 + 1$, $y(4) = 33$, forward differences: $-1, 2, 6$

4. Estimate the population in 1895 and 1925 from the following statistics:

Year x : 1891 1901 1911 1921 1931
 Population y : 46 66 81 93 101

Hint: Forward differences: 20, -5 , 2, -3 ;

Backward differences: 8, -4 , -1 , -3 .

Ans. 54.85, 96.84

5. Compute the first and tenth term of the following series assuming that values of y are consecutive.

x : 3 4 5 6 7 8 9
 y : 2.7 6.4 12.5 21.6 34.3 51.2 72.9

Hint: Forward differences: 3.7, 2.4, 0.6, 0;

Backward differences: 21.7, 4.8, 0.6, 0.

Ans. $y(1) = 0.1$, $y(10) = 100$

6. Construct an empirical formula for the function y specified in the following table. Hence find $y(-1)$, $y(0.5)$,

x : 0 1 2 3 4 5
 y : 5.2 8.0 10.4 12.4 14.0 15.2

Ans. $y = 5.2 + 3x - 0.2x^2$, $y(-1) = 2$, $y(0.5) = 6.65$

7. Determine $\log_{10} 1044$ using backward formula from the data below:

x : 1000 1010 1020
 $\log_{10} x$: 3 3.0043214 3.0086002
 x : 1030 1040 1050
 $\log_{10} x$: 3.0128372 3.017033 3.601193

Hint: Backward differences: 0.004156, 0.0000401, 0.0000008.

Ans. 3.0187005

Extrapolation

8. Compute $\sin 14^\circ$ and $\sin 56^\circ$ from the data below:

x : 15° 20° 25° 30° 35°
 $\sin x$: 0.2588 0.342 0.4226 0.5 0.5736
 x : 40° 45° 50° 55°
 $\sin x$: 0.6428 0.7071 0.706 0.8192

Hint: Forward differences: 0.0832, -0.0026 , -0.0006

Backward differences: 0.0532, -0.0057 , -0.0003

Ans. $\sin 14^\circ = 0.24192$, $\sin 56^\circ = 0.82904$

9. Find the polynomial of degree four which takes the following values:

x : 2 4 6 8 10
 y : 0 0 1 0 0

Hint: Differences: 0, 1, -3 , 6.

Ans. $\frac{1}{64}[x^4 - 24x^3 + 196x^2 - 624x + 640]$

10. Estimate the number of students who secured marks between 40 and 45 from the following table:

32.18 — HIGHER ENGINEERING MATHEMATICS—VIII

| | | | |
|--------------------|----------|----------|----------|
| Marks x : | 30 to 40 | 40 to 50 | 50 to 60 |
| No. Students y : | 31 | 42 | 51 |
| Marks x : | 60 to 70 | 70 to 80 | |
| No. Students y : | 35 | 31 | |

Ans. $y(45) = 47.87 \approx 48$, number of students between 40 and 45 is $48 - 31 = 17$

11. Compute $y(1.5)$ and $y(8.5)$ from the following data:

| | | | | | | | | |
|-------|---|---|----|----|-----|-----|-----|-----|
| x : | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| y : | 1 | 8 | 27 | 64 | 125 | 216 | 343 | 512 |

Hint: F.D.: 7, 12, 6, 0, 0, B.D.: 169, 42, 6, 0, 0.

Ans. $y(1.5) = 3.375$, $y(8.5) = 614.125$

12. If $F(\phi) = \int_0^\phi \frac{dt}{\sqrt{1 - \frac{1}{2} \sin^2 t}}$ (elliptic integral), compute $F(23.5)$ by both N-G forward and backward formulae.

| | | | | | | |
|-------------|--------|--------|--------|-------|--------|--------|
| ϕ : | 21 | 22 | 23 | 24 | 25 | 26 |
| $F(\phi)$: | 0.3706 | 0.3887 | 0.4068 | 0.425 | 0.4433 | 0.4616 |

Hint: F.D.: $\phi = 22$, $F(22) = 0.3887$, 0.0181, 0.0001

B.D.: $\phi = 25$, $F(25) = 0.4433$, 0.0183, 0, -0.0001.

Ans. Forward: $F(23.5) = 0.4159$, Backward: 0.41588.

32.5 CENTRAL DIFFERENCES

Observe that the Newton-Gregory forward difference formula involves only the leading differences Δy_0 , $\Delta^2 y_0$, $\Delta^3 y_0$ etc. corresponding to the leading term (initial value) x_0 . Thus only those values of function were used which lie on one side of the chosen initial value. Similarly, the Newton-Gregory backward difference formula used one-sided values ∇y_n , $\nabla^2 y_n$, $\nabla^3 y_n$ which lie on one side of y_n . Interpolation formulae that contain both preceding and succeeding values of the function w.r.t., the initial value, give very useful results. For this purpose, the differences located in a horizontal row (line) corresponding to the initial values x_0 and y_0 in a diagonal difference table are used. These are known as central differences and are used in the Gauss, Stirling and Bessel interpolation formulae, **for interpo-**

Table 32.7: Central differences table

| x | y | δy | $\delta^2 y$ | $\delta^3 y$ | $\delta^4 y$ | $\delta^5 y$ | $\delta^6 y$ |
|-------|-------|---------------------------|----------------|----------------------------|----------------|----------------------------|----------------|
| x_0 | y_0 | $\delta y_{\frac{1}{2}}$ | | | | | |
| x_1 | y_1 | $\delta y_{\frac{3}{2}}$ | $\delta^2 y_1$ | $\delta^3 y_{\frac{3}{2}}$ | | | |
| x_2 | y_2 | $\delta y_{\frac{5}{2}}$ | $\delta^2 y_2$ | $\delta^3 y_{\frac{5}{2}}$ | $\delta^4 y_2$ | | |
| x_3 | y_3 | $\delta y_{\frac{7}{2}}$ | $\delta^2 y_3$ | $\delta^3 y_{\frac{7}{2}}$ | $\delta^4 y_3$ | $\delta^5 y_{\frac{7}{2}}$ | $\delta^6 y_3$ |
| x_4 | y_4 | $\delta y_{\frac{9}{2}}$ | $\delta^2 y_4$ | $\delta^3 y_{\frac{9}{2}}$ | $\delta^4 y_4$ | | |
| x_5 | y_5 | $\delta y_{\frac{11}{2}}$ | $\delta^2 y_5$ | | | | |
| x_6 | y_6 | | | | | | |

lation near the middle of the table, taken as the initial value. Central differences are defined by the operator δ as follows:

$$\delta y_{\frac{1}{2}} = y_1 - y_0, \delta y_{\frac{3}{2}} = y_2 - y_1, \dots, \delta y_{n-\frac{1}{2}} = y_n - y_{n-1}$$

Higher order central differences are

$$\delta^2 y_1 = \delta y_{\frac{3}{2}} - \delta y_{\frac{1}{2}}, \delta^2 y_2 = \delta y_{\frac{5}{2}} - \delta y_{\frac{3}{2}}, \text{ etc.}$$

Note 1: The subscript of δy for any difference is the average of the subscripts of the two members of the difference.

Note 2: Differences on the same horizontal line have the same suffix.

Note 3: Odd order differences are known only for half values of the suffix (having fractional suffix) while even order differences for only integral values of the suffix.

Note 4: Observe that $\Delta y_0 = y_1 - y_0 = \nabla y_1 = \delta y_{\frac{1}{2}}$. Also $\Delta^3 y_2 = \nabla^3 y_5 = \delta^3 y_{\frac{7}{2}}$ etc. i.e., same numbers occur in the same positions but identified in different ways.

In order to derive the central-differences interpolation formulas of Gauss, Stirling and Bessel, we rearrange the central differences table with the *initial values* x_0 and y_0 placed at the middle of the table as shown below. Here

$$x_i = x_0 + ih \quad \text{for } i = 0, \pm 1, \pm 2, \dots$$

$$y_i = f(x_i) \quad \text{and}$$

$$\Delta y_i = y_{i+1} - y_i, \Delta^2 y_i = \Delta y_{i+1} - \Delta y_i \quad \text{etc.}$$

32.6 STIRLING AND BESSEL'S INTERPOLATION FORMULAE

Gaussian Interpolation Formulae

Consider $(2n + 1)$ equally spaced points

$$x_{-n}, x_{-(n-1)}, \dots, x_{-1}, x_0, x_1, \dots, x_{n-1}, x_n$$

where

$$\Delta x_i = x_{i+1} - x_i = h = \text{constant}$$

with $i = -n, -(n-1), \dots, -1, 0, 1, \dots, n-1, n$.

Let $P(x)$ be a polynomial of degree $2n$, given by

$$P(x) = a_0 + a_1(x-x_0) + \dots + a_{2n}(x-x_{-(n-1)}) \dots (x-x_{-1}) \times (x-x_0)(x-x_1) \dots (x-x_{n-1})(x-x_n).$$

If $P(x_i) = y_i = f(x_i)$ for $i = 0, \pm 1, \pm 2, \dots, \pm n$ then $a_0 = y_0, a_1 = \frac{\Delta y_0}{h}, a_2 = \frac{\Delta^2 y_{-1}}{2!h^2}, \dots, a_{2n} = \frac{\Delta^{2n} y_{-n}}{(2n)!h^{2n}}$.

Introducing $q = \frac{x-x_0}{h}$, we get Gauss first (GI) interpolation formula

$$\begin{aligned} P(x) = & y_0 + q \Delta y_0 + \frac{q(q-1)}{2!} \Delta^2 y_{-1} \\ & + \frac{(q+1)q(q-1)}{3!} \Delta^2 y_{-1} \\ & + \frac{(q+1)q(q-1)(q-2)}{4!} \Delta^2 y_{-2} + \dots \\ & + \frac{(q+n-1) \dots (q-n)}{(2n)!} \Delta^{2n} y_{-n} \end{aligned} \quad (1)$$

Similarly, Gaussian second (GII) interpolation formula is

$$\begin{aligned} P(x) = & y_0 + q \Delta y_{-1} \\ & + \frac{(q+1)q}{2!} \Delta^2 y_{-1} + \frac{(q+1)q(q-1)}{3!} \Delta^3 y_{-2} \\ & + \frac{(q+2)(q+1)q(q-1)}{4!} \Delta^4 y_{-2} + \dots \\ & + \frac{(q+n)(q+n-1) \dots (q-n+1)}{(2n)!} \Delta^{2n} y_{-n} \end{aligned} \quad (2)$$

To shift the initial value from (x_0, y_0) to (x_1, y_1) replace q by $q-1$ and increase the indices in R.H.S. of (2) by (1). This yields another Gaussian

Table 32.8 Central differences table

| x | y | Δy | $\Delta^2 y$ | $\Delta^3 y$ | $\Delta^4 y$ | $\Delta^5 y$ | $\Delta^6 y$ |
|----------|----------|-----------------|-------------------|-------------------|-------------------|-------------------|-------------------|
| x_{-4} | y_{-4} | Δy_{-4} | | | | | |
| x_{-3} | y_{-3} | Δy_{-3} | $\Delta^2 y_{-4}$ | | | | |
| x_{-2} | y_{-2} | Δy_{-2} | $\Delta^2 y_{-3}$ | $\Delta^3 y_{-4}$ | | | |
| x_{-1} | y_{-1} | Δy_{-1} | $\Delta^2 y_{-2}$ | $\Delta^3 y_{-3}$ | $\Delta^4 y_{-4}$ | $\Delta^5 y_{-4}$ | $\Delta^6 y_{-4}$ |
| x_0 | y_0 | Δy_0 | $\Delta^2 y_{-1}$ | $\Delta^3 y_{-2}$ | $\Delta^4 y_{-3}$ | $\Delta^5 y_{-3}$ | $\Delta^6 y_{-3}$ |
| x_1 | y_1 | Δy_1 | $\Delta^2 y_0$ | $\Delta^3 y_{-1}$ | $\Delta^4 y_{-1}$ | $\Delta^5 y_{-2}$ | $\Delta^6 y_{-2}$ |
| x_2 | y_2 | Δy_2 | $\Delta^2 y_1$ | $\Delta^3 y_0$ | $\Delta^4 y_0$ | $\Delta^5 y_{-1}$ | |
| x_3 | y_3 | Δy_3 | $\Delta^2 y_2$ | $\Delta^3 y_1$ | | | |
| x_4 | y_4 | | | | | | |

— G_2

— G_1

..... G_3

32.20 — HIGHER ENGINEERING MATHEMATICS—VIII

interpolation (GIII) formula

$$P(x) = y_1 + (q-1)\Delta y_0 + \frac{q(q-1)}{2!}\Delta^2 y_0 + \frac{q(q-1)(q-2)}{3!}\Delta^3 y_{-1} + \frac{(q+1)q(q-1)(q-2)}{4!}\Delta^4 y_{-1} + \dots + \frac{(q+n-1)\dots(q-n)}{(2n)!}\Delta^{2n} y_{-(n-1)} \quad (3)$$

Stirling's Interpolation Formula

is the arithmetic mean of GI and GII i.e., of (1) and (2)

$$P(x) = y_0 + q \frac{\Delta y_{-1} + \Delta y_0}{2} + \frac{q^2}{2}\Delta^2 y_{-1} + \frac{q(q^2-1)}{3!} \frac{\Delta^3 y_{-2} + \Delta^3 y_{-1}}{2} + \frac{q^2(q^2-1)}{4!}\Delta^4 y_{-2} + \frac{q(q^2-1)(q^2-2^2)}{5!} \frac{\Delta^5 y_{-3} + \Delta^5 y_{-2}}{2} + \dots \quad (4)$$

Bessel's Interpolation Formula

is the arithmetic mean of GI and GIII i.e., of (1) and (3).

$$P(x) = y_0 + q\Delta y_0 + \frac{q(q-1)}{2} \frac{\Delta^2 y_{-1} + \Delta^2 y_0}{2} + \frac{(q-\frac{1}{2})q(q-1)}{3!}\Delta^3 y_{-1}$$

$$+ \frac{q(q-1)(q+1)(q-2)}{4!} \frac{\Delta^4 y_{-2} + \Delta^4 y_{-1}}{2} + \dots$$

Note 1: It is advised to use Stirling's formula for $|q| \leq 0.25$ and Bessel's formula for $0.25 \leq q \leq 0.75$.

Note 2: Stirling's formula consists of the even differences along the central line and mean of the odd differences just above and below the central line

$$-y_0 - \frac{\Delta y_{-1}}{\Delta y_0} - \frac{\Delta^3 y_{-2}}{\Delta^5 y_{-1}} - \frac{\Delta^5 y_{-3}}{\Delta^5 y_{-2}} - \Delta^6 y_{-3} - \text{central line.}$$

Note 3: Bessel's formula consists of means of even differences along and below the central line and odd differences below the central line

$$y_0 - \frac{\Delta^2 y_{-1}}{\Delta y_0} - \frac{\Delta^4 y_{-2}}{\Delta^2 y_0} - \frac{\Delta^6 y_{-3}}{\Delta^4 y_{-1}} - \frac{\Delta^8 y_{-4}}{\Delta^6 y_{-2}} - \text{central line.}$$

WORKED OUT EXAMPLES

Example 1: Using *Stirling's* formula, compute $f(1.22)$ from the following data:

| | | | | | |
|----------|-------|-------|-------|-------|-------|
| $x :$ | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 |
| $f(x) :$ | 0.841 | 0.891 | 0.932 | 0.963 | 0.985 |

Solution: Choose origin as $x_0 = 1.2$ given $h =$ interval size $= 0.1$ then $q = \frac{x-x_0}{h} = \frac{1.22-1.2}{0.1} = 0.2$
The central differences table is 32.9 below.
Since $q = 0.2$ lies in between $-\frac{1}{4}$ and $\frac{1}{4}$, Stirling's formula is applicable.

Table 32.9

| x | q | y | Δy | $\Delta^2 y$ | $\Delta^3 y$ | $\Delta^4 y$ |
|-----|-----|------------------|-------------------------|----------------------------|----------------------------|---------------------------|
| 1.0 | -2 | $y_{-2} = 0.841$ | | | | |
| 1.1 | -1 | $y_{-1} = 0.891$ | $\Delta y_{-2} = 0.05$ | | | |
| 1.2 | 0 | $y_0 = 0.932$ | $\Delta y_{-1} = 0.041$ | $\Delta^2 y_{-2} = -0.009$ | | |
| 1.3 | 1 | $y_1 = 0.963$ | $\Delta y_0 = 0.031$ | $\Delta^2 y_{-1} = -0.01$ | $\Delta^3 y_{-2} = -0.001$ | |
| 1.4 | 2 | $y_2 = 0.985$ | $\Delta y_1 = 0.022$ | $\Delta^2 y_0 = -0.009$ | $\Delta^3 y_{-1} = +0.001$ | $\Delta^4 y_{-2} = 0.002$ |

Stirling's formula is

$$y = y_0 + q \left(\frac{\Delta y_{-1} + \Delta y_0}{2} \right) + \frac{q^2}{2!} \Delta^2 y_{-1} + \frac{q(q^2 - 1)}{3!} \left(\frac{\Delta^3 y_{-2} + \Delta^3 y_{-1}}{2} \right) + \frac{q^2(q^2 - 1)}{4!} \Delta^4 y_{-2} + \dots$$

Substituting the values from the table (underlined)

$$\begin{aligned} y(1.22) &= 0.932 + 0.2 \frac{(.041 + .031)}{2} + \frac{(0.2)^2}{2!} (-0.01) \\ &\quad + \frac{(0.2)[(0.2)^2 - 1]}{6} \frac{(-0.001 + 0.001)}{2} \\ &\quad + \frac{(0.2)^2[(0.2)^2 - 1]}{24} (0.002) \\ y(1.22) &= 0.9389968. \end{aligned}$$

Example 2: Use *Bessel's* formula to compute $f(1.95)$ from the following data:

| | | | | | | | |
|----------|-------|-------|-------|-------|-------|-------|-------|
| x : | 1.7 | 1.8 | 1.9 | 2.0 | 2.1 | 2.2 | 2.3 |
| $f(x)$: | 2.979 | 3.144 | 3.283 | 3.391 | 3.463 | 3.997 | 4.491 |

Solution: Choose the origin at $x_0 = 2.0$, given $h = 0.1$ so $q = \frac{x - x_0}{h} = \frac{1.95 - 2.0}{0.1} = -0.5$. Since $q = -0.5$ lies between $-\frac{1}{4}$ and $\frac{3}{4}$, Bessel's formula is applicable. The central difference table is:

Table 32.10:

| x | q | y | Δy | $\Delta^2 y$ | $\Delta^3 y$ | $\Delta^4 y$ | $\Delta^5 y$ |
|------------|-----|--------------|--------------|---------------|--------------|--------------|--------------|
| 1.7 | -3 | 2.979 | | | | | |
| | | | 0.165 | | | | |
| 1.8 | -2 | 3.144 | | -0.026 | | | |
| | | | 0.139 | | -0.005 | | |
| 1.9 | -1 | 3.283 | | -0.031 | | 0 | |
| | | | 0.108 | | -0.005 | | 0.503 |
| <u>2.0</u> | 0 | <u>3.391</u> | | <u>-0.036</u> | | <u>0.503</u> | |
| | | | <u>0.072</u> | | <u>0.498</u> | | -1.503 |
| 2.1 | 1 | 3.463 | | <u>0.462</u> | | <u>-1.0</u> | |
| | | | 0.53 | | -0.502 | | |
| 2.2 | 2 | 3.997 | | -0.04 | | | |
| | | | 0.494 | | | | |
| 2.3 | 3 | 4.491 | | | | | |

The Bessel's formula is

$$y = y_0 + q \Delta y_0 + \frac{q(q-1)}{2!} \left(\frac{\Delta^2 y_{-1} + \Delta^2 y_0}{2} \right) + \frac{\left(q - \frac{1}{2}\right) q(q-1)}{3!} \Delta^3 y_{-1} + \frac{(q+1)q(q-1)(q-2)}{4!} \left(\frac{\Delta^4 y_{-2} + \Delta^4 y_{-1}}{2} \right)$$

Substituting the values from the table (underlined)

$$\begin{aligned} y(1.95) &= 3.391 + (-0.5)(0.072) \\ &\quad + \frac{(-0.5)(-0.5-1)}{2} \frac{(-0.036 + 0.462)}{2} \\ &\quad + \frac{\left(-0.5 - \frac{1}{2}\right)(-0.5)(-0.5-1)}{6} (0.498) \\ &\quad + \frac{(-0.5+1)(0.5)(-0.5-1)(-0.5-2)}{24} \frac{(0.503-1.0)}{2} \\ y(1.95) &= 3.362917. \end{aligned}$$

EXERCISE

1. Compute $\sinh 1.41710$ from the following data:

| | | | | | |
|-------------|---------|---------|---------|---------|---------|
| x : | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 |
| $\sinh x$: | 1.1752 | 1.33565 | 1.50946 | 1.69838 | 1.90430 |
| x : | 1.5 | 1.6 | 1.7 | 1.8 | |
| $\sinh x$: | 2.12928 | 2.37557 | 2.64563 | 2.94217 | |

Hint: Use Stirlings with $x_0 = 1.4$, $y_0 = 1.90430$, differences 0.20592, 0.22498, 0.01906, 0.00206, 0.00225.

Ans. 1.94136

2. Calculate $f(0.5437)$ for the probability integral $f(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$ with the following data:

| | | | | |
|----------|-----------|-----------|-----------|-----------|
| x : | 0.51 | 0.52 | 0.53 | 0.54 |
| $f(x)$: | 0.5292437 | 0.5378987 | 0.5464641 | 0.5549392 |
| x : | 0.55 | 0.56 | 0.57 | |
| $f(x)$: | 0.5633233 | 0.5716157 | 0.5798158 | |

Hint: Use Stirlings with $x_0 = 0.54$, $y_0 = 0.5549392$, differences 0.0084751, 0.0083841, -0.0000910, -0.0000007, 0.

32.22 — HIGHER ENGINEERING MATHEMATICS—VIII

Ans. 0.5580520

3. Compute e^x when $x = 0.644$ by (a) Stirling; (b) Bessel's formula from the following data. Also find $e^{0.638}$ by (a) Stirling; (b) Bessel's formulae.

| | | | | |
|---------|-----------|----------|----------|----------|
| $x :$ | 0.61 | 0.62 | 0.63 | 0.64 |
| $e^x :$ | 1.840431 | 1.858928 | 1.877610 | 1.896481 |
| $x :$ | 0.65 | 0.66 | 0.67 | |
| $e^x :$ | 1.9515541 | 1.934792 | 1.954237 | |

Hint:

- a, b.** Differences: $x_0 = 0.64$, $y_0 = 1.896481$,
0.018871, 0.019060, 0.000189, 0,
0.000002, 0.000002.
c. $x_0 = 0.64$, $x_n = 0.638$, $q = -0.2$
d. $x_0 = 0.63$, $x_n = 0.638$, $q = 0.8$

Ans. **a.** 1.904082

b. 1.904082

c. 1.892692

d. 1.89262

4. Find $f(16)$ by Stirling's formula from the following data:

| | | | | | | | |
|----------|---|--------|--------|--------|-------|--------|--------|
| $x :$ | 0 | 5 | 10 | 15 | 20 | 25 | 30 |
| $f(x) :$ | 0 | 0.0875 | 0.1763 | 0.2679 | 0.364 | 0.4663 | 0.5774 |

Hint: $x_0 = 15$, $y_0 = 0.2679$, Differences:
0.0916, 0.0961, 0.0045, 0.0017, 0.0017,

| $x :$ | 20 | 24 | 28 | 32 |
| $y :$ | 2854 | 3162 | 3544 | 3992 |

Hint: $x_0 = 24$, $h = 4$, $p = \frac{25-24}{4} = \frac{1}{4}$; $y_0 = 3162$, Differences: 382, 74, 66, -8.

Ans. 3250.875

32.7 LAGRANGE'S INTERPOLATION

The interpolation formulae derived so far, are applicable only when argument x is equally spaced (equidistant $x_{i+1} - x_i = h = \text{constant}$). Lagrange's interpolation formula is a more general one and can be applied for arbitrarily specified points i.e., for unequally spaced argument (i.e., $x_{i+1} - x_i = h = \text{variable}$). For example tables of empirical data contain variable intervals.

Fig. 32.11

In order to construct a polynomial $L_n(x)$ having (i) degree not exceeding n and (ii) satisfying the $(n + 1)$ set of points i.e., $L_n(x_i) = y_i$ for $i = 0, 1, 2, \dots, n$ choose

$$L_n(x) = \sum_{i=0}^n P_i(x) \cdot y_i \quad (1)$$

Geometrically, the second condition implies that the curve $y = L_n(x)$ meets the curve $y = f(x)$ at these $(n + 1)$ points $x_0, x_1, x_2, \dots, x_n$. Since the desired polynomial $L_i(x)$ vanishes at n points

$x_0, x_1, \dots, x_{i-1}, x_{i+1}, \dots, x_n$ and $L_i(x_i) = y_i$ choose

$$P_i(x) = c_i(x - x_0)(x - x_1) \cdots (x - x_{i-1}) \times \\ \times (x - x_{i+1}) \cdots (x - x_n) \quad (2)$$

where c_i is a constant coefficient. To satisfy the first condition, at $x = x_j$

$$L_n(x_j) = \sum_{i=0}^n P_i(x_j)y_j = y_j$$

we must have

$$P_i(x_j) = \delta_{ij} = \begin{cases} 1, & \text{if } j = i \\ 0, & \text{if } j \neq i \end{cases}$$

This determines c_i , put $x = x_i$ in (2), then

$$1 = P_i(x_i) = c_i(x_i - x_0)(x_i - x_1) \cdots (x_i - x_{i-1}) \\ \cdot (x_i - x_{i+1}) \cdots (x_i - x_n)$$

or

$$c_i = \frac{1}{(x_i - x_0)(x_i - x_1) \cdots (x_i - x_{i-1})(x_i - x_{i+1}) \cdots (x_i - x_n)}$$

Substituting c_i in (2), we get the Lagrangian coefficient functions

$$P_i(x) = \frac{(x - x_0)(x - x_1) \cdots (x - x_{i-1})(x - x_{i+1}) \cdots (x - x_n)}{(x_i - x_0)(x_i - x_1) \cdots (x_i - x_{i-1})(x_i - x_{i+1}) \cdots (x_i - x_n)} \quad (3)$$

The degree of the polynomial $P_i(x)$ is not higher than n (i.e., $\leq n$). Substituting (3) in (1), we get the required Lagrange's interpolation formula

$$y = L_n(x) = \sum_{i=0}^n y_i \cdot \frac{(x - x_0)(x - x_1) \cdots (x - x_{i-1})(x - x_{i+1}) \cdots (x - x_n)}{(x_i - x_0)(x_i - x_1) \cdots (x_i - x_{i-1})(x_i - x_{i+1}) \cdots (x_i - x_n)}$$

or in the expanded form

$$y = L_n(x) = \frac{(x - x_1)(x - x_2) \cdots (x - x_n)}{(x_0 - x_1)(x_0 - x_2) \cdots (x_0 - x_n)} y_0 \\ + \frac{(x - x_0)(x - x_2) \cdots (x - x_n)}{(x_1 - x_0)(x_1 - x_2) \cdots (x_1 - x_n)} y_1 + \\ \cdots \cdots \cdots \\ + \frac{(x - x_0)(x - x_1) \cdots (x - x_{i-1})(x - x_{i+1}) \cdots (x - x_n)}{(x_i - x_0)(x_i - x_1) \cdots (x_i - x_{i-1})(x_i - x_{i+1}) \cdots (x_i - x_n)} y_i \\ \cdots \cdots \cdots \\ + \frac{(x - x_0)(x - x_1)(x - x_2) \cdots (x - x_{n-1})}{(x_n - x_0)(x_n - x_1)(x_n - x_2) \cdots (x_n - x_{n-1})} y_n \quad (4)$$

Note: If the points are equally spaced, Lagrange's interpolation polynomial coincides with the corresponding Newton's interpolation polynomial.

To determine y at a point x^* , put $x = x^*$ in (4). The unique polynomial (4) containing y_i explicitly is applicable for both unequally spaced and equally spaced points, abscissa $x_0, x_1, \dots, x_n$ need not be in order, but inconvenient to move from one interpolation polynomial to another of degree one greater.

Note: The given function $y = f(x)$ can be split into partial fractions by dividing (4) throughout by $(x - x_0)(x - x_1) \cdots (x - x_i) \cdots (x - x_n)$ having $n + 1$ factors. Then

$$\frac{f(x)}{(x - x_0) \cdots (x - x_i) \cdots (x - x_n)} \\ = \frac{y_0}{(x_0 - x_1)(x_0 - x_2) \cdots (x_0 - x_n)} \cdot \frac{1}{(x - x_0)} + \\ + \cdots \frac{y_1}{(x_1 - x_0)(x_1 - x_2) \cdots (x_1 - x_n)} \cdot \frac{1}{x - x_1} + \\ \cdots \cdots \cdots \\ + \frac{y_n}{(x_n - x_0)(x_n - x_1) \cdots (x_n - x_{n-1})} \cdot \frac{1}{(x - x_n)} \\ = \frac{A_0}{x - x_0} + \frac{A_1}{x - x_1} + \cdots + \frac{A_n}{x - x_n}$$

where $A_0, A_1, \dots, A_n$ coefficients are completely determined by the points $(x_0, y_0), (x_1, y_1) \cdots (x_n, y_n)$.

32.8 INVERSE INTERPOLATION USING LAGRANGE'S INTERPOLATION FORMULA

In the inverse interpolation, for a given value of y , the corresponding value of x is to be determined. For example to find value of the root x for which the function $y = f(x)$ becomes zero is an inverse interpolation problem. Inverse interpolation problem is similar to direct interpolation since the roles of x and y are interchanged.

Now interchanging the roles of x and y , the Lagrange's interpolation formula for inverse inter-

Fig. 32.12

polution takes the form given by

$$x = \sum_{i=0}^n \frac{(y-y_1)(y-y_2) \cdots (y-y_{i-1})(y-y_{i+1}) \cdots (y-y_n)}{(y_i-y_1)(y_i-y_2) \cdots (y_i-y_{i-1})(y_i-y_{i+1}) \cdots (y_i-y_n)} \cdot x_i$$

or in the expanded form

$$\begin{aligned} x = & \frac{(y-y_1)(y-y_2) \cdots (y-y_n)}{(y_0-y_1)(y_0-y_2) \cdots (y_0-y_n)} x_0 + \\ & + \frac{(y-y_0)(y-y_2) \cdots (y-y_n)}{(y_1-y_0)(y_1-y_2) \cdots (y_1-y_n)} \cdot x_1 + \cdots + \\ & + \frac{(y-y_1)(y-y_2) \cdots (y-y_{i-1})(y-y_{i+1}) \cdots (y-y_n)}{(y_i-y_1)(y_i-y_2) \cdots (y_i-y_{i-1})(y_i-y_{i+1}) \cdots (y_i-y_n)} \cdot x_i + \\ & + \cdots + \frac{(y-y_0)(y-y_1) \cdots (y-y_{n-1})}{(y_n-y_0)(y_n-y_1) \cdots (y_n-y_{n-1})} \cdot x_n \quad (5) \end{aligned}$$

Putting $y = y^*$ in (5), we get the value of x^* .

WORKED OUT EXAMPLES

Example 1: Use Lagrange's interpolation formula to fit a polynomial to the following data. Hence find $y(-2)$, $y(1)$ and $y(4)$.

| | | | | |
|-------|----|---|---|---|
| $x :$ | -1 | 0 | 2 | 3 |
| $y :$ | -8 | 3 | 1 | 2 |

Solution: Here $x_0 = -1$, $x_1 = 0$, $x_2 = 2$, $x_3 = 3$ and $y_0 = -8$, $y_1 = 3$, $y_2 = 1$, $y_3 = 2$. Using

Lagrange's interpolation formula to this

$$\begin{aligned} y = f(x) = & \frac{(x-0)(x-2)(x-3)}{(-1-0)(-1-2)(-1-3)}(-8) + \\ & + \frac{(x+1)(x-2)(x-3)}{(0+1)(0-2)(0-3)} \cdot 3 + \frac{(x+1)(x-0)(x-3)}{(2+1)(2-0)(2-3)} \cdot 1 + \\ & + \frac{(x+1)(x-0)(x-2)}{(3+1)(3-0)(3-2)} \cdot 2 \\ = & \frac{2}{3}x(x-2)(x-3) + \frac{1}{2}(x+1)(x-2)(x-3) - \\ & - \frac{1}{6}x(x+1)(x-3) + \frac{1}{6}(x+1)x(x-2) \\ = & (x-2)(x-3) \left(\frac{7x+3}{6} \right) + \frac{1}{6}x(x+1) \end{aligned}$$

$$y = \frac{1}{6}[7x^3 - 31x^2 + 28x + 18]$$

is the required 3rd degree polynomial.

$$y(-2) = \frac{1}{6}[-56 - 124 - 56 + 18] = -\frac{218}{6} = -36.33$$

$$y(1) = \frac{1}{6}[7 - 31 + 28 + 18] = \frac{22}{6} = 3.666$$

$$y(4) = \frac{1}{6}[448 - 496 + 112 + 18] = \frac{82}{6} = 13.666.$$

Partial fractions

Example 2: Express the function

$$\frac{x^2 + 6x - 1}{(x^2 - 1)(x - 4)(x - 6)}$$

as a sum of partial fractions, using Lagrange's formula.

Solution: Consider $f(x) = x^2 + 6x - 1$. Tabulate $f(x)$ at the roots of the denominator of the given expression i.e., at $x = -1, +1, 4, 6$.

| | | | | |
|----------|----|---|----|----|
| $x :$ | -1 | 1 | 4 | 6 |
| $f(x) :$ | -6 | 6 | 39 | 71 |

We fit a polynomial using Lagrange's formula

$$\begin{aligned} f(x) = & \frac{(x-1)(x-4)(x-6)}{(-1-1)(-1-4)(-1-6)} \cdot (-6) + \\ & + \frac{(x+1)(x-4)(x-6)}{(1+1)(1-4)(1-6)} \cdot 6 + \frac{(x+1)(x-1)(x-6)}{(4+1)(4-1)(4-6)} \cdot 39 + \\ & + \frac{(x+1)(x-1)(x-4)}{(6+1)(6-1)(6-4)} \cdot 71 \end{aligned}$$

$$f(x) = \frac{3}{35}(x-1)(x-4)(x-6) + \frac{1}{5}(x+1)(x-4)(x-6) - \frac{13}{10}(x+1)(x-1)(x-6) + \frac{71}{70}(x+1)(x-1)(x-4)$$

Dividing both sides by $(x^2 - 1)(x - 4)(x - 6)$,

$$\begin{aligned} \frac{f(x)}{(x^2 - 1)(x - 4)(x - 6)} &= \frac{x^2 + 6x - 1}{(x^2 - 1)(x - 4)(x - 6)} = \frac{3}{35} \frac{1}{x + 1} + \frac{1}{5} \frac{1}{x - 1} - \\ &\quad - \frac{13}{10} \frac{1}{x - 4} + \frac{71}{70} \frac{1}{x - 6}. \end{aligned}$$

Inverse interpolation

Example 3: Compute the value of x , when $y = 8$ by inverse interpolation using Lagrange's formula

$$\begin{array}{cccc} x : & -2 & -1 & 1 & 2 \\ y : & -7 & 2 & 0 & 11 \end{array}$$

Solution: Here $x_0 = -2, x_1 = 1, x_2 = 1, x_3 = 2$ and $y_0 = -7, y_1 = 2, y_2 = 0, y_3 = 11$. Now by Lagrange's formula, we have

$$\begin{aligned} x &= \frac{(y - 2)(y - 0)(y - 11)}{(-7 - 2)(-7 - 0)(-7 - 11)}(-2) + \\ &\quad + \frac{(y + 7)(y - 0)(y - 11)}{(2 + 7)(2 - 0)(2 - 11)}(-1) + \frac{(y + 7)(y - 2)(y - 11)}{(0 + 7)(0 - 2)(0 - 11)}(1) + \\ &\quad + \frac{(y + 7)(y - 2)(y - 0)}{(11 + 7)(11 - 2)(11 - 0)} \cdot (2) \end{aligned}$$

Put $y = 8$, then

$$\begin{aligned} x &= \frac{6(8)(-3)}{(-9)(-7)(-18)}(-2) + \frac{(15)(8)(-3)}{(9)(2)(-9)}(-1) + \\ &\quad + \frac{(15)(6)(-3)}{7(-2)(-11)}(1) + \frac{(15)(6)8}{(18)(9)(11)}2 \\ x &= -\frac{8}{21} - \frac{20}{9} - \frac{135}{77} + \frac{80}{99} = -3.5483. \end{aligned}$$

EXERCISE

Lagrange's interpolation

Use Lagrange's interpolation formula to solve the following problems:

- Given (1, 2), (3, 5), (7, 12), (13, 20) find (4, ?).

Hint: $-\frac{27}{144}(2) + \frac{81}{80}(5) + \frac{27}{144}(12) - \frac{9}{720}(20)$.

Ans. 6.6875

- Fit a polynomial of third degree and find $y(0.2)$ from the following data:

$$\begin{array}{cccc} x_i : & 0 & 0.1 & 0.3 & 0.5 \\ y_i : & -0.5 & 0 & 0.2 & 1 \end{array}$$

Ans. $-0.15004, \frac{125}{3}x^3 - 30x^2 + \frac{73}{12}x - 0.5$

- Fit a polynomial of 3rd degree

$$\begin{array}{cccc} x : & 0 & 1 & 3 & 4 \\ y : & -12 & 0 & 6 & 12 \end{array}$$

Ans. $x^3 - 7x^2 + 18x - 12$

- Determine $p(v = 21)$ given the following:

$$\begin{array}{cccccc} v : & 10 & 15 & 22.5 & 33.75 & 50.625 & 75.937 \\ p : & 0.3 & 0.675 & 1.519 & 3.417 & 7.689 & 17.3 \end{array}$$

Ans. 1.323

- Compute $f(9)$ from the following data:

$$\begin{array}{cccccc} x : & 5 & 7 & 11 & 13 & 17 \\ f(x) : & 150 & 392 & 1452 & 2366 & 5202 \end{array}$$

Ans. $-\frac{50}{3} + \frac{3136}{15} + \frac{3872}{3} - \frac{2366}{3} + \frac{578}{5} = 810$

- Determine $f(323.5)$ from the data given below:

$$\begin{array}{cccc} x : & 321.0 & 322.8 & 324.2 & 325.0 \\ f(x) : & 2.50651 & 2.50893 & 2.51081 & 2.51188 \end{array}$$

Ans. 2.50987

- Given (300, 2.4771), (304, 2.4829), (305, 2.4843), (307, 2.4871), find (301, ?).

Ans. 2.4786

- Compute $f(27)$ from the data below:

$$\begin{array}{cccc} x : & 14 & 17 & 31 & 35 \\ f(x) : & 68.7 & 64.0 & 44.0 & 39.1 \end{array}$$

Ans. 49.3.

Inverse interpolation

- Determine $x(7)$ from the tabulated data:

$$\begin{array}{ccc} x : & 1 & 3 & 4 \\ y : & 4 & 12 & 19 \end{array}$$

Ans. ?

32.26 — HIGHER ENGINEERING MATHEMATICS—VIII

10. Find $x(12)$ using Lagrange's technique

| | | | | | | |
|-------|-----|-----|-----|------|------|------|
| $x :$ | 1.2 | 2.1 | 2.8 | 4.1 | 4.9 | 6.2 |
| $y :$ | 4.2 | 6.8 | 9.8 | 13.4 | 15.5 | 19.6 |

Ans. 3.55

11. Let $y(x) = \frac{2}{\sqrt{11}} \int_0^x e^{-t^2} dt$ be the probability integral. Given:

| | | | | |
|----------|-----------|-----------|-----------|-----------|
| $x :$ | 0.46 | 0.47 | 0.48 | 0.49 |
| $y(x) :$ | 0.4846555 | 0.4937452 | 0.5027498 | 0.5116683 |

Determine for what value of x , $y(x) = \frac{1}{2}$.

Ans. 0.476937

12. Find x corresponding to $y = 10$

| | | | | |
|-------|----|----|----|----|
| $x :$ | 10 | 15 | 17 | 20 |
| $y :$ | 3 | 7 | 11 | 17 |

Ans. $x = 16.641$

13. Compute the value of x when $y = 15$

| | | | | |
|-------|----|----|----|----|
| $x :$ | 5 | 6 | 9 | 11 |
| $y :$ | 12 | 13 | 14 | 16 |

Ans. $\frac{5}{4} - 6 + \frac{27}{2} + \frac{11}{4} = \frac{46}{4} = 11.5$

14. Determine $x(0)$ by inverse interpolation

| | | | | |
|-------|----|----|-------|----|
| $x :$ | 1 | 2 | 2.5 | 3 |
| $y :$ | -6 | -1 | 5.625 | 16 |

Ans. 2.122.

ratio given by

$$[x_i, x_{i+1}] = \frac{y_{i+1} - y_i}{x_{i+1} - x_i}, \quad i = 0, 1, 2, \dots$$

For example, $[x_0, x_1] = \frac{y_1 - y_0}{x_1 - x_0}$, $[x_1, x_2] = \frac{y_2 - y_1}{x_2 - x_1}$ etc.

Similarly, the second order divided differences

$$[x_i, x_{i+1}, x_{i+2}] = \frac{[x_{i+1}, x_{i+2}] - [x_i, x_{i+1}]}{x_{i+2} - x_i}$$

for $i = 0, 1, 2, \dots$

$$\text{For example, } [x_0, x_1, x_2] = \frac{[x_1, x_2] - [x_0, x_1]}{x_2 - x_0}.$$

In general, the n th order divided differences:

$$[x_i, x_{i+1}, \dots, x_{i+n}] = \frac{[x_{i+1}, \dots, x_{i+n}] - [x_i, \dots, x_{i+n-1}]}{x_{i+n} - x_i}$$

for $n = 1, 2, 3, \dots$; $i = 0, 1, 2, \dots$

Special case

If $x_{i+1} - x_i = h = \text{constant}$ i.e., when x is equally spaced, then divided differences reduce to forward (or backward) differences. Consider

$$\begin{aligned} [x_0, x_1] &= \frac{y_1 - y_0}{x_1 - x_0} = \frac{1}{h}(y_1 - y_0) = \frac{1}{h}\Delta y_0, \\ [x_0, x_1, x_2] &= \frac{[x_1, x_2] - [x_0, x_1]}{x_2 - x_0} = \frac{1}{2h} \left[\frac{\Delta y_1}{h} - \frac{\Delta y_0}{h} \right] \\ &= \frac{1}{h^2 \cdot 2!} \Delta^2 y_0. \end{aligned}$$

In general.

$$[x_0, x_1, x_2, \dots, x_n] = \frac{1}{h^n n!} \Delta^n y_0 \quad \text{or}$$

$$[x_k, x_{k+i}, \dots, x_{k+n}] = \frac{1}{h^n \cdot n!} \cdot \Delta^n y_k.$$

32.9 DIVIDED DIFFERENCES

In constructing the finite (forward and backward) differences tables, it is assumed that the independent variable x is equally spaced, i.e., $x_{i+1} - x_i = h = \text{constant}$ for $i = 0, 1, 2, \dots$. When x is unequally spaced, with variable interval, the concept of finite differences is generalized to "divided differences", which takes into consideration (account) of the changes in the values of the argument x .

Let the tabulated function $y = f(x)$ consists of $(x_0, y_0), (x_1, y_1), \dots, (x_n, y_n) \dots$ with unequal intervals, $x_{i+1} - x_i \neq 0$ for $i = 0, 1, 2, \dots$. Then the first order divided difference, denoted by $[x_i, x_{i+1}]$, is the

Properties

1. The divided differences operator denoted by Δ is linear because $\Delta cf(x) = c\Delta f(x)$ and $\Delta(f(x) \pm g(x)) = \Delta f(x) \pm \Delta g(x)$, c being a constant.
2. The divided differences are symmetrical i.e.,

$$[x_0, x_1] = \frac{y_1 - y_0}{x_1 - x_0} = \frac{y_0}{x_0 - x_1} + \frac{y_1}{x_1 - x_0}$$

$$= \frac{y_0 - y_1}{x_0 - x_1} = [x_1, x_0]$$

Similarly,

$$\begin{aligned} [x_0, x_1, x_2] &= \frac{[x_1, x_2] - [x_0, x_1]}{x_2 - x_0} \\ &= \frac{1}{x_2 - x_0} \left\{ \left[\frac{y_1}{x_1 - x_2} + \frac{y_2}{x_2 - x_1} \right] - \left[\frac{y_0}{x_0 - x_1} + \frac{y_1}{x_1 - x_0} \right] \right\} \\ &= \frac{y_0}{(x_0 - x_1)(x_0 - x_2)} + \frac{y_1}{(x_1 - x_0)(x_1 - x_2)} + \frac{y_2}{(x_2 - x_0)(x_2 - x_1)} \\ &= [x_1, x_2, x_0] = [x_2, x_0, x_1]. \end{aligned}$$

- 3. Lemma:** If $y = P(x)$ is an n th degree polynomial, then its divided difference of n th order is constant. Consequently, the $(n + 1)$ th order divided differences is zero i.e.,

$$[x, x_0, \dots, x_{n-1}] = c = \text{constant and}$$

$$[x, x_0, \dots, x_{n-1}, x_n] = \frac{c - c}{x - x_n} = 0$$

which follows from the fact that

$$[x, x_0] = \frac{P(x) - P(x_0)}{x - x_0}$$

is a polynomial of degree $(n - 1)$ in x , and

$$[x, x_0, x_1] = \frac{p(x, x_0) - p(x_0, x_1)}{(x - x_1)}$$

is a polynomial of degree $(n - 2)$ in x , and so on.

Thus $[x, x_0, x_1, \dots, x_n, x_{n-1}]$ is a polynomial of degree $(n - n)$ i.e., zero degree in x .

Note: Order of any divided difference is one less than the number of values of the argument in it i.e., 3rd order differences contain four values of x .

32.10 NEWTON'S DIVIDED DIFFERENCES FORMULA

When another interpolation point is added to the tabulated data, the Lagrangian coefficients are to be recalculated, resulting a different Lagrange's polynomial of higher degree. This difficulty is removed

in the Newton's divided differences formula (or *Newton's general interpolation formula* or *Newton's interpolation formula for unequally spaced values of the argument*) in which polynomial of higher degree is obtained simply by addition of new terms (to the already existing formula).

Consider

$$\begin{aligned} [x, x_0] &= \frac{y - y_0}{x - x_0} \quad \text{or} \\ y &= y_0 + (x - x_0)[x, x_0] \end{aligned} \quad (1)$$

$$\begin{aligned} \text{Now } [x, x_0, x_1] &= \frac{[x, x_0] - [x_0, x_1]}{x - x_1} \quad \text{or} \\ [x, x_0] &= [x_0, x_1] + (x - x_1)[x, x_0, x_1] \end{aligned} \quad (2)$$

Substituting (2) in (1), we have

$$\begin{aligned} y &= y_0 + (x - x_0)[x_0, x_1] + \\ &\quad + (x - x_0)(x - x_1)[x, x_0, x_1] \end{aligned} \quad (3)$$

Again

$$\begin{aligned} [x, x_0, x_1, x_2] &= \frac{[x, x_0, x_1] - [x_0, x_1, x_2]}{x - x_2} \quad \text{or} \\ [x, x_0, x_1] &= [x_0, x_1, x_2] + \\ &\quad + (x - x_2)[x, x_0, x_1, x_2] \end{aligned} \quad (4)$$

Substituting (4) in (3), we get

$$\begin{aligned} y &= y_0 + (x - x_0)[x_0, x_1] + (x - x_0)(x - x_1)[x_0, x_1, x_2] + \\ &\quad + (x - x_0)(x - x_1)(x - x_2)[x, x_0, x_1, x_2]. \end{aligned}$$

Continuing this way, we arrive at the Newton's divided differences formula as

$$\begin{aligned} y = f(x) &= y_0 + (x - x_0)[x_0, x_1] + \\ &\quad + (x - x_0)(x - x_1)[x_0, x_1, x_2] + \\ &\quad + (x - x_0)(x - x_1)(x - x_2)[x_0, x_1, x_2] + \dots + \\ &\quad + (x - x_0)(x - x_1) \dots (x - x_{n-1})[x_0, x_1, \dots, x_n] \end{aligned} \quad (5)$$

Note that the approximate relation (5) is obtained by suppressing the error term $E(x)$ where

$$E(x) = (x - x_0) \dots (x - x_n)[x, x_0, x_1, \dots, x_n].$$

32.28 — HIGHER ENGINEERING MATHEMATICS—VIII

Note: Various interpolation formulae obtained so far are ‘different’ forms of the same (unique) polynomial.

WORKED OUT EXAMPLES

Difference formula

Example 1: Find Newton’s divided differences polynomial for the data in the table below. Also find $f(2.5)$

| | | | | | |
|----------|-----|-----|-----|-----|------|
| $x :$ | -3 | -1 | 0 | 3 | 5 |
| $f(x) :$ | -30 | -22 | -12 | 330 | 3458 |

Solution: The divided differences table is:

Table 32.11

| x | $y = f(x)$ | Divided differences of order | | | |
|-----|------------|--|---|------------------------------|---------------------------|
| | | 1 | 2 | 3 | 4 |
| -3 | -30 | | | | |
| -1 | -22 | $\frac{-22-(-30)}{-1-(-3)} = \frac{8}{2} = 4$ | | | |
| 0 | -12 | $\frac{-12-(-22)}{0-(-1)} = \frac{10}{1} = 10$ | $\frac{10-4}{0-(-3)} = \frac{6}{3} = 2$ | | |
| 3 | 330 | $\frac{330-(-12)}{3-0} = 114$ | $\frac{114-10}{3-(-1)} = 26$ | $\frac{26-2}{3-(-3)} = 4$ | |
| 5 | 3458 | $\frac{3458-330}{5-3} = 1564$ | $\frac{1564-114}{5-0} = 290$ | $\frac{290-26}{5-(-1)} = 44$ | $\frac{44-4}{5-(-3)} = 5$ |

Here $x_0 = -3$, $x_1 = -1$, $x_2 = 0$, $x_3 = 3$, $x_4 = 5$, and $y_0 = -30$, $y_1 = -22$, $y_2 = -12$, $y_3 = 330$, $y_4 = 3458$. The divided differences are

$$[x_0, x_1] = 4, [x_1, x_2] = 10,$$

$$[x_2, x_3] = 114, [x_3, x_4] = 1564,$$

$$[x_0, x_1, x_2] = \frac{[x_1, x_2] - [x_0, x_1]}{x_2 - x_0} = 2, [x_1, x_2, x_3] = 26,$$

$$[x_2, x_3, x_4] = 290. \text{ Now}$$

$$[x_0, x_1, x_2, x_3] = \frac{[x_1, x_2, x_3] - [x_0, x_1, x_2]}{x_3 - x_0} = 4$$

$$[x_1, x_2, x_3, x_4] = \frac{[x_2, x_3, x_4] - [x_1, x_2, x_3]}{x_4 - x_1} = 44$$

and finally

$$[x_0, x_1, x_2, x_3, x_4] = \frac{[x_1, x_2, x_3, x_4] - [x_0, x_1, x_2, x_3]}{x_4 - x_0} = 5$$

The Newton’s divided difference polynomial is

$$y = f(x) = y_0 + (x - x_0)[x_0, x_1] + (x - x_0)(x - x_1)[x_0, x_1, x_2] + (x - x_0)(x - x_1)(x - x_2)[x_0, x_1, x_2, x_3] + (x - x_0)(x - x_1)(x - x_2)(x - x_3)[x_0, x_1, x_2, x_3, x_4]$$

Substituting the above data

$$y = f(x) = -30 + (x + 3)(4) + (x + 3)(x + 1)(2) + (x + 3)(x + 1)(x - 0)(4) + (x + 3)(x + 1)x(x - 3)(5) \\ y = f(x) = 5x^4 + 9x^3 - 27x^2 - 21x - 12$$

is the required 4th degree polynomial. Now when $x = 2.5$,

$$y = f(2.5) = 5(2.5)^4 + 9(2.5)^3 - 27(2.5)^2 - 21(2.5) - 12 \\ = 102.6785.$$

EXERCISE

Newton’s divided differences formula

Using Newton’s divided differences formula (Newton’s general interpolation formula) solve the following problems:

1. Find $f(8)$.

| | | | | | | |
|---------|----|-----|-----|-----|------|------|
| $x:$ | 4 | 5 | 7 | 10 | 11 | 13 |
| $f(x):$ | 48 | 100 | 294 | 900 | 1210 | 2028 |

Hint: Divided differences are 52, 15, 1, 0.

Ans. 448

2. Fit a polynomial and find $f(1)$ and $f(8)$.

| | | | | | |
|----------|----|----|----|-----|------|
| x : | -1 | 0 | 3 | 6 | 7 |
| $f(x)$: | 3 | -6 | 39 | 822 | 1611 |

Hint: Divided differences are -9, 6, 5, 1.

Ans. $x^4 - 3x^3 + 5x^2 - 6$, $f(1) = -3$, $f(8) = 2874$.

3. Find value of y for $x = 5.6075$.

| | | | | | |
|-------|-----------|-----------|-----------|---------|-----------|
| x : | 5.6 | 5.602 | 5.605 | 5.607 | 5.608 |
| y : | .77556588 | .77682686 | .77871250 | .779965 | .78059114 |

Hint: Divided differences are 0.6305, -0.38668, -0.9485714, -20.595237.

Ans. 0.77729893

4. Find $\log 323.5$.

| | | | | |
|------------|---------|---------|---------|---------|
| x : | 321.0 | 322.8 | 324.2 | 325.0 |
| $\log x$: | 2.50651 | 2.50893 | 2.51081 | 2.51188 |

Hint: Divided differences are 0.00134444, -0.00000158, -0.00000022.

Ans. 2.50987

5. Fit a cubic polynomial.

| | | | | |
|----------|---|---|----|-----|
| x : | 0 | 1 | 2 | 5 |
| $f(x)$: | 2 | 3 | 12 | 147 |

Hint: Divided differences are 1, 4, 1.

Ans. $x^3 + x^2 - x + 2$

6. Obtain the Newton's divided difference interpolating polynomial and hence find $f(3)$.

| | | | | | | |
|----------|---|----|----|---|---|----|
| x : | 0 | 1 | 2 | 4 | 5 | 6 |
| $f(x)$: | 1 | 14 | 15 | 5 | 6 | 19 |

Hint: Divided differences are 13, -6, 1, 0, 0.

Ans. $x^3 - 9x^2 + 21x + 1$, $f(3) = 10$

7. Fit a cubic polynomial and find $f(6)$.

| | | | | |
|----------|-----|-----|----|----|
| x : | 3 | 7 | 9 | 10 |
| $f(x)$: | 168 | 120 | 72 | 63 |

Hint: Divided differences are -12, -2, 1.

Ans. $x^3 - 21x^2 + 119x - 27$, $f(6) = 147$

8. Form the table of divided differences:

| | | | | | | |
|----------|----|-----|-----|-----|------|------|
| x : | 4 | 5 | 7 | 10 | 11 | 13 |
| $f(x)$: | 48 | 100 | 294 | 900 | 1210 | 2028 |

Extend the table to include values $x = 2$ and $x = 15$.

Hint: Divided differences: 52, 15, 1, 0, 0.

Ans. $x^3 - x^2$, $y(2) = 4$, $y(15) = 3150$.

9. Fit a polynomial to the data $(-4, 1245)$, $(-1, 33)$, $(0, 5)$, $(2, 9)$, $(5, 1335)$. Hence find $f(1)$ and $f(7)$.

Ans. $3x^4 - 5x^3 + 6x^2 - 14x + 5$, $f(1) = -5$, $f(7) = 5689$

10. Calculate $f(1.5)$.

| | | | | | |
|----------|---|---|----|----|-----|
| x : | 1 | 2 | 3 | 4 | 5 |
| $f(x)$: | 0 | 7 | 26 | 63 | 124 |

Hint: Divided differences are 7, 12, 6, 0.

Ans. $f(1.5) = 2.25$

11. Calculate $f(9)$.

| | | | | | |
|----------|-----|-----|------|------|------|
| x : | 5 | 7 | 11 | 13 | 17 |
| $f(x)$: | 150 | 392 | 1452 | 2366 | 5202 |

Hint: Divided differences are 121, 24, 1.

Ans. 810

12. Determine the Newton's general interpolation polynomial and hence find $f(-3)$ and $f(9)$.

| | | | | | |
|----------|------|----|---|---|------|
| x : | -4 | -1 | 0 | 2 | 5 |
| $f(x)$: | 1245 | 33 | 5 | 9 | 1335 |

Hint: Divided differences are -404, 94, -14, 3.

Ans. $3x^4 - 5x^3 + 6x^2 - 14x + 5$, $f(-3) = 479$, $f(9) = 16403$.

32.11 ERRORS IN POLYNOMIAL INTERPOLATION

Computing of values for a tabulated function at points *not* in the table is known as interpolation. Thus, interpolation means to estimate a missing function value by taking a weighted average of known (given) function values at neighbouring points.

Suppose the function $y = f(x)$ is known (given) at $(n + 1)$ points (x_0, y_0) , $(x_1, y_1) \dots (x_n, y_n)$. A poly-

nomial of degree n , $P_n(x)$ is known as the interpolating polynomial when $P_n(x)$ passes through (satisfies) these $(n + 1)$ points. $P_n(x)$ can be constructed using only the numerical values x_k and y_k and does not need any order derivatives of $f(x)$. The approximation $P_n(x)$ is known as interpolated value when $x_0 < x < x_n$ and extrapolated value when $x < x_0$ or $x_n < x$.

The error is zero at tabulated points $x_0, x_1, \dots, x_n$; while it may be nonzero at points *not* in the table. Error may increase when number of interpolation is increased (classical example: $f(x) = (1 + 25x^2)^{-1}$ in $[-1, 1]$).

The error term associated with the n th degree polynomial $P_n(x)$ is obtained by using the generalized Rolle's theorem and is given by

$$E(x) = f(x) - P_n(x) \\ = (x - x_0)(x - x_1) \dots (x - x_n) \cdot \frac{f^{(n+1)}(\xi)}{(n+1)!} \quad (1)$$

Here ξ is any value in the smallest interval that contains $\{x, x_0, x_1, \dots, x_n\}$. The disadvantage with this error expression is that the derivative of f is not known (since the function $f(x)$ itself is not known except at the tabulated points). Note that the error term (1) is same for Lagrange polynomial and interpolating polynomial obtained from divided-difference table.

Error estimation when $f(x)$ is unknown: When $f(x)$ is unknown, $\frac{f^{(n)}(x)}{n!}$ can be approximated by the n th order divided difference

i.e., $\frac{f^{(n)}(x)}{n!} = f[x_0, x_1, \dots, x_n] = f_0^{[n]} = n$ th order divided difference.

Thus the error of the interpolation is approximately given by the next term that would be added.

The *next-term* rule is a most valuable rule for estimating the error of interpolation as follows:

$E_n(x) \approx$ value of the next term

that would be added to $P_n(x)$.

$$= f_0^{[n+1]}(x - x_0)(x - x_1)(x - x_2) \dots (x - x_{n-1}).$$

The interpolating polynomial that fits a divided dif-

ference table at $x = x_0, x_1, x_2, \dots, x_n$ is given by

$$P_n(x) = f_0^{[0]} + (x - x_0)f_0^{[1]} + (x - x_0)(x - x_1)f_0^{[2]} \\ + (x - x_0)(x - x_1)(x - x_2)f_0^{[3]} + \dots \\ + (x - x_0)(x - x_1) \dots (x - x_{n-1})f_0^{[n]}$$

Thus for $P_1(x)$ the next term to be added is $f_0^{[2]} \cdot (x - x_0)(x - x_1)$.

WORKED OUT EXAMPLES

Example 1: Find the error of the interpolates for $f(1.25)$ using polynomial of degree 1, 2, 3, 4, (b). Estimate the error using the next-term rule. Here $f(x) = e^{x^2-1}$ and $x_0 = 1, x_1 = 1.1, x_2 = 1.2, x_3 = 1.3, x_4 = 1.4$

Solution: The divided difference table is

| x_i | $f(x_i)$ | $f_i^{[1]}$ | $f_i^{[2]}$ | $f_i^{[3]}$ | $f_i^{[4]}$ |
|-------|----------|-------------|-------------|-------------|-------------|
| 1 | 1 | 2.3368 | 4.2675 | 6.105 | 7.65 |
| 1.1 | 1.23368 | 3.1903 | 6.099 | 9.165 | |
| 1.2 | 1.55271 | 4.4101 | 8.8485 | | |
| 1.3 | 1.99372 | 6.1798 | | | |
| 1.4 | 2.61170 | | | | |

Here

$$f_0^{[1]} = f[x_0, x_1] = \frac{f_1 - f_0}{x_1 - x_0},$$

$$f_0^{[2]} = f[x_0, x_1, x_2] = \frac{f(x_1, x_2) - f(x_0, x_1)}{x_2 - x_0} \text{ etc.}$$

The interpolating polynomials of degree 1, 2, 3 are

$$P_1(x) = f_0 + f_0^{[1]}(x - x_0) = 1 + 2.3368(x - 1)$$

$$P_2(x) = f_0 + f_0^{[1]}(x - x_0) + f_0^{[2]}(x - x_0)(x - x_1)$$

$$P_2(x) = 1 + 2.3368(x - 1) + 4.2675(x - 1)(x - 1.1)$$

$$P_3(x) = f_0 + f_0^{[1]}(x - x_0) + f_0^{[2]}(x - x_0)(x - x_1)$$

$$+ f_0^{[3]}(x - x_0)(x - x_1)(x - x_2)$$

$$= 1 + 2.3368(x - 1) + 4.2675(x - 1)(x - 1.1)$$

$$+ 6.105(x - 1)(x - 1.1)(x - 1.2)$$

$$P_4(x) = 1 + 2.3368(x - 1) + 4.2675(x - 1)(x - 1.1)$$

$$+ 6.105(x - 1)(x - 1.1)(x - 1.2)$$

$$+ 7.65(x - 1)(x - 1.1)(x - 1.2)(x - 1.3)$$

Interpolated values at $x = 1.25$ are

$$P_1(1.25) = 1.5842, P_2(1.25) = 1.7442,$$

$$P_3(1.25) = 1.7556468, P_4(1.25) = 1.75496;$$

The exact value $f(1.25) = e^{(1.25)^2-1}$

$$= 1.7550546571$$

Here 1st, 2nd, 3rd, 4th, 5th derivatives are

$$f'(x) = 2xe^{x^2-1}, f'' = 2(1+2x)e^{x^2-1},$$

$$f''' = 4(x+2x^2+1)e^{x^2-1},$$

$$f^{IV} = 4(4x^3+2x^2+6x+1)e^{x^2-1};$$

$$f^V = 8e^{x^2-1}(4x^4+2x^3+12x^2+3x+3).$$

Error using

$$E_n(x) = \frac{f^{(n+1)}(\xi)}{(n+1)!}(x-x_0)(x-x_1)\cdots(x-x_n)$$

with $\xi = 1.3$.

$$E_1(x) = 0.89717$$

$$E_2(x) = 0.0035388, E_3(x) = -0.000130682$$

$$E_4(x) = -0.0000133947$$

Errors of interpolation for $f(1.25)$

| Degree | Interpolated value | Actual error | Error
using $E_n(x)$ | Error
next-term rule |
|--------|--------------------|--------------|-------------------------|--|
| 1 | 1.5842 | 0.17085467 | 0.89717 | $(4.2675)(1.25-1)$
$\times (1.25-1.1) = 0.1600$ |
| 2 | 1.7442 | 0.01085467 | - 0.0035388 | 0.0114 |
| 3 | 1.7556468 | - 0.00059213 | - 0.00013068 | - 0.000717 |
| 4 | 1.75496 | 0.00009467 | - 0.000013394 | |

Exact value: $f(1.25) = 1.755054657$

EXERCISE

- Find the error of the interpolates for $f(1.75)$ using polynomials of degree 1, 2, 3. (b) Estimate the error using the next-term rule. Here $f(x) = x^2e^{-x/2}$.

- Find an approximation to $\sin 0.34$ and find a bound for the error using a polynomial of degree 3 and given that $\sin 0.30 = 0.29552$, $\sin 0.32 = 0.31457$, $\sin 0.33 = 0.32404$, $\sin 0.35 = 0.34290$.

Ans. $\sin 0.34 = 0.33348$, Error bound: 1.2×10^{-9}

Ans. Divided difference table

| x_i | $f(x_i)$ | $f_i^{[1]}$ | $f_i^{[2]}$ | $f_i^{[3]}$ | $f_i^{[4]}$ |

32.32 — HIGHER ENGINEERING MATHEMATICS—VIII

3. Find a bound for the error in approximation $f(1.09)$ using 3rd degree polynomial and the data $f(1.00) = 0.1924$, $f(1.05) = 0.2414$, $f(1.10) = 0.2933$, $f(1.15) = 0.3492$ for the function $f(x) = \log_{10} \tan x$.

Ans. $f(1.09) = 0.2826$, Error bound: 7.4×10^{-6}

4. Approximate $f(1.03)$ using interpolating polynomial of degree 1, 2, 3 using $x_0 = 1$, $x_1 = 1.05$, $x_2 = 1.07$, $x_3 = 1.1$, $x_4 = 1.15$ compare the actual error to the error bound and to error obtained by next-term rule of $f(x) = 3xe^x - e^{2x}$.
5. Write the error term $E_3(x)$ for cubic Lagrange interpolation to $f(x) = x^5 - 5x^4$ where interpo-

lation is to be exact at the four nodes $x_0 = -1$, $x_1 = 0$, $x_2 = 3$, $x_3 = 4$.

Ans. $f^{(4)}(c) = 120(c-1)$ for all c , so that $E_3(x) = 5(x+1)(x-3)(x-4)(c-1)$

6. For $f(x) = \sin x$ on $[0, 1]$, determine the step size h so that linear Lagrange interpolation has an accuracy of 10^{-6} .

Ans. $|E_1(x)| = 5 \times 10^{-7}$, $|f^{(2)}(c)| \leq |-\sin(1)| = 0.84147098 = M_2$, $h^2 \frac{M_2}{8} = \frac{h^2}{8} (0.84147098) < 5 \times 10^{-7}$ or $h < 0.00218027$

7. Let $f(x) = \log(1+x^2)$. Consider the following divided difference table. Estimate the error for interpolate $f(2)$ using a quadric interpolate with the points 1.91, 1.97, 2.02.

| x_i | $f(x_i)$ | $f_i^{[1]}$ | $f_i^{[2]}$ | $f_i^{[3]}$ |
|-------|----------|-------------|-------------|--------------------------|
| 1.88 | 1.511693 | | | |
| 1.91 | 1.536459 | 0.825333 | | |
| 1.97 | 1.585330 | 0.8145167 | -0.1224067 | |
| 2.02 | 1.625390 | 0.8012000 | -0.1210609 | 0.96128×10^{-2} |
| 2.11 | 1.696001 | 0.7845555 | -0.1188893 | 1.0858×10^{-2} |
| 2.18 | 1.749617 | 0.7659571 | -0.1162400 | 1.26157×10^{-2} |

Ans. $P_2(x) = 1.536459 + 0.8145167(x - 1.91) - 0.1210609(x - 1.91)(x - 1.97)$
 Error $\simeq 10^{-2}(0.09)(0.03)(0.02) = 0.54 \times 10^{-6}$
 Interpolated value: $P^2(2) = 1.609439$
 Exact value: $f(2) = \log 5 = 1.6094379$

Note: Third order divided differences are all approximately equal to 10^{-2} .

8. Develop a divided differences table for the following data.

| | | | | | | |
|-------|---------|---------|---------|---------|---------|---------|
| x : | 0.3 | 0.42 | 0.5 | 0.58 | 0.66 | 0.72 |
| y : | 1.04403 | 1.08462 | 1.11803 | 1.15603 | 1.19817 | 1.23223 |

Estimate error at $x = 0.55$ using linear interpolation, at $x = 0.60$ using quadratic interpolation, at $x = 0.46$ using cubic interpolation. Exact values are $f(0.46) = 1.10073$, $f(0.55) = 1.14127$, $f(10.6) = 1.16619$.

Ans. $P_1(0.55) = 1.14178$ based on 0.5, 0.58
 $P_2(0.6) = 1.16618$ based on 0.5, 0.58, 0.66
 $P_3(0.46) = 1.04403$ based on 0.3, 0.42, 0.5, 0.58

32.12 SYMBOLIC RELATIONS AND SEPARATION OF SYMBOLS

Let $x_0, x_1, \dots, x_n$ be a set of tabular points which are equally spaced i.e.,

$$x_i = x_0 + ih, i = 0, 1, 2, \dots, n.$$

Then

$$\nabla f(x_i) = f(x_i) - f(x_i - h)$$

is the backward-difference operator,

$$\Delta f(x_i) = f(x_i + h) - f(x_i)$$

is the forward-difference operator

$$\delta f(x_i) = f\left(x_i + \frac{h}{2}\right) - f\left(x_i - \frac{h}{2}\right)$$

is the central-difference operator. The shift operators are defined as

$$E(f(x_i)) = f(x_i + h)$$

$$E^{-1}(f(x_i)) = f(x_i - h)$$

entries in the difference table can be interpreted as either forward or backward differences.

Symbolic relations are established using these symbolic operators. Standing alone, all these operators are without any significance and are meaningless unless operated on a function, like $\int$ or $\frac{d}{dx}$ or $\sqrt{\quad}$. These operators are linear operators i.e., say

$$\Delta(c_1 f_1 + c_2 f_2) = c_1 \Delta f_1 + c_2 \Delta f_2$$

and obey laws of algebra.

Relationship between the Operators

| | Δ | ∇ | E | δ |
|----------|--|---|--|--|
| Δ | Δ | $(1 - \nabla)^{-1} - 1$ | E^{-1} | $\frac{1}{2}\delta^2 + \delta\sqrt{1 + \frac{1}{4}\delta^2}$ |
| ∇ | $1 - (1 + \Delta)^{-1}$ | ∇ | $1 - E^{-1}$ | $-\frac{1}{2}\delta^2 + \delta\sqrt{1 + \frac{1}{4}\delta^2}$ |
| E | $\Delta + 1$ | $(1 - \nabla)^{-1}$ | E | $\frac{1}{2}\delta^2 + \delta\sqrt{1 + \frac{1}{4}\delta^2} + 1$ |
| δ | $\Delta(1 + \Delta)^{-\frac{1}{2}}$ | $\nabla(1 - \nabla)^{-\frac{1}{2}}$ | $E^{\frac{1}{2}} - E^{-\frac{1}{2}}$ | δ |
| μ | $(1 + \frac{\Delta}{2})(1 + \Delta)^{\frac{1}{2}}$ | $(1 - \frac{\nabla}{2})(1 - \nabla)^{-\frac{1}{2}}$ | $\frac{E^{\frac{1}{2}} + E^{-\frac{1}{2}}}{2}$ | $\sqrt{1 + \frac{1}{4}\delta^2}$ |

The averaging operator is defined as

$$\mu(f(x_i)) = \frac{1}{2} \left[f\left(x_i + \frac{h}{2}\right) + f\left(x_i - \frac{h}{2}\right) \right]$$

Higher order differences are obtained by repeated applications of the difference operators. Let $f_i = f(x_i)$. Then

$$\nabla^n f(x_i) = \nabla^{n-1} f_i - \nabla^{n-1} f_{i-1}$$

$$\Delta^n f(x_i) = \Delta^{n-1} f_{i+1} - \Delta^{n-1} f_i$$

$$E^n f(x_i) = f(x_i + nh)$$

$$E^{-n} f(x_i) = f(x_i - nh)$$

$$\delta^n f(x_i) = \delta^{n-1} f_{i+\frac{1}{2}} - \delta^{n-1} f_{i-\frac{1}{2}}$$

$$= \sum_{j=0}^n (-1)^j \frac{n!}{j!(n-j)!} f_{i+\frac{n}{2}-j}$$

Note that the differences $\Delta^k f_0$ lie on a straight line sloping downward to the right. The differences $\nabla^k f_3$ lie on a straight line sloping upward to the right. The differences $\delta^{2k} f_2$ lie on a horizontal line. Thus the

Some of the above relations can be established as follows:

$$(a) \Delta(f(x_0)) = f(x_0 + h) - f(x_0) = E(f(x_0)) - f(x_0) = (E - 1)(f(x_0))$$

$$\text{Thus } \Delta = (E - 1)$$

$$(b) \nabla(f(x)) = f(x) - f(x + h) = f(x) - E^{-1}(f(x)) = (1 - E^{-1})(f(x))$$

$$\text{Thus } \nabla = (1 - E^{-1})$$

$$(c) \delta(f(x)) = f\left(x + \frac{h}{2}\right) - f\left(x - \frac{h}{2}\right) = E^{\frac{1}{2}} f(x) - E^{-\frac{1}{2}} f(x) = (E^{\frac{1}{2}} - E^{-\frac{1}{2}})(f(x))$$

$$\text{Thus } \delta = (E^{\frac{1}{2}} - E^{-\frac{1}{2}})$$

$$(d) \mu(f(x)) = \frac{1}{2} \left[f\left(x + \frac{h}{2}\right) + f\left(x - \frac{h}{2}\right) \right]$$

$$= \frac{1}{2} \left[E^{\frac{1}{2}} f(x) + E^{-\frac{1}{2}} f(x) \right]$$

$$= \frac{1}{2} \left[E^{\frac{1}{2}} + E^{-\frac{1}{2}} \right] (f(x))$$

$$\text{Thus } \delta = E^{\frac{1}{2}} - E^{-\frac{1}{2}}$$

32.34 — HIGHER ENGINEERING MATHEMATICS—VIII

Similarly other results in the above table can be proved.

Now using laws of algebra, we can prove the following.

$$\begin{aligned} \text{(i)} \quad E\nabla &= E(1 - E^{-1}) = E - 1 = \Delta \\ \nabla E &= (1 - E^{-1})E = E - 1 = \Delta \\ \text{Thus } E^n \nabla^n &= \nabla^n E^n = \Delta^n \end{aligned}$$

$$\text{(ii)} \quad \text{Since } \Delta = E - 1$$

$$\begin{aligned} \Delta^n &= (E - 1)^n = E^n - nE^{n-1} + \binom{n}{2}E^{n-2} \\ &\quad - \binom{n}{3}E^{n-3} + \dots \\ \Delta^n f(x) &= E^n f - nE^{n-1}f + \binom{n}{2}E^{n-2}f \\ &\quad - \binom{n}{3}E^{n-3}f + \dots \\ &= f(x + nh) - nf[x + (n-1)h] \\ &\quad + \binom{n}{2}f[x + (n-2)h] + \dots \end{aligned}$$

Thus

$$\Delta^n f = f_n - nf_{n-1} + \binom{n}{2}f_{n-2} - \binom{n}{3}f_{n-3} + \dots$$

$$\text{(iii)} \quad \text{Newton-Gregory forward formula: We know that } E = 1 + \Delta, \text{ so } E^n = (1 + \Delta)^n$$

Then

$$\begin{aligned} f_n &= E^n f_0 = (1 + \Delta)^n f_0 \\ &= [1 + n\Delta + \binom{n}{2}\Delta^2 + \binom{n}{3}\Delta^3 + \dots]f_0 \\ f_n &= f_0 + n\Delta f_0 + \binom{n}{2}\Delta^2 f_0 + \binom{n}{3}\Delta^3 f_0 + \dots \end{aligned}$$

$$\text{(iv)} \quad \text{Newton-Gregory backward formula}$$

Since $E = (1 - \nabla)^{-1}$, $E^n = (1 - \nabla)^{-n}$. Then

$$\begin{aligned} f_n &= E^n f_0 = (1 - \nabla)^{-n} f_0 \\ &= \left[1 + n\nabla + \binom{n+1}{2}\nabla^2 + \right. \\ &\quad \left. + \binom{n+2}{3}\nabla^3 + \dots \right] f_0 \\ f_n &= f_0 + n\nabla f_0 + \binom{n+1}{2}\nabla^2 f_0 + \\ &\quad + \binom{n+2}{3}\nabla^3 f_0 + \dots \end{aligned}$$

$$\begin{aligned} &= f_0 + n\nabla f_{-1} + \binom{n+1}{2}\Delta^2 f_{-2} + \\ &\quad + \binom{n+2}{3}\Delta^3 f_{-3} + \dots \end{aligned}$$

WORKED OUT EXAMPLES

Example 1: Prove that $\nabla^6 y_8 = \Delta^6 y_2$.

$$\begin{aligned} \text{Solution: } \nabla^6 &= (1 - E^{-1})^6 \\ &= (1 - 6E^{-1} + 15E^{-2} - 20E^{-3} \\ &\quad + 15E^{-4} - 6E^{-5} + E^{-6}) \end{aligned}$$

So

$$\begin{aligned} \nabla^6 y_8 &= (1 - 6E^{-1} + 15E^{-2} - 20E^{-3} \\ &\quad + 15E^{-4} - 6E^{-5} + E^{-6})y_8 \\ \nabla^2 y_8 &= y_8 - 6y_7 + 15y_6 - 20y_5 + 15y_4 - 6y_3 + y_2 \end{aligned}$$

Also

$$\begin{aligned} \nabla^6 y_2 &= (E - 1)^6 y_2 = (E^6 - 6E^5 + 15E^4 \\ &\quad - 20E^3 + 15E^2 - 6E + 1)y_2 \\ &= y_8 - 6y_7 + 15y_6 - 20y_5 + 15y_4 - 6y_3 + y_2 \end{aligned}$$

$$\text{Thus } \nabla^6 y_8 = \Delta^6 y_2$$

Example 2: Show that $\nabla^r f_k = \Delta^r f_{k-r}$

Solution:

$$\begin{aligned} \text{RHS} &= \Delta^r f_{k-r} = (E - 1)^r f_{k-r} \quad (\because \Delta = E - 1) \\ &= E^r (1 - E^{-1})^r f_{k-r} \quad (\because \nabla = 1 - E^{-1}) \\ &= E^r \nabla^r f_{k-r} = \nabla^r E^r f_{k-r} = \nabla^2 f_k \\ \therefore E^r f_{k-r} &= f_{k-r+r} \end{aligned}$$

Example 3: Show that $\delta = 2 \sin h \left(\frac{hD}{2} \right)$.

$$\begin{aligned} \text{Solution: } \delta &= E^{\frac{1}{2}} - E^{-\frac{1}{2}} = e^{\frac{hD}{2}} - e^{-\frac{hD}{2}} \\ (\because E &= e^{hD}) = 2 \sin h \left(\frac{hD}{2} \right). \end{aligned}$$

Example 4: Prove that $(\Delta + 1)(1 - \nabla) = 1$

$$\begin{aligned} \text{Solution: } \text{Since } \Delta &= E - 1, \Delta + 1 = E \text{ and } \nabla = \\ &1 - E^{-1} \text{ so } 1 - \nabla = E^{-1} \\ \text{Then } (\Delta + 1)(1 - \nabla) &= E \cdot E^{-1} = 1 \end{aligned}$$

Example 5: Show that $\Delta \nabla = \delta^2$

$$\begin{aligned} \text{Solution: } \Delta \nabla &= (E - 1)(1 - E^{-1}) \\ &= E - 1 - 1 + E^{-1} \\ &= (E - E^{-1})^2 \end{aligned}$$

$$\text{Now } \delta = (E^{\frac{1}{2}} - E^{-\frac{1}{2}})$$

$$\begin{aligned} \delta^2 &= (E^{\frac{1}{2}} - E^{-\frac{1}{2}})^2 = (E - 2 + E^{-1}) \\ &= (E - E^{-1})^2 \end{aligned}$$

$$\text{Hence } \Delta \nabla = \delta^2$$

Example 6: Show that $\frac{\Delta^2}{E} x^3 = 6xh^2$

Solution:

$$\begin{aligned} \text{LHS} &= \frac{\Delta^2}{E} x^3 = \frac{(E-1)^2}{E} x^3 \\ &= \left(\frac{E^2 + 1 - 2E}{E} \right) x^3 = (E - 2 + E^{-1}) x^3 \\ &= (x+h)^3 - 2x^3 + (x-h)^3 \\ &= (x^3 + 3x^2h + 3xh^2 + h^3) - 2x^3 \\ &\quad + (x^3 - 3x^2h + 3xh^2 - h^3) \\ &= 6xh^2 \end{aligned}$$

Example 7: Show that $(\Delta + \nabla)^2(x^2 + x) = 8$ with $h = 1$

Solution: Since $\Delta = E - 1$ and $\nabla = 1 - E^{-1}$. We have

$$\begin{aligned} (\Delta + \nabla)^2(x^2 + x) &= (E - 1 + 1 - E^{-1})^2 = (E - E^{-1})^2 \\ &= E^2 + E^{-2} - 2 \end{aligned}$$

So

$$\begin{aligned} (\Delta + \nabla)^2 &= (E^2 + E^{-2} - 2)(x^2 + x) \\ &= E^2(x^2 + x) + E^{-2}(x^2 + x) - 2(x^2 + x) \\ &\quad [(x+2)^2 + (x+2)] + [(x-2)^2 + (x-2)] \\ &\quad - 2(x^2 + x) = 8 \end{aligned}$$

Example 8: Show that $u_0 + Eu_0 \cdot x + E^2u_0 \cdot x^2 + E^3u_0 \cdot x^3 + \dots$

$$= \left[\frac{1}{1-x} + \frac{x}{(1-x)^2} \Delta + \frac{x^2}{(1-x)^3} \Delta^2 + \dots \right] u_0$$

Solution: Rewriting LHS as

$$\text{LHS} = (1 + xE + x^2E^2 + x^3E^3 + \dots)u_0$$

$$= \left(\frac{1}{1-xE} \right) u_0 = \left[\frac{1}{1-x(1+\Delta)} \right] u_0$$

since $E = 1 + \Delta$

$$\begin{aligned} &= \left[\frac{1}{1-x-x\Delta} \right] u_0 = \frac{1}{1-x} \left[\frac{1}{1-\frac{x\Delta}{1-x}} \right] u_0 \\ &= \frac{1}{1-x} \left[1 + \frac{x\Delta}{1-x} + \frac{x^2\Delta^2}{(1-x)^2} + \dots \right] u_0 \\ &= \left[\frac{1}{1-x} + \frac{x}{(1-x)^2} \Delta + \frac{x^2}{(1-x)^3} \Delta^2 + \dots \right] u_0 \end{aligned}$$

Example 9: Show that $\delta E^{\frac{1}{2}} = \Delta$

$$\text{Solution: } E^{\frac{1}{2}} f(x) = f(x + \frac{h}{2})$$

$$\begin{aligned} \delta E^{\frac{1}{2}}(f(x)) &= \delta[f(x + \frac{h}{2})] \\ &= f(x + \frac{h}{2} + \frac{h}{2}) - f(x + \frac{h}{2} - \frac{h}{2}) \\ &= f(x+h) - f(x) \\ &= \Delta f(x) \end{aligned}$$

Example 10: Prove that $\nabla - \Delta = -\Delta \nabla$

Solution:

$$\begin{aligned} \text{LHS : } \nabla - \Delta &= (1 - E^{-1}) - (E - 1) \\ &= 2 - E - E^{-1} \end{aligned}$$

$$\begin{aligned} \text{RHS : } -\Delta \nabla &= -(E - 1)(1 - E^{-1}) \\ &= -[E - 1 - 1 + E^{-1}] \\ &= 2 - E - E^{-1} \end{aligned}$$

Example 11: Show that $\nabla + \Delta = \frac{\Delta}{\nabla} - \frac{\nabla}{\Delta}$

$$\begin{aligned} \text{Solution: LHS} &= \nabla + \Delta = (1 - E^{-1}) + (E - 1) \\ &= E - E^{-1} \end{aligned}$$

Now

$$\frac{\Delta}{\nabla} = \frac{E - 1}{1 - E^{-1}} = \frac{E(E - 1)}{(E - 1)} = E$$

$$\frac{\nabla}{\Delta} = \frac{1 - E^{-1}}{E - 1} = \frac{1}{E} \left(\frac{1 - E^{-1}}{1 - E^{-1}} \right) = E^{-1}$$

$$\text{RHS : } \frac{\Delta}{\nabla} - \frac{\nabla}{\Delta} = E - E^{-1}$$

EXERCISE

1. Show that $e^x = \left(\frac{\Delta^2}{E} \right) e^x \cdot \frac{Ee^x}{\Delta^2 e^x}$ taking h as the interval of difference.

Hint: $\left(\frac{\Delta^2}{E}\right) e^x = \Delta^2 E^{-1} e^x = \Delta^2 e^{x-h} = e^{-h}$

RHS: $e^{-h} \Delta^2 e^x \cdot \frac{E e^x}{\Delta^2 e^x} = e^{-h} e^{x+h} = e^x$

2. Prove that

(a) $\Delta^3 y_2 = \nabla^3 y_5$

(b) $\Delta = \frac{1}{2} \delta^2 + \delta \sqrt{1 + \frac{\delta^2}{4}}$

(c) $2 + \Delta = (E^{\frac{1}{2}} + E^{-\frac{1}{2}})(1 + \Delta)^{\frac{1}{2}}$

(d) $hD = \log(1 + \Delta) = -\log(1 - \Delta) = \sinh^{-1}(\mu\delta)$

3. Prove that

(a) $\delta = \Delta(1 + \Delta)^{-\frac{1}{2}} = \nabla(1 - \nabla)^{-\frac{1}{2}}$

(b) $\mu^2 = 1 + \frac{\delta^2}{4}$

(c) $\delta(E^{\frac{1}{2}} + E^{-\frac{1}{2}}) = \Delta E^{-1} + \Delta$

4. Show that $\nabla y_{n+1} = h[1 + \frac{1}{2} \nabla + \frac{5}{12} \nabla^2 + \dots] y'_n$

5. Show that

(a) $u_1 x + u_2 x^2 + u_3 x^3 + \dots = \left(\frac{x}{1-x}\right)^2 \Delta u_1 + \left(\frac{x}{1-x}\right)^3 \Delta^2 u_1 + \dots$

(b) $u_0 + \frac{u_1 x}{1!} + \frac{u_2 x^2}{2!} + \frac{u_3 x^3}{3!} + \dots = e^x(u_0 + x \Delta u_0 + \frac{x^2}{2!} \Delta^2 u_0 + \frac{x^3}{3!} \Delta^3 u_0 + \dots)$

6. Prove that $E^{\frac{1}{2}} = \left(\frac{1}{2} + \frac{\delta^2}{4}\right)^{\frac{1}{2}} + \frac{\delta}{2}$

7. Show that $\nabla^2 = h^2 D^2 - h^3 D^3 + \frac{7}{12} h^4 D^4 + \dots$

8. Show that $E = e^{hD}$

Hint: $E(f(x)) = f(x+h)$, expand by Taylor's series, $E(f(x)) = f(x) + hf' + \frac{h^2}{2!} f'' + \frac{h^3}{3!} f''' + \dots$

$$\begin{aligned} &= f(x) + hDf + \frac{h^2}{2!} D^2 f + \frac{h^3}{3!} D^3 f + \dots \\ &= \left[1 + hD + \frac{h^2 D^2}{2!} + \frac{h^3 D^3}{3!} + \dots\right] f \\ &= e^{hD}(f(x)) \end{aligned}$$

Prove the following.

9. $\Delta(f_i g_i) = f_i \Delta g_i + g_{i+1} \Delta f_i$

10. $\Delta f_i^2 = (f_i + f_{i+1}) \Delta f_i$

11. $\Delta\left(\frac{1}{f_i}\right) = -\frac{\Delta f_i}{f_i f_{i+1}}$

12. $\Delta\left(\frac{f_i}{g_i}\right) = \frac{(g_i \Delta f_i - f_i \Delta g_i)}{g_i g_{i+1}}$

32.13 NUMERICAL DIFFERENTIATION

Numerical differentiation or approximate differentiation is used when the function $y = f(x)$ is (i) given in tabular form (ii) function is highly complex. The basic idea in numerical differentiation is to replace the given function $y = f(x)$ on the interval $[a, b]$ by an interpolating polynomial $P(x)$ and set $f'(x) = P'(x)$; $f''(x) = P''(x)$ etc. Numerical differentiation is less exact than interpolation. Although $f(x_1) = P(x_1)$, $f'(x_1)$ need not be equal to $p'(x_1)$. (see figure).

Fig. 32.13

Numerical Differentiation Using Newton's Forward Formula

Suppose $y = f(x)$ is specified in an interval $[a, b]$ at equally spaced points $x_i = x_0 + ih (i = 1, 2, \dots, n)$ by means of the values $y_i = f(x_i)$. Replace the tabulated function $y = f(x)$ by Newton's forward interpolation polynomial passing through the $(n+1)$ points $x_0, x_1, \dots, x_n$. Thus

$$\begin{aligned} y(x) &= y_0 + q \Delta y_0 + \frac{q(q-1)}{2!} \Delta^2 y_0 + \frac{q(q-1)(q-2)}{3!} \Delta^3 y_0 + \frac{q(q-1)(q-2)(q-3)}{4!} \Delta^4 y_0 + \dots \quad (1) \end{aligned}$$

where $q = \frac{x-x_0}{h}$ and $h = x_{i+1} - x_i$, for $i = 0, 1, \dots$. Here q is a function of x and $\frac{dq}{dx} = \frac{1}{h}$. Rewriting (1)

$$\begin{aligned} y(x) &= y_0 + q \Delta y_0 + \frac{q^2 - q}{2} \Delta^2 y_0 + \frac{q^3 - 3q^2 + 2q}{6} \Delta^3 y_0 + \frac{q^4 - 6q^3 + 11q^2 - 6q}{24} \Delta^4 y_0 + \dots \quad (1^*) \end{aligned}$$

Differentiating (1*) w.r.t. x , we have

$$\begin{aligned}\frac{dy}{dx} &= \frac{dy}{dq} \cdot \frac{dq}{dx} = \frac{1}{h} \frac{dy}{dq} = \\ &= \frac{1}{h} \left[\Delta y_0 + \frac{2q-1}{2} \Delta^2 y_0 + \frac{3q^2-6q+2}{6} \Delta^3 y_0 \right. \\ &\quad \left. + \frac{4q^3-18q^2+22q-6}{24} \Delta^4 y_0 + \dots \right] \quad (2)\end{aligned}$$

Similarly, differentiating (2) once again w.r.t. x , we get

$$\begin{aligned}\frac{d^2 y}{dx^2} &= \frac{d}{dx} \left(\frac{dy}{dx} \right) = \frac{1}{h} \frac{d}{dq} \left(\frac{dy}{dx} \right) \\ &= \frac{1}{h^2} \left[\Delta^2 y_0 + (q-1) \Delta^3 y_0 \right. \\ &\quad \left. + \frac{6q^2-18q+11}{12} \Delta^4 y_0 + \dots \right] \quad (3)\end{aligned}$$

Higher order derivatives can be computed similarly.

Special case

When derivative is required at a basic tabulated point x_i , then choose $x = x_0$, so $q = 0$ (since each tabular value may be taken as the initial value x_0). Thus

$$\begin{aligned}\left. \frac{dy}{dx} \right|_{x=x_0} &= y'(x_0) = \frac{1}{h} \left[\Delta y_0 - \frac{1}{2} \Delta^2 y_0 + \frac{\Delta^3 y_0}{3} \right. \\ &\quad \left. - \frac{\Delta^4 y_0}{4} + \frac{\Delta^5 y_0}{5} - \dots \right] \quad (4)\end{aligned}$$

and

$$\begin{aligned}\left. \frac{d^2 y}{dx^2} \right|_{x=x_0} &= y''(x_0) = \frac{1}{h^2} \left[\Delta^2 y_0 - \Delta^3 y_0 \right. \\ &\quad \left. + \frac{11}{12} \Delta^4 y_0 - \frac{5}{6} \Delta^5 y_0 + \dots \right] \quad (5)\end{aligned}$$

Similarly,

$$y'''(x_0) = \frac{1}{h^3} \left[\Delta^3 y_0 - \frac{3}{2} \Delta^4 y_0 + \frac{7}{4} \Delta^5 y_0 + \dots \right] \quad (6)$$

$$y''''(x_0) = \frac{1}{h^4} \left[\Delta^4 y_0 - 2 \Delta^5 y_0 + \dots \right] \quad (7)$$

Thus formulas (2), (3) (and (4), (5) in special case) given the derivatives of $y(x)$.

Numerical Differentiation Using Newton's Backward Formula

In this case, we replace $y(x)$ by Newton backward interpolation formula:

$$\begin{aligned}y(x) &= y_n + q \nabla y_n + \frac{q(q+1)}{2!} \nabla^2 y_n \\ &\quad + \frac{q(q+1)(q+2)}{3!} \nabla^3 y_n + \dots\end{aligned}$$

Differentiating w.r.t. x ,

$$\begin{aligned}y'(x) &= \frac{1}{h} \left[\nabla y_n + \frac{1}{2} (2q+1) \nabla^2 y_n \right. \\ &\quad \left. + \frac{3q^2+6q+2}{6} \nabla^3 y_n + \dots \right] \quad (8)\end{aligned}$$

$$\begin{aligned}y''(x) &= \frac{1}{h^2} \left[\nabla^2 y_n + (q+1) \nabla^3 y_n \right. \\ &\quad \left. + \frac{6q^2+18q+11}{12} \nabla^4 y_n + \dots \right] \quad (9)\end{aligned}$$

Special case: When $x = x_n$, then $q = 0$.

$$y'(x_n) = \frac{1}{h} \left[\nabla y_n + \frac{1}{2} \nabla^2 y_n + \frac{1}{3} \nabla^3 y_n + \frac{1}{4} \nabla^4 y_n + \dots \right] \quad (10)$$

$$y''(x_n) = \frac{1}{h^2} \left[\nabla^2 y_n + \nabla^3 y_n + \frac{11}{12} \nabla^4 y_n + \dots \right] \quad (11)$$

WORKED OUT EXAMPLES

Example: Compute $f'(x)$ and $f''(x)$ at (a) $x = 16$; (b) $x = 15$; (c) $x = 24$; (d) $x = 25$ from the following table:

| | | | | | | |
|---------------------|-------|-------|-------|-------|-------|-----|
| x : | 15 | 17 | 19 | 21 | 23 | 25 |
| $f(x) = \sqrt{x}$: | 3.873 | 4.123 | 4.359 | 4.583 | 4.796 | 5.8 |

Compare with the exact values.

Solution:

a. To find f' , f'' at $x = 16, 15$, use the forward differences results.

$$f'(x) = \frac{1}{h} \left[\Delta y_0 + \frac{2q-1}{2} \Delta^2 y_0 + \frac{3q^2-6q+2}{6} \Delta^3 y_0 + \dots \right]$$

32.38 — HIGHER ENGINEERING MATHEMATICS—VIII

Table 32.12: The finite difference table

| x | $y = \sqrt{x}$ | Δy | $\Delta^2 y$ | $\Delta^3 y$ | $\Delta^4 y$ | $\Delta^5 y$ |
|-----|----------------|------------|--------------|--------------|--------------|--------------|
| 15 | 3.873 | | | | | |
| 17 | 4.123 | 0.250 | | | | |
| 19 | 4.359 | 0.236 | -0.014 | | | |
| 21 | 4.583 | 0.224 | -0.012 | 0.002 | | |
| 23 | 4.796 | 0.213 | -0.011 | 0.001 | -0.001 | |
| 25 | 5.000 | 0.204 | -0.009 | 0.002 | 0.001 | 0.002 |

$$+ \frac{4q^3 - 18q^2 + 22q - 6}{24} \Delta^4 y_0 \Big]$$

Here $q = \frac{x-x_0}{h}$, $x_0 = 15$, $h = 2$ and $x = 16$, then
 $q = \frac{16-15}{2} = \frac{1}{2} = 0.5$,
 Also $\Delta y_0 = 0.250$, $\Delta^2 y_0 = -0.014$, $\Delta^3 y_0 = 0.002$,
 $\Delta^4 y_0 = -0.001$.

$$\therefore f'(16) = \frac{1}{2} \left[0.250 + 0 + \frac{3(.5)^2 - 6(.5) + 2}{6} (.002) \right. \\ \left. + \frac{4(.5)^3 - 18(.5)^2 + 22(.5) - 6}{24} (-0.001) \right]$$

$$f'(16) = 0.1249375 \quad (\text{Exact value: } 0.125)$$

Similarly,

$$f''(16) = \frac{1}{2^2} [-0.014 + (0.5 - 1)(.002) \\ + \frac{6(.5)^2 - 18(.5) + 11}{12} (-.001)]$$

$$f''(16) = -0.0038229 \quad (\text{Exact value} = -0.00390625)$$

b. When $x = 15$ (which is a tabulated point), then
 $q = 0$

$$f'(15) = \frac{1}{2} \left[0.250 - \frac{1}{2}(-0.014) + \frac{1}{3}(0.002) - \frac{1}{4}(-0.001) \right]$$

$$f'(15) = 0.128958 \quad (\text{Exact value: } 0.12909)$$

$$f''(15) = \frac{1}{4} \left[-0.014 - 0.002 + \frac{11}{12}(-0.001) \right]$$

$$f''(15) = -0.004229 \quad (\text{Exact value: } -0.0043033).$$

For (c) and (d) use Newton's backward formulae since $x = 24$ and $x = 25$ are at the end of the table.

c. Here $q = \frac{x-x_n}{h}$, $x = 24$, $x_n = 25$, $h = 2$, $q = \frac{24-25}{2} = -0.5$, $q = -0.5$. Here $\nabla y_n = .204$,
 $\nabla^2 y_n = -0.009$, $\nabla^3 y_n = 0.002$, $\nabla^4 y_n = 0.001$.

$$f'(24) = \frac{1}{2} \left[.204 + \frac{1}{2}(2(.5) + 1)(-0.009) \right. \\ \left. + \frac{3(-.5)^3 + 6(-.5) + 2}{6} (0.002) \right]$$

$$= 0.09727 \quad (\text{Exact value: } 0.10206)$$

$$f''(24) = \frac{1}{2^2} \left[-0.009 + (-.5 + 1)(0.002) \right. \\ \left. + \frac{6(-.5)^2 + 18(-.5) + 11}{12} (0.001) \right]$$

$$= -0.00242708 \quad (\text{Exact value: } -0.002126293)$$

d. When $x = 25$ which is a tabulated value, $q = 0$.
 Then

$$f'(25) = \frac{1}{2} \left[.204 + \frac{1}{2}(-0.009) + \frac{1}{3}(.002) + \frac{1}{4}(.001) \right]$$

$$= 0.100208 \quad (\text{Exact value: } 0.100)$$

$$f''(25) = \frac{1}{2^2} \left[-0.009 + 0.002 + \frac{11}{12}(.001) \right]$$

$$= -0.00225 \quad (\text{Exact value: } -0.002)$$

Note: $y = \sqrt{x}$, $y'(x) = \frac{1}{2\sqrt{x}}$, $y'' = \frac{-1}{4x^{3/2}}$.

EXERCISE

- Using forward differences find the first and second derivatives of y at $x = 2$ for the data given below:

| | | | | | |
|-------|---|---|---|---|----|
| x : | 2 | 4 | 6 | 8 | 10 |
| y : | 0 | 0 | 1 | 0 | 0 |

Hint: Differences are 0, 1, -3, 6.

Ans. -1.5, 2.375

- Compute $y'(1)$, $y''(1)$ and $y'(3)$ from the following data:

x : 1 2 3 4 5 6 7 8
 y : 2.105 2.808 3.614 4.604 5.857 7.451 9.467 11.985

Hint: Differences: .703, .103, .081, -0.002 .

Ans. $y'(1)=0.6925$, $y''(1)=0.0201$; $y'(3)=.883$

3. Determine $y'(2)$, $y''(2)$, $y'''(2)$, $y''''(2)$, $y'(1.5)$, $y''(1.5)$ from the data below, compare with exact values:

x : 0 1 2 3 4 5
 y : 0 1 8 27 64 125

Hint: Differences: 1, 6, 6, 0, 0.

Ans. $y'(2) = 12$, $y''(2) = 12$, $y'''(2) = 6$, $y''''(2) = 0$, $y'(1.5) = 6.75$, $y''(1.5) = 9$. Exact value: $y = x^3$, $y' = 3x^2$, $y'' = 6x$, $y''' = 6$, $y'''' = 0$.

4. Compute $y'(1.05)$, $y''(1.05)$, $y'(1.25)$, $y''(1.25)$ from the following data:

x : 1.00 1.05 1.10 1.15 1.20 1.25 1.30
 y : 1.00 1.0247 1.04881 1.07238 1.09544 1.11803 1.14017

Ans. $y'(1.05) = 0.48763$, $y''(1.05) = -0.2144$, $y'(1.25) = 0.44733$, $y''(1.25) = -0.158332$

5. Find $y'(50)$ of the tabulated function $y = \log_{10} x$, given below:

x : 50 55 60 65
 y : 1.6990 1.7404 1.7782 1.8129

Hint: Forward differences: 414, -36 , 5, $h = 5$. Exact value: 0.0087.

Ans. $0.0087 (= \frac{1}{5}(0.0414 + 0.008 + 0.0002))$

6. The following table contains the path $y = f(t)$ traversed in time t by a point moving in a straight line. Using finite forward differences upto order five inclusive, find the velocity $v = \frac{dy}{dt}$ and acceleration $A = \frac{d^2y}{dt^2}$ at the point of times: $t = 0, 0.01, 0.02, 0.03, 0.04, 0.05$

time t in sec: 0 0.01 0.02 0.03 0.04 0.05
 Path $y(t_i)$ in cm: 0 1.519 6.031 13.397 23.396 35.721

t : 0.06 0.07 0.08 0.09
 $y(t_i)$ 50 65.798 82.635 100

Hint: Forward differences are 2.993, -0.139 , -0.082 , -0.004 . Exact: $y = 100(1 - \cos \frac{50\pi t}{9})$, $V = \frac{dy}{dt} = \frac{5000\pi}{9} \sin(\frac{50\pi t}{9})$, $W = \frac{d^2y}{dt^2} = \frac{250000\pi^2}{81} \cos(\frac{50\pi t}{9})$.

Ans.

Table 32.13

| t | V | W | V_{exact} | W_{exact} |
|------|--------|-------|--------------------|--------------------|
| 0.00 | 0.4 | 30600 | 0.0 | 30462 |
| 0.01 | 303.6 | 29780 | 303.08 | 30001 |
| 0.02 | 596.3 | 28780 | 596.98 | 28625 |
| 0.03 | 873.2 | 26250 | 872.66 | 26381 |
| 0.04 | 1121.7 | 23360 | 1121.9 | 23340 |

7. Compute $y'(1.1)$, $y''(1.1)$, $y'(1.6)$, $y''(1.6)$ given:

x : 1.0 1.1 1.2 1.3 1.4 1.5 1.6
 y : 7.989 8.403 8.781 9.129 9.451 9.750 10.031

Hint: Forward differences: .414, -0.36 , 0.006, -0.002 , 0.002, -0.003 , backward differences .281, -0.018 , 0.005, -0.001 , -0.001 , -0.003 .

Ans. $y'(1.1) = 3.946$, $y''(1.1) = -3.545$, $y'(1.6) = 2.727$, $y''(1.6) = -1.703$

8. Determine $y'(0)$, $y''(0)$ from following data:

x : 0 1 2 3 4 5
 y : 4 8 15 7 6 2

Ans. $y'(0) = -27.9$, $y''(0) = 117.67$.

32.14 NUMERICAL INTEGRATION

Let $f(x)$ be continuous on the interval $[a, b]$ and its antiderivative $F(x)$ is known. Then the definite integral of $f(x)$ from a to b may be evaluated using Newton-Leibnitz formula

$$\int_a^b f(x)dx = F(b) - F(a) \quad (1)$$

where $f'(x) = f(x)$.

However, computation of the definite integral by (1) becomes difficult or practically impossible when (i) the antiderivative $F(x)$ can not be found by elementary means or is too involved (ii) when the integrand $f(x)$ is specified in tabular form.

32.40 — HIGHER ENGINEERING MATHEMATICS—VIII

The numerical integration of a single integral is known as **mechanical quadrature** and uses the geometrical interpretation of the definite integral $\int_a^b f(x)dx$ as the area under the curve $y = f(x)$ between the ordinates $x = a$ and $x = b$. The basic integration rule is to replace $f(x)$ by a simple polynomial $\phi(x)$, say Lagrange's interpolation polynomial in $[a, b]$. Thus

$$\int_a^b f(x)dx \sim \int_a^b \phi(x)dx \quad (2)$$

Choosing interval size $h = \frac{b-a}{n}$, divide the interval $[a, b]$ into n intervals by means of $(n+1)$ equally spaced points $x_0 = a$, $x_i = x_0 + ih$, $i = 1, 2, 3, \dots, n-1$, $x_n = b$. Let $y_i = f(x_i)$ for $i = 0, 1, 2, \dots, n$.

Integrating the integral in the R.H.S. of (2), we get Newton-Cotes formula of the form

$$\int_a^b f(x)dx \sim c \cdot h \cdot \sum_{i=0}^n w_i \cdot f(x_i) \quad (3)$$

[Since the end points x_0, x_n are used in (3), these formula are known as 'closed' type.]

Here m is the degree of the polynomial $\phi(x)$, c is the coefficient and w_i are weights, given in the following table:

Table 32.14

| Case | m | c | w_0 | w_1 | w_2 | w_3 | Name of the rule |
|------|-----|---------------|-------|-------|-------|-------|---------------------------------|
| I. | 0 | 1 | 1 | | | | Rectangular and mid point rules |
| II. | 1 | $\frac{1}{2}$ | 1 | 1 | | | Trapezoidal rule |
| III. | 2 | $\frac{1}{3}$ | 1 | 4 | 1 | | Simpson's $\frac{1}{3}$ rule |
| IV. | 3 | $\frac{3}{8}$ | 1 | 3 | 3 | 1 | Simpson's $\frac{3}{8}$ rule |

The degree m of the polynomial $\phi(x)$ used in the derivation of the above formula are 0, 1, 2, 3 respectively.

Derivation of Trapezoidal, Simpson's $\frac{1}{3}$ and Simpson's $\frac{3}{8}$ Rule Formula:

The basic idea in numerical integration is to replace the unknown tabulated function $y = f(x)$ by an n th

degree polynomial $P_n(x)$ say Newton-Gregory forward interpolation formula and carry on the integration. Thus

$$\begin{aligned} I &= \int_{x_0}^{x_n} f(x)dx \simeq \int_{x_0}^{x_n} P_n(x)dx \\ &\simeq \int_{q=0}^n \left[y_0 + q \Delta y_0 + \frac{q(q-1)}{2!} \Delta^2 y_0 \right. \\ &\quad \left. + \frac{q(q-1)(q-2)}{3!} \Delta^3 y_0 + \dots \right. \\ &\quad \left. + \frac{q(q-1)(q-2) \dots (q-n+1)}{n!} \Delta^n y_0 \right] dq \end{aligned}$$

Here the new variable is $q = \frac{x-x_0}{h}$, so $dq = \frac{dx}{h}$.

Trapezoidal Rule

Take $n = 1$ (two points, one interval)

$$\begin{aligned} \int_0^1 y dx &= h \int_0^1 (y_0 + q \Delta y_0) dq = h \left[y_0 q + \Delta y_0 \cdot \frac{q^2}{2} \right] \Big|_{q=0}^1 \\ &= h \left[y_0 + \frac{\Delta y_0}{2} \right] = h \left[y_0 + \frac{y_1 - y_0}{2} \right] \\ &= \frac{h(y_1 + y_0)}{2} = \frac{h}{2} (y_1 + y_0). \end{aligned}$$

Applying this to successive intervals, we get

$$\begin{aligned} \int_{x_0}^{x_n} y dx &= \int_{x_0}^{x_1} y dx + \int_{x_1}^{x_2} y dx + \dots + \int_{x_{n-1}}^{x_n} y dx \\ &= \frac{h}{2} (y_0 + y_1) + \frac{h}{2} (y_1 + y_2) + \dots + \frac{h}{2} (y_{n-1} + y_n) \end{aligned}$$

$$I = \frac{h}{2} [y_0 + 2(y_1 + y_2 + \dots + y_{n-1}) + y_n]$$

Simpson's $\frac{1}{3}$ Rule

Take $n = 2$ (three points, two intervals, curve (polynomial) parabola).

$$\begin{aligned} \int_{x_0}^{x_2} y dx &= h \int_0^2 \left[y_0 + q \Delta y_0 + \frac{q(q-1)}{2} \Delta^2 y_0 \right] dq \\ &= h \left[y_0 \cdot q + \frac{q^2}{2} \Delta y_0 + \frac{\Delta^2 y_0}{2} \left(\frac{q^3}{3} - \frac{q^2}{2} \right) \right] \Big|_{q=0}^2 \\ &= h \left[2y_0 + 2\Delta y_0 + \frac{1}{3} \Delta^2 y_0 \right] \end{aligned}$$

$$\begin{aligned}
 &= h \left[2y_0 + 2(y_1 - y_0) + \frac{1}{3}(y_2 - 2y_1 + y_0) \right] \\
 &= \frac{h}{3} [y_0 + 4y_1 + y_2].
 \end{aligned}$$

Applying for successive intervals (*the number of intervals must be even or the number of points is odd*).

$$\begin{aligned}
 \int_{x_0}^{x_n} y \, dx &= \int_{x_0}^{x_2} y \, dx + \int_{x_2}^{x_4} y \, dx + \cdots + \int_{x_{n-2}}^{x_n} y \, dx \\
 &= \frac{h}{3} [y_0 + 4y_1 + y_2] + \frac{h}{3} [y_2 + 4y_3 + y_4] + \cdots \\
 &\quad + \frac{h}{3} [y_{n-2} + 4y_{n-1} + y_n]
 \end{aligned}$$

$$I = \frac{h}{3} [y_0 + 2(y_2 + y_4 + \cdots + y_{n-2}) + 4(y_1 + y_3 + \cdots + y_{n-1}) + y_n]$$

Simpson's $\frac{3}{8}$ Rule

Take $m = 3$, number of intervals 3 and number of points 4: (number of intervals should be multiples of 3 i.e., $3N$).

$$\begin{aligned}
 \int_{x_0}^{x_3} y \, dx &= h \int_0^3 \left[y_0 + q \Delta y_0 + \frac{q(q-1)\Delta^2 y_0}{2} \right. \\
 &\quad \left. + \frac{q(q-1)(q-2)}{3!} \Delta^3 y_0 \right] dq \\
 &= h \left[3y_0 + \frac{9}{2} \Delta y_0 + \frac{9}{4} \Delta^2 y_0 + \frac{3}{8} \Delta^3 y_0 \right] \\
 &= h \left[3y_0 + \frac{9}{2} (y_1 - y_0) + \frac{9}{4} (y_2 - 2y_1 + y_0) + \right. \\
 &\quad \left. + \frac{3}{8} (y_3 - 3y_2 + 3y_1 - y_0) \right] \\
 &= \frac{3}{8} h [y_0 + 3y_1 + 3y_2 + y_3].
 \end{aligned}$$

Applying repeatedly

$$\begin{aligned}
 \int_{x_0}^{x_n} y \, dx &= \frac{3}{8} h [y_0 + 2(y_3 + y_6 + \cdots + y_{n-3}) + 3(y_1 + y_2 \\
 &\quad + y_4 + y_5 + \cdots + y_{n-2} + y_{n-1}) + y_n].
 \end{aligned}$$

Thus

Rectangular rule on $[x_0, x_1]$

(i)

Mid point rule on $[x_0, x_1]$

(ii)

Trapezoidal rule on $[x_0, x_1]$

(iii)

(iv)

Simpson's $\frac{3}{8}$ rule on $[x_0, x_3]$

(v)

Boole's rule on $[x_0, x_4]$

(vi)

Fig. 32.14

Trapezoidal Rule

When $n = 1$, $h = b - a$, then

$$\int_a^b f(x)dx = \int_a^b y dx \simeq \frac{h}{2}[y_0 + y_1]. \quad (4)$$

Generalized or Composite or Multiple Segment Trapezoidal Rule

When $h = \frac{b-a}{n}$ (i.e., interval is divided into n intervals).

$$\begin{aligned} \int_a^b y dx &= \frac{h}{2}[y_0 + y_1] + \frac{h}{2}[y_1 + y_2] + \cdots + \frac{h}{2}[y_{n-1} + y_n] \\ &= \frac{h}{2}[y_0 + 2(y_1 + y_2 + \cdots + y_{n-1}) + y_n]. \quad (5) \end{aligned}$$

Simpson's $\frac{1}{3}$ Rule

When $n = 2$,

$$\int_a^b y dx = \frac{h}{3}[y_0 + 4y_1 + y_2].$$

Generalized Simpson's $\frac{1}{3}$ Rule

When $n = 2m$ (even) number of intervals

$$\begin{aligned} \int_a^b y dx &= \frac{h}{3}[(y_0 + 4y_1 + y_2)] + \frac{h}{3}[y_2 + 4y_3 + y_4] + \cdots \\ &\quad + \frac{h}{3}[y_{n-2} + 4y_{n-1} + y_n] \\ &= \frac{h}{3}[(y_0 + y_n) + 2(y_2 + y_4 + \cdots + y_{n-2}) \\ &\quad + 4(y_1 + y_3 + \cdots + y_{n-1})]. \end{aligned}$$

Simpson's $\frac{3}{8}$ Rule

When $n = 3$

$$\int_a^b y dx = \frac{3h}{8}[y_0 + 3y_1 + 3y_2 + y_3].$$

Generalized Simpson's $\frac{3}{8}$ Rule

$$\begin{aligned} \int_a^b y dx &= \frac{3h}{8}[y_0 + 3y_1 + 3y_2 + y_3] \\ &\quad + \frac{3h}{8}[y_3 + 3y_4 + 3y_5 + y_6] + \cdots \end{aligned}$$

$$\begin{aligned} &+ \frac{3h}{8}[y_{n-3} + 3y_{n-2} + 3y_{n-1} + y_n] \\ &= \frac{3h}{8}[(y_0 + y_n) + 2(y_3 + y_6 + \cdots + y_{n-3}) \\ &\quad + 3(y_1 + y_2 + y_4 + y_5 + \cdots + y_{n-2} + y_{n-1})]. \end{aligned}$$

Weddle Rule

When ($n = 6$),

$$\int_a^b y dx = \frac{3h}{10}[y_0 + 5y_1 + y_2 + 6y_3 + y_4 + 5y_5 + y_6].$$

Generalized Weddle Rule

$$\begin{aligned} \int_{a=x_0}^{b=x_0+nh} y dx &= \frac{3h}{10}[y_0 + 5y_1 + y_2 + 6y_3 + y_4 + 5y_5 + y_6] \\ &\quad + \frac{3h}{10}[y_6 + 5y_7 + y_8 + 6y_9 + y_{10} + 5y_{11} \\ &\quad + y_{12}] + \cdots + \frac{3h}{10}[y_{n-6} + 5y_{n-5} + y_{n-4} \\ &\quad + 6y_{n-3} + y_{n-2} + 5y_{n-1} + y_n]. \end{aligned}$$

Note: While there is no restriction for the number of intervals in trapezoidal rule, number of sub intervals n in the case of Simpson's $\frac{1}{3}$ rule must be even, for Simpson's $\frac{3}{8}$ rule must be multiple of 3, for Weddle's rule must be multiple of 6.

WORKED OUT EXAMPLES

Example 1: Given that $y = \log x$, and

x : 4.0 4.2 4.4 4.6 4.8 5.0 5.2
 y : 1.3863 1.4351 1.4816 1.5261 1.5686 1.6094 1.6487

evaluate $I = \int_4^{5.2} \log x dx$ by (a) Trapezoidal rule; (b) Simpson's $\frac{1}{3}$ rule; (c) Simpson's $\frac{3}{8}$ rule; (d) Weddle's rule; (e) Compare it with exact value.

Solution:

a. By trapezoidal rule, ($h = 0.2$)

$$\begin{aligned} I &= \frac{0.2}{2}[1.3863 + 1.6487 + 2(1.4351 + 1.4816 \\ &\quad + 1.5261 + 1.5686 + 1.6094)] \end{aligned}$$

$$I = 1.8276551$$

b. By Simpson's $\frac{1}{3}$ rule

$$I = \frac{0.2}{3} [1.3863 + 1.6487 + 2(1.4816 + 1.5686) + 4(1.4351 + 1.5261 + 1.6094)]$$

$$I = 1.8278472$$

c. By Simpson's $\frac{3}{8}$ rule

$$I = \frac{3}{8} (0.2) [1.3863 + 1.6487 + 2(1.5261) + 3(1.4351 + 1.4816) + (1.5686 + 1.6094)]$$

$$I = 1.8278470$$

d. By Weddle's rule

$$I = \frac{3}{10} (0.2) [1.3863 + 5(1.4351 + 1.6094) + 6(1.5261) + 1.4816 + 1.5686 + 1.6487]$$

$$I = 1.8278474$$

e. By integrating by parts

$$I = \int_5^{5.2} \ln x \, dx = x \cdot \ln x - \int x \cdot \frac{1}{x} dx = x \cdot \ln x - x \Big|_4^{5.2}$$

$$= (5.2 \ln 5.2 - 5.2) - (4 \ln 4 - 4) = 3.373 - 1.54517$$

$$I = 1.827822556.$$

Example 2: The half ordinates in feet of the mid ship section of a vessel are 12.5, 12.8, 12.9, 13, 13, 12.8, 12.4, 11.8, 10.4, 6.8, 0.5 and the ordinates are 2 feet apart. Find the centre of gravity of the section.

Solution: Centre of gravity $(\bar{x}, 0)$.

| | | | | | | |
|------------|-------|-------|-------|-------|-----|------|
| $x:$ | 0 | 2 | 4 | 6 | 8 | 10 |
| half | | | | | | |
| ordinates: | 12.5 | 12.8 | 12.9 | 13 | 13 | 12.8 |
| $y:$ | 25 | 25.6 | 25.8 | 26 | 26 | 25.6 |
| $xy:$ | 0 | 51.2 | 103.2 | 156 | 208 | 256 |
| $x:$ | 12 | 14 | 16 | 18 | 20 | |
| half | | | | | | |
| ordinates: | 12.4 | 11.8 | 10.4 | 6.8 | 0.5 | |
| $y:$ | 24.8 | 23.6 | 20.8 | 13.6 | 1 | |
| $xy:$ | 297.6 | 330.4 | 332.8 | 244.8 | 20 | |

$$\text{Here } \bar{x} = \frac{\int_0^{20} xy \, dx}{\int_0^{20} y \, dx} = \frac{I_1}{I_2}$$

where by Simpson's $\frac{1}{3}$ rule

$$I_1 = \frac{1}{3} (2) [20 + 332.8 + 4(51.2 + 156 + 256 + 330.4 + 244.8) + 2(103.2 + 208 + 297.6 + 332.8)]$$

$$I_1 = 4037.8666$$

$$I_2 = \frac{1}{3} (2) [25 + 1 + 4(25.6 + 26 + 25.6 + 23.6 + 13.6) + 2(25.8 + 26 + 24.8 + 20.8)]$$

$$I_2 = 452.2666$$

$$\therefore \bar{x} = \frac{4037.8666}{452.2666} = 8.928066154 \approx 8.93.$$

Example 3: The speeds of an electric train at various times after leaving one station until it stops at the next station are given in the following table (Table 11.15). Find the distance between the two stations.

Table 32.15

| | | | | | | | | | |
|-----------------|---|---------------|----|-----------------|----|----------------|----|----------------|----------------|
| Speed in mph | 0 | 13 | 33 | $39\frac{1}{2}$ | 40 | 40 | 36 | 15 | 0 |
| Time in minutes | 0 | $\frac{1}{2}$ | 1 | $1\frac{1}{2}$ | 2 | $2\frac{1}{2}$ | 3 | $3\frac{1}{4}$ | $3\frac{1}{2}$ |

Solution: Let $v = \frac{ds}{dt}$ be the velocity of the train at any time t . Then s , the distance between the two stations (with a lapse of $3\frac{1}{2}$ minutes) is

$$s = \int_{t=0}^{3\frac{1}{2}} \frac{ds}{dt} dt = \int_{t=0}^{3\frac{1}{2}} v \, dt = \int_0^3 v \, dt + \int_3^{3\frac{1}{2}} v \, dt$$

since the time interval are not the same. By applying Simpson's $\frac{1}{3}$ rule with $h = \frac{1}{2}$ and $h = \frac{1}{4}$, we have

Table 32.16

| | | | | | | | | | |
|---------------|---|-----------------|----------------|-----------------|----------------|----------------|----------------|------------------|-----------------|
| Speed in mph | 0 | 13 | 33 | $39\frac{1}{2}$ | 40 | 40 | 36 | 15 | 0 |
| Time in hours | 0 | $\frac{1}{120}$ | $\frac{1}{60}$ | $\frac{1}{40}$ | $\frac{1}{30}$ | $\frac{1}{24}$ | $\frac{1}{20}$ | $\frac{13}{240}$ | $\frac{7}{480}$ |

$$s = s_1 + s_2 = \frac{1}{3} \cdot \frac{1}{120} \left[0 + 36 + 4(13 + 39\frac{1}{2} + 40) + 2(33 + 40) \right] + \frac{1}{3} \cdot \frac{1}{240} [36 + 0 + 4(15)]$$

$$= \frac{23}{15} + \frac{2}{15} = \frac{25}{15} = \frac{5}{3} = 1\frac{2}{3} = 1.666 \text{ miles}$$

Thus the distance between the two stations is 1.666 miles.

EXERCISE

Evaluate approximately the following integrals:

Trapezoidal rule

- Use trapezoidal rule to evaluate (a) $\int_1^{10} \frac{dx}{x}$, $n = 10$; (b) $\int_0^1 \frac{dx}{1+x^2}$, $n = 4$; (c) $\int_0^1 \frac{\sin x}{x} dx$, $n = 4$.

Ans. a. $\frac{1}{2} \left[1 + 0.1 + 2 \left(\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} + \frac{1}{8} + \frac{1}{9} \right) \right] = 2.3788$

b. $\frac{1}{4} \cdot \left[\frac{1}{2} \left(1 + \frac{1}{2} \right) + \frac{16}{17} + \frac{4}{5} + \frac{16}{25} \right] = 0.7828$

c. $\frac{1}{4} \cdot \frac{1}{2} [1 + 0.84 + 2(.9898 + 0.95885 + .90885)] = 0.9445$

- Using the following data evaluate by T.R.

a.

| | | | | | | | |
|----|-------|-------|-------|-------|-------|-------|-------|
| x: | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| y: | 2.105 | 2.808 | 3.614 | 4.604 | 5.857 | 7.451 | 9.467 |

b.

| | | | | | | | | | |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| x: | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 | 1.5 | 1.6 | 1.7 | 1.8 |
| f(x): | 1.543 | 1.668 | 1.811 | 1.971 | 2.151 | 2.352 | 2.577 | 2.828 | 3.107 |

with (i) $h = 0.1$; (ii) $h = 0.2$; (iii) $h = 0.4$.

Ans. a. $\int_1^7 y dx = \frac{1}{2} [2.105 + 2(2.808 + 3.614 + 4.604 + 5.851 + 7.451) + 9.467] = 30.120$

b. $\int_1^{1.8} f(x) dx = 1.7683 (h = 0.1), 1.7728 (h = 0.2), 1.7904 (h = 0.4)$.

- Integrate $\int_0^\pi \sin x dx$, $n = 10$.

Hint:

| | | | | | | | | | | | |
|--------|---|------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------|
| x: | 0 | $\frac{\pi}{10}$ | $\frac{2\pi}{10}$ | $\frac{3\pi}{10}$ | $\frac{4\pi}{10}$ | $\frac{5\pi}{10}$ | $\frac{6\pi}{10}$ | $\frac{7\pi}{10}$ | $\frac{8\pi}{10}$ | $\frac{9\pi}{10}$ | π |
| sin x: | 0 | .309 | .5878 | .809 | .951 | 1 | .951 | .809 | .5878 | .309 | 0 |

Ans. 6.3138

- Evaluate $\int_0^1 \frac{dx}{1+x^2}$, $n = 10$.

Hint:

| | | | | | | | | | | | |
|-------|---|-----|-----|------|------|----|------|-----|-----|-----|----|
| x: | 0 | .1 | .2 | .3 | .4 | .5 | .6 | .7 | .8 | .9 | 1 |

Ans. 0.6547

Simpson's $\frac{1}{3}$ rule

- Integrate approximately $\int_1^{1.04} f(x) dx$ from the following data:

| | | | | | |
|-------|-------|-------|-------|-------|-------|
| x: | 1 | 1.01 | 1.02 | 1.03 | 1.04 |
| f(x): | 3.953 | 4.066 | 4.182 | 4.300 | 4.421 |

Hint: $h = 0.1$.

Ans. 0.16734, $I = \frac{0.1}{3} [(3.953) + (4.421) + 4(4.066 + 4.182 + 4.3)]$

- Evaluate $\log e^7$ by Simpson's $\frac{1}{3}$ rule.

Hint: $I = \int_0^6 \frac{dx}{1+x}$.

Ans. 1.9588

- Compute $\int_0^{\frac{\pi}{2}} \sqrt{\sin x} dx$.

Hint: $n = 6, h = \frac{\pi}{12}$.

Ans. 1.18728, $I = \frac{\pi}{3} \cdot \frac{1}{12} [0 + 1 + 4(.50874 + 0.8409 + 0.98282) + 2(0.70711 + 0.9306)]$

- Compute $I = \int_0^1 \frac{dx}{1+x}$, $n = 10, h = 0.1$.

Ans. 0.69315

- Integrate approximately $\int_0^\pi \sin x dx$, $n = 10$.

Ans. 3.0778

- Compute $\int_0^1 \frac{dx}{1+x^2}$, $n = 10$.

Ans. 0.785425

- A river is 80 feet wide. The depth d in feet at a distance x feet from one bank is given by:

| | | | | | | | | | |
|----|---|----|----|----|----|----|----|----|----|
| x: | 0 | 10 | 20 | 30 | 40 | 50 | 60 | 70 | 80 |
| d: | 0 | 4 | 7 | 9 | 12 | 15 | 14 | 8 | 3 |

Find approximately the area of cross section of the river.

Hint: $I = \int_0^{80} d dx = \frac{1}{3} (10) [0 + 3 + 4(4 + 9 + 15 + 8) + 2(7 + 12 + 14)]$

Ans. 710 sq. feet

- A body of weight w tons is acted upon by a variable force F tons weight. It acquires a speed of v mph after travelling y yards where $v^2 = \frac{89.8}{w} \int F(y) dy$. If $w = 600$ and F is given by the table below, estimate the velocity at the end of 400 yards from the starting point.

| | | | | | | | |
|-------|----|----|-----|-----|-----|-----|-----|
| y: | 0 | 50 | 100 | 150 | 200 | 300 | 400 |
| f(y): | 90 | 62 | 45 | 34 | 26 | 15 | 8 |

Hint: $\int_0^{400} F dy = \int_0^{200} + \int_{200}^{400}$ with $h_1 = 50, h_2 = 100$.

Ans. $v = 44.16$ mph

13. Find the approximate mileage travelled by a train between 11.50 AM to 12.30 PM from the following data:

| | | | | | |
|--------------|----------|----|-------|-------|-------|
| time t : | 11.50 AM | 12 | 12.10 | 12.20 | 12.30 |
| speed (mph): | 24.2 | 35 | 41.3 | 42.8 | 39.2 |

Hint: $I = s \int_{t=11.50}^{12.30} v dt = \frac{1}{6} \left(\frac{1}{3} \right) [24.2 + 39.2 + 4(35.0 + 42.8) + 2(41.3)].$

Ans. $s = \text{distance} = 25.4$ miles

Simpson's $\frac{3}{8}$ rule

14. Evaluate $\log_e 7$ by Simpson's $\frac{3}{8}$ th rule.

Hint: $I = \int_0^6 \frac{dx}{1+x} = \log_e(1+x)|_0^6 = \log_e 7$

| $f(x)$: | .746 | .6923 | .64 | .5906 | .5434 | 0.5 | |

Ans. 0.7603725

Boole's Rule of Integration

The goal in numerical integration is to approximate $\int_a^b f(x) dx$ using $(N + 1)$ sample points (x_0, f_0) , $(x_1, f_1) \dots, (x_N, f_N)$ where f_k denotes $f(x_k)$.

Boole's rule is obtained by using a 4th degree Lagrange interpolating polynomial based on the

nodes x_0, x_1, x_2, x_3 and x_4 . Consider the approximation formula

$$\int_0^4 g(t)dt = w_0g(0) + w_1g(1) + w_2g(2) + w_3g(3) + w_4g(4) \quad (1)$$

we determine the weights w_0, w_1, w_2, w_3, w_4 assuming that (1) is exact for the functions $g(t) = 1, t, t^2, t^3, t^4$. Thus when $g(t) = 1$ then $g(0) = g(1) = g(2) = g(3) = g(4) = 1$. From (1)

$$\int_1^4 1 \cdot dt = 4 = w_0 + w_1 + w_2 + w_3 + w_4 \quad (2)$$

For $g(t) = t$, $g(0) = 0$, $g(1) = 1$, $g(2) = 2$, $g(3) = 3$, $g(4) = 4$ so from (1)

$$\int_0^4 t dt = \frac{t^2}{2} \Big|_0^4 = 8 = 0 + w_1 + 2w_2 + 3w_3 + 4w_4 \quad (3)$$

Similarly for $g(t) = t^2, t^3, t^4$ from (1) we get

$$\frac{64}{3} = w_1 + 4w_2 + 9w_3 + 16w_4 \quad (4)$$

$$64 = w_1 + 8w_2 + 27w_3 + 64w_4 \quad (5)$$

$$\frac{1024}{5} = w_1 + 16w_2 + 81w_3 + 256w_4 \quad (6)$$

Solving equations (1) to (6) we get $w_0 = \frac{14}{45}$, $w_1 = \frac{64}{45}$, $w_2 = \frac{24}{45}$, $w_3 = \frac{64}{45}$, $w_4 = \frac{14}{45}$.

Thus the Boole's rule for the interval $[x_0, x_4]$

$$\int_{x_0}^{x_4} f(x)dx \approx \frac{2h}{45} [7f_0 + 32f_1 + 12f_2 + 32f_3 + 7f_4] \quad (7)$$

Composite Boole's Rule

When Boole's rule is repeated over 4 M subintervals of $[a, b]$, we get the composite Boole's rule as

$$\int_a^b f(x)dx \approx \frac{2h}{45} \sum_{k=1}^M [7f_{4k-4} + 32f_{4k-3} + 12f_{4k-2} + 32f_{4k-1} + 7f_{4k}] \quad (8)$$

Note: To apply Boole's rule, the number of subintervals should be multiples of 4 (i.e., 4, 8, 12...) and the numbers of nodes must be odd.

WORKED OUT EXAMPLES

Example 1: Evaluate $\int_1^5 \frac{dx}{x}$ by Boole's rule.

Solution: Take $h = \frac{5-1}{4} = 1$ so that there 4 subintervals.

$$\begin{array}{cccccc} x & 1 & 2 & 3 & 4 & 5 \\ f(x) = \frac{1}{x} & 1 & \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \end{array}$$

Using Boole's rule

$$\begin{aligned} \int_1^5 \frac{dx}{x} &\approx \frac{2 \cdot 1}{45} \left[7 \cdot 1 + 32 \left(\frac{1}{2} \right) + 12 \left(\frac{1}{3} \right) + 32 \left(\frac{1}{4} \right) + 7 \cdot \frac{1}{5} \right] \\ &= \frac{364}{225} = 1.61777 \end{aligned}$$

while the exact value is $\ln 5 - \ln 1 = 1.60943$

Example 2: Find the distance travelled by a submarine under polar ice cap from the following table showing the velocity at variance times

| t
time
(hr) | 0.00 | 0.25 | 0.50 | 0.75 | 1.00 | 1.25 | 1.50 | 1.75 | 2.00 |
|-----------------------------|------|------|------|------|------|------|------|------|------|
| Velocity
$v(t)$
km/hr | 6.0 | 7.5 | 8.0 | 9.0 | 8.5 | 10.5 | 9.5 | 7.0 | 6.0 |

Solution: We know that

$$d = \text{distance travelled} = \int_{t=0}^2 v(t)dt$$

We evaluate this definite integral by Boole's rule with $4 \cdot 2 = 8$ subintervals. Here $h = \frac{2-0}{8} = \frac{1}{4} = 0.25$ (and 9 node points). Applying the composite Boole's rule we get

$$\begin{aligned} d &= \frac{2h}{45} [7f_0 + 32f_1 + 12f_2 + 32f_3 + 7f_4] \\ &\quad + \frac{2h}{45} [7f_4 + 32f_5 + 12f_6 + 32f_7 + 7f_8] \\ &= \frac{2(0.25)}{45} [7(6) + 32(7.5) + 12(8) + 32(9) + 7(8.5)] \\ &\quad + \frac{2(0.25)}{45} [7(8.5) + 32(10.5) + 12(9.5) + 32(7.0) \\ &\quad + 7(6.0)] \\ &= 16.6777 \end{aligned}$$

EXERCISE

1. Evaluate $\int_0^1 \frac{dx}{1+x^2}$ by Boole's rule with 12 subintervals.

Ans. Exact value: $\frac{\pi}{4} = 0.7854$, by Boole's rule: 0.8236

Hint: $\frac{2}{45} \cdot \frac{1}{12} [7\{1 + 2(0.9 + 0.746 + 0.692) + 0.5\} + 32\{0.993 + 0.94 + 0.85 + 0.746 + 0.64 + 0.543\} + 12\{0.973 + 0.8 + 0.59\}] = 0.8236$

2. Evaluate $\int_{0.2}^{1.4} (\sin x - \ln x + e^x) dx$

Ans. Exact value: 4.05025, $n = 12$, $h = 0.1$, by Boole's: 4.04235

Hint: $\frac{2(0.1)}{45} [7\{3.0295 + 2(2.8976 + 3.559) + 4.3704\} + 32\{2.8493 + 2.821 + 3.01465 + 3.348 + 3.8 + 4.3705\} + 12\{2.797 + 3.166 + 4.0698\}] = 4.04235$

3. A river is 80 feet wide. The depth d in feet at a distance x from one bank (side) of the river is given below.

x : 0 10 20 30 40 50 60 70 80

d : 0 4 7 9 12 15 14 8 3

Find approximately the area of cross section of the river.

Ans. 708

Hint: $n = 8$, $h = 10$

Area = $\frac{2(10)}{45} [7\{0 + 2(12) + 3\} + 32\{4 + 9 + 15 + 8\} + 12\{7 + 14\}] = 708$

4. Find the distance between two stations from the following data consisting of the speeds of an electric train at various times after leaving one station until it stops at the next station.

| | | | | | | | | | |
|------------------------------|---|----|----|-----------------|----|----|----|----|---|
| Speed of train $v(t)$ in mph | 0 | 13 | 33 | $39\frac{1}{2}$ | 40 | 40 | 36 | 15 | 0 |
|------------------------------|---|----|----|-----------------|----|----|----|----|---|

| | | | | | | | | | |
|-----------|---|---------------|---|----------------|---|----------------|---|----------------|---|
| t in mt | 0 | $\frac{1}{2}$ | 1 | $1\frac{1}{2}$ | 2 | $2\frac{1}{2}$ | 3 | $3\frac{1}{2}$ | 4 |
|-----------|---|---------------|---|----------------|---|----------------|---|----------------|---|

Ans. 1.788148 miles

Hint: Distance = $\int_0^4 v(t) dt$, $n = 8$, $h = \frac{1}{2} \text{ mt} = \frac{1}{120} \text{ hr}$, $= \frac{2}{45} \cdot \frac{1}{120} [7(0 + 40 + 40 + 0) + 32(13 + 39\frac{1}{2} + 40 + 15) + 12(33 + 36)]$

32.15 SPLINE INTERPOLATION

In analyzing experimental data, in ascertaining the relations among variables and in design work, the common problem encountered is fitting a curve through specified points in a plane. *Interpolating curve* is a curve that passes through a set of points in a plane and the curve is said to *interpolate* at these points.

It is observed that approximation of arbitrary functions on a closed interval becomes oscillatory for higher-degree polynomials. By dividing the given interval into a collection of subintervals, *piecewise polynomial approximation* consists of constructing a (generally) different approximating polynomial on each subinterval. *Cubic spline interpolation* is the most common piecewise approximation using cubic polynomial, known as *spline function*, connecting each pair of data points (or nodes or knots). Cubic splines are third-order curves employed to connect each pair of data points.

Consider a set of $(n + 1)$ data points, which need not be evenly spaced, $(x_0, f(x_0))$, $(x_1, f(x_1))$, $(x_2, f(x_2)) \dots (x_n, f(x_n))$

or (x_i, f_i) for $i = 0, 1, 2, \dots, n$. (1)

Between each pair of adjacent points from x_i to x_{i+1} , we fit an n th degree polynomial $s_i(x)$. Thus the spline (function) curve can be of any degree. By far, cubic splines are the most popular and are useful version in engineering practice since the cubic spline interpolation gives an interpolation formula that is smooth in the first derivative and continuous, both within an interval and its boundaries (end points x_0 and x_n). The name 'spline' is originated from the draftman's spline which is a drafting aid consisting of a thin flexible rod or strip of wood that is bent to draw a smooth curve through the points to be interpolated.

Linear Splines

Linear splines are first-order splines defined by linear functions. Geometrically they are straight lines connecting two adjacent data points. For a given set of $(n + 1)$ data points (1), the set of linear functions defining linear splines in the ' n ' intervals are:

$$S_1(x) = f(x_0) + m_0(x - x_0); x_0 \leq x \leq x_1.$$

$$S_2(x) = f(x_1) + m_1(x - x_1); x_1 \leq x \leq x_2.$$

Fig. 32.15 Piecewise linear interpolation

$$S_n(x) = f(x_{n-1}) + m_{n-1}(x - x_{n-1});$$

$$x_{n-1} \leq x \leq x_n$$

Here m_i is the slope of the straight line connecting the data points (or nodes) x_i and x_{i+1} and is given by

$$m_i = \frac{f(x_{i+1}) - f(x_i)}{x_{i+1} - x_i} \quad (2)$$

Fitting of linear splines is piecewise linear interpolation and the interpolating curve is broken curve joining ' n ' straight line segments. Disadvantage of linear splines is that at the point (known as *knot*) where two splines meet, the slope changes abruptly i.e., first derivative is discontinuous.

Quadratic Splines

Interpolation of second-order polynomials leads to quadratic splines having continuous first derivatives at the knots.

For each interval we fit a parabola given by

$$s_i(x) = a_i x^2 + b_i x + c_i$$

For $n + 1$ data points we have n intervals. So we should determine $3 \times n$ unknown constants (a 's, b 's and c 's). The $3n$ conditions to find the $3n$ unknowns are given by the following equations.

1. At the interior knots, the function values must be equal.

$$a_{i-1}x_{i-1}^2 + b_{i-1}x_{i-1} + c_{i-1} = f(x_{i-1})$$

$$a_i x_{i-1}^2 + b_i x_{i-1} + c_i = f(x_{i-1})$$

for $i = 2, n$ giving rise to $2(n - 1) = 2n - 2$ conditions.

2. The first and last functions must pass through the two end points x_0 and x_n .

$$a_0 x_0^2 + b_0 x_0 + c_0 = f(x_0)$$

$$a_n x_n^2 + b_n x_n + c_n = f(x_n)$$

giving 2 conditions.

3. At the interior knots, the first derivatives $f'(x) = 2ax + b$ must be equal.

$$2a_{i-1}x_i + b_{i-1} = 2a_i x_i + b_i$$

for $i = 2$ to n giving $n - 1$ conditions

4. Assume that the second derivative is zero at the first point x_0 . Then the first two points are connected by a straight line, so $a_1 = 0$.

Thus solving $(2n - 2) + 2 + (n - 1) + 1 = 3n$ conditions above we get the $3n$ unknown constants a, b, c 's. The drawback is the straight line connecting the first two points.

Cubic Splines

A spline of at least $(m + 1)$ order should be used in order to make sure that the m th derivatives are continuous at knots. Cubic splines employing third order polynomials are very popular in practice because they ensure that the first and second derivatives are continuous.

Fig. 32.16 Piecewise cubic spline approximation

Let us fit a (different) third order polynomial

$$S_i(x) = a_i x^3 + b_i x^2 + c_i x + d_i \quad (3)$$

for **each** of the n intervals between the $(n + 1)$ data points (knots) $(i = 0, 1, 2, \dots, n)$. The problem is to find the $4 \times n = 4n$ unknown constants

($a'_i s$, $b'_i s$, $c'_i s$ and $d'_i s$). We have the following conditions

- $2n - 2$ conditions since the function values must be equal at the $(n - 1)$ interior knots.
- 2 conditions since the first and last functions must pass through the two end points x_0 and x_n .
- $(n - 1)$ conditions since the first derivatives must be equal at the $(n - 1)$ interior points.
- $(n - 1)$ conditions since the second derivatives must be equal at the $(n - 1)$ interior knots.

The above conditions are summed to $(2n - 2) + (2) + (n - 1) + (n - 1) = 4n - 2$, thus short of 2 more conditions to solve the $4n$ unknown constants. Two end point constraint are assumed as follows:

Natural spline for which the end point constraints are assumed as “second derivatives at the end knots are zero” i.e., $S''(x_0) = S''(x_n) = 0$. Natural splines are more frequently used in which the end cubic (in the first and last intervals) approach linearity (straight line) at their extremities. This matches precisely with the drafting spline.

The cubic spline for *each* interval (x_{i-1}, x_i) is given by

$$\begin{aligned} S_i(x) = & \frac{f''(x_{i-1})}{6(x_i - x_{i-1})}(x_i - x)^3 \\ & + \frac{f''(x_i)}{6(x_i - x_{i-1})}(x - x_{i-1})^3 \\ & + \left[\frac{f(x_{i-1})}{(x_i - x_{i-1})} - \frac{f''(x_{i-1})(x_i - x_{i-1})}{6} \right] (x_i - x) + \\ & + \left[\frac{f(x_i)}{(x_i - x_{i-1})} - \frac{f''(x_i) \cdot (x_i - x_{i-1})}{6} \right] (x - x_{i-1}). \end{aligned} \quad (4)$$

Equation (4) contains only two unknowns $f''(x_{i-1})$ and $f''(x_i)$, the second derivatives at the end points of the interval (x_{i-1}, x_i) , which are determined from the following equation.

$$\begin{aligned} (x_i - x_{i-1})f''(x_{i-1}) + 2(x_{i+1} - x_{i-1})f''(x_i) \\ + (x_{i+1} - x_i)f''(x_{i+1}) \\ = \frac{6}{(x_{i+1} - x_i)}[f(x_{i+1}) - f(x_i)] \end{aligned}$$

$$+ \frac{6}{(x_i - x_{i-1})}[f(x_{i-1}) - f(x_i)] \quad (5)$$

Equation (5) written for the $(n - 1)$ interior points results in $(n - 1)$ simultaneous equations for the second derivatives. Note that these $(n - 1)$ equations form a tridiagonal system which can be solved in an extremely efficient manner using computer algorithms.

WORKED OUT EXAMPLES

Example 1: Fit a linear spline to the following data:

| | | | | |
|--------------|---|-----|---|-----|
| x : | 1 | 3 | 6 | 8 |
| $y = f(x)$: | 4 | 5.5 | 7 | 9.5 |

Estimate the value at $x = 2, 4, 7$.

Solution: There are $n = 4$ points and 3 intervals. Assume that $x_0 = 1$, $x_1 = 3$, $x_2 = 6$, $x_3 = 8$, $f(x_0) = 4$, $f(x_1) = 5.5$, $f(x_2) = 7$, $f(x_3) = 9.5$. The three first order linear splines in the 3 intervals are:

$$f(x) = f(x_0) + m_0(x - x_0), \quad x_0 \leq x \leq x_1$$

$$f(x) = f(x_1) + m_1(x - x_1), \quad x_1 \leq x \leq x_2$$

$$f(x) = f(x_2) + m_2(x - x_2), \quad x_2 \leq x \leq x_3$$

Here $m_i = \frac{f(x_{i+1}) - f(x_i)}{x_{i+1} - x_i}$ is the slope of straight line connecting the two points. For the given data

$$m_0 = \frac{f(x_1) - f(x_0)}{x_1 - x_0} = \frac{5.5 - 4}{3 - 1} = \frac{1.5}{2} = 0.75$$

$$m_1 = \frac{f(x_2) - f(x_1)}{x_2 - x_1} = \frac{7 - 5.5}{6 - 3} = \frac{1.5}{3} = 0.5$$

$$m_2 = \frac{f(x_3) - f(x_2)}{x_3 - x_2} = \frac{9.5 - 7}{8 - 6} = \frac{2.5}{2} = 1.25$$

Thus the three linear splines are

$$f(x) = 4 + 0.75(x - 1), \quad \text{when } 1 \leq x \leq 3$$

$$f(x) = 5.5 + 0.5(x - 3), \quad \text{when } 3 \leq x \leq 6$$

$$f(x) = 7 + 1.25(x - 6), \quad \text{when } 6 \leq x \leq 8$$

Since $x = 2$ lies in the first interval $1 \leq x \leq 3$, we

32.50 — HIGHER ENGINEERING MATHEMATICS—VIII

get $f(2)$ from the first equation.

$$f(2) = 4 + 0.75(2 - 1) = 4.75$$

Similarly $f(7) = 7 + 1.25(7 - 6) = 8.25$.

Since $x = 4$ lies in the second interval $3 \leq x \leq 6$, we get $f(4)$ from the second equation:

$$f(4) = 5.5 + 0.5(4 - 3) = 6$$

Example 2: Fit quadratic splines to the following data. Use the results to estimate the value at $x = 2, 4, 7$.

| | | | | |
|---------|---|-----|---|-----|
| $x:$ | 1 | 3 | 6 | 8 |
| $f(x):$ | 4 | 5.5 | 7 | 9.5 |

Solution: For the 4 data points in 3 intervals we fix three quadratic splines of the form

$$S_i(x) = a_i x^2 + b_i x + c_i$$

we have to determine $3 \times 3 = 9$ unknown $a_1, b_1, c_1, a_2, b_2, c_2, a_3, b_3, c_3$. We need $3 \cdot 3 = 9$ equations or conditions to determine these 9 unknowns. There are two interior points x_1 and x_2 .

- Function values must be equal at the two interior points, giving rise to 4 equations.

$$a_{i-1}x_{i-1}^2 + b_{i-1}x_i + c_{i-1} = f(x_{i-1})$$

$$a_i x_{i-1}^2 + b_i x_{i-1} + c_i = f(x_{i-1})$$

for $i = 2$ to 3.

$$\text{For } i = 2, a_1 x_1^2 + b_1 x_1 + c_1 = f(x_1)$$

$$a_2 x_1^2 + b_2 x_1 + c_2 = f(x_1)$$

$$\text{i.e., } 9a_1 + 3b_1 + c_1 = 5.5 \quad (1)$$

$$9a_2 + 3b_2 + c_2 = 5.5 \quad (2)$$

$$\text{For } i = 3, a_2 x_2^2 + b_2 x_2 + c_2 = f(x_2)$$

$$a_3 x_2^2 + b_3 x_2 + c_3 = f(x_2)$$

$$\text{i.e., } 36a_2 + 6b_2 + c_2 = 7 \quad (3)$$

$$36a_3 + 6b_3 + c_3 = 7 \quad (4)$$

- The first and last functions must pass through the end points x_0 and x_n giving rise to 2 equations.

$$a_1 x_0^2 + b_1 x_0 + c_1 = f(x_0)$$

$$a_n x_n^2 + b_n x_n + c_n = f(x_n)$$

i.e.,

$$a_1 + b_1 + c_1 = 4 \quad (5)$$

$$64a_3 + 8b_3 + c_3 = 9.5 \quad (6)$$

- The first derivatives at the interior knots must be equal.

$$f'(x) = 2ax + b$$

$$2a_{i-1}x_i + b_{i-1} = 2a_i x_i + b_i$$

for $i = 2, 3$

$$2a_1 x_2 + b_1 = 2a_2 x_2 + b_2$$

$$2a_2 x_3 + b_2 = 2a_3 x_3 + b_3$$

$$\text{i.e., } 6a_1 + b_1 = 6a_2 + b_2 \quad (7)$$

$$12a_2 + b_2 = 12a_3 + b_3 \quad (8)$$

- Assume that the second derivative is zero at the first point i.e.,

$$a_1 = 0 \quad (9)$$

Using (9) $a_1 = 0$ in (1) and (5) we get

$$3b_1 + c_1 = 5.5$$

$$b_1 + c_1 = 4$$

solving $b_1 = 0.75, c_1 = 3.25$

From (2) and (3) we get

$$9a_2 + 3b_2 + c_2 = 5.5$$

$$36a_2 + 6b_2 + c_2 = 7$$

$$\frac{27a_2 + 3b_2}{36a_2 + 6b_2 + c_2} = 1.5$$

Form (7) $6a_2 + b_2 = 0 + b_1 = 0.75$

Solving $a_2 = \frac{-0.75}{9}, b_2 = 1, c_2 = 4$

From (4) and (6)

$$36a_3 + 6b_3 + c_3 = 7$$

$$64a_3 + 8b_3 + c_3 = 9.5$$

Subtracting $28a_3 + 2b_3 = 2.5$

From (8): $12a_3 + b_3 = 12a_2 + b_2 = 0$

Solving $a_3 = \frac{2.5}{4}, b_3 = -7.5, c_3 = 29.5$

Thus the values of the 9 coefficients are

$a_1 = 0, b_1 = 0.75, c_1 = 3.25,$

$a_2 = \frac{-0.75}{9}, b_2 = 1, c_2 = 4,$

$a_3 = \frac{2.5}{4}, b_3 = -7.5, c_3 = 29.5,$

Then the three required quadratic splines are

$S_1(x) = 0 + 0.75x + 3.25$, in $1 \leq x \leq 3$

$S_2(x) = \frac{-0.75}{9}x^2 + x + 4$, in $3 \leq x \leq 6$

$$S_3(x) = \frac{2.5}{4}x^2 - 7.5x + 29.5, \text{ in } 6 \leq x \leq 8$$

$$\text{At } x = 2, S_1(2) = 4.75$$

$$\text{At } x = 4, S_2(4) = 6.6666$$

$$\text{At } x = 7, S_3(7) = 7.625$$

Example 3: Fit cubic splines to the following data and estimate the value at $x = 2, 4, 7$ and $y'(4)$.

| | | | | |
|-------------|---|-----|---|-----|
| $x:$ | 1 | 3 | 6 | 8 |
| $y = f(x):$ | 4 | 5.5 | 7 | 9.5 |

Solution: Assume a cubic spline a third order polynomial

$$S_i(x) = a_i x^3 + b_i x^2 + c_i x + d_i$$

For the 4 data points and 3 intervals, we have to determine $4 \times 3 = 12$ unknown constants $a_1, b_1, c_1, d_1, a_2, b_2, c_2, d_2, a_3, b_3, c_3, d_3$.

1. The second derivatives at the end knots are zero; i.e., $f''(1) = f''(8) = 0$.
2. The second derivatives at the end of each interval (at the two interior points) are given by

$$\begin{aligned} & (x_i - x_{i-1})f''(x_{i-1}) + 2(x_{i+1} - x_{i-1})f''(x_i) \\ & + (x_{i+1} - x_i)f''(x_{i+1}) \\ & = \frac{6}{(x_{i+1} - x_i)}[f(x_{i+1}) - f(x_i)] + \\ & + \frac{6}{(x_i - x_{i-1})}[f(x_{i-1}) - f(x_i)] \end{aligned} \quad (1)$$

For $i = 1$, from (i) we have

$$\begin{aligned} & (x_1 - x_0)f''(x_0) + 2(x_2 - x_0)f''(x_1) + (x_2 - x_1)f''(x_2) \\ & = \frac{6}{(x_2 - x_0)}[f(x_2) - f(x_1)] + \frac{6}{(x_1 - x_0)}[f(x_0) - f(x_1)] \end{aligned}$$

with $x_0 = 1, x_1 = 3, x_2 = 6, f_0 = 4, f_1 = 5.5, f_2 = 7$, we have

$$\begin{aligned} & (3 - 1)f''(1) + 2(6 - 1)f''(3) + (6 - 3)f''(6) \\ & = \frac{6}{(6 - 1)}[7 - 5.5] + \frac{6}{(3 - 1)}[4 - 5.5]. \end{aligned}$$

For natural spline, $f''(1) = 0$. So above equation reduces to

$$10f''(3) + 3f''(6) = -2.7 \quad (2)$$

Similarly for $i = 2$, from (1) we have

$$(x_2 - x_1)f''(x_1) + 2(x_3 - x_1)f''(x_2) + (x_3 - x_2)f''(x_3)$$

$$= \frac{6}{(x_3 - x_2)}[f(x_3) - f(x_2)] +$$

$$+ \frac{6}{(x_2 - x_1)}[f(x_1) - f(x_2)]$$

with $x_1 = 3, x_2 = 6, x_3 = 8, f_1 = 5.5, f_2 = 7, f_3 = 9.5$, we get $(6 - 3)f''(3) + 2(8 - 3)f''(6) + (8 - 6)f''(8)$

$$= \frac{6}{(8 - 6)}[9.5 - 7] + \frac{6}{(6 - 3)}[5.5 - 7].$$

For natural spline $f''(8) = 0$. So above equation reduces to

$$3f''(3) + 10f''(6) = 4.5 \quad (3)$$

solving (2) and (3) we get

$$f''(3) = -0.4451, f''(6) = 0.58352$$

The equation of the cubic spline is

$$\begin{aligned} S_i = & \frac{f''(x_{i-1})}{6(x_i - x_{i-1})}(x_i - x)^3 + \frac{f''(x_i)}{6(x_i - x_{i-1})}(x - x_{i-1})^3 \\ & + \left[\frac{f(x_{i-1})}{(x_i - x_{i-1})} - \frac{f''(x_{i-1})(x_i - x_{i-1})}{6} \right] (x_i - x) \\ & + \left[\frac{f(x_i)}{(x_i - x_{i-1})} - \frac{f''(x_i)(x_i - x_{i-1})}{6} \right] (x - x_{i-1}) \end{aligned} \quad (4)$$

For $i = 1$,

$$\begin{aligned} S_1(x) = & \frac{f''(x_0)}{6(x_1 - x_0)}(x_1 - x)^3 + \frac{f''(x_1)}{6(x_1 - x_0)}(x - x_0)^3 \\ & + \left[\frac{f(x_0)}{x_1 - x_0} - \frac{f''(x_0)(x_1 - x_0)}{6} \right] (x_1 - x) \\ & + \left[\frac{f(x_1)}{x_1 - x_0} - \frac{f''(x_1)(x_1 - x_0)}{6} \right] (x - x_0) \end{aligned}$$

with $x_0 = 1, x_1 = 3, x_2 = 6, f_0 = 4, f_1 = 5.5, f_2 = 7, f''(1) = 0, f''(3) = -0.4451, f''(6) = 0.58352$ the above equation reduces to

$$S_1(x) = 0 + \frac{(-0.4451)}{6(3 - 1)}(x - 1)^3 +$$

32.52 — HIGHER ENGINEERING MATHEMATICS—VIII

$$+ \left[\frac{4}{(3-1)} - 0 \right] (3-x) \\ + \left[\frac{5.5}{(3-1)} - (-0.4451) \frac{(3-1)}{6} \right] (x-1) \quad (5)$$

Thus the cubic spline in the first interval [1, 3] is

$$S_1(x) = -0.0371(x-1)^3 + 2(3-x) + 2.898(x-1)$$

For $i = 2$, from (4) we get

$$S_2(x) = \frac{f''(x_1)}{6(x_2-x_1)}(x_2-x)^3 + \frac{f''(x_2)}{6(x_2-x_1)}(x-x_1)^3 \\ + \left[\frac{f(x_1)}{(x_2-x_1)} - \frac{f''(x_1)(x_2-x_1)}{6} \right] (x_2-x) \\ + \left[\frac{f(x_2)}{(x_2-x_1)} - \frac{f''(x_2)(x_2-x_1)}{6} \right] (x-x_1)$$

with the substitution of data, we get

$$S_2(x) = \frac{-0.4451}{6(6-3)}(6-x)^3 + \frac{0.58352}{6(6-3)}(x-3)^3 \\ + \left[\frac{5.5}{(6-3)} - \frac{(-0.4451)(6-3)}{6} \right] (6-x) \\ + \left[\frac{7}{6-3} - \frac{(0.58352)(6-3)}{6} \right] (x-3) \quad (6)$$

Thus the second cubic spline in the second interval [3, 6] is

$$S_2(x) = -0.02473(6-x)^3 + 0.03242(x-3)^3 \\ + (2.05588)(6-x) + (2.04154)(x-3)$$

Similarly for $i = 3$, from (4) we get

$$S_3(x) = \frac{f''(x_2)}{6(x_3-x_2)}(x_3-x)^3 + \frac{f''(x_3)}{6(x_3-x_2)} \\ + \left[\frac{f(x_2)}{(x_3-x_2)} - \frac{f''(x_2)(x_3-x_2)}{6} \right] (x_3-x) \\ + \left[\frac{f(x_3)}{(x_3-x_2)} - \frac{f''(x_3)(x_3-x_2)}{6} \right] (x-x_2)$$

with the given data

$$f_3(x) = \frac{0.58352}{6(8-6)}(8-x)^3 + 0 \\ + \left[\frac{7}{8-6} - \frac{0.58352}{6}(8-6) \right] (8-x) \\ + \left(\frac{8}{8-6} - 0 \right) (x-6)$$

Thus the third cubic spline in the 3rd interval [6, 8] is

$$S_3(x) = 0.04863(8-x)^3 + 3.3055(8-x) \\ + 4(x-6) \quad (7)$$

Now using (5), (6), (7), we get

$$f_1(2) = 4.8609$$

$$f_2(4) = 5.98788$$

$$f_3(7) = 7.35413$$

Since 4 is in the interval [3, 6] differentiate $f_2(x)$ to find $f'(4)$. So

$$f'_1(x) = +0.07419(6-x)^2 + 0.09726(x-3)^2 \\ - 2.05588 + 2.04154$$

Thus $f'(4) = 0.37968$

EXERCISE

1. Obtain the natural cubic spline approximation for the following data

$$\begin{array}{cccc} x: & 0 & 1 & 2 & 3 \\ f(x): & 1 & 2 & 33 & 244 \end{array}$$

Ans. $f_1(x) = -4x^3 + 5x + 1$ in $[0, 1]$
 $f_2(x) = 50x^3 - 162x^2 + 167x - 53$ in $[1, 2]$
 $f_3(x) = -46x^3 + 414x^2 - 985x + 715$ in $[2, 3]$

2. Fit a natural cubic spline to the following data

$$\begin{array}{cccc} x: & 1 & 2 & 3 & 4 \\ y: & 1 & 5 & 11 & 8 \end{array}$$

Hence compute $y(1.5)$, $y'(2)$

Ans. $y(1.5) = 103/40$, $y'(2.0) = 94/15$
 $f_1(x) = \frac{1}{15}[17x^3 - 51x^2 + 94x - 45]$ in $1 \leq x \leq 2$
 $f_2(x) = \frac{1}{15}[-55x^3 + 381x^2 - 770x + 531]$ in $2 \leq x \leq 3$
 $f_3(x) = \frac{1}{15}[38x^3 - 456x^2 + 1741x - 1980]$ in $3 \leq x \leq 4$

3. Fit a natural cubic spline and evaluate the spline at 0.66, 1.75.

$$\begin{array}{cccc} x: & 0.0 & 1.0 & 1.5 & 2.25 \\ f(x): & 2.000 & 4.4366 & 6.7134 & 13.9130 \end{array}$$

Ans. $f_1(x) = 0.3820(x - 0)^3 + 0(x - 0)^2 + 2.0546(x - 0) + 2.000$ in $[0, 1.0]$
 $f_2(x) = 3.1199(x - 1)^3 + 1.146(x - 1)^2 + 3.2005(x - 1) + 4.4366$ in $[1, 1.5]$
 $f_3(x) = -2.5893(x - 1.5)^3 + 5.8259(x - 1.5)^2 + 6.6866(x - 1.5) + 6.7134$ in $[1.5, 2.25]$
 $f_1(0.66) = 3.4659$ Exact: 3.4340
 $f_3(1.75) = 8.7087$ Exact: 8.4467
 Exact $f(x) = 2e^x - x^2$

4. Fit a natural cubic spline to the following data

$$\begin{array}{cccc} x: & 0 & 1 & 2 & 3 \\ y: & 0 & 0.5 & 2 & 1.5 \end{array}$$

Ans. $S_1(x) = 0.4x^3 + 0.1x$ in $0 \leq x \leq 1$
 $S_2(x) = -(x - 1)^3 + 1.2(x - 1)^2 + 1.3(x - 1) + 0.5$ in $1 \leq x \leq 2$
 $S_3(x) = 0.6(x - 2)^3 - 1.8(x - 2)^2 + 0.7(x - 2) + 2.0$ in $2 \leq x \leq 3$.

5. Fit a cubic natural spline

$$\begin{array}{cccc} x: & 0 & 1 & 2 \\ y: & 4 & 1 & 2 \end{array}$$

Ans. $s_1(x) = 4 - 4x + x^3$ in $[0, 1]$
 $s_2(x) = 1 - (x - 1) + 3(x - 1)^2 - (x - 1)^3$ in $[1, 2]$

6. Fit (a) linear spline (b) quadratic spline (c) cubic natural spline to the following data.

$$\begin{array}{cccccc} x: & 3.0 & 4.5 & 7.0 & 9.0 \\ y = f(x): & 2.5 & 1.0 & 2.5 & 0.5 \end{array}$$

Evaluate the function at $x = 5$.

- Ans. (a) Linear splines

$$\begin{aligned} f_1(x) &= 2.5 - (x - 3) \text{ in } [3, 4.5] \\ f_2(x) &= 1.0 + 0.6(x - 4.5) \text{ in } [4.5, 7] \\ f_3(x) &= 2.5 - 1(x - 7) \text{ in } [7, 9] \\ f_2(5) &= 1.3 \end{aligned}$$

- (b) Quadratic splines

$$\begin{aligned} f_1(x) &= -x + 5.5 \text{ in } [3, 4.5] \\ f_2(x) &= 0.64x^2 - 6.76x + 18.46 \text{ in } [4.5, 7.0] \\ f_3(x) &= -1.6x^2 + 24.6x - 91.3 \text{ in } [7.0, 9.0] \\ f_2(5) &= 0.66 \end{aligned}$$

- (c) Cubic natural splines

In $[3, 4.5]$

$$\begin{aligned} f_1(x) &= 0.193939(x - 3)^3 + 1.66667(4.5 - x) + 0.23030(x - 3) \\ f_2(x) &= 0.1163647(7 - x)^3 - 0.116364(x - 4.5)^3 - 0.327273(7 - x) + 1.727273(x - 4.5) \end{aligned}$$

in $[4.5, 7]$

$$\begin{aligned} f_3(x) &= -0.145455(9 - x)^3 + 1.831818(9 - x) + 0.25(x - 7) \text{ in } [7, 9] \\ f_2(5) &= 1.1255 \end{aligned}$$

7. Fit natural cubic splines for the following data.

$$\begin{array}{cccccc} x: & -10 & 0 & 10 & 20 & 30 \\ y: & .99815 & .99987 & .99973 & .99823 & .99567 \end{array}$$

- Ans. In $-10 \leq x \leq 0$.

$$\begin{aligned} f_1(x) &= -0.00000042(x + 10)^3 + 0.000214(x + 10) + .99815 \end{aligned}$$

In $0 \leq x \leq 10$

$$\begin{aligned} f_2(x) &= 0.00000024x^3 - 0.0000126x^2 + .000088x + .99987 \end{aligned}$$

In $10 \leq x \leq 20$

$$\begin{aligned} f_3(x) &= -0.00000004(x - 10)^3 - 0.000054(x - 10)^2 - 0.000092(x - 10) + .9973 \end{aligned}$$

In $20 \leq x \leq 30$

$$\begin{aligned} f_4(x) &= .00000022(x - 20)^3 - 0.0000066(x - 20)^2 - 0.000212(x - 20) + .99823 \end{aligned}$$

32.16 NUMERICAL METHODS IN LINEAR ALGEBRA: GAUSS-SEIDEL METHOD

Solutions to system of non-homogeneous linear equations in n unknowns can be obtained by direct (or reduction or elimination) methods such as Cramer's rule, matrix inversion method, Gaussian elimination, Gauss-Jordan method, Cholesky's (Crout's) method. The solutions can also be obtained by indirect (or iterative methods) which include the Gauss-Seidel method, (South Well's) relaxation method, Sweep method.

Diagonal:

A system of simultaneous linear equations is called a diagonal system if in each equation the coefficient of a different unknown is greater in absolute value than the sum of the absolute values of the other coefficients.

Usually, the large coefficient appears in the main diagonal position a_{ii} . Gauss-Seidel method is an iterative method which gives approximate solution by successive approximations. This method will always converge rapidly if the system is diagonal.

[illegible]

Note 2: Choice of initial value will not affect the solution (we get same solution) but will affect the number of iterations for convergence.

WORKED OUT EXAMPLES

$$\begin{bmatrix} 5 & -1 & 0 \\ -1 & 5 & -1 \\ 0 & -1 & 5 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 9 \\ 4 \\ -6 \end{bmatrix}$$
$$\left. \begin{aligned} x_1 &= \frac{9}{5} + \frac{1}{5}x_2 \\ x_2 &= \frac{4}{5} + \frac{1}{5}x_1 + \frac{1}{3}x_3 \\ x_3 &= -\frac{6}{5} + \frac{1}{5}x_2 \end{aligned} \right\} (*)$$
$$\begin{cases} x_1^{(3)} = \frac{9}{5} + \frac{1}{5}(1.0128) = 2.00256 \\ x_2^{(3)} = \frac{4}{5} + \frac{1}{5}(2.00256) - \frac{1}{3}(-0.99744) = 0.868032 \\ x_3^{(3)} = \frac{-6}{5} + \frac{1}{5}(.868032) = -1.0263936. \end{cases}$$

Similarly, we get at the 4th iteration $x_1^{(4)} = 2.002048$, $x_2^{(4)} = 1.0000829$, $x_3^{(4)} = -0.99998$

At 5th iteration: $x_1^{(5)} = 2.0000165$, $x_2^{(5)} = 1.0000073$, $x_3^{(5)} = -0.99999$

(b) Initial approximation: $x_1^{(0)} = \frac{9}{5}$, $x_2^{(0)} = \frac{4}{5}$, $x_3^{(0)} = \frac{-6}{5}$

1st iteration : 1.96, 0.952, -1.0096

2st iteration : 1.9904, 0.99616, -1.000768

3st iteration : 1.999232, 0.99969, -1.000064

4st iteration : 1.999938, 0.99997, 1.0000049

5st iteration : 1.999994, 0.99999, -1.0000004

Note 1: Exact solution is 2, 1, -1

EXERCISE

Solve the following system of equations by Gauss-Seidel method:

$$\begin{aligned} 1. \quad & 10x_1 + 8x_2 + 6x_3 = 16.4, \quad 10x_2 + 8x_3 + 4x_4 = -3.8, \quad 2x_1 + 10x_3 + 2x_4 = 36.9, \\ & x_1 + 6x_3 + 10x_4 = 30.9 \end{aligned}$$

Ans. $x_1 = 2.4$, $x_2 = -3.2$, $x_3 = 3$, $x_4 = 1.05$. At 6th iteration: $x_1 = 2.3721$, $x_2 = -3.19096$, $x_3 = 3.00525$, $x_4 = 1.049632$

$$2. \quad 8x_1 + x_2 - x_3 = 8, \quad 2x_1 + x_2 + 9x_3 = 12, \quad x_1 - 7x_2 + 2x_3 = -4.$$

Ans. $x_1 = 1$, $x_2 = 1$, $x_3 = 1$

$$3. \quad \text{Start with } (2, 2, -1) \text{ and solve } 5x_1 - x_2 + x_3 = 10, 2x_1 + 4x_2 = 12, x_1 + x_2 + 5x_3 = -1.$$

Ans. $x_1 = 2.5555$, $x_2 = 1.7222$, $x_3 = -1.0555$

$$4. \quad 10x_1 + x_2 + x_3 = 12, \quad 2x_1 + 10x_2 + x_3 = 13, \quad 2x_1 + 2x_2 + 10x_3 = 14.$$

Ans. $x_1 = 1$, $x_2 = 1$, $x_3 = 1$

$$5. \quad 10x_1 - 2x_2 - x_3 - x_4 = 3, \quad -2x_1 + 10x_2 - x_3 - x_4 = 15, \quad -x_1 - x_2 + 10x_3 - 2x_4 = 27, \quad -x_1 - x_2 - 2x_3 + 10x_4 = -9.$$

Ans. $x_1 = 1$, $x_2 = 2$, $x_3 = 3$, $x_4 = 0$

$$6. \quad 4x_1 + 2x_2 + x_3 = 11, \quad -x_1 + 2x_2 = 3, \quad 2x_1 + x_2 + 4x_3 = 16.$$

Ans. $x_1 = 1$, $x_2 = 2$, $x_3 = 3$

$$7. \quad 20x_1 + x_2 - 2x_3 = 17, \quad 3x_1 + 20x_2 - x_3 = -18, \quad 2x_1 - 3x_2 + 20x_3 = 25.$$

Ans. $x_1 = 1$, $x_2 = -1$, $x_3 = 1$.

$$8. \quad 3x_1 - 0.1x_2 - 0.2x_3 = 7.85, \quad 0.1x_1 + 7x_2 - 0.3x_3 = -19.3, \quad 0.3x_1 - 0.2x_2 + 10x_3 = 71.4.$$

Ans. $x_1 = 3$, $x_2 = -2.5$, $x_3 = 7$

$$9. \quad 27x_1 + 6x_2 - x_3 = 85, \quad 6x_1 + 15x_2 + 2x_3 = 72, \quad x_1 + x_2 + 54x_3 = 110.$$

Ans. $x_1 = 2.4255$, $x_2 = 3.5730$, $x_3 = 1.9260$

$$10. \quad x_1 - 8x_2 + 3x_3 = -4, \quad 2x_1 + x_2 + 9x_3 = 12, \quad 8x_1 + 2x_2 - 2x_3 = 8.$$

Ans. $x_1 = 1$, $x_2 = 1$, $x_3 = 1$.

32.17 LARGEST EIGEN VALUE AND THE CORRESPONDING EIGEN VECTOR: BY POWER METHOD

Bounds for eigen values λ of an arbitrary n rowed square matrix $A = (a_{jk})$ are given by circular disks from **Gershgorin theorem**

$$|a_{kk} - \lambda| \leq |a_{k1}| + |a_{k2}| + \cdots + |a_{k,k-1}| + |a_{k,k+1}| + \cdots + |a_{kn}|$$

for some k where $1 \leq k \leq n$. Thus all the eigen values lie within these n circular disks (some may be identical) with centres at the diagonal elements a_{kk} and radii equal to the sum of the absolute values of the elements of the k th row baring a_{kk} (except a_{kk}).

Ex: $A = \begin{pmatrix} 5 & 1 \\ 1 & 5 \end{pmatrix}$, eigen values 4, 6. Gershgorin circular disks : 2 : centres 5, 5, radii 1, 1.

Fig. 32.18

However, to find the approximate values of all the eigen values and eigen vectors, iteration method or power method is used. Power method is particularly used when only the largest and/or the smallest eigen

values of a matrix are desired. The advantage of this method is that the eigen vector associated with the largest eigen value is also obtained simultaneously. Also the intermediate (remaining) eigen values can also be found, after “sweeping” the already found largest and/or smallest eigen values.

Power Method

Let $\lambda_1, \lambda_2, \dots, \lambda_n$ be the eigen values and $V_1, V_2, \dots, V_n$ be the corresponding eigen vectors of a n -rowed square matrix A . Assume that λ_1 is the absolutely largest eigen value of A i.e.,

$$|\lambda_1| > |\lambda_2| \geq |\lambda_3| \geq \dots \geq |\lambda_n|.$$

Consider $V = \alpha_1 V_1 + \alpha_2 V_2 + \dots + \alpha_n V_n$ where $\alpha_1, \alpha_2, \dots, \alpha_n$ are scalars. Then

$$\begin{aligned} AV &= \alpha_1 AV_1 + \alpha_2 AV_2 + \dots + \alpha_n AV_n \\ &= \alpha_1 \lambda_1 V_1 + \alpha_2 \lambda_2 V_2 + \dots + \alpha_n \lambda_n V_n \end{aligned}$$

Pre multiplying by A

$$A^2 V = \alpha_1 \lambda_1^2 V_1 + \alpha_2 \lambda_2^2 V_2 + \dots + \alpha_n \lambda_n^2 V_n.$$

Thus for any positive integer p

$$\begin{aligned} A^p V &= \alpha_1 \lambda_1^p V_1 + \alpha_2 \lambda_2^p V_2 + \dots + \alpha_n \lambda_n^p V_n \\ A^p V &= \lambda_1^p \left[\alpha_1 V_1 + \alpha_2 \left(\frac{\lambda_2}{\lambda_1} \right)^p V_2 + \dots + \alpha_n \left(\frac{\lambda_n}{\lambda_1} \right)^p V_n \right] \end{aligned}$$

provided $\alpha_1 \neq 0$. All terms in R.H.S. except the first term have limit zero since λ_1 is the dominant value and p is large.

Now

$$\frac{A^{p+1} V}{A^p V} = \frac{\lambda_1^{p+1} \cdot \alpha_1 V_1}{\lambda_1^p \alpha_1 V_1} = \lambda_1$$

Also the required eigen vector corresponding to this largest eigen value is

$$\lambda_1^{-p} A^p V = \alpha_1 V_1.$$

Power method procedure

Step I: Choose an arbitrary real vector $x_0 \neq 0$. Generally, X_0 is chosen as

$$X_0 = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

or any other value like $X_0 = [10000]^T$ etc.

Step II: Compute $X_1 = AX_0, X_2 = AX_1, X_3 = AX_2, \dots, X_s = AX_{s-1}$. Put $X = X_{s-1}, Y = X_s$

Step III: Compute $m_0 = x^T x, m_1 = x^T y, m_2 = y^T y$

Step IV: Largest eigen value $= \lambda_1 = \frac{m_1}{m_0}$,

ϵ , the error in $\lambda_1 : |\epsilon| \leq \sqrt{\frac{m_2}{m_0} - \lambda_1^2}$,

Eigen vector corresponding to λ_1 is $Y = X_s$.

[This eigen vector can be normalized either by dividing the eigen vector by the magnitude of its first component or by its largest component or by normalizing to a unit length.]

Determination of Smallest Eigen Value

$$AX = \lambda X$$

$$A^{-1}AX = A^{-1}\lambda X$$

$$\frac{1}{\lambda}X = A^{-1}X$$

Thus if λ is eigen value of A , then the reciprocal $\frac{1}{\lambda}$ is the eigen value of A^{-1} . Then the reciprocal of the largest eigen value of A^{-1} will be the smallest eigen value of A .

Procedure:

Step I: Determine A^{-1}

Step II: Calculate λ^* dominant eigen value of A^{-1}

Step III: $\frac{1}{\lambda^*}$ is the smallest eigen value of A .

Determination of Intermediate (remaining) Eigen Values

$$Ax = \lambda x$$

$$(A - \lambda_1 I)x = (\lambda - \lambda_1)x$$

Then $(\lambda - \lambda_1)$ is an eigen value of $(A - \lambda_1 I)$. Thus ‘sweeping’ the dominant eigen value, $(A - \lambda_1 I)$ will have remaining eigen values dominant, say λ_2 which can be found by power method.

WORKED OUT EXAMPLES

Example 1: Find the largest eigen value and the corresponding eigen vector of the matrix

$$A = \begin{bmatrix} -2 & 0 & -1 \\ 1 & -1 & 1 \\ 2 & 2 & 0 \end{bmatrix}$$

Find the error in the value of the largest eigen value.

Solution: Choose the initial vector $X_0 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$,

$$\text{Then } X_1 = AX_0 = \begin{bmatrix} -2 & 0 & -1 \\ 1 & -1 & 1 \\ 2 & 2 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} -3 \\ 1 \\ 4 \end{bmatrix}.$$

$$\text{Now } X_2 = AX_1 = \begin{bmatrix} -2 & 0 & -1 \\ 1 & -1 & 1 \\ 2 & 2 & 0 \end{bmatrix} \begin{bmatrix} -3 \\ 1 \\ 4 \end{bmatrix} = \begin{bmatrix} 2 \\ 0 \\ -4 \end{bmatrix}.$$

$$\text{Then } X_3 = AX_2 = \begin{bmatrix} -2 & 0 & -1 \\ 1 & -1 & 1 \\ 2 & 2 & 0 \end{bmatrix} \begin{bmatrix} 2 \\ 0 \\ -4 \end{bmatrix} = \begin{bmatrix} 0 \\ -2 \\ 4 \end{bmatrix}.$$

continuing these iterations, we get

$$X_4 = AX_3 = \begin{bmatrix} -4 \\ 6 \\ -4 \end{bmatrix}, \quad X_5 = AX_4 = \begin{bmatrix} 12 \\ -14 \\ 4 \end{bmatrix},$$

$$X_6 = AX_5 = \begin{bmatrix} -28 \\ 30 \\ -4 \end{bmatrix}, \quad X_7 = AX_6 = \begin{bmatrix} 60 \\ -62 \\ 4 \end{bmatrix},$$

$$X_8 = AX_7 = \begin{bmatrix} -124 \\ 126 \\ -4 \end{bmatrix} \text{ and } X_9 = AX_8 = \begin{bmatrix} 252 \\ -254 \\ 4 \end{bmatrix}.$$

Put $X = X_8$ and $Y = X_9$. Then

$$m_0 = X^T X = [-124 \ 126 \ -4] \begin{bmatrix} -124 \\ 126 \\ -4 \end{bmatrix} = 31268$$

$$m_1 = X^T Y = [-124 \ 126 \ -4] \begin{bmatrix} 252 \\ -254 \\ 4 \end{bmatrix} = -63268$$

$$m_2 = Y^T Y = [252 \ -254 \ 4] \begin{bmatrix} 252 \\ -254 \\ 4 \end{bmatrix} = 128036.$$

$$\text{The largest eigen value} = \lambda_1 = \frac{m_1}{m_0} = \frac{-63268}{31268}$$

$$\lambda_1 = -2.0234105$$

(at the 9th iteration).

The corresponding eigen vector is

$$X_9 = \begin{bmatrix} 252 \\ -254 \\ 4 \end{bmatrix} \quad \text{or} \quad X_9 = \begin{bmatrix} 1 \\ -1.007936 \\ 0.0015 \end{bmatrix}$$

The error in the largest eigen value is ϵ

$$\begin{aligned} |\epsilon| &\leq \sqrt{\frac{m_2}{m_0} - \lambda_1^2} = \sqrt{\frac{128036}{31268} - (-2.023415)^2} \\ &= \sqrt{4.094793 - 4.094208} = \sqrt{0.00058473} \\ &= 0.02418. \end{aligned}$$

Note that the exact three eigen values of A are $-2, -1, 0$.

Example 2: Find the absolutely smallest eigen value of the matrix

$$A = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{bmatrix}$$

Solution: We know that if λ is an eigen value of A then the reciprocal $\frac{1}{\lambda}$ is the eigen value of A^{-1} . Thus the largest eigen value of A^{-1} is the smallest eigen value of A .

Choose $X_0 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$ and apply power method, for

A^{-1} . Now

$$B = A^{-1} = \frac{1}{4} \begin{bmatrix} 3 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 3 \end{bmatrix}$$

$$X_1 = BX_0 = \frac{1}{4} \begin{bmatrix} 3 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 3 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \frac{1}{4} \begin{bmatrix} 6 \\ 8 \\ 6 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 3 \\ 4 \\ 3 \end{bmatrix}.$$

$$X_2 = B^2 X_0 = \frac{1}{4} \begin{bmatrix} 3 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 3 \end{bmatrix} \frac{1}{2} \begin{bmatrix} 3 \\ 4 \\ 3 \end{bmatrix} = \frac{1}{8} \begin{bmatrix} 20 \\ 28 \\ 20 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 5 \\ 7 \\ 5 \end{bmatrix}$$

$$X_3 = BX_2 = B^3 X_0 = \frac{1}{4} \begin{bmatrix} 3 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 3 \end{bmatrix} \frac{1}{2} \begin{bmatrix} 5 \\ 7 \\ 5 \end{bmatrix}$$

$$\begin{aligned}
 &= \frac{1}{8} \begin{bmatrix} 34 \\ 48 \\ 34 \end{bmatrix} = \frac{1}{4} \begin{bmatrix} 17 \\ 24 \\ 17 \end{bmatrix} \\
 X_4 &= B^4 X_0 = \frac{1}{4} \begin{bmatrix} 3 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 3 \end{bmatrix} \frac{1}{4} \begin{bmatrix} 17 \\ 24 \\ 17 \end{bmatrix} \\
 &= \frac{1}{16} \begin{bmatrix} 116 \\ 260 \\ 116 \end{bmatrix} = \frac{1}{16} \begin{bmatrix} 116 \\ 164 \\ 116 \end{bmatrix} \\
 X_4 &= \frac{1}{4} \begin{bmatrix} 29 \\ 41 \\ 29 \end{bmatrix},
 \end{aligned}$$

$$X_5 = B X_4 = \frac{1}{4} \begin{bmatrix} 3 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 3 \end{bmatrix} \frac{1}{4} \begin{bmatrix} 29 \\ 41 \\ 29 \end{bmatrix} = B^5 X_0$$

$$X_5 = \frac{1}{16} \begin{bmatrix} 198 \\ 280 \\ 198 \end{bmatrix}.$$

$$X_6 = B X_5 = B^6 X_0 = \frac{1}{64} \begin{bmatrix} 1352 \\ 1912 \\ 1352 \end{bmatrix} = \frac{1}{8} \begin{bmatrix} 169 \\ 239 \\ 169 \end{bmatrix}$$

Put $X = X_5$, $Y = X_6$, $m_0 = X^T X = \frac{1}{64} \cdot (39202)$
 $m_1 = x^T y = \frac{1}{64} (66922)$.

Then the largest eigen value of B is $\frac{m_1}{m_0} = 1.70710$

The reciprocal $\frac{1}{1.70710} = 0.58578$ is the smallest eigen value of A .

Example 3: Find the bounds for eigen values of A .

where $A = \begin{bmatrix} 1 & 0 & -1 \\ 1 & 2 & 1 \\ 2 & 2 & 3 \end{bmatrix}$.

Solution: The bounds for eigen values are given by

three Gershgorin circular disks c_1, c_2, c_3

c_1 : centre 1 and radius $|0| + |-1| = 1$,

c_2 : centre 2 and radius $1 + 1 = 2$

c_3 : centre 3 and radius $2 + 2 = 4$

The actual eigen values 1, 2, 3 of A lies within these three circular disks c_1, c_2 and c_3 .

Fig. 32.19

(Ex. 1 to 5)

1. $A = \begin{bmatrix} 2 & 2 & 1 \\ 1 & 3 & 1 \\ 1 & 2 & 2 \end{bmatrix}$

Hint: $X_0 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$, $X_1 = A X_0 = \begin{bmatrix} 5 \\ 5 \\ 5 \end{bmatrix} = 5 \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$,

$X_2 = 25 \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$, $X_3 = 125 \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$, $X_4 = 625 \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$,

$X_5 = 3125 X_0$, $X_6 = 15625 X_0$, $X_7 = 78125 X_0$.

Put $m_0 = X_6$, $m_1 = X_7$, $\lambda_1 = \frac{m_1}{m_0} =$

$\frac{(12625)(78125)(3)}{(15625^2)(3)} = 5$, $\frac{m_2}{m_0} = 25$, $|\epsilon| = 0$

Ans. 5 (Actual eigen values are 1, 1, 5)

2. $\begin{bmatrix} -3 & 2 & 1 \\ 1 & -2 & 1 \\ 1 & 2 & -3 \end{bmatrix}$

Hint: $X_0 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$, $X_1 = \begin{bmatrix} -3 \\ 1 \\ 1 \end{bmatrix}$, $X_2 = \begin{bmatrix} 12 \\ -4 \\ -4 \end{bmatrix}$,

$X_3 = \begin{bmatrix} -48 \\ 16 \\ 16 \end{bmatrix}$, $X_4 = \begin{bmatrix} 192 \\ -64 \\ -64 \end{bmatrix}$, $m_2 = 45056$,

$m_1 = -11264$, $m_0 = 2816$, $\frac{m_2}{m_0} = 16$, $\frac{m_1}{m_0} = \lambda_1 = -4$, $|\epsilon| = 0$

Ans. -4

3. $A = \begin{bmatrix} 1 & 0 & -1 \\ 1 & 2 & 1 \\ 2 & 2 & 3 \end{bmatrix}$

EXERCISE

Find the largest eigen value of the matrix A and the error in the largest eigen value $|\epsilon| \leq \sqrt{\frac{m_2}{m_0} - \lambda_1^2}$.

$$\text{Hint: } X_1 = \begin{bmatrix} 0 \\ 4 \\ 7 \end{bmatrix}, X_2 = \begin{bmatrix} -7 \\ 15 \\ 29 \end{bmatrix}, X_3 = \begin{bmatrix} -36 \\ 52 \\ 103 \end{bmatrix}, \\ X_4 = \begin{bmatrix} -139 \\ 171 \\ 341 \end{bmatrix}, X_5 = \begin{bmatrix} -480 \\ 544 \\ 1087 \end{bmatrix}, X_6 = \begin{bmatrix} -1567 \\ 1695 \\ 3389 \end{bmatrix}.$$

$m_2 = 16813835$, $m_1 = 5358083$, $m_0 = 1707905$, $q = \frac{m_1}{m_0}$. Exact eigen values are 1, 1, 3.

Ans. 3.131722.

$$4. A = \begin{bmatrix} 2 & 0 & 1 & 0 \\ 0 & 0 & 3 & 1 \\ 1 & 3 & 4 & -2 \\ 0 & 1 & -2 & 0 \end{bmatrix}$$

Hint: $X_1 = [3 \ 4 \ 6 \ -1]^T$, $X_2 = [12 \ 17 \ 41 \ -8]^T$, $X_3 = [65 \ 115 \ 243 \ -65]^T$, $m_2 = 80724$, $m_1 = 13218$, $m_0 = 2178$, $|\epsilon| = 0.48184$.

Ans. 6.0688705

$$5. A = \begin{bmatrix} 9 & 10 & 8 \\ 10 & 5 & -1 \\ 8 & -1 & 3 \end{bmatrix}$$

Hint:

$$X_1 = [27 \ 14 \ 10]^T, X_2 = [463 \ 330 \ 232]^T,$$

$$X_3 = [9323 \ 6048 \ 4070]^T,$$

$$X_4 = [176947 \ 119400 \ 80746]^T$$

$$X_5 = [3432491 \ 2285724 \ 1538414]^T$$

$$X_6 = [66056971 \ 44215116 \ 29789446]$$

$$X_7 = [1.2749 \times 10^9, 8.5185 \times 10^8, 5.7360 \times 10^8]$$

$$m_0 = 7.2059 \times 10^{15}, m_1 = 1.3896 \times 10^{17}.$$

Ans. 19.284197

6. Determine the largest eigen value and the corresponding eigen vector of the matrix

$$A = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{bmatrix}$$

Hint: $x_0 = [1 \ 0 \ 0]^T$, $X_1 = [1, -0.5 \ 0]^T$, $X_2 = 2.8[1 \ -1 \ .43]^T$, $X_3 = 3.43[.87 \ -1 \ 0.54]^T$, $X_4 = 3.41[.8 \ -1 \ .61]^T$, $X_5 = 3.41[.76 \ -1 \ .65]^T$, $X_6 = 3.41[.74 \ -1 \ .67]^T$

Ans. 3.41, $[0.74, -1, 0.67]^T$

7. Find the largest eigen value and the corresponding eigen vector of the matrix A where

$$A = \begin{bmatrix} 4 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 1 \end{bmatrix}$$

Hint: $[1 \ 1 \ 1]$, $[5 \ 4 \ 2]$, $[24 \ 15 \ 6]$, $[111 \ 60 \ 21]$, $[504 \ 252 \ 81]$, $[2268 \ 1089 \ 333]$, $[10161 \ 4779 \ 1492]$, $[45433, 21141, 6201]$, $[202833, 93906, 27342]$, $[905238, 417987, 121248]$, $[4038939, 1862460, 539235]$.

Ans. 4.46, $[0.9 \ 0.42 \ .12]^T$

$$8. A = \begin{bmatrix} 1 & 2 & 0 \\ 2 & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix}$$

Ans. 3.0, $[1 \ 1 \ 0]$

$$9. A = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix}$$

Hint: Exact value: 4, $[\frac{2}{3} \ 1]^T$

Ans. 3.987, $[.668 \ 1]^T$

$$10. A = \begin{bmatrix} 1 & 6 & 1 \\ 1 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$$

Hint: $X_0 = [1 \ 0 \ 0]$, $X_1 = [1 \ 1 \ 0]$, $X_2 = 3[2.3 \ 1 \ 0]$, $X_3 = 4[2.1 \ 1.1 \ 0]$, $X_4 = 4[2.2 \ 1.1 \ 0]$, $X_5 = 4.4[2 \ 1 \ 0]$, $X_6 = 4[2 \ 1 \ 0]$, $X_7 = 4[2 \ 1 \ 0]$.

Ans. 4, $[2 \ 1 \ 0]^T$

11. Determine the bounds for the eigen values of the matrix A where

$$(a) A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$$

Ans. $\lambda = 0$; Circles c_1, c_2 ; centres 0, 0 and radii 1, 0 respectively.

$$(b) A = \begin{bmatrix} 3 & 4 \\ 4 & -3 \end{bmatrix}$$

32.60 — HIGHER ENGINEERING MATHEMATICS—VIII

Ans. $\lambda = \pm 5$; centres: 3, -3; radii 4, 4 respectively

$$(c) A = \begin{bmatrix} 6 & 0 & -3 \\ 0 & 6 & 3 \\ -3 & 3 & 2 \end{bmatrix}$$

Ans. $\lambda = 6, 4 \pm \sqrt{22} = 6, 8.6904, -0.6904$
circular disks with centres at 6, 6, 2 and
radii $|-3|, 3, |-3| + 3$ respectively.

$$(d) A = \begin{bmatrix} 26 & -2 & 2 \\ 2 & 21 & 4 \\ 4 & 2 & 28 \end{bmatrix}$$

Ans. $\lambda = 30, 25, 20$; circles: centers 26, 21, 28
radii: $|-2| + 2, 2 + 4, 4 + 2$.

Chapter 33

Numerical Solutions of ODE and PDE

INTRODUCTION

Analytical solutions can be obtained only for selected class of ODE & PDE, using series solutions, Laplace transform, Fourier transform, separation of variables technique etc. For certain problems, analytical solutions can not be obtained. However numerical solutions can be obtained to the desired degree of accuracy using computers, in all the above cases. The advantage is that numerical solutions can be obtained for problems involving irregularly shaped boundaries and is easy to program on computer. The only serious disadvantage with these numerical solutions is that they lack the generality of the analytical solutions. When the initial conditions are changed, the numerical solution must be calculated again. Taylor's series, Picard's, Modified Euler's, Runge-Kutta 4th order, Milne's predictor-corrector and Adame-Bashforth-Milne's methods for solution of first order ODE are considered in this chapter. Numerical solutions of PDE: one dimensional heat equation, wave equation and two-dimensional Laplace's equation are studied.

33.1 NUMERICAL SOLUTIONS OF FIRST ORDER ORDINARY DIFFERENTIAL EQUATIONS

Differential equation is the most important mathematical model for physical phenomena such as the motion of objects, fluids, heat flow, bending and cracking of materials, vibrations, chemical reactions.

Since an n th order D.E. can in general, be reduced to a system of n first order D.E., in essence, it would be sufficient to examine a first order O.D.E.

$$\frac{dy}{dx} = f(x, y) \quad (1)$$

together with an initial condition (I.C.)

$$y(x_0) = y_0 \quad (2)$$

Numerical solutions of first order O.D.E. (1) plays a vital role, since analytical solutions of (1) are rare (except in standard forms).

Taylor's Series Method

Consists of expanding the function $y(x)$ in powers of $(x - x_0)$:

$$y(x) = y(x_0) + y'(x_0) \cdot (x - x_0) + \frac{y''(x_0)}{2!}(x - x_0)^2 + \frac{y'''(x_0)}{3!}(x - x_0)^3 + \dots + \frac{y^{(n)}(x_0)}{n!}(x - x_0)^n + \dots \quad (3)$$

In (3), $y(x_0)$ is known from I.C. (2). The remaining coefficients $y'(x_0)$, $y''(x_0)$, $\dots$, $y^{(n)}(x_0)$ etc. are obtained by successively differentiating (1) and evaluating at x_0 . Substituting these values in (3), $y(x)$ at any point can be calculated from (3), provided $h = x - x_0$ is small.

When $x_0 = 0$, then Taylor's series (3) takes simpler form

$$y(x) = y(0) + y'(0) \cdot x + \frac{y''(0)}{2!} \cdot x^2 + \dots + \frac{y^{(n)}(0)}{n!} \cdot x^n + \dots \quad (4)$$

Modified Euler's Method

For small changes Δx in x , the change in y is $\Delta y \approx \frac{dy}{dx} \Delta x$. Thus

$$f(y + \Delta y) - f(y) = \Delta y = \frac{dy}{dx} \Delta x.$$

Using $\frac{dy}{dx} = f(x, y)$ at (x_i, y_i) , we have

$$y'_i = f(x_i, y_i) \quad (5)$$

$$\boxed{\tilde{y}_{i+1} = y_i + h f(x_i, y_i)} \quad \text{Predictor} \quad (6)$$

Equation (6) is known as *Euler's method*. Using (5) as a predictor equation find

$$\tilde{y}'_{i+1} = f(x_{i+1}, \tilde{y}_{i+1}). \quad (7)$$

Using the average of the slopes (5) and (7), we get

$$y_{i+1} = y_i + \frac{y'_i + \tilde{y}'_{i+1}}{2}.$$

$$\boxed{y_{i+1} = y_i + h \frac{f(x_i, y_i) + f(x_{i+1}, \tilde{y}_{i+1})}{2}} \quad \text{Corrector} \quad (8)$$

Fig. 33.1

The Equation (8) is known as the corrector equation. Thus the method using the predictor (6) and corrector (8) is known as the *modified Euler's method* or Heun's method or Euler-Cauchy method or Euler-Trapezoidal method or improved Euler method or Euler's predictor-corrector method.

Runge-Kutta 4th Order Method

The one-step methods like Taylor series method, Euler's method or modified Euler's method evaluate y at a pivota point x_i , thus giving the starting values for the multi-step methods which use recurrence equations, at these preceding pivotal points. Runge-Kutta method is another one such one-step (or single step) method, which is also self-starting like

the Taylor's Euler's, methods. Runge-Kutta methods achieves the accuracy of a Taylor series method without requiring the calculation of higher derivatives. A two parameter h, k family of formulas of fourth order accuracy are known as Runge-Kutta fourth order method and are given by the following formulae:

$$y_{i+1} = y_i + \frac{1}{6}(k_1 + 2k_2 + 2k_3 + k_4) \quad (9)$$

where

$$\left. \begin{aligned} k_1 &= h f(x_i, y_i) \\ k_2 &= h f\left(x_i + \frac{h}{2}, y_i + \frac{k_1}{2}\right) \\ k_3 &= h f\left(x_i + \frac{h}{2}, y_i + \frac{k_2}{2}\right) \\ k_4 &= h f(x_i + h, y_i + k_3) \end{aligned} \right\} \quad (10)$$

Note: When f is independent of y , (9) reduce's to Simpson's $\frac{1}{3}$ rule,

$$\left(\frac{h}{2}\right) \frac{1}{3} \left[f(x_i) + 4f\left(x_i + \frac{h}{2}\right) + f(x_i + h) \right].$$

The only disadvantage with R-K method is the repeated evaluation of function $f(x, y)$ at several points.

Milne's Predictor-Corrector Method

Is a multi-step method which uses the previously calculated four values of the dependent variable y and its derivative y' in the subsequent steps. Integrating

$$\int_{x_{n-3}}^{x_{n+1}} \frac{dy}{dx} dx = \int_{x_{n-3}}^{x_{n+1}} f(x, y) dx$$

where R.H.S. is evaluated by Simpson's $\frac{1}{3}$ rule for the extended interval x_{n-2} to x_n to x_{n-3} to x_{n+1} .

$$y_{n+1} - y_{n-3} = \frac{4h}{3} (2y'_{n-2} - y'_{n-1} + 2y'_n) \quad \text{or}$$

$$y_{n+1} = y_{n-3} + \frac{4h}{3} (2y_{n-2}^i - y_{n-1}^i + 2y_n^i) \quad (11)$$

(11) is known as the predictor formula. Using (11), calculate $y_{n+1}^i = f(x_{n+1}, y_{n+1}^i)$. Integrating between x_{n-1} to x_{n+1} using Simpson's $\frac{1}{3}$ rule.

$$y_{n+1} = y_{n-1} + \frac{h}{3} (y_{n-1}^i + 4y_n^i + y_{n+1}^i) \quad (12)$$

(12) is known as the corrector formula. The next pair of values y_{n+2}, y_{n+2}^i are obtained in a similar way first using (11) to find y_{n+2} , then y_{n+2}^i by $f(x_{n+2}, y_{n+2})$.

With this value the corrector value of y_{n+2} is obtained from (12).

WORKED OUT EXAMPLES

Taylor's series method

Example 1: Using Taylor series expansion evaluate the integral of $y' - 2y = 3e^x$, $y(0) = 0$ at (a) $x = 0.1(0.1)0.3$; (b) $x = 1.0$; 1.1.

Solution: Rewriting $y' = 2y + 3e^x$, $y(0) = 0$. Differentiating and evaluating at $x = 0$,

$$y'(0) = 2y(0) + 3e^0 = 2 \cdot 0 + 3 \cdot 1 = 3$$

$$y'' = 2y' + 3e^x, \quad y''(0) = 2y'(0) + 3 = 2 \cdot 3 + 3 = 9$$

$$y''' = 2y'' + 3e^x, \quad y'''(0) = 2y''(0) + 3 = 2 \cdot 9 + 3 = 21$$

$$y'''' = 2y''' + 3e^x, \quad y''''(0) = 2y'''(0) + 3 = 2 \cdot 21 + 3 = 45$$

$$y''''' = 2y'''' + 3e^x, \quad y'''''(0) = 2y''''(0) + 3 = 2 \cdot 45 + 3 = 93$$

In general,

$$y^{(n+1)}(x) = 2y^{(n)}(x) + 3e^x \text{ or } y^{(n+1)}(0) = 2y^{(n)}(0) + 3.$$

The Taylor's series expansion of $y(x)$ about 0 is

$$\begin{aligned} y(x) = & y(0) + xy'(0) + x^2 \frac{y''(0)}{2!} + x^3 \frac{y'''(0)}{3!} \\ & + x^4 \frac{y''''(0)}{4!} + x^5 \frac{y'''''(0)}{5!} + \dots \end{aligned}$$

$$y(0.1) = 3(0.1) + 4.5(0.1)^2 + 3.5(0.1)^3 + \frac{15}{8}(0.1)^4 + \frac{31}{40}(0.1)^5$$

$$y(0.1) = 0.34869$$

Similarly, put $x = 0.2$ in (1)

$$\begin{aligned} y(0.2) &= 0.6 + 0.18 + 0.028 + 0.003 + 0.000248 \\ &= 0.811244. \end{aligned}$$

$$\begin{aligned} y(0.3) &= 0.9 + 0.405 + .0945 + .015187 + .0018832 \\ &= 1.4165702 \end{aligned}$$

Put $x = 1$ in (1)

$$y(1) = 3 + \frac{9}{2} + \frac{7}{2} + \frac{15}{8} + \frac{31}{40} = 13.65$$

Put $x = 1.1$ in (1)

$$y(1.1) = 3.3 + 5.445 + 4.6585 + 2.745 + 1.248 = 17.39.$$

Modified Euler's method

Example 2: Intensity of radiation is directly proportional to the amount of remaining radioactive substance. The DE is $y' = -ky$, where $k = 0.01$, $t_0 = 0$, $y_0 = 100$ g. Determine how much substance will remain at the moment $t = 100$ sec. Find the solution by (a) Euler's method, (b) Modified Euler's method with $h = 25$.

Solution: Here $h = 25$, $f(t, y) = -ky$, $f(t, y) = -0.01y$, since $\frac{dy}{dt} = f(t, y) = -ky$. (a) Euler's method (see Table 33.1).

Table 33.1 Euler's method

| t | y_i | $f_i = f(t_i, y_i)$ | $\Delta y_i = hf_i$ | $y_{i+1} = y_i + \Delta y_i$ |
|-----|-----------|---------------------|---------------------|-----------------------------------|
| 0 | 100 | -1 | -25 | $100 + (-25) = 75$ |
| 25 | 75 | -0.75 | -18.75 | $75 - 18.75 = 56.25$ |
| 50 | 56.25 | -0.5625 | -14.0625 | $56.25 - 14.0625 = 42.1875$ |
| 75 | 42.1875 | -0.421875 | -10.546875 | $42.1875 - 10.546875 = 31.640625$ |
| 100 | 31.640625 | | | |

Substituting the values of $y'(0)$, $y''(0)$, ...

$$y(x) = 0 + 3x + \frac{9}{2}x^2 + \frac{21}{6}x^3 + \frac{45}{24}x^4 + \frac{93}{120}x^5 + \dots$$

$$y(x) = 3x + 4.5x^2 + 3.5x^3 + \frac{15}{8}x^4 + \frac{31}{40}x^5 + \dots \quad (1)$$

Now put $x = 0.1$ in (1)

(b) Modified Euler's method: $h = 25$, $f(t, y) = -0.01y$ (see Table 33.2).

= 78.125 |
| 25 | 78.125 | -0.78125 | $78.125 + 25(-0.78)$
= 58.59 | $(-0.01)(58.59)$
= -0.5859 | $\frac{25}{2}(-0.78 - 0.59)$
= -17.09 | $78.125 - 17.09$
= 61.034 |
| 50 | 61.034 | -0.61 | 45.7755 | -0.4578 | -13.35 | 47.68 |
| 75 | 47.68 | -0.4768 | 35.76 | -0.3576 | -10.43 | 37.25 |
| 100 | 37.25 | | | | | |

Note: Exact solution: $y = 100e^{-kt}$, At $t = 100$, $y = 36.7879$.

$y(0) = 1.5$ on $[0, 1]$.

Solution: Here choose $h = 0.2$ given $f(x, y) = y - x$, $x_0 = 0$, $y_0 = 1.5$.
See Table 33.3 on p. 33.5.

Milne's predictor-corrector method

Example 4: Using Milne's predictor-corrector method evaluate the integral of $y' - 4y = 0$ at $x = 0.4$, 0.5 given that $y(0) = y_0 = 1$, $y_1 = y(0.1) = 1.492$, $y_2 = y(0.2) = 2.226$, $y_3 = y(0.3) = 3.320$.

Solution: Here $\frac{dy}{dx} = 4y$, so $f(x, y) = y' = 4y$, $h = 0.1$, $x_0 = 0$, $x_1 = 0.1$, $x_2 = 0.2$, $x_3 = 0.3$, $x_4 = 0.4$, $x_5 = 0.5$.

Predictor: $y_{n+1} = y_{n-3} + \frac{4h}{3}(2y_{n-2}^i - y_{n-1}^i + 2y_n^i)$

with $n = 3$,

$$y_4 = y_0 + \frac{4h}{3}(2y_1^i - y_2^i + 2y_3^i).$$

Here $h = 0.1$, $y_0 = 1$, $y_1^i = 4y_1 = 4(1.492) = 5.968$.

$$y_2^i = 4y_2 = 4(2.226) = 8.904, y_3^i = 4y_3 = 4(3.32) = 13.28$$

$$\therefore y_4 = y(x_4) = y(0.4) = 1 + \frac{4(0.1)}{3}[2(5.968) - 8.904 + 2(13.28)]$$

$$y_4 = 1 + \frac{4(0.1)}{3}(29.592) = 1 + 3.9456 = 4.9456$$

$$\text{So } y_4^i = 4y_4 = 4(4.9456) = 19.7824$$

Corrector

$$y_{n+1} = y_{n-1} + \frac{h}{3}(y_{n-1}^i + 4y_n^i + y_{n+1}^i)$$

with $n = 3$,

$$y_4 = y_2 + \frac{h}{3}(y_2^i + 4y_3^i + y_4^i)$$

$$\therefore y_4 = y(x = 0.4) = 2.226 + \frac{0.1}{3}(2.226 + 4(13.28) + 19.7824)$$

$$y_4 = 2.226 + 2.72688 = 4.95288$$

with $n = 4$, predictor

$$y_5 = y_1 + \frac{4h}{3}[2y_2^i - y_3^i + 2y_4^i]$$

Since $y' = 4y$, $y_i^i = 4y_i$

$$\begin{aligned} y_5 &= 1.492 + \frac{4(0.1)}{3}4[2y_2 - y_3 + 2y_4] \\ &= 1.492 + \frac{16(0.1)}{3}[2(2.226) - 3.320 + 2(4.95288)] \\ y_5 &= 7.3788 \end{aligned}$$

Correct with $n = 4$,

$$y_5 = y_3 + \frac{h}{3}[y_3^i + 4y_4^i + y_5^i]$$

$$y_5 = y_3 + \frac{4h}{3}[y_3 + 4y_4 + y_5] \quad (\text{since } y_i^i = 4y_i)$$

$$= 3.320 + \frac{4(0.1)}{3}[3.320 + 4(4.95288) + 7.3788]$$

$$y_5 = y(x = 0.5) = 3.320 + 4.06804 = 7.3880426.$$

Note: The exact solution is $y = e^{4x} + c$, with $y(0) = 1$, $c = 0$ so $y = e^{4x}$. Then $y(0.4) = e^{4(0.4)} = 4.953032425$ and $y(0.5) = e^{4(0.5)} = 7.389056099$.

Note: Exact solution: $y(x) = e^x - 1 - x$, $y(1) = e^1 - 1 - 1 = 0.718281828$.

EXERCISE

Taylor series

1. Evaluate the integral of $y'' + yy' - x^2 = 0$, $y(0) = 1$, $y'(0) = 1$ at $x = 0.1(0.1)0.3$ by Taylor series.

Hint: $y(x) = 1 + x - \frac{x^2}{2!} + \frac{5x^4}{4!} - \frac{8x^5}{5!} + \dots$
Ans. $y(0.1) = 1.095$, $y(0.2) = 1.180$, $y(0.3) = 1.257$

2. Find the first five terms of the expansion in a power series of the solution $y = y(x)$, $z = z(x)$ of the system $y'(x) = y \cos x - z \sin x$, $z'(x) = y \sin x + 2 \cos x$, with initial conditions $y(0) = 1$, $z(0) = 0$.

Ans. $y(x) = 1 + x + \frac{x^2}{2} - 5\frac{x^4}{4!} + \dots$, $z(x) = \frac{x^2}{2} + \frac{x^3}{2} + \frac{5x^4}{4!} + \dots$

3. Find $y(0.1)$ by Taylor's series expansion when $y' = x - y^2$, $y(0) = 1$.

Hint: $y(x) = 1 - x + \frac{3}{2}x^2 - \frac{4}{3}x^3 - \frac{17}{12}x^4 - \frac{31}{20}x^5 + \dots$

Ans. $y(0.1) = 0.9138$

4. Given $y' = x^2 + y^2$, $y(0) = 0$, determine the first three non-zero terms in Taylor series and hence obtain $y(1)$.

Ans. $y(x) = \frac{1}{3}x^3 + \frac{1}{63}x^7 + \frac{2}{2079}x^{11}$, $y(1) = 0.3502$.

5. Determine the three terms in the Taylor's series solution to the Blasius equation $y''' + yy'' = 0$, $y(0) = 0$, $y'(0) = 0$, $y''(0) = 1$.

Ans. ?

6. Compute $y(0.1)$ and $y(0.2)$ by Taylor's series method if $y' = x^2y - 1$, $y(0) = 1$.

Hint: $y(x) = 1 - x + \frac{x^3}{3} - \frac{x^4}{4} + \dots$

Ans. $y(0.1) = 0.9033$, $y(0.2) = 0.80227$.

Euler's method

7. Evaluate the integral of $y' - y^2 = 0$ by Euler's predictor-corrector method at $x = 0.1, 0.2$ with initial condition $y(0) = 1$.

Ans. $y(0.1) = 1.1105$, $y(0.2) = 1.24827$.

8. Evaluate by Euler's method

a. $y' - y^2 = 0$, $y(0) = 1$, at $x = 0.1, 0.2, 0.3$

b. $y' = y - x$, $y(0) = 2$, at $x = 0.2, 0.4, 0.6$.

Ans. **a.** $y(0.1)=1.1$, $y(0.2)=1.221$, $y(0.3)=1.37$

b. $y(0.2) = 2.4$, $y(0.4) = 2.84$, $y(0.6) = 3.328$

9. Use Heun's method to integrate $y' = 4e^{0.8x} - 0.5y$ from $x = 0$ to 4 with a step size of 1 and with $y(0) = 2$.

Hint: $y = \frac{4}{1.3}(e^{0.8x} - e^{-0.5x}) + 2e^{-0.5x}$ is exact solution.

Ans. $y(1) = 6.70108$, $y(2) = 16.319$, $y(3) = 37.199$, $y(4) = 83.377$

10. Solve the following initial value problems by modified Euler's method.

a. $y' = x + y$, $y(0) = 1$, $h = 0.1$, $x = 0(0.1)0.3$

b. $y' = \ln(x + y)$, $y(0) = 2$, $h = 0.2$, $x = 0(0.2)0.8$

c. $y' = x + |\sqrt{y}|$, $y(0) = 1$, $h = 0.2$, $x = 0(0.2)0.6$

Ans. **a.** 1.1105, 1.2432, 1.4004

b. 2.0656, 2.1416, 2.2272, 2.3217

c. 1.2309, 1.5253, 1.8861

Runge-Kutta 4th order method

11. Integrate the D.E. $y' = y - \frac{2x}{y}$, $y(0) = 1$ from 0 to 2 by R-K method with $h = 0.2$.

Ans. $y(0.2) = 1.1832$, $y(0.4) = 1.3416$, $y(0.6) = 1.4832$, $y(0.8) = 1.61251$, $y(1.0) = 1.7321$, $y(1.2) = 1.844$, $y(1.4) = 1.9495$, $y(1.6) = 2.049$, $y(1.8) = 2.145$, $y(2.0) = 2.2366$

12. Integrate D.E. $y' = x + y$, $y(0) = 0$, $h = 0.2$ by R-K method, from 0 to 1 .

Ans. $y(0.2) = 0.0214$, $y(0.4) = 0.0918$, $y(0.6) = 0.222$, $y(0.8) = 0.4255$, $y(1.0) = 0.718$

13. Using R-K method, find the solution of $y' = 0.25y^2 + x^2$ with initial condition $y(0) = -1$ on $[0, 0.5]$ with $h = 0.1$.

Ans. $-0.97528, -0.94978, -0.92154, -0.8887, -0.84945$

14. Integrate D.E. by R-K method given $y' = -2xy^2, y(0) = 1, h = 0.2$ on $[0, 1]$.

Ans. $y(0.2) = .9615, y(0.4) = .862, y(0.6) = .73527, y(0.8) = .6097, y(1.0) = .500073$

15. Apply R-K method to solve

a. $y' = x + y, y(0) = 1, h = 0.2$, and find $y(0.2)$

b. $y' = \frac{y^2 - x^2}{y^2 + x^2}, y(0) = 1, h = 0.2, x = 0(0.2)0.4$

Ans. a. $y(0.2) = 0.2428$

b. $y(0.2) = 1.196, y(0.4) = 1.3752$.

Milne's predictor-corrector method

16. Use Milne's predictor-corrector method to integrate $y' = 4e^{0.8x} - 0.5y$ from $x = 0$ to $x = 4$ with a step size of 1 and with $y(0) = 2$.

Ans. 6.20485, 14.86, 33.7242, 75.4329

17. Compute $y(0.8)$ and $y(1.0)$ by Milne's method if $y' = 1 + y^2, y(0) = 0, y(0.2) = 0.2027, y(0.4) = 0.4228, y(0.6) = 0.6841$.

Hint: $y'(0) = 1, y'(0.2) = 1.0411, y'(0.4) = 1.1787, y'(0.6) = 1.4681, y_{\text{predictor}}(0.8) = 1.0239, y'(0.8) = 2.048$

Ans. $y(0.8) = 1.0294, y(1) = 1.5549$

18. Find $y(0.4)$ and $y(0.5)$ by Milne's method if $y' + y = 2e^x, y_0 = 2, y_1 = 2.010, y_2 = 2.04, y_3 = 2.09, h = 0.1$.

Ans. $\tilde{y}_4 = 2.162, y_4 = 2.162, \tilde{y}_5 = 2.255, y_5 = 2.2546$

19. Calculate y at $x = 0.4$, and $x = 0.5$, if $y' = x + y$ and $y_0 = 1, y_1 = 1.1103, y_2 = 1.2428, y_3 = 1.3997, h = 0.1$.

Ans. $\tilde{y}_4 = 1.5836, y_4 = 1.5836, \tilde{y}_5 = 1.7974, y_5 = 1.7974$

20. Determine $y(0.8), y(1.0)$ by Milne's P-C method when $y' = x - y^2, y(0) = 0$.

Hint: $y_1 = 0.02, y_1^i = 0.1996, y_2 = 0.0795,$

$$y_2^i = 0.3937, y_3 = 0.1762, y_3^i = 0.5689$$

$$\left(y = \frac{x^2}{2} - \frac{x^5}{20} + \frac{x^8}{160} - \frac{x^{11}}{4400} \right).$$

Ans. $y(0.8) = 0.3046, y(1.0) = 0.4555$.

33.2 PICARD'S METHOD OF SUCCESSIVE APPROXIMATION*

A problem involving ODEs is not completely specified by its equations. Boundary conditions (B.C.s), which are algebraic conditions on the values of the function $y(x)$, play crucial role in determining how to attack the problem numerically. Initial value problems involve condition(s) specified at some starting value x_0 , while in (two-point) boundary value problems boundary conditions are specified at more than one point x .

Picard's method of successive approximation and Taylor's series are single step methods in which the solutions are obtained in analytical form as power series in x .

Picard's Method of Successive Approximation

The particular solution of the initial value problem consisting of an ordinary first order differential equation

$$\frac{dy}{dx} = f(x, y) \quad (1)$$

with initial condition $y(x_0) = y_0$ is obtained by integrating (1). Then

$$\int_{y_0}^y dy = \int_{x_0}^x f(x, y) dx$$

or

$$y(x) = y_0 + \int_{x_0}^x f(x, y) dx \quad (2)$$

In the Picard's method, the first approximation y_1 is obtained by replacing y in $f(x, y)$ in RHS of (2) by y_0 and then evaluating the integral (which is now a function of x) wrt x . The second approximation y_2

*Emile Picard (1856–1941), French mathematician.

33.8 — HIGHER ENGINEERING MATHEMATICS—VIII

is then obtained by replacing y in $f(x, y)$ of RHS of (2) by y_1 and integrating wrt x . Successive approximations are obtained similarly. In practice, Picard's method is restricted to a limited class of problems in which the integral in RHS of (2) can be evaluated easily. Thus

$$y_1 = y_0 + \int_{x_0}^x f(x, y_0) dx$$

$$y_2 = y_0 + \int_{x_0}^x f(x, y_1) dx$$

$$y_3 = y_0 + \int_{x_0}^x f(x, y_2) dx$$

and so on yielding a sequence of functions $y_1, y_2, y_3, \dots$ giving rise to a better approximation.

WORKED OUT EXAMPLES

Example 1: Solve the differential equation

$$\frac{dy}{dx} = x^2 - y, \quad y(0) = 1$$

by Picard's method of successive approximations to get the value of y at $x = 1$. Use terms through x^5 , compare it with the exact analytical solution.

Solution: Integrating the D.E., we obtain

$$\int_{y_0}^y dy = \int_{x_0}^x (x^2 - y) dx$$

$y(x) = y(x_0) + \int_{x_0}^x (x^2 - y) dx = 1 + \int_0^x (x^2 - y) dx$
The first approximation y_1 is obtained by replacing y by $y_0 = 1$ in the integrand in RHS integral. Thus

$$y_1 = 1 + \int_0^x (x^2 - 1) dx = 1 + \frac{x^3}{3} - x$$

To obtain the second approximation y_2 , replace y by $1 - x + \frac{x^3}{3}$ in the integrand of the RHS integral. Thus

$$y_2 = 1 + \int_0^x \left[x^2 - \left(1 - x + \frac{x^3}{3} \right) \right] dx$$

$$y_2 = 1 + \frac{x^3}{3} - x + \frac{x^2}{x} - \frac{x^4}{12}$$

Now the third approximation y_3 is obtained by replacing y by $y_2 = 1 - x + \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{12}$. Thus

$$y_3 = 1 + \int_0^x \left[x^2 - \left\{ 1 - x + \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{12} \right\} \right] dx$$

Integrating we get

$$y_3 = 1 + \frac{x^3}{3} - x - \frac{x^4}{12} + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^5}{60}$$

$$y_3 = 1 - x + \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{12} + \frac{x^5}{60}$$

Similarly replacing y by y_3 and integrating wrt x we get the fourth approximation y_4 as

$$y_4 = 1 + \int_0^x \left[x^2 - \left\{ 1 - x + \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{12} + \frac{x^5}{60} \right\} \right] dx$$

$$y_4 = 1 - x + \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{60} - \frac{x^6}{360} \quad (*)$$

The exact solution of given DE is

$$y = x^2 - 2x + 2 - e^{-x}$$

Expanding e^{-x} in x , the exact solution is

$$y(x) = x^2 - 2x + 2 - \left[1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} - \frac{x^4}{4!} + \frac{x^5}{5!} - \frac{x^6}{6!} + \dots \right]$$

$$y(x) = 1 - x + \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} - \frac{x^6}{720} + \dots \quad (**)$$

Thus the fourth approximation $y_4(*)$ coincides with the exact analytical solution $y(**)$ up to the 4th power of x . Now

$$y_4(x=1) = 1 - 1 + \frac{1}{2} + \frac{1}{6} - \frac{1}{24} + \frac{1}{60} - \frac{1}{360} = 0.638888$$

$$y(x=1) = 1 - 1 + \frac{1}{2} + \frac{1}{6} - \frac{1}{24} + \frac{1}{120} - \frac{1}{720} = 0.6319444$$

Example 2: Obtain the Picard's second approximation for the initial value problem

$$\frac{dy}{dx} = \frac{x^2}{y^2 + 1}, y(0) = 0.$$

Find $y(1)$.

Solution: The first approximation is

$$y_1 = y_0 + \int_0^x \frac{x^2}{y^2 + 1} dx = 0 + \int_0^x \frac{x^2}{y^2 + 1} dx$$

Replacing y by $y_0 = 0$, we get

$$y_1 = \int_0^x \frac{x^2}{0^2 + 1} dx = \frac{x^3}{3}$$

Replacing y by $y_1 = \frac{x^3}{3}$ we get the second approximation y_2 as

$$y_2 = \int_0^x \frac{x^2}{\left(\frac{x^3}{3}\right)^2 + 1} dx = \tan^{-1}\left(\frac{x^3}{3}\right) - 0$$

In the third approximation

$$y_3 = \int_0^x \frac{x^2}{\left(\tan^{-1}\frac{x^3}{3}\right)^2 + 1} dx$$

The integration is difficult. This is the drawback of the method.

Expanding $\tan^{-1}$, we get from second approximation

$$y_2 = \tan^{-1}\left(\frac{x^3}{3}\right) = \left(\frac{x^3}{3}\right) - \left(\frac{x^3}{3}\right)^3 \frac{1}{3} + \left(\frac{x^3}{3}\right)^5 \frac{1}{5} \dots$$

$$y_2 = \frac{x^3}{3} - \frac{x^9}{81} + \frac{x^{15}}{1215} \dots$$

$$\text{At } x = 1, y_2(1) = \frac{1}{3} - \frac{1}{81} + \frac{1}{1215} = 0.321810699.$$

EXERCISE

Using Picard's successive approximation, solve the following initial value problems.

1. $y' = x - y^2, y(0) = 1$. Find $y(0.1)$.

Ans. $y_2 = 1 - x + \frac{3}{2}x^2 - \frac{2}{3}x^3 + \frac{x^4}{4} - \frac{x^5}{20},$
 $y(0.1) = 0.914357$

2. $y' = x^2 + y^2, y(0) = 0$, find $y(0.4)$

Ans. $y_3 = \frac{x^3}{3} + \frac{1}{63}x^7 + \frac{2}{2079}x'' + \frac{1}{59535}x^{15}, y(0.4) = 0.02135938$

3. $y' = x + y, y(0) = 1$. Find $y(1)$. Compare with exact solution.

Ans. $y_5 = 1 + x + x^2 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{720}$
 Exact solution: $y = 1 + x + x^2 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \dots$
 $y_5(1) = 3.434, y(1) = 3.44$

4. $y' = \frac{y-x}{y+x}, y(0) = 1$. Find $y(0.1)$.

Ans. $y_1 = 1 - x + 2 \log(1 + x), y_2$ is difficult for evaluation. $y_1(0.1) = 0.9828$

5. $y' = x + y + xy, y(0) = 1$, find $y(0.1)$

Ans. $y_3 = 1 + x + x^2 + \frac{x^3}{3} + \frac{5}{12}x^4 + \frac{11}{60}x^5 + \frac{x^6}{24}$
 $y_3(0.1) = 1.1103768$

33.3 ADAMS-BASHFORTH-MOULTON METHOD (ABM METHOD)

Predictor-corrector is often loosely used to denote the multistep or multivalued integration technique for ODEs. The most popular predictor-corrector methods are probably the Adams-Bashforth-Moulton schemes, which have good stability properties unlike the Milne's method which is unstable due to the corrector. The predictor-corrector method consists of three separate processes. The predictor step P , evaluation of derivative y'_{n+1} from the latest value of y , call as E and the corrector step, call as C . Iterating m times with the corrector in this notation, may be written as $P(EC)^m$. Since E is superior, the strategy is PECE i.e., predict, evaluate, correct and evaluate.

Adams-Bashforth-Moulton (ABM) Method is a non self-starting four step method which uses four initial points $(x_0, y_0), (x_1, y_1), (x_2, y_2)$ and (x_3, y_3) , obtained already by any one of the single-step methods to generate the points (x_n, y_n) for $n \geq 4$. It requires only two function evaluations of $f(x, y)$ per step.

A Lagrange cubic polynomial based on the four points from x_{n-3} to x_n , is integrated over one step

33.10 — HIGHER ENGINEERING MATHEMATICS—VIII

Fig. 33.2 Integration on the interval x_k, x_{k+1}

from x_n to x_{n+1} yielding the *Adams-Bashforth predictor*.

$$y_{n+1} = y_n + \frac{h}{24} [55f_n - 59f_{n-1} + 37f_{n-2} - 9f_{n-3}] \quad (1)$$

The tentative computed value of y at x_{n+1} obtained from the predictor formula (1), together with values of y at x_n, x_{n-1}, x_{n-2} are used to construct a second cubic polynomial, which is then integrated over the interval x_n to x_{n+1} , yielding the *Adams-Moulton corrector*:

$$y_{n+1} = y_n + \frac{h}{24} [9f_{n+1} + 19f_n - 5f_{n-1} + f_{n-2}] \quad (2)$$

The step size h , should be decreased, when the difference between predicted and corrected values reaches or exceeds the accuracy criterion.

WORKED OUT EXAMPLES

Example 1: Solve $y' = x^2 - y$, $y(0) = 1$ on the interval $[0, 0.5]$ with step size $h = 0.05$ and with initial values $y(0.05) = 0.95127058$, $y(0.10) = 0.90516258$, $y(0.15) = 0.86179202$. Compare with true (exact) solution.

Solution: Here $f(x, y) = x^2 - y$. $h = 0.05$ $x_0 = 0$, $y_0 = 1$, $f(x_0, y_0) = f_0 = 0^2 - 1 = -1$
 $x_1 = 0.05$, $y_1 = 0.95127058$, $f(x, y) = f_1 = (0.05)^2 - 0.95127058$ so $f_1 = -0.94877058$.
 $x_2 = 0.10$, $y_1 = 0.90516258$, so $f(x_2, y_2) = f_2 = (0.10)^2 - 0.90516258 = -0.89516258$
 $x_3 = 0.15$, $y_3 = 0.86179202$ so $f(x_3, y_3) = f_3 = (0.15)^2 - 0.86179202 = -0.83929202$
 Use Adams-Bashforth predictor ($n = 3$)

$$y_4 = y_3 + \frac{h}{24} [55f_3 - 59f_2 + 37f_1 - 9f_0]$$

substituting the above starting values

$$\begin{aligned} y_4 &= 0.86179202 + \frac{0.05}{24} [55(-0.83929202) \\ &\quad - 59(-0.89516258) + 37(-0.94877058) \\ &\quad - 9(-1)] \end{aligned}$$

$$= 0.86179202 + \frac{0.05}{24} [-19.45097924]$$

$$y_4 = 0.86179202 - 0.040522873 = 0.821269146$$

Using this tentative predictor value, compute $f_4 = f(x_4, y_4) = f(0.20, 0.821269146)$

$$f_4 = (0.20)^2 - 0.821269146 = -0.781269146$$

Now we utilize this value of f_4 in the Adams-Moulton corrector ($n = 3$)

$$y_4 = y_3 + \frac{h}{24} [9f_4 + 19f_3 - 5f_2 + f_1]$$

substituting the above data, we get

$$\begin{aligned} y_4 &= 0.86179202 + \frac{0.05}{24} [9(-0.781269146) \\ &\quad + 19(-0.83929202) - 5(-0.89516258) \\ &\quad + (-0.94877058)] \end{aligned}$$

$$= 0.86179202 + \frac{0.05}{24} [-19.45092837]$$

$$y_4 = 0.86179202 - 0.040522767 = 0.821269252$$

The exact (true) solution is

$$y(x) = x^2 - 2x + 2 - e^{-x}$$

so $y(0.20) = 0.821269246$. Calculating further values with ABM method we get the following data:

| n | x | Adams-Bashforth Moulton method $y(x)$ | Exact solution $y(x)$ | Error |
|-----|------|---------------------------------------|-----------------------|-------------------------|
| 4 | 0.20 | 0.821269252 | 0.821269246 | 6×10^{-9} |
| 5 | 0.25 | 0.7836992 | 0.783699216 | 1.69×10^{-8} |
| 6 | 0.30 | 0.7491818 | 0.749181779 | $+2.068 \times 10^{-8}$ |
| 7 | 0.40 | 0.6896800 | 0.689679954 | 4.6036×10^{-8} |
| 8 | 0.50 | 0.6434694 | 0.64346934 | 5.9716×10^{-8} |

Note: For $n = 4$, we have the following predictor corrector formulas.

Predictor: $y_5 = y_4 + \frac{h}{24} [55f_4 - 55f_3 + 37f_2 - 9f_1]$

Corrector: $y_5 = y_4 + \frac{h}{24} [9f_5 + 19f_4 - 5f_3 + f_2]$.

Here

$$f_4 = f(0.2, 0.821269252) = (0.2)^2 - 0.821269252 = -0.781269252$$

EXERCISE

ABM Method

Solve by ABM method using the given initial values. Compare with exact solution.

- $y' = -2x - y$, $y(0) = -1$, find $y(0.4)$, $y(0.5)$
 $y(0) = -1$, $y(0.1) = -0.9145122$,
 $y(0.2) = -0.8561923$, $y(0.3) = -0.8224547$

Ans. At 0.4, Predictor value = -0.8109687

Corrector value : -0.8109652

Exact solution: $y(x) = -3e^{-x} - 2x + 2$

$y(0.4) = \text{Exact value} = -0.8109601$

At 0.5 = P : -0.8195978 , C : -0.819505 ,

E : -0.8195920

- $y' = (x - y)/2$, $y(0) = 1$, $h = 0.125$, find y on $[0, 1]$. Compare with exact solution. Initial values are : $y(0.125) = 0.94323919$, $y(0.250) = 0.89749071$, $y(0.375) = 0.86208736$.

Exact solution: $y(x) = 3e^{-x/2} - 2 + x$

Ans. $y(0.5) = 0.83640227$, $y(0.625) = 0.81984673$,
 $y(0.75) = 0.81186762$, $y(0.875) = 0.81194530$, $y(1.0) = 0.81959166$

- $y' = 2xy^2$, $y(0) = 1$, $h = 0.05$, find y on $[0, 0.5]$
 Compare with exact solution.

Initial values are $y(0.05) = 1.0025063$,
 $y(0.10) = 1.0101010$, $y(0.15) = 1.0230179$.

Exact solution: $y(x) = 1/(1 - x^2)$

Ans. $y(0.2) = 1.0416675$, $y(0.25) = 1.0666688$
 $y(0.3) = 1.0989052$, $y(0.4) = 1.1904878$,
 $y(0.5) = 1.3333631$

- $y' = y^2 \sin x$, $y(0) = 1$, find y on $[0.05]$, $h = 0.05$.
 Initial values: $y(0.05) = 1.0012513$, $y(0.10) = 1.0050209$, $y(0.15) = 1.0113564$.

Exact solution: $y(x) = \sec x$

Ans. $y(0.2) = 1.0203389$, $y(0.25) = 1.0320852$,
 $y(0.3) = 1.0467519$, $y(0.4) = 1.0857051$
 $y(0.5) = 1.1394953$.

- $y' = -\frac{x}{y}$, $y(1) = 1$, find y on $[1, 1.4]$. $h = 0.05$
 Initial values $y(1.05) = 0.94736477$, $y(1.10) = 0.88881944$, $y(1.15) = 0.82310388$
 Exact solution: $y(x) = (2 - x^2)^{1/2}$

Ans. $y(1.2) = 0.7483205$, $y(1.25) = 0.6613998$,
 $y(1.3) = 0.5566583$, $y(1.35) = 0.4208572$,
 $y(1.4) = 0.1974740$.

- $y' = x^3 + y^2$, $y(0) = 0$, $h = 0.1$. Find y on $[0, 1.2]$. Initial values are $y(0.2) = 0.0004$,
 $y(0.4) = 0.0064$, $y(0.6) = 0.0325$

Ans. $y(0.8) = 0.1035$, $y(0.9) = 0.1669$, $y(1.0) = 0.2574$, $y(1.1) = 0.3836$, $y(1.2) = 0.5581$

33.4 NUMERICAL SOLUTIONS TO PARTIAL DIFFERENTIAL EQUATIONS

Many physical phenomena can be modelled mathematically by partial differential equations, whose theory is quite difficult and numerical methods most difficult and needs extensive computation. Although analytical solutions can be obtained by separation of variable technique and integral transforms (Fourier

33.12 — HIGHER ENGINEERING MATHEMATICS—VIII

transforms), in many complicated cases one has to resort to numerical methods. Initial value problems or time dependent problems consists of two types: hyperbolic problems (containing both f_{xx} and f_{tt} term as in wave equation) and parabolic problems (which contain only f_{xx} and f_t but no f_{tt} term as in the heat equation). For these problems, the solution is known at an initial time and then propagates through space in time. The domain is open (goes to infinity) somewhere for example, in time. The other type of problems is the boundary value problem where the domain is closed and is entirely surrounded by boundary values. These problems are called elliptic (and are time independent as in the case of Laplace equation).

The dimension of a partial differential equation is the number of space variables x, y, z appearing in the equation as independent variables (apart from the independent variable time t). Thus a one-dimensional heat equation or one-dimensional wave equation involves only one space variable say x (and of course time t). Similarly two-dimensional Laplace equation contains two space variables say x and y .

The central idea in numerical methods to partial differential equations is to discretize the partial differential equation by replacing it, approximately, by a finite system of algebraic equations. One such important discretization method is finite differences, in which the derivatives are replaced by finite differences. The entire given domain is discretized by a discrete set of points, as follows:

Introducing $x_i = x_0 + ih$, $i = 0, \pm 1, \pm 2, \pm 3, \dots$ and $t_j = t_0 + jk$, $j = 0, \pm 1, \pm 2, \pm 3, \dots$, the (numerical) solution is obtained at the discrete points (x_i, t_j) known as grid or nodal or lattice or mesh or pivotal points of the computational grid. Here $h = \text{constant}$ is spacing (or size of interval) in x -direction while $k = \text{constant}$ is spacing in t -direction.

33.5 NUMERICAL SOLUTION TO ONE-DIMENSIONAL HEAT EQUATION

Consider the initial boundary value problem of the parabolic one-dimensional heat equation.

$$\text{P.D.E: } \frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}, 0 \leq x \leq L, t \geq 0 \quad (1)$$

Two boundary conditions (B.C.'s):

$$u(0, t) = 0 \quad u(L, t) = 0 \quad (2)$$

One initial condition (I.C.)

$$u(x, 0) = f(x) \quad (3)$$

Fig. 33.3

Replacing u_t and u_{xx} by finite differences, equation (1) is approximated by a finite difference equation.

$$\frac{1}{k} (u_{i,j+1} - u_{i,j}) = \frac{c^2}{h^2} (u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) \quad (4)$$

Here h is mesh size in x -direction i.e., $h = \frac{L}{N}$ and k is mesh size in t -direction. Rewriting (4),

$$u_{i,j+1} = (1 - 2r)u_{i,j} + r(u_{i+1,j} + u_{i-1,j}) \quad (5)$$

where $r = \frac{c^2 k}{h^2}$. This method is known as *Schmidt explicit method* because the unknown $u_{i,j+1}$ is explicitly expressed in terms of the known (given) values $u_{i,j}; u_{i+1,j}; u_{i-1,j}$; whereas in the *implicit method* such as the Crank-Nicolson method the equations are implicit i.e., coupled and one has to solve a system of linear equations. Formula (5) provides a marching scheme to compute u at the mesh points. This method is convergent and stable if $r = \frac{c^2 k}{h^2} \leq \frac{1}{2}$. In particular for $r = \frac{1}{2}$, (5) reduces to

$$u_{i,j+1} = \frac{1}{2}(u_{i+1,j} + u_{i-1,j}) \quad (6)$$

which is known as *Bender-Schmidt recurrence relation*. So the values of h, k are so chosen (c is already given) that $r \leq \frac{1}{2}$. For $r > \frac{1}{2}$ the method is divergent and unstable.

Stencil (pattern, molecule or star)

Finite difference approximations are often presented in terms of stencils or coefficient schemes which shows the pattern of connection in the difference equations. The entries in the stencil are coefficients in the difference equation.

For example the explicit method given by (5) is represented as a stencil shown below:

$$\left\{ \begin{array}{c} \textcircled{-1} u_{i,j+1} \\ | \\ \textcircled{r} \text{---} \textcircled{1-2r} \text{---} \textcircled{r} \\ | \quad \quad | \\ u_{i-1,j} \quad u_{i,j} \quad u_{i+1,j} \end{array} \right\} = 0$$

i.e., $(-1)u_{i,j+1} + r(u_{i-1,j}) + (1-2r)u_{i,j} + ru_{i+1,j} = 0$

WORKED OUT EXAMPLES

Example 1: Solve the initial boundary value problem:

$$\frac{\partial f}{\partial t} = 2 \frac{\partial^2 f}{\partial x^2} \quad (1)$$

$$f(0, t) = 10 \quad (2)$$

$$f(6, t) = 18 \quad (3)$$

$$f(x, 0) = \frac{x^2}{2} \quad (4)$$

with $h = 1$ and $\tau = \frac{1}{8}$ by explicit method.

Solution: $m = \frac{a\tau}{h^2}$. Here $a = 2, h = 1, \tau = \frac{1}{8}$ so $m = \frac{1}{4}$. The explicit formula $f_{i,j+1} = (1-2m)f_{ij} + m(f_{i+1,j} + f_{i-1,j})$ with $m = \frac{1}{4}$ becomes

$$f_{i,j+1} = \frac{1}{2}f_{ij} + \frac{1}{4}(f_{i+1,j} + f_{i-1,j}) \quad (4)$$

Here first row $t = 0$, consists of the initial values given by IC(3): $f(x, 0) = \frac{x^2}{2}$ at $x = 1, 2, 3, 4, 5$. The first column $x = 0$, gives the first boundary condition $f(0, t) = 10$. The last column $x = 6$, gives the second boundary condition $f(6, t) = 18$. The remaining values of f are calculated using (4). As $t \rightarrow \infty$, the process reaches steady state, so $f_{xx} = 0, f(x) = c_1x + c_2, 10 = f(0) = 0 + c_2 \therefore c_2 = 10, 18 = f(6) = 6.c_1 + 10$

$\therefore c_1 = \frac{4}{3}$, analytical exact solution as $t \rightarrow \infty$ is $f(x) = \frac{4}{3}x + 10$. These are plotted for $t \rightarrow \infty$ in the last row of the Table 33.7.

Table 33.7

| $t = 1\frac{1}{8}$ | 10 | 8.20 | 7.40 | 8.15 | 10.45 | 13.93 | 18 |
| $t = 1\frac{1}{4}$ | 10 | 8.45 | 7.79 | 8.54 | 10.75 | 14.08 | 18 |
| $t = 1\frac{3}{8}$ | 10 | 8.67 | 8.14 | 8.91 | 11.03 | 14.23 | 18 |
| $t = 1\frac{1}{2}$ | 10 | 8.87 | 8.47 | 9.25 | 11.30 | 14.37 | 18 |
| $t = \infty$ | 10 | $11\frac{1}{3}$ | $12\frac{2}{3}$ | 14 | $15\frac{1}{2}$ | $16\frac{2}{3}$ | 18 |

Example 2: Solve the above problem by Bender-Schmidt recurrence equation; with $h = 1$ and τ determined accordingly.

Solution: $m = \frac{a\tau}{h^2} = \frac{2\tau}{1}$. For Bender-Schmidt $m = \frac{1}{2} \therefore \tau = \text{time interval size} = \frac{1}{4}$. (See Table 33.8.)

Non-dimensional form

Example 3: Transform the heat equation

$$U_T = c^2 U_{XX}, \text{ where } 0 \leq X \leq L$$

to non-dimensional form.

Solution: Introducing

$$u = \frac{U}{u_0} \quad \text{and} \quad x = \frac{X}{L}, \quad t = \frac{c^2 T}{L^2}, \quad \text{we have}$$

$$\frac{\partial u}{\partial x} = \frac{\partial U}{\partial X} \cdot \frac{\partial X}{\partial x} = L \frac{\partial U}{\partial X}, \quad \frac{\partial^2 u}{\partial x^2} = \frac{\partial}{\partial x} \left(L \frac{\partial U}{\partial X} \right) \frac{\partial X}{\partial x}$$

| | $t = \frac{7}{4}$ | 10 | 9.42 | 9.05 | 10.20 | 11.77 | 14.78 | 18 | |
| | $t = 2$ | 10 | 9.53 | 9.81 | 10.41 | 12.49 | 14.89 | 18 | |
| | $t = \frac{9}{4}$ | 10 | 9.90 | 9.97 | 10.15 | 12.65 | 15.25 | 18 | |
| | $t = \frac{5}{2}$ | 10 | 9.99 | 10.53 | 11.31 | 13.20 | 15.33 | 18 | |

$$\frac{\partial^2 u}{\partial x^2} = L \frac{\partial^2 U}{\partial X^2} \cdot L = L^2 \frac{\partial^2 U}{\partial X^2}. \quad \text{Similarly,}$$

$$\frac{\partial u}{\partial t} = \frac{\partial U}{\partial T} \frac{\partial T}{\partial t} = \frac{L^2}{c^2} \frac{\partial U}{\partial T}. \quad \text{Then}$$

$$U_T = \frac{\partial U}{\partial T} = \frac{c^2}{L^2} \frac{\partial u}{\partial t} = c^2 U_{XX} = c^2 \frac{\partial^2 U}{\partial X^2} = c^2 \cdot \frac{1}{L^2} \frac{\partial^2 u}{\partial x^2}$$

$$\text{Thus } \frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} \quad \text{i.e., } u_t = u_{xx}$$

for $0 \leq \frac{x}{L} \leq \frac{L}{L}$ i.e., $0 \leq x \leq L$. This form is known as non-dimensional standard form. Similarly, the wave equation

$$U_{TT} = a^2 U_{XX} \quad \text{where } 0 \leq X \leq L$$

can be transformed to non-dimensional standard form

$$u_{tt} = u_{xx} \quad \text{where } 0 \leq x \leq 1.$$

EXERCISE

Numerical solution to one-dimensional heat equation

- Using Schmidt explicit method, solve $u_t = u_{xx}$, $0 \leq x \leq 1$, $u(0, t) = 0$, $u(1, t) = 0$, $u(x, 0) = 2x$ when $0 \leq x \leq 0.5$ and

$u(x, 0) = 2(1 - x)$ when $0.5 \leq x \leq 1$ for $h = 1$, $k = 0.001$ at $t = 0.001, 0.002$.

Ans.

$$x : 0 \quad .1 \quad .2 \quad .3 \quad .4 \quad .5 \quad .6 \quad .7 \quad .8 \quad .9 \quad 1.0$$

$$u(x, 0.001) : 0 \quad .2 \quad .4 \quad .6 \quad .8 \quad .96 \quad .8 \quad .6 \quad .4 \quad .2 \quad 0$$

$$u(x, 0.002) : 0 \quad .2 \quad .4 \quad .6 \quad .796 \quad .928 \quad .796 \quad .6 \quad .4 \quad .2 \quad 0$$

- Use Schmidt explicit method to obtain numerical solution of $u_t = u_{xx}$, $u(0, t) = u(1, t) = 0$, $u(x, 0) = \sin \pi x$, with $h = \frac{1}{3}$, $k = \frac{1}{36}$ for two levels.

Hint: Here $r = \frac{kc^2}{h^2} = \frac{1}{36} \cdot \frac{1}{\left(\frac{1}{3}\right)^2} = \frac{1}{4}$ so

$$u_{i,j+1} = \frac{1}{4} [u_{i-1,j} + 2u_{ij} + u_{i+1,j}]$$

$$\text{Ans.} \quad \begin{array}{cccc} x = & 0 & \sqrt{3}/2 & \sqrt{3}/2 & 0 \\ t = \frac{1}{36} : & 0 & .65 & .65 & 0 \\ t = \frac{2}{36} : & 0 & .49 & .49 & 0 \end{array}$$

- Use Schmidt explicit method to solve $u_t = u_{xx}$, $u(0, t) = u(1, t) = 0$, $u(x, 0) = \sin \pi x$; for $0 \leq t \leq 0.2$, with $r = 0.25$.

Hint: $r = k/h^2 = 0.25$, so $k = 0.01$, $u_{i,j+1} = 0.25 (u_{i-1,j} + 2u_{ij} + u_{i+1,j})$. Value at $x = 0.6$ is same as at $x = 0.4$; Value at $x = 0.8$ is same as at $x = 0.2$ due to symmetry.

Ans.

Table 33.9

| | $x = 0.2$ | $x = 0.4$ |
|------------|-----------|-----------|
| $t = 0 :$ | 0.588 | 0.951 |
| $t = 0.04$ | 0.393 | 0.637 |
| $t = 0.08$ | 0.263 | 0.426 |
| $t = 0.12$ | 0.176 | 0.285 |
| $t = 0.16$ | 0.118 | 0.191 |
| $t = 0.20$ | 0.079 | 0.128 |

- Using Bender-Schmidt (explicit method with $r = \frac{1}{2}$) solve $u_{xx} - 2u_t = 0$, $u(0, t) = u(4, t) = 0$, $u(x, 0) = x(4 - x)$, with $h = 1$, $k = 1$.

Ans. Solve $2u_{xx} - u_t = 0$, $u(x, 0) = 50(4 - x)$, $u(0, t) = 0$, $u(4, t) = 0$, with $h = 1$, $\tau = 0.25$.

Hint: use Bender-Schmidt scheme.

Ans. At $t = 1.50$; $u = 0, 6.25, 12.5, 6.25, 0$ (after six iterations)

Table 33.10

| $t \setminus x$ | 0 | 1 | 2 | 3 | 4 |

33.6 NUMERICAL SOLUTION TO ONE-DIMENSIONAL WAVE EQUATION

Consider the initial boundary value problem of hyperbolic one-dimensional wave equation

$$\text{P.D.E : } \frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial x^2}, 0 \leq x \leq L, t \geq 0 \quad (1)$$

Two boundary conditions:

$$u(0, t) = u(L, t) = 0 \quad (2)$$

Two initial conditions: Prescribed initial displacement:

$$u(x, 0) = f(x) \quad (3)$$

Prescribed initial velocity:

$$u_t(x, 0) = g(x) \quad (4)$$

The finite difference approximation of (1) is

$$\begin{aligned} \frac{1}{k^2} (u_{i,j+1} - 2u_{ij} + u_{i,j-1}) \\ = \frac{a^2}{h^2} (u_{i+1,j} - 2u_{ij} + u_{i-1,j}) \end{aligned} \quad (5)$$

This explicit method converges and stable for $0 < r \leq 1$. Here h is mesh size in x -direction and k is the mesh size in t -direction. For a given a^2 , choose h and k such that

$$r = \frac{a^2 k^2}{h^2} = 1.$$

Then Equation (5) simplifies to

$$u_{i,j+1} = u_{i-1,j} + u_{i+1,j} - u_{i,j-1} \quad (6)$$

The numerical solution is generally represented in the form of an open ended table, consisting of n columns, headed by $x_i = x_0 + ih$, where the mesh size $h = \frac{L-0}{n}$. Here $x_0 = 0, x_n = L$.

Step I All the entries in the first column are zeros, given by the first boundary condition $u(0, t) = 0$.

Step II Similarly, all the entries in last column are zeros, given by the second boundary condition.

$$u(L, t) = 0.$$

Step III Each row represents a time step. Entries in first row, are calculated using (3) the first initial condition $u(x, 0) = f(x)$ for $x_i = x_0 + ih, i = 1, 2, 3, \dots, n$.

Step IV Observe that formula (6) involves 3 time steps namely the future $(j + 1)$ in terms of the present (j) and the past $j - 1$. At this stage, from step III, the first row gives only on time step $(j = 0)$. So use (4) the second initial condition which gives rise to another (second) row which will be the second time step $(j = 1)$.

Now from I.C. (4) in difference form is

$$\frac{1}{2k} (u_{i1} - u_{i,-1}) = g_i$$

or

$$u_{i,-1} = u_{i1} - 2k g_i \quad (7)$$

where $g_i = g(ih)$. For $t = 0$ (i.e., $j = 0$), we have from (6)

$$u_{i1} = u_{i-1,0} + u_{i+1,0} - u_{i,-1} \quad (8)$$

Substitute $u_{i,-1}$ from (7) into (8), we get

$$u_{i1} = u_{i-1,0} + u_{i+1,0} - (u_{i1} - 2k g_i) \quad \text{or}$$

$$u_{i1} = \frac{1}{2} (u_{i-1,0} + u_{i+1,0}) + k g_i \quad (9)$$

Equation (9) expresses u_{i1} in terms of the initial data. For $i = 0, 1, 2, \dots, n$, Equation (9) gives the entries in the second row.

Step V Now that we have two rows, one from I.C.

33.16 — HIGHER ENGINEERING MATHEMATICS—VIII

(3) and one from I.C. (4), we can calculate third row entries by formula (6) using the first ($j = 0$) and second row ($j = 1$) entries. Continuing this process the 4th row is calculated by (6) using 2nd and 3rd row entries. Subsequent rows are obtained similarly. Stencil for formula (6)

$$\left. \begin{array}{l} \text{Time row } \dots \\ j+1 \\ \text{Time row } \dots \\ j \\ \text{Time row } \dots \\ j-1 \end{array} \right\} \left\{ \begin{array}{c} \textcircled{1} u_{i,j+1} \\ \vdots \\ \textcircled{-1} u_{i-1,j} \dots \dots \textcircled{-1} u_{i+1,j} \\ \vdots \\ \textcircled{1} u_{i,j-1} \end{array} \right\} u = 0$$

i.e., $u_{i,j+1} + u_{i,j-1} = u_{i-1,j} + u_{i+1,j}$

WORKED OUT EXAMPLES

Numerical solution to one-dimensional wave equation

Examples: Compute numerically the solution of the one-dimensional wave equation $25f_{xx} - f_{tt} = 0$ with boundary conditions $f(0, t) = f(5, t) = 0$ and with initial conditions $f(x, 0) = 20x$, when $0 \leq x \leq 1$ and $f(x, 0) = 25(1 - \frac{x}{5})$ when $1 \leq x \leq 5$; $\frac{\partial f}{\partial t} \Big|_{t=0} = 0$.

Solution: Here $a^2 = 25$, choose $h = 1$ mesh size in x . Since

$$\frac{a^2 t^2}{h^2} = 1 \text{ so } \frac{25\tau^2}{1} = 1 \text{ or } \tau = \frac{1}{5}, \text{ mesh size in } t.$$

Initial values: At $t = 0$, (initial displacement).

$$f(x, 0) = \begin{cases} 20x, & 0 \leq x \leq 1 \\ 25(1 - \frac{x}{5}), & 1 \leq x \leq 5 \end{cases} \quad \text{IC (1)}$$

For $x = 0$, $f_{00} = 0$, for $x = 1$, $f_{10} = 20$, for $x = 2$, $f_{20} = 15$, $f_{30} = 10$, $f_{40} = 5$, $f_{50} = 0$. These six values form the first row in the table.

Since at $\frac{\partial f}{\partial t}(x, 0) = 0$, I.C. (2)
the initial velocity is zero so

$$f_{i1} = \frac{1}{2} (f_{i-1,0} + f_{i+1,0}). \quad \text{IC (2)}$$

$$\text{For } i = 1, f_{11} = \frac{1}{2} (f_{00} + f_{20}) = \frac{1}{2} (0 + 15) = 7.5,$$

$$\text{For } i = 2, f_{21} = \frac{1}{2} (f_{10} + f_{30}) = \frac{1}{2} (20 + 10) = 15$$

$$\text{For } i = 3, f_{31} = \frac{1}{2} (f_{20} + f_{40}) = \frac{1}{2} (15 + 5) = 10$$

$$\text{For } i = 4, f_{41} = \frac{1}{2} (f_{30} + f_{50}) = \frac{1}{2} (10 + 0) = 5$$

These six values form the second row in the table. The remaining displacements are calculated from

$$f_{i,j+1} = f_{i-1,j} + f_{i+1,j} - f_{i,j-1} \quad (*)$$

which involves 2 time steps (at J and $J - 1$). Then the resulting (Table 33.12) is given below:

Table 33.12

| $f(0, t=0)$ | | | | | $f(5, t)=0$ | | |
|------------------|----|---------------|----------------|---------------|---------------|--------------|---|
| B.C.(1)↓ | | | | | ↓B.C.(2) | | |
| $t \backslash x$ | 0 | 1 | 2 | 3 | 4 | 5 | |
| I.C.(1) | 0 | $f_{10} = 20$ | $f_{20} = 15$ | $f_{30} = 10$ | $f_{40} = 5$ | $f_{50} = 0$ | |
| I.C.(2) | 1 | 0 | $f_{11} = 7.5$ | $f_{21} = 15$ | $f_{31} = 10$ | $f_{41} = 5$ | 0 |
| | 2 | 0 | -5 | 2.5 | 10 | 5 | 0 |
| | 3 | 0 | -5 | -10 | -2.5 | 5 | 0 |
| | 4 | 0 | -5 | -10 | -15 | -7.5 | 0 |
| | 5 | 0 | -5 | -10 | -15 | -20 | 0 |
| | 6 | 0 | -5 | -10 | -15 | -7.5 | 0 |
| | 7 | 0 | -5 | -10 | -2.5 | 5 | 0 |
| | 8 | 0 | -5 | 2.5 | 10 | 5 | 0 |
| | 9 | 0 | 7.5 | 15 | 10 | 5 | 0 |
| | 10 | 0 | 20 | 15 | 10 | 5 | 0 |

The values in the 2nd, 3rd, 4th, ..., 10th row are calculated using the formula (*). The displacement function $f(x, t)$ goes through a complete oscillation (cycle) in 10 steps, indicating a periodic behaviour with period $T = 10\tau = 10(\frac{1}{5}) = 2$.

EXERCISE

Numerical solution to one-dimensional wave equation

1. Evaluate the pivotal values of $16u_{xx} = u_{tt}$, $u(0, t) = u(5, t) = 0$, $u(x, 0) = x^2(5 - x)$, $u_t(x, 0) = 0$, with $h = 1$ and up to one half of the period of vibration.

Hint: Period of vibration $= \frac{2L}{a} = \frac{2.5}{4}$ since $a^2 = 16$, $L = 5$. Period: $\frac{5}{2}$ secs or compute up to $t = \frac{5}{4}$ secs. From $u_t(x, 0) = 0$, $u_{i1} = u_{i0}$ so 1st and 2nd row are same.

Ans.

Table 33.13

| $t \backslash x$ | 0 | 1 | 2 | 3 | 4 | 5 |
|------------------|---|-----|-----|-----|----|---|
| 0 | 0 | 4 | 12 | 18 | 16 | 0 |

33.7 NUMERICAL SOLUTION TO TWO-DIMENSIONAL LAPLACE EQUATION

Consider the boundary value problem of elliptic Laplace equation in two-dimensions defined in a rectangular domain with prescribed boundary conditions as follows:

$$\text{P.D.E : } \frac{\partial^2 u}{\partial x^2} = \frac{\partial^2 u}{\partial y^2} = 0, \quad 0 < x < a, \quad 0 < y < b \quad (1)$$

Four B.C's

$$\begin{aligned} u(0, y) &= p(y), u(x, 0) = q(x), \\ u(a, y) &= r(y), u(x, b) = s(x) \end{aligned} \quad (2)$$

Fig. 33.4

33.18 — HIGHER ENGINEERING MATHEMATICS—VIII

The rectangular domain is discretized by dividing OA into M equal parts of size $\Delta x = \frac{a}{M} = h$, and dividing OB into N equal parts of size $\Delta y = \frac{b}{N} = k$. Thus the function $u(x, y)$ is to be determined at the nodal points $p_{ij} = (x_i, y_j) = (i\Delta x, j\Delta y) = (ih, jk)$ for $i = 0, 1, 2, \dots, M$ and $j = 0, 1, 2, \dots, N$. Replacing (1) by finite difference, we have

$$\frac{u_{i-1,j} - 2u_{ij} + u_{i+1,j}}{h^2} + \frac{u_{i,j-1} - 2u_{ij} + u_{i,j+1}}{k^2} = 0$$

For a square domain, $h = k$. The above equation reduces to

$$u_{ij} = \frac{1}{4} [u_{i-1,j} + u_{i+1,j} + u_{i,j-1} + u_{i,j+1}] \quad (3)$$

(3) is known as the **standard five points formula** and represented by the stencil.

$$\left\{ \begin{array}{ccc} & \textcircled{-1}_{i,j+1} & \\ \textcircled{-1}_{i,j-1} & \textcircled{-4}_{i,j} & \textcircled{-1}_{i,j+1} \\ & \textcircled{-1}_{i,j-1} & \end{array} \right\} u = 0$$

Since Laplace's equation is invariant under rotation of axes through 45° , we get a **five point diagonal formula**

$$u_{ij} = \frac{1}{4} [u_{i-1,j-1} + u_{i+1,j-1} + u_{i+1,j+1} + u_{i-1,j+1}] \quad (4)$$

with stencil

$$\left\{ \begin{array}{ccc} \textcircled{1}_{i-1,j-1} & & \textcircled{1}_{i-1,j+1} \\ & \textcircled{-4}_{i,j} & \\ \textcircled{1}_{i+1,j-1} & & \textcircled{1}_{i+1,j+1} \end{array} \right\} u = 0$$

Generally, standard five point formula is preferred over the diagonal formula.

Procedure: Suppose the square domain is divided

into a grid as follows:

Here the boundary values $c_1, c_2, \dots, c_{16}$ are given. To find the unknown function u at the 9 grid or mesh points 1, 2, 3, $\dots$, 9, first use the diagonal formula to compute first u_5 and then u_7, u_9, u_1, u_3 in that order. They are given by

$$u_5 = \frac{1}{4} [c_1 + c_5 + c_9 + c_3]$$

$$u_7 = \frac{1}{4} [c_{15} + u_5 + c_{11} + c_{13}]$$

$$u_9 = \frac{1}{4} [u_5 + c_7 + c_9 + c_{11}]$$

$$u_1 = \frac{1}{4} [c_1 + c_3 + u_5 + c_{15}]$$

$$u_3 = \frac{1}{4} [c_3 + c_5 + c_7 + u_5]$$

Now making use of these values u_5, u_7, u_9, u_1, u_3 compute the remaining values u_8, u_4, u_6, u_2 (in any order) by standard five points formula, as follows:

$$u_8 = \frac{1}{4} [u_5 + u_9 + c_{11} + c_7]$$

$$u_4 = \frac{1}{4} [u_1 + u_5 + u_7 + c_{15}]$$

$$u_6 = \frac{1}{4} [u_3 + c_7 + u_9 + u_5]$$

$$u_2 = \frac{1}{4} [c_3 + u_3 + u_5 + u_1]$$

The accuracy of these 9 values u_1 to u_9 can be improved by using iterative methods such as (i) **Jacobi's method** (ii) **Gauss-Seidel method** (iii) **Successive over relaxation method**. In the **Gauss-Seidel method** (also known as **Leibman's method**) a standard five point formula is used wherein the

latest (last available) values of u are utilized. If n denotes the iteration number then the value of u at the $(n + 1)$ th iteration is given by

$$u_{i,j}^{n+1} = \frac{1}{4} \left[u_{i-1,j}^{(n+1)} + u_{i+1,j}^{(n)} + u_{i,j-1}^{(n+1)} + u_{i,j+1}^{(n)} \right] \quad (5)$$

Observe that in R.H.S. of (5), the latest values

$$u_{i-1,j}^{n+1} \text{ and } u_{i,j-1}^{n+1} \text{ are utilized.}$$

Note: Solution of Laplace equation is known as **harmonic** function.

WORKED OUT EXAMPLES

Example 1: Compute a solution to the Laplace's equation $\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} = 0$ at all mesh (grid) points of the following square in which the boundary values are indicated, using five point formula.

Solution: Let us index the mesh points as $f_1, f_2, f_3, \dots, f_9$. First calculate f_5 using standard five point formula and then calculate f_1, f_3, f_7, f_9 using diagonal formula. Now the remaining values f_2, f_4, f_6, f_8 are again calculated by standard five point formula. Thus by standard formula

$$f_5 = \frac{1}{4} [0 + 17.0 + 21.9 + 12.1] = 12.525.$$

Now use diagonal formula

$$f_1 = \frac{1}{4} [0 + 0 + 17.0 + 12.525] = 7.38$$

$$f_3 = \frac{1}{4} [17.0 + 18.6 + 21.9 + 12.525] = 17.28$$

$$f_7 = \frac{1}{4} [12.1 + 0 + 0 + 12.525] = 6.16$$

$$f_9 = \frac{1}{4} [12.1 + 12.525 + 21.9 + 9] = 13.66$$

Resorting to standard formula

$$f_2 = \frac{1}{4} [7.38 + 17 + 17.28 + 12.525] = 13.55$$

$$f_4 = \frac{1}{4} [0 + 7.38 + 12.525 + 6.16] = 6.52$$

$$f_6 = \frac{1}{4} [12.525 + 17.28 + 21 + 13.66] = 16.12$$

$$f_8 = \frac{1}{4} [6.16 + 12.525 + 13.66 + 12.1] = 11.11.$$

Example 2: Solve the above problem, using the values of $f_1, f_2, \dots, f_9$ as the initial approximation, by Gauss-Seidel (or Leibman's) method.

Solution:

$$f_{i,j}^{(n+1)} = \frac{1}{4} [f_{i-1,j}^{(n+1)} + f_{i+1,j}^{(n)} + f_{i,j-1}^{(n+1)} + f_{i,j+1}^{(n)}]$$

1st iteration:

$$f_1 = \frac{1}{4} [0 + 11.1 + 13.55 + 6.52] = 7.7925 \simeq 7.79$$

$$f_2 = \frac{1}{4} [7.79 + 17.0 + 17.28 + 12.525] = 13.65$$

$$f_3 = \frac{1}{4} [13.65 + 19.7 + 21.9 + 16.12] = 17.84$$

$$f_4 = \frac{1}{4} [0 + 7.79 + 12.525 + 6.16] = 6.62$$

$$f_5 = \frac{1}{4} [16.12 + 11.11 + 13.65 + 6.62] = 11.875$$

$$f_6 = \frac{1}{4} [21.0 + 13.66 + 17.84 + 11.875] = 16.09$$

$$f_7 = \frac{1}{4} [11.11 + 8.7 + 0 + 6.62] = 6.607$$

$$f_8 = \frac{1}{4} [13.66 + 12.1 + 11.875 + 6.607] = 11.06$$

$$f_9 = \frac{1}{4} [17.0 + 12.8 + 16.09 + 11.06] = 14.238$$

2nd iteration

$$f_1 = \frac{1}{4} [0 + 13.65 + 6.62 + 11.1] = 7.84$$

$$f_2 = \frac{1}{4} [7.84 + 17.84 + 11.87 + 17] = 13.639 \simeq 13.64$$

$$f_3 = \frac{1}{4} [13.64 + 16.09 + 19.7 + 21.9] = 17.83$$

$$f_4 = \frac{1}{4} [0 + 7.84 + 6.607 + 11.873] = 6.58$$

33.20 — HIGHER ENGINEERING MATHEMATICS—VIII

$$f_5 = \frac{1}{4} [6.58 + 13.64 + 11.01 + 16.09] = 11.843$$

$$f_6 = \frac{1}{4} [11.843 + 17.833 + 14.238 + 21] = 16.2285$$

$$f_7 = \frac{1}{4} [6.58 + 11.059 + 8.7 + 0] = 6.58$$

$$f_8 = \frac{1}{4} [12.11 + 6.587 + 14.238 + 11.843] = 11.19$$

$$f_9 = \frac{1}{4} [11.19 + 16.25 + 17 + 12.8] = 14.31.$$

Note that in every calculation, the latest (last available) values of f has been taken into the right hand side of the formula.

Ans: 7.8, 13.6, 17.8, 6.6, 11.9, 16.2, 6.6, 11.2, 14.3.

EXERCISE

- 1 (a) Determine the values of the interior lattice points of a square region of the harmonic function u with boundary conditions prescribed as shown in the figure.

- (b) Iterate by Gauss-Seidel (Leibman's) method.

Ans. (a) $u_1 = 7.4, u_2 = 13.6, u_3 = 17.3, u_4 = 6.5, u_5 = 12.5, u_6 = 16.1, u_7 = 6.2, u_8 = 11.1, u_9 = 13.7$

- (b) $u_1 = 7.9, u_2 = 13.7, u_3 = 17.9, u_4 = 6.6, u_5 = 11.9, u_6 = 16.3, u_7 = 6.6, u_8 = 11.2, u_9 = 14.3$ (after 3 iterations)

- 2 (a) Compute solution of Laplace's equation in the following square grid with prescribed boundary conditions.

- (b) Iterate the values by Gauss-Seidel method.

Ans. (a) $u_1 = 6.25, u_2 = 9.38, u_3 = 6.25, u_4 = 18.75, u_5 = 25, u_6 = 18.75, u_7 = 43.75, u_8 = 53.12, u_9 = 43.75$

- (b) 7.17, 9.86, 7.16, 18.78, 25.04, 18.77, 42.88, 52.70, 42.87 (after 3 iterations)

3. Compute solution of Laplace's equation in the square grid.

Hint: Solve the system of equations

$$u_2 + u_3 - 4u_1 + 100 + 100 = 0$$

$$u_1 + u_4 - 4u_2 + 100 + 0 = 0$$

$$u_1 + u_4 - 4u_3 + 100 + 0 = 0$$

$$u_2 + u_3 - 4u_4 + 0 + 0 = 0$$

Ans. $u_1 = 75, u_2 = 50, u_3 = 50, u_4 = 25$

- 4 (a) Determine $u_1, u_2, u_3, \dots, u_9$ if u satisfies Laplace's equation in the grid with given boundary condition.

(b) Iterate by Gauss-Seidel method.

Hint: Use symmetry about AB and CD .

Ans. (a) $u_1 = u_3 = u_7 = u_9 = 1125$, $u_2 = u_8 = 1188$, $u_5 = 1500$, $u_6 = u_4 = 1438$

(b) $u_1 = 939$, $u_2 = 1001$, $u_4 = 1251$, $u_5 = 1126$ (after 12 iterations)

5. Solve Laplace's equation.

Hint: Solve the four equations

$$40 + 60 + u_2 + u_3 - 4u_1 = 0$$

$$60 + 50 + u_1 + u_4 - 4u_2 = 0$$

$$20 + 10 + u_1 + u_4 - 4u_3 = 0$$

$$20 + 40 + u_3 + u_2 - 4u_4 = 0$$

Ans. $u_1 = 43.33$, $u_2 = 46.66$, $u_3 = 26.66$, $u_4 = 33.33$

6. If $\nabla^2 u = 0$, find u at the mesh points.

Hint: Square is symmetric about both the diagonals AC and BD .

Ans. $u_1 = 25$, $u_3 = 15$, $u_2 = 20$, $u_5 = 20$

Chapter 34

Matrices and Determinants

34.1 INTRODUCTION

Matrix means an “arrangement” or “array” Matrices (plural of matrix) were introduced by Cayley in 1860. A matrix ‘A’ is rectangular array of $m \cdot n$ numbers (or functions) arranged in m horizontal lines (known as ‘rows’) and in n vertical lines (known as ‘columns’), denoted by $A_{m \times n}$. These $m \cdot n$ numbers are known as the elements or entries of the matrix A and are enclosed in brackets [], or () or $\| \|$. The *order* of the matrix is $m \times n$.

When $m \neq n$, the matrix is said to be rectangular. Row matrix (or row vector) $B_{1 \times n}$ is a matrix having only one row (and several columns), column matrix (or column vector) $C_{m \times 1}$ is a matrix having only one column (and several rows). A matrix is said to be a n -square matrix or simply *square* matrix if $m = n$. Thus the number of rows and number of columns in a square matrix are equal.

The elements of the matrix A are denoted by a_{ij} and are located by the double subscript notation ij where the first subscript i denotes the row (position) and the second subscript j denotes the column position. Thus capital letters are used to denote matrices, while the corresponding small letters with double subscript notation are used to denote the elements (or entries). Thus $A = [a_{ij}]$.

Null or zero matrix denoted by 0 is a matrix with all its elements zero.

Equality: Two matrices A and B are said to be equal if they are of the same order and $a_{ij} = b_{ij}$ for every i and j . Otherwise they are unequal, denoted by $A \neq B$.

34.2 MATRIX ALGEBRA

Sum (or difference): $C_{m \times n} = A_{m \times n} \pm B_{m \times n}$ then C is said to be the sum (or difference) of A and B provided $c_{ij} = a_{ij} \pm b_{ij}$ for i, j i.e. the elements of C are obtained by adding (or subtracting) the corresponding elements of A and B .

Note that addition or subtraction of matrices A and B is possible only when both A and B are of the same order.

Submatrix of A is a matrix obtained from A after deleting some rows or columns or both.

Scalar multiplication: For any non zero scalar k , we have $C = kA$ when $c_{ij} = ka_{ij}$ i.e. every element of A is multiplied by k . Thus $-B$ is considered as B multiplied by -1 .

Properties:

1. $A + B = B + A$ commutative
2. $A + (B \pm C) = (A + B) \pm C$ associative
3. $k(A + B) = kA + kB$ distributive
4. $A - B \neq B - A$ not commutative

Transpose of a matrix A of order $m \times n$ is denoted by A^T or A' is obtained from A by interchanging the rows and columns. Thus $B = A^T$ is of $n \times m$ order and $b_{ji} = a_{ij}$ for any i, j , i.e. the i, j^{th} element of A is placed in the j, i^{th} location in A^T .

Properties:

1. $(A^T)^T = A$
2. $(kA)^T = kA^T$
3. $(A + B)^T = A^T + B^T$

34.2 — MATHEMATICAL METHODS

Matrix multiplication: Two matrices A and B are said to be conformable for multiplication if the number of columns in A is equal to the number of rows in B . Then the product of two matrices $A_{m \times p}$ and $B_{p \times n}$ is a matrix $C_{m \times n}$ where

$$c_{ij} = \sum_{k=1}^p a_{ik}b_{kj} \quad \text{for } i = 1 \text{ to } m \text{ and } j = 1 \text{ to } n$$

i.e., i, j^{th} element in the product matrix C is obtained by adding the p products obtained by multiplying each entry of the i^{th} row of A by the corresponding entry of the j^{th} column of B . Thus matrix multiplication amounts to multiplication of rows (of the first matrix) into columns (of the second matrix) i.e., row by column multiplication.

$m \begin{bmatrix} \overrightarrow{A} \end{bmatrix} \cdot p \begin{bmatrix} \overrightarrow{B} \end{bmatrix} = m \begin{bmatrix} \overrightarrow{C} \end{bmatrix}$ i.e. mn scalar products of the m rows of A with n columns of B .

In the product $C = AB$, the matrix B is *premultiplied* or multiplied from the left by A ; while the matrix A is *post multiplied* or multiplied from the right by B .

Properties:

1. $(kA)B = k(AB) = A(kB) = kAB$
2. $A(BC) = (AB)C$
3. $(A + B)C = AC + BC$
4. $A(B + C) = AB + AC$

However

5. $AB \neq BA$ in general (not commutative)
6. $AB = 0$ does not necessarily imply that $A = 0$ or $B = 0$ or $BA = 0$.

Also

7. $AB = AC$ does not necessarily imply that $B = C$, even when $A \neq 0$.
8. $(AB)^T = B^T A^T$

i.e., transpose of a product is the product of the transposes.

34.3 SPECIAL SQUARE MATRICES

The elements a_{ii} of an n -square matrix are known as *diagonal* elements. *Trace* of matrix $A =$

trace of $A = \sum_{i=1}^n a_{ii}$ = sum of the *diagonal* elements.

Result: trace $(A + B) = \text{trace } A + \text{trace } B$,
trace $(kA) = k \text{ trace } A$.

A is *singular* matrix if $|A| = 0$. A is *Non-singular* matrix if $|A| \neq 0$

Upper triangular matrix if $a_{ij} = 0$ for $i > j$ i.e., can have non zero entries only on and *above* the main diagonal while any entry *below* the diagonal is zero.

Lower triangular matrix if $a_{ij} = 0$ for $i < j$. A matrix is said to be *triangular* if it is either upper or lower triangular matrix.

Diagonal matrix if any entry above or below, the main diagonal is zero. However zero entries may be present in the diagonal. Thus

$$a_{ij} = 0 \text{ for } i \neq j$$

(however $a_{ii} = 0$, not for all i).

Scalar matrix is a diagonal matrix in which all the diagonal entries are equal to a constant k i.e., $a_{ii} = k$ for every i and $a_{ij} = 0$ for any i and j , ($i \neq j$).

Identity matrix denoted by I is a scalar matrix with $k = 1$. Thus

$$I_3 = I_{3 \times 3} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Positive integral power of a matrix A , denoted by A^n , is obtained by multiplying A by itself n times.

34.4 DIFFERENCES BETWEEN DETERMINANTS AND MATRICES

| Determinant D | Matrix A |
|--|--|
| 1. It has a numerical value | It has no value. It is a symbol representing an array of many numbers on which algebra can be performed. |
| 2. It can only be square | It can be rectangular |
| 3. It is zero when elements of any <i>one</i> row (or column) are zero | It is zero <i>only</i> when <i>all</i> the elements in the matrix are zero |
| 4. It is multiplied by k if elements of any <i>one</i> row (or column) are multiplied by k | It is multiplied by k , if <i>all</i> the elements of the matrix are multiplied by k |
| 5. Its value remains unaltered by the interchange of rows and columns. | It gets altered (giving rise to a new matrix) when rows and columns are interchanged |
| 6. Its value is $-D$ when adjacent rows (or columns) are interchanged. | It gets changed to a new matrix when adjacent rows (or columns) are interchanged. |

WORKED OUT EXAMPLES

Example 1: Classify the following matrices. Also find the order of the matrices.

- (a) $\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 3 & 4 & 5 \\ 3 & -4 & 0 & 6 \\ -7 & \frac{3}{2} & 8 & 10 \\ 5 & 6 & 7 & 9 \end{bmatrix}$ (b) $\begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \end{bmatrix}$ (c) $[2 \ 4 \ 6 \ 7 \ 8]$
- (d) $\begin{bmatrix} 2 & 3 & 1 & 0 \\ 0 & -5 & 3 & 7 \\ 0 & 0 & 0 & 10 \\ 0 & 0 & 0 & 6 \end{bmatrix}$ (e) $\begin{bmatrix} 5 & 0 & 0 \\ 7 & -2 & 0 \\ 9 & 8 & 12 \end{bmatrix}$
- (f) $\begin{bmatrix} 5 & 0 & 0 \\ 0 & -6 & 0 \\ 0 & 0 & 0 \end{bmatrix}$ (g) $\begin{bmatrix} k & 0 & 0 & 0 \\ 0 & k & 0 & 0 \\ 0 & 0 & k & 0 \\ 0 & 0 & 0 & k \end{bmatrix}$
- (h) $\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$ (i) $[13]$

Solution:

- (a) Rectangular matrix of order 5×4
 (b) Column matrix of order 4×1
 (c) Row matrix of order 1×5
 (d) Upper triangular matrix, 4×4 (square)
 (e) Lower triangular matrix, 3×3 (square)
 (f) Diagonal matrix, 3×3 (square)
 (g) Scalar matrix, 4×4 (square)
 (h) Null or zero matrix, 3×3 (square)
 (i) 1×1 matrix which identifies the single entry

Example 2: Suppose matrix A has m rows and $m + 6$ columns and matrix B has n rows and $12 - n$ columns. If both AB and BA exists, determine the orders of the matrices A and B .

Solution: Since $A_{m \times m+6} B_{n \times 12-n}$ exists, the number of columns in A must be equal to the number of rows in B i.e. $m + 6 = n$ or $m - n = -6$.

Similarly $B_{n \times 12-n} A_{m \times m+6}$ exists,
 $12 - n = m$ or $m + n = 12$

solving $m = 3, n = 9$. The order of A is 3×9 and of B is 9×3 .

Example 3: Determine AB and BA if $A - B = \begin{bmatrix} 2 & 3 \\ 1 & 2 \end{bmatrix}$ and $A + B = \begin{bmatrix} 5 & 7 \\ 4 & 1 \end{bmatrix}$. Is $AB = BA$.

Solution: Adding $A - B = \begin{bmatrix} 2 & 3 \\ 1 & 2 \end{bmatrix} = C$

$A + B = \begin{bmatrix} 6 & 7 \\ 5 & 2 \end{bmatrix} = D$ we get

$2A = C + D = \begin{bmatrix} 2 & 3 \\ 1 & 2 \end{bmatrix} + \begin{bmatrix} 6 & 7 \\ 5 & 2 \end{bmatrix} = \begin{bmatrix} 8 & 10 \\ 6 & 4 \end{bmatrix}$ so

$A = \begin{bmatrix} 4 & 5 \\ 3 & 2 \end{bmatrix}$. Then

$B = D - A = \begin{bmatrix} 6 & 7 \\ 5 & 2 \end{bmatrix} - \begin{bmatrix} 4 & 5 \\ 3 & 2 \end{bmatrix} = \begin{bmatrix} 2 & 2 \\ 2 & 0 \end{bmatrix}$

So $AB = \begin{bmatrix} 4 & 5 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} 2 & 2 \\ 2 & 0 \end{bmatrix} = \begin{bmatrix} 18 & 8 \\ 10 & 6 \end{bmatrix}$ and

$BA = \begin{bmatrix} 2 & 2 \\ 2 & 0 \end{bmatrix} \begin{bmatrix} 4 & 5 \\ 3 & 2 \end{bmatrix} = \begin{bmatrix} 14 & 14 \\ 8 & 10 \end{bmatrix}$.

Note that $AB \neq BA$, in general.

Example 4: If $A = \begin{bmatrix} 11 & -25 \\ 4 & -9 \end{bmatrix}$ show that $A^n = \begin{bmatrix} 1 + 10n & -25n \\ 4n & 1 - 10n \end{bmatrix}$ using mathematical induction.

Solution: Consider $A^2 = A \cdot A$

$$= \begin{bmatrix} 11 & -25 \\ 4 & -9 \end{bmatrix} \begin{bmatrix} 11 & -25 \\ 4 & -9 \end{bmatrix}$$

$$A^2 = \begin{bmatrix} 21 & -50 \\ 8 & -19 \end{bmatrix} \begin{bmatrix} 1 + 10 \cdot 2 & -25 \cdot 2 \\ 4 \cdot 2 & 1 - 10 \cdot 2 \end{bmatrix}$$

$$\text{Now } A^3 = A \cdot A^2 = \begin{bmatrix} 11 & -25 \\ 4 & -9 \end{bmatrix} \begin{bmatrix} 21 & -50 \\ 8 & -19 \end{bmatrix}$$

$$= \begin{bmatrix} 31 & -75 \\ 12 & -29 \end{bmatrix}$$

So

$$A^3 = \begin{bmatrix} 1 + 10 \cdot 3 & -25 \cdot 3 \\ 4 \cdot 3 & 1 - 10 \cdot 3 \end{bmatrix}.$$

Assume $A^k = \begin{bmatrix} 1 + 10k & -25k \\ 4k & 1 - 10k \end{bmatrix}$. Then

34.4 — MATHEMATICAL METHODS

$$\begin{aligned}
 A^{k+1} &= A \cdot A^k = \begin{bmatrix} 11 & -25 \\ 4 & -9 \end{bmatrix} \begin{bmatrix} 1+10k & -25k \\ 4k & 1-10k \end{bmatrix} \\
 &= \begin{bmatrix} 11+10k & -25-25k \\ 4+4k & -9-10k \end{bmatrix} \\
 &= \begin{bmatrix} 1+10(k+1) & -25(k+1) \\ 4(k+1) & 1-10(k+1) \end{bmatrix}
 \end{aligned}$$

By mathematical induction the result follows.

Example 5: If $A = \begin{pmatrix} 8 & -4 \\ 2 & 2 \end{pmatrix}$ prove that $A^2 - 10A + 24I = 0$.

$$\begin{aligned}
 \text{Solution: } A^2 &= A \cdot A = \begin{pmatrix} 8 & -4 \\ 2 & 2 \end{pmatrix} \begin{pmatrix} 8 & -4 \\ 2 & 2 \end{pmatrix} \\
 &= \begin{pmatrix} 56 & -40 \\ 20 & -4 \end{pmatrix}. \quad \text{Then } A^2 - 10A + 24I = \\
 &= \begin{pmatrix} 56 & -40 \\ 20 & -4 \end{pmatrix} - 10 \begin{pmatrix} 8 & -4 \\ 2 & 2 \end{pmatrix} + 24 \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \\
 &= \begin{pmatrix} 56-80+24 & -40+40+0 \\ 20-20+0 & -4-20+24 \end{pmatrix} \\
 &= \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} = 0
 \end{aligned}$$

Example 6: Show that $AB = AC$ does not necessarily imply that $B = C$ where $A = \begin{bmatrix} 1 & -3 & 2 \\ 2 & 1 & -3 \\ 4 & -3 & -1 \end{bmatrix}$,

$$B = \begin{bmatrix} 1 & 4 & 1 & 0 \\ 2 & 1 & 1 & 1 \\ 1 & -2 & 1 & 2 \end{bmatrix}, C = \begin{bmatrix} 2 & 1 & -1 & -2 \\ 3 & -2 & -1 & -1 \\ 2 & -5 & -1 & 0 \end{bmatrix}$$

Solution: $A_{3 \times 3} B_{3 \times 4} = D_{3 \times 4}$

$$= \begin{bmatrix} -3 & -3 & 0 & 1 \\ 1 & 15 & 0 & -5 \\ -3 & 15 & 0 & -5 \end{bmatrix}$$

$= A_{3 \times 3} C_{3 \times 4}$ however $B \neq C$.

Example 7: Verify that

- (a) $AB = BA = 0$, (b) $AC = A$,
 (c) $CA = C$, (d) $ACB = CBA$,
 (e) $(A \pm B)^2 = A^2 + B^2$,
 (f) $(A - B)(A + B) = A^2 - B^2$

$$\text{where } A = \begin{bmatrix} 2 & -3 & -5 \\ -1 & 4 & 5 \\ 1 & -3 & -4 \end{bmatrix},$$

$$B = \begin{bmatrix} -1 & 3 & 5 \\ 1 & -3 & -5 \\ -1 & 3 & 5 \end{bmatrix}, C = \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix}$$

Solution:

$$\begin{aligned}
 \text{(a) } AB &= \begin{bmatrix} 2 & -3 & -5 \\ -1 & 4 & 5 \\ 1 & -3 & -4 \end{bmatrix} \begin{bmatrix} -1 & 3 & 5 \\ 1 & -3 & -5 \\ -1 & 3 & 5 \end{bmatrix} \\
 &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = 0
 \end{aligned}$$

Similarly

$$\begin{aligned}
 BA &= \begin{bmatrix} -1 & 3 & 5 \\ 1 & -3 & -5 \\ -1 & 3 & 5 \end{bmatrix} \begin{bmatrix} 2 & -3 & -5 \\ -1 & 4 & 5 \\ 1 & -3 & -4 \end{bmatrix} \\
 &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = 0
 \end{aligned}$$

Thus $AB = BA = 0$

$$\text{(b) } AC = \begin{bmatrix} 2 & -3 & -5 \\ -1 & 4 & 5 \\ 1 & -3 & -4 \end{bmatrix} \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix}$$

$$= \begin{bmatrix} 2 & -3 & -5 \\ -1 & 4 & 5 \\ 1 & -3 & -4 \end{bmatrix} = A$$

$$\begin{aligned}
 \text{(c) } CA &= \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix} \begin{bmatrix} 2 & -3 & -5 \\ -1 & 4 & 5 \\ 1 & -3 & -4 \end{bmatrix} \\
 &= \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix} = C
 \end{aligned}$$

(d) $ACB = (AC)B = (A)B = AB = 0$

$$CBA = C(BA) = C \cdot 0 = 0$$

(e) $(A \pm B)^2 = A^2 \pm AB \pm BA + B^2 = A^2 + B^2$
 since $AB = BA = 0$

(f) $(A - B)(A + B) = A^2 - BA + AB - B^2 = A^2 - B^2$
 since $AB = BA = 0$

Example 8: Prove that (a) trace $(A + B) = \text{trace } A + \text{trace } B$ (b) trace $(kA) = k \text{ trace } A$.

$$\begin{aligned}
 \text{Solution: } \text{(a) Trace } (A + B) &= \sum_{i=1}^n (a_{ii} + b_{ii}) \\
 &= \sum a_{ii} + \sum b_{ii} = \text{trace } A + \text{trace } B
 \end{aligned}$$

$$(b) \text{ Trace } (kA) = \sum_{i=1}^n (ka_{ii}) = k \sum_{i=1}^n a_{ii} = k \text{ trace } A$$

Example 9: Express $A = \begin{bmatrix} 5 & -2 & 1 \\ 7 & 1 & -5 \\ 3 & 7 & 4 \end{bmatrix}$ as the product of LU where L and U are lower and upper triangular matrices (known as *LU-decomposition* or Factorization).

Solution: Let the lower triangular matrix be

$$L = \begin{bmatrix} l_{11} & 0 & 0 \\ l_{21} & l_{22} & 0 \\ l_{31} & l_{32} & l_{33} \end{bmatrix} \text{ while } U = \begin{bmatrix} u_{11} & u_{12} & u_{13} \\ 0 & u_{22} & u_{23} \\ 0 & 0 & u_{33} \end{bmatrix}$$

be the upper triangular matrix. Then

$$A = \begin{bmatrix} 5 & -2 & 1 \\ 7 & 1 & -5 \\ 3 & 7 & 4 \end{bmatrix} = LU$$

$$\begin{bmatrix} l_{11} & 0 & 0 \\ l_{21} & l_{22} & 0 \\ l_{31} & l_{32} & l_{33} \end{bmatrix} \begin{bmatrix} u_{11} & u_{12} & u_{13} \\ 0 & u_{22} & u_{23} \\ 0 & 0 & u_{33} \end{bmatrix}$$

Equating the corresponding component on both sides, we have $l_{11}u_{11} = 5$, $l_{11}u_{12} = -2$, $l_{11}u_{13} = 1$, $l_{21}u_{11} = 7$, $l_{21}u_{12} + l_{22}u_{22} = 1$, $l_{21}u_{13} + l_{22}u_{23} = -5$, $l_{31}u_{11} = 3$, $l_{31}u_{12} + l_{32}u_{22} = 7$, $l_{31}u_{13} + l_{32}u_{23} + l_{33}u_{33} = 4$.

Since there are 12 unknowns and 9 equations only, to get a unique solution, assume that

$$l_{11} = l_{22} = l_{33} = 1$$

Now $u_{11} = 5$, $u_{12} = -2$, $u_{13} = 1$. Then $l_{21} = \frac{7}{u_{11}} = \frac{7}{5}$, $u_{22} = (1 - l_{21}u_{12})/l_{22} = [1 - \frac{7}{5}(-2)]/1 = \frac{19}{5}$, $u_{23} = (-5 - l_{21}u_{13})/l_{22} = (-5 - \frac{7}{5} \cdot 1) = -\frac{32}{5}$, $l_{31} = \frac{3}{u_{11}} = \frac{3}{5}$.

Similarly $l_{32} = \frac{41}{19}$, $u_{33} = \frac{327}{19}$. Thus $A = LU =$

$$\begin{bmatrix} 1 & 0 & 0 \\ \frac{7}{5} & 1 & 0 \\ \frac{3}{5} & \frac{41}{19} & 1 \end{bmatrix} \begin{bmatrix} 5 & -2 & 1 \\ 0 & \frac{19}{5} & -\frac{32}{5} \\ 0 & 0 & \frac{327}{19} \end{bmatrix}$$

34.5 MATRICES

EXERCISE

$$1. \text{ If } A = \begin{bmatrix} 2 & 2 & -3 \\ 5 & 0 & 2 \\ 3 & -1 & 4 \end{bmatrix}, B = \begin{bmatrix} 3 & -4 & 2 \\ 4 & 2 & 5 \\ 2 & 0 & 3 \end{bmatrix},$$

$$C = \begin{bmatrix} 4 & 6 & 2 \\ 0 & 3 & 2 \\ 7 & -2 & 3 \end{bmatrix}$$

find (a) $A + B$, (b) $A - B$, (c) $-3B$, (d) verify $A + (B - C) = (A + B) - C$, (e) Find D such that $C + D = B$, (f) AB , (g) BA , (h) Is $AB = BA$, (i) AC , (j) verify $A(B + C) = AB + AC$ (k) Is $AB = AC$, (l) Is $AC = CA$

$$\text{Ans. (a) } A + B = \begin{bmatrix} 5 & -2 & -1 \\ 9 & 2 & 7 \\ 5 & -1 & 7 \end{bmatrix}$$

$$(b) A - B = \begin{bmatrix} -1 & 6 & -5 \\ 1 & -2 & -3 \\ 1 & -1 & 1 \end{bmatrix}$$

$$(c) -3B = \begin{bmatrix} -9 & 12 & -6 \\ -12 & -6 & -15 \\ -6 & 0 & -9 \end{bmatrix}$$

$$(e) \text{ Hint: } B - C = \begin{bmatrix} -1 & -10 & 0 \\ +4 & -1 & 3 \\ -5 & 2 & 0 \end{bmatrix} = D$$

$$(f) AB = \begin{bmatrix} 8 & -4 & 5 \\ 19 & -20 & 16 \\ 13 & -14 & 13 \end{bmatrix}$$

$$(g) BA = \begin{bmatrix} -8 & 4 & -9 \\ 33 & 3 & 12 \\ 13 & 1 & 9 \end{bmatrix}$$

(h) No. In general $AB \neq BA$

$$(i) AC = \begin{bmatrix} -13 & 24 & -1 \\ 34 & 26 & 16 \\ 40 & 12 & 16 \end{bmatrix}$$

$$(j) \text{ Hint: } B + C = \begin{bmatrix} 7 & 2 & 4 \\ 4 & 5 & 7 \\ 9 & -2 & 6 \end{bmatrix}$$

$$(l) \text{ No } (j) \text{ Hint: } CA = \begin{bmatrix} 44 & 6 & 8 \\ 21 & -2 & 14 \\ 13 & 11 & -13 \end{bmatrix}, \text{ No}$$

$$AC \neq CA$$

2. Determine the orders of the matrices A having m rows and $m + 5$ columns and B having n rows and $11 - n$ columns if both AB and BA exist.

34.6 — MATHEMATICAL METHODS

Ans. $A_{3 \times 8}; B_{8 \times 3}$

3. Compute the product AB, BA given that $A + B = \begin{bmatrix} 1 & -1 \\ 3 & 0 \end{bmatrix}$ and $A - B = \begin{bmatrix} 3 & 1 \\ 1 & 4 \end{bmatrix}$. Is $BA = AB$

Ans. $AB = \begin{bmatrix} -2 & -2 \\ 0 & -6 \end{bmatrix}, BA = \begin{bmatrix} -4 & -2 \\ -2 & -4 \end{bmatrix}$, No

Hint: $A = \begin{bmatrix} 2 & 0 \\ 2 & 2 \end{bmatrix}, B = \begin{bmatrix} -1 & -1 \\ 1 & -2 \end{bmatrix}$

4. State why in general (a) $(A \pm B)^2 \neq A^2 \pm 2AB + B^2$ (b) $A^2 - B^2 \neq (A - B)(A + B)$ (c) Verify the results (a) and (b) for A and B in the above problem 3.

Ans. Since $AB \neq BA$ in general.

5. If $A = \begin{bmatrix} 1 & 2 & 2 \\ 0 & 2 & 1 \\ -1 & 2 & 2 \end{bmatrix}$, verify that $A^3 - 5A^2 + 8A - 4I = 0$

6. If $A = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}$ show that $A^n = \begin{bmatrix} \cos n\theta & -\sin n\theta \\ \sin n\theta & \cos n\theta \end{bmatrix}$ by using mathematical induction.

7. Is $AB = BA$ given that

$$A = \begin{bmatrix} 1 & 3 & 0 \\ -1 & 2 & 1 \\ 0 & 0 & 2 \end{bmatrix}, B = \begin{bmatrix} 2 & 3 & 4 \\ 1 & 2 & 3 \\ -1 & 1 & 2 \end{bmatrix}$$

8. Determine the values of x for which the matrix A

$$\text{is nonsingular where } A = \begin{bmatrix} 1 & 2x & 3x \\ 1 & 1 & 2 \\ x & 3 & 0 \end{bmatrix}$$

Ans. A is nonsingular for any x other than 3 and $\frac{2}{3}$

Hint: $|A| = 3x^2 - 11x + 6$
 $= (x - 3)(x - \frac{2}{3}) = 0$

9. If $A = \begin{bmatrix} 3 & 1 \\ 0 & 1 \end{bmatrix}, B = \begin{bmatrix} 1 & 5 \\ 7 & 2 \end{bmatrix}$ then find (a) A^T (b) B^T (c) $(A + B)^T$ (d) $(A - B)^T$ (e) $A^T + B^T$ (f) $A^T - B^T$ (g) Verify $(A + B)^T = A^T + B^T$ (h) Is $(A - B)^T = A^T - B^T$ (i) $(AB)^T$ (j) $B^T A^T$ (k) Verify that $(AB)^T = B^T A^T$

Ans. (a) $A^T = \begin{bmatrix} 3 & 0 \\ 1 & 1 \end{bmatrix}$ (b) $B^T = \begin{bmatrix} 1 & 7 \\ 5 & 2 \end{bmatrix}$

$$(c) (A + B)^T = \begin{bmatrix} 4 & 7 \\ 6 & 3 \end{bmatrix}$$

$$(d) (A - B)^T = \begin{bmatrix} 2 & -7 \\ -4 & -1 \end{bmatrix}$$

$$(e) A^T + B^T = \begin{bmatrix} 4 & 7 \\ 6 & 3 \end{bmatrix} \quad (g) \text{ True}$$

$$(h) (A - B)^T = A^T - B^T$$

$$(i) (AB)^T = \begin{bmatrix} 10 & 7 \\ 17 & 2 \end{bmatrix}$$

$$(j) B^T A^T = \begin{bmatrix} 10 & 7 \\ 17 & 2 \end{bmatrix}$$

(k) True

10. Express $A = \begin{bmatrix} 3 & 5 & 2 \\ 0 & 8 & 2 \\ 6 & 2 & 8 \end{bmatrix}$ as product LU where L and U are lower and upper triangular matrices.

Ans. $L = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 2 & -1 & 1 \end{bmatrix}, U = \begin{bmatrix} 3 & 5 & 2 \\ 0 & 8 & 2 \\ 0 & 0 & 6 \end{bmatrix}$

34.6 DETERMINANTS

Although determinants are inefficient in practical computations, they are useful in vector algebra, differential equations and eigenvalue problems. A *determinant* is a scalar (numerical value) associated with only *square matrix* $A = [a_{ij}]$ and is denoted as determinant of A or $\det A$ or $|A|$. Thus a determinant is a scalar-valued function whose domain is a set of square matrices. A determinant of an $n \times n$ square matrix A is a scalar given by

$$D = \det A = \begin{vmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{vmatrix} \quad (1)$$

The determinant D is said to be of order n and contains n^2 elements or quantities (which may be numbers or functions), arranged in n rows and n columns.

The principal diagonal of the determinant is the sloping line of elements from left top corner a_{11} to a_{nn} .

Note that in the matrix representation the elements a_{ij} are enclosed between brackets [] or () or ||, whereas in the determinant the elements are enclosed between vertical lines or bars ||. For $n = 2$, the second order determinant is defined by

$$D = \det A = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11} a_{22} - a_{21} a_{12}. \quad (2)$$

i.e. second order determinant = difference between the product of elements of principal diagonal and the product of the elements of the other diagonal.

For $n = 1$,

$$D = \det[a_{11}] = [a_{11}] = a_{11}$$

Note: Here vertical bars does not denote *absolute value*. Thus $\det [-5] = |-5| = -5$

Minor of an element a_{ij} of a matrix A , denoted by M_{ij} , is an $(n - 1)$ order determinant of the submatrix of A obtained by omitting the i th row and j th column in A .

Cofactor of an element a_{ij} of a matrix A , denoted by C_{ij} , is a signed minor of a_{ij}

$$\text{i.e. } C_{ij} = (-1)^{i+j} M_{ij}$$

Laplace Expansion

Laplace Expansion is the expansion of determinant in terms of the cofactors. For $n \geq 2$

$$D = \sum_{j=1}^n a_{ij} C_{ij} = a_{i1} C_{i1} + a_{i2} C_{i2} + \cdots + a_{in} C_{in}$$

(row wise for any $i = 1, 2, \dots$ or n) (3)

or

$$D = \sum_{i=1}^n a_{ij} C_{ij} = a_{1j} C_{1j} + a_{2j} C_{2j} + \cdots + a_{nj} C_{nj} \quad (4)$$

(column wise for any $j = 1, 2, \dots$ or n).

Thus the value of a determinant is the sum of the products of elements of *any row (or column)* and *their* respective cofactors. However sum of products formed by multiplying the elements of a row (or col-

umn) of A by the corresponding cofactors of *another* row (or column) of A is zero i.e. $\sum_{k=1}^n a_{ik} C_{jk} = \delta_{ij} |A|$

or $\sum_{k=1}^n a_{kj} C_{ki} = \delta_{ij} |A|$. Here δ_{ij} is the Kronecker delta. So it is convenient to choose the row or column in the determinant with zeros in it, since these terms in the expansion will vanish. The expansion of D by (3) or (4) involves $n!$ determinants since D is defined in terms of n determinants of order $(n - 1)$, each of which is in turn defined in terms of $(n - 1)$ determinants of order $(n - 2)$ and then $(n - 2)$ determinants of order $(n - 3)$ and so on. As the number of calculations of an n th order determinant is $N(n) \sim en!$, even for $n = 25$, computing time is 4×10^{19} sec $\approx 10^{12}$ years. However with the use of several properties of determinants which are listed below, the determinant can be triangularized. In this case, the number of calculations $N(n) \sim \frac{2n^3}{3}$. For $n = 25$, computation time is 0.01 second (against 10^{12} years which is incredible!)

Properties of Determinants

1. If all the elements of *any one* row (or column) are zero, then $\det A = 0$.
2. If any two rows (or columns) are proportional to each other, then $\det A = 0$.
3. If any row (or column) is a linear combination of other rows (or columns), then $\det A = 0$.
4. If all the elements of any row or column are multiplied by k , giving rise to a new matrix B , then $\det B = k \cdot \det A$.
5. If $B = kA$ then $\det B = \det (kA) = k^n \det A$.
6. $\det (A^T) = \det (A)$.
7. In general, $\det (\alpha A + \beta B) \neq \alpha \det (A) + \beta \det (B)$ i.e. determinant () is *not* linear.
8. If any two rows (or columns) of A are interchanged, yielding a new matrix B then $\det B = -\det A$.
9. If k times the elements of any row (or column) in A are added to the corresponding elements of any row (or column) in A , giving rise to a new matrix B , then $\det B = \det A$. This operation is written symbolically as

34.8 — MATHEMATICAL METHODS

$$r_i \rightarrow r_i + k r_j$$

i.e., elements of j th row multiplied by k are added to the corresponding elements of the i th row. Here the i th row gets modified. Similarly

$$c_i \rightarrow c_i + k c_j$$

10. If A is a (upper or lower) triangular matrix or diagonal matrix then

$$\det A = a_{11} \cdot a_{22} \cdots a_{nn}$$

i.e. value of the determinant is the product of the diagonal elements.

11. If each element of a row (or column) consists of ' m ' terms (two: binomials, three: trinomial etc), then the determinant is expressed as the sum of ' m ' determinants. Suppose any row (or column) of A is a binomial say $a = b + c$ then

$$\det A|_a = \det A|_b + \det A|_c.$$

Here $A|_a$ is the original matrix, $A|_b$ is the matrix obtained from the original matrix $A|_a$ by replacing a by b and similarly $A|_c$ by replacing a by c .

Extending this, if the elements of say three rows (or columns) consists of m, n, p terms respectively then the original determinants can be expressed as the sum of $m \cdot n \cdot p$ determinants as stated above.

Product of Determinants

12. For any $n \times n$ matrices A and B

$$\det(AB) = \det(BA) = \det A \cdot \det B$$

Note: If A is singular, then AB is also singular so $\det A = 0, \det AB = 0$. Thus $0 = 0$

13. If $C = \det A \cdot \det B$, then the i, j th element of C is obtained by multiplying the i th row (or column) of A with j th column (or row) of B . Note that in matrix multiplication i, j th element is obtained by multiplying the i th row of A with j th column of B . Whereas in determinant multiplication, ij th element is obtained either by multiplying (i th row of A with j th column of B) or (i th row of A with j th row of B) or (i th column of A with j th column of B) or (i th column of A with j th row of B). Thus, in determinant multiplication we can multiply row

by row, row by column, column by row or column by column.

14. Derivative of a Determinant

If the elements a_{ij} of a matrix A are differentiable functions of a parameter t , then the derivative of the determinant A equals to sum of n determinants obtained by replacing in all possible ways the elements of one row (or column) of $|A|$ by their derivatives wrt ' t ', i.e.

$$\begin{aligned} \frac{d}{dt} (\det A) = & \begin{vmatrix} \frac{da_{11}}{dt} & \cdots & \frac{da_{1n}}{dt} \\ a_{21} & \cdots & a_{2n} \\ \vdots & & \vdots \\ a_{n1} & \cdots & a_{nn} \end{vmatrix} + \begin{vmatrix} a_{11} & \cdots & a_{1n} \\ \frac{da_{21}}{dt} & \cdots & \frac{da_{2n}}{dt} \\ \vdots & & \vdots \\ a_{n1} & \cdots & a_{nn} \end{vmatrix} + \\ & + \cdots + \begin{vmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & & \vdots \\ a_{n-1,1} & \cdots & a_{n-1,n} \\ \frac{da_{n1}}{dt} & \cdots & \frac{da_{nn}}{dt} \end{vmatrix} \end{aligned}$$

15. Factor Theorem

Consider an n th order functional determinant A in which the elements a_{ij} are functions of x . Suppose for $x = x^*$, any two rows (or columns) of A become equal, then $\det A = 0$. Then $\det A$ must contain a factor $(x - x^*)$. Suppose for $x = x^*$, k rows (or columns) become identical then $\det A = 0$. So consequently $\det A$ must contain a factor $(x - x^*)^{k-1}$.

16. Singular

A matrix A is said to be singular if $|A| = 0$, otherwise A is said to be nonsingular i.e., determinant of A is non zero ($|A| \neq 0$).

WORKED OUT EXAMPLES

Example 1: Find all the cofactors and evaluate

$$A = \begin{vmatrix} -2 & 3 \\ -4 & 5 \end{vmatrix}$$

Solution: C_{11} = cofactor of $-2 = 5$,

C_{12} = cofactor of $3 = 4$,

C_{21} = cofactor of $-4 = -3$,

C_{22} = cofactor of 5 = -2

By Laplace expansion about the first row,

$$|A| = -2 \cdot C_{11} + 3 \cdot C_{12} = -2(5) + 3(4) \\ = -10 + 12 = 2$$

By Laplace expansion about the second row

$$|A| = -4 C_{21} + 5 C_{22} = -4(-3) + 5(-2) \\ = 12 - 10 = 2$$

Similarly about first column

$$|A| = (-2)(5) - 4(-3) = -10 + 12 = 2$$

About 2nd column, $|A| = 3(+4) + 5(-2) = 2$

Example 2: Find the minors M_{21} , M_{13} , cofactors C_{22} , C_{32} and evaluate the determinant

$$|A| = \begin{vmatrix} 12 & 27 & 12 \\ 28 & 18 & 24 \\ 70 & 15 & 40 \end{vmatrix}$$

$$\text{Solution: } M_{21} = \text{minor of } 28 = \begin{vmatrix} 27 & 12 \\ 15 & 40 \end{vmatrix}$$

$$= 1080 - 180 = 900$$

$$M_{13} = \text{Minor of } 12 = \begin{vmatrix} 28 & 18 \\ 70 & 15 \end{vmatrix} = -840$$

$$C_{22} = \text{cofactor of } 18 = (-1)^{2+2} M_{22} = \begin{vmatrix} 12 & 12 \\ 70 & 40 \end{vmatrix} \\ = -360$$

$$C_{32} = \text{cofactor of } 15 = (-1)^{3+2} M_{32} = - \begin{vmatrix} 12 & 12 \\ 28 & 24 \end{vmatrix} \\ = -(-48) = 48. \text{ Expanding the determinant by element of first row, we have} \\ |A| = 12(18 \cdot 40 - 15 \cdot 24) - 27(28 \cdot 40 - 70 \cdot 24) \\ + 12(28 \cdot 15 - 70 \cdot 18) \\ = 12(360) - 27(-560) + 12(-840) = 4320 + 15120 - 11080 \\ = 9360$$

Example 3: Evaluate $|A|$ by triangularization where

$$|A| = \begin{vmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 4 & 3 \\ 3 & 4 & 2 & 1 \\ 4 & 3 & 1 & 2 \end{vmatrix}$$

$$\text{Solution: } R_2 \rightarrow R_2 - 2R_1, R_3 \rightarrow R_3 - 3R_1,$$

$$R_4 \rightarrow R_4 - 4R_1$$

$$|A| \sim \begin{vmatrix} 1 & 2 & 3 & 4 \\ 0 & -3 & -2 & -5 \\ 0 & -2 & -7 & -11 \\ 0 & -5 & -11 & -14 \end{vmatrix}$$

Expanding by first column and taking minus from the three rows,

$$|A| = (-1) \begin{vmatrix} 3 & 2 & 5 \\ 2 & 7 & 11 \\ 5 & 11 & 14 \end{vmatrix} R_2 \rightarrow R_2 - R_1 \\ = (-1) \begin{vmatrix} 3 & 2 & 5 \\ -1 & 5 & 6 \\ 5 & 11 & 14 \end{vmatrix}$$

$$R_1 \rightarrow R_1 + 3R_2 = (-1) \begin{vmatrix} 0 & 17 & 23 \\ -1 & 5 & 6 \\ 0 & 36 & 44 \end{vmatrix}$$

Expanding by first column

$$|A| = (-1) \cdot (-1) \cdot (-1) [17 \cdot 44 - 23 \cdot 36] \\ |A| = -[748 - 828] = 80$$

Example 4: Evaluate

$$A = \begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 2 & 1 \\ 0 & 0 & 0 & 3 & 2 & 1 \\ 0 & 0 & 4 & 3 & 2 & 1 \\ 0 & 5 & 4 & 3 & 2 & 1 \\ 6 & 5 & 4 & 3 & 2 & 1 \end{vmatrix}$$

Solution: Interchanging all the rows and columns we get

$$|A| = -|B| = - \begin{vmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 2 & 0 & 0 & 0 & 0 \\ 1 & 2 & 3 & 0 & 0 & 0 \\ 1 & 2 & 3 & 4 & 0 & 0 \\ 1 & 2 & 3 & 4 & 5 & 0 \\ 1 & 2 & 3 & 4 & 5 & 6 \end{vmatrix} = -(1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6) \\ = -720$$

since B is an lower triangular matrix.

$$\text{Example 5: Find the value of } \begin{vmatrix} 1 & 15 & 14 & 4 \\ 12 & 6 & 7 & 9 \\ 8 & 10 & 11 & 5 \\ 13 & 3 & 2 & 16 \end{vmatrix}$$

34.10 — MATHEMATICAL METHODS

Solution: $R_3 \rightarrow R_3 - R_2, R_4 \rightarrow R_4 - R_1$

$$= \begin{vmatrix} 1 & 15 & 14 & 4 \\ 12 & 6 & 7 & 9 \\ -4 & 4 & 4 & -4 \\ 12 & -12 & -12 & 12 \end{vmatrix}$$

Taking 4 from 3rd row and 12 from 4th row,

$$= 4 \cdot 12 \begin{vmatrix} 1 & 15 & 14 & 4 \\ 12 & 6 & 7 & 9 \\ -1 & 1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{vmatrix};$$

$$R_4 \rightarrow R_4 + R_1 = 48 \begin{vmatrix} 1 & 15 & 14 & 4 \\ 12 & 6 & 7 & 9 \\ -1 & 1 & 1 & -1 \\ 0 & 0 & 0 & 0 \end{vmatrix}$$

$$= 48 \cdot 0 = 0$$

since all the entries of the 4th row are zero.

Example 6: Evaluate $\begin{vmatrix} a+2b & a+4b & a+6b \\ a+3b & a+5b & a+7b \\ a+4b & a+6b & a+8b \end{vmatrix}$

Solution: Performing $R_3 \rightarrow R_3 - R_2, R_1 \rightarrow R_1 - R_2$,

$$\begin{vmatrix} a+2b & a+4b & a+6b \\ b & b & b \\ 2b & 2b & 2b \end{vmatrix} = 0 \text{ since the last two rows are proportional.}$$

Example 7: Evaluate the n th order determinant

$$\Delta = \begin{vmatrix} a & b & \cdots & b & b \\ b & a & \cdots & b & b \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ b & b & \cdots & a & b \\ b & b & \cdots & b & a \end{vmatrix}$$

Solution: Adding all the $(n-1)$ columns to the first column,

$$\Delta = \begin{vmatrix} a+(n-1)b & b & \cdots & b & b \\ a+(n-1)b & a & \cdots & b & b \\ a+(n-1)b & b & \cdots & b & b \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ a+(n-1)b & b & \cdots & b & a \end{vmatrix}$$

$$= a + (n-1)b \begin{vmatrix} 1 & b & b & \cdots & b \\ 1 & a & b & \cdots & b \\ 1 & b & a & \cdots & b \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & b & b & \cdots & a \end{vmatrix}$$

when $a = b$, $R_1 = R_2 = R_3 = \cdots = R_n$ i.e. all the n rows are identical and so determinant Δ vanishes. Thus by factor theorem, $(a-b)^{n-1}$ is a factor of Δ . Thus $\Delta = (a-b)^{n-1} [a + (n-1)b]$.

Example 8: Show that $\begin{vmatrix} a+b & b+c & c+a \\ b+c & c+a & a+b \\ c+a & a+b & b+c \end{vmatrix}$

$$= 2 \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}$$

Solution: Here the 3 rows contain binomials. So the given determinant can be expressed as the sum of $2 \cdot 2 \cdot 2 = 8$ determinants as follows.

$$\begin{vmatrix} a+b & b+c & c+a \\ b+c & c+a & a+b \\ c+a & a+b & b+c \end{vmatrix} = \begin{vmatrix} a & b+c & c+a \\ b & c+a & a+b \\ c & a+b & b+c \end{vmatrix} + \begin{vmatrix} b & b+c & c+a \\ c & c+a & a+b \\ a & a+b & b+c \end{vmatrix} + \begin{vmatrix} a & b & c+a \\ b & c & a+b \\ c & a & b+c \end{vmatrix} + \begin{vmatrix} a & c & c+a \\ b & a & a+b \\ c & b & b+c \end{vmatrix} + \begin{vmatrix} b & b & c+a \\ c & c & a+b \\ a & a & b+c \end{vmatrix} + \begin{vmatrix} b & c & c+a \\ c & a & a+b \\ a & b & b+c \end{vmatrix} + \begin{vmatrix} a & b & c \\ b & a & a+b \\ c & a & b \end{vmatrix} + \begin{vmatrix} a & c & c \\ b & a & a \\ c & b & b \end{vmatrix}$$

In this the 3rd determinant is zero because the 1st and 2nd columns are identical. Then

$$= \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} + \begin{vmatrix} a & b & a \\ b & c & b \\ c & a & c \end{vmatrix} + \begin{vmatrix} a & c & c \\ b & a & a \\ c & b & b \end{vmatrix} + \begin{vmatrix} a & c & a \\ b & a & b \\ c & b & c \end{vmatrix} + \begin{vmatrix} b & c & c \\ c & a & a \\ a & b & b \end{vmatrix} + \begin{vmatrix} b & c & a \\ c & a & b \\ a & b & c \end{vmatrix} + \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} + \begin{vmatrix} b & c & a \\ c & a & b \\ a & b & c \end{vmatrix}$$

Since in these 2nd, 3rd, 4th, 5th determinants are zero because of identical columns.

$$\begin{aligned}
 &= \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} + (-1)(-1) \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} \\
 &= 2 \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}
 \end{aligned}$$

Example 9: Prove that for the n th order determinant Δ where

$$\begin{aligned}
 \Delta &= \begin{vmatrix} 1+a_1 & a_2 & a_3 & \cdots & a_n \\ a_1 & 1+a_2 & a_3 & \cdots & a_n \\ a_1 & a_2 & 1+a_3 & \cdots & a_n \\ \vdots & & & \ddots & \\ a_1 & a_2 & a_3 & \cdots & 1+a_n \end{vmatrix} \\
 &= 1 + a_1 + a_2 + \cdots + a_n.
 \end{aligned}$$

Solution: Performing $R_2 \rightarrow R_2 - R_1, R_3 \rightarrow R_3 - R_1, \dots, R_n \rightarrow R_n - R_1$ (i.e. subtracting the first row from the remaining $(n-1)$ rows) we get

$$\Delta = \begin{vmatrix} 1+a_1 & a_2 & a_3 & a_4 & \cdots & a_n \\ -1 & 1 & 0 & 0 & \cdots & 0 \\ -1 & 0 & 1 & 0 & \cdots & 0 \\ -1 & 0 & 0 & 1 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ -1 & 0 & 0 & 0 & \cdots & 0 & 1 \end{vmatrix}$$

Adding $C_2, C_3, \dots, C_n$ columns to the first column C_1 i.e. $C_1 \rightarrow C_1 + C_2 + C_3 + \cdots + C_n$, we have

$$\Delta = \begin{vmatrix} 1+a_1+a_2+\cdots+a_n & a_2 & a_3 & a_4 & \cdots & a_n \\ 0 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \end{vmatrix}$$

Since this is an upper triangular matrix, $\Delta =$ product of the diagonal elements.

$$\Delta = (1 + a_1 + a_2 + \cdots + a_n) \cdot 1 \cdot 1 \cdot \dots \cdot 1$$

Example 10: Solve the following equation

$$\Delta = |A| = \begin{vmatrix} a-x & c & b \\ c & b-x & a \\ b & a & c-x \end{vmatrix} = 0$$

or for what value of x , Δ is zero (i.e., matrix A is singular).

Solution: Adding C_2, C_3 columns to the first column C_1 , i.e. $C_1 \rightarrow C_1 + C_2 + C_3$ we have

$$\begin{aligned}
 \Delta &= \begin{vmatrix} a-x+c+b & c & b \\ c+b-x+a & b-x & a \\ b+a+c-x & a & c-x \end{vmatrix} \\
 &= (a+b+c-x) \begin{vmatrix} 1 & c & b \\ 1 & b-x & a \\ 1 & a & c-x \end{vmatrix}
 \end{aligned}$$

performing $R_2 \rightarrow R_2 - R_1, R_3 \rightarrow R_3 - R_1$ we get

$$\begin{aligned}
 \Delta &= (a+b+c-x) \begin{vmatrix} 1 & c & b \\ 0 & b-x-c & a-b \\ 0 & a-c & c-x-b \end{vmatrix} \\
 &= (a+b+c-x) \cdot 1 \cdot [(b-x-c)(c-x-b) - (a-c)(a-b)] \\
 &= (a+b+c-x) (x^2 - a^2 - b^2 - c^2 + ab + bc + ca).
 \end{aligned}$$

Thus $\Delta = 0$ when $x = a + b + c$ or

$$x = \pm \sqrt{a^2 + b^2 + c^2 - ab - bc - ca}$$

Example 11: Compute the product directly (a) Row by column (b) Row by row (c) Column by column (d) Column by row (e) By individually, calculating the determinants where

$$A = \begin{vmatrix} 1 & 1 & -1 \\ 2 & 1 & 3 \\ 1 & 0 & 1 \end{vmatrix}, B = \begin{vmatrix} -2 & 1 & 1 \\ 3 & 1 & 0 \\ -1 & 2 & 4 \end{vmatrix}$$

Solution: Product of the determinants

(a) Row by column

$$AB = \begin{vmatrix} 1 & 1 & 1 \\ 2 & 1 & 3 \\ 1 & 0 & 1 \end{vmatrix} \begin{vmatrix} -2 & 1 & 1 \\ 3 & 1 & 0 \\ -1 & 2 & 4 \end{vmatrix} = \begin{vmatrix} 2 & 0 & -3 \\ -4 & 9 & 14 \\ -3 & 3 & 5 \end{vmatrix} = -39$$

(b) Row by row

$$AB = \begin{vmatrix} 1 & 1 & -1 \\ 2 & 1 & 3 \\ 1 & 0 & 1 \end{vmatrix} \begin{vmatrix} -2 & 1 & 1 \\ 3 & 1 & 0 \\ -1 & 2 & 4 \end{vmatrix} = \begin{vmatrix} -2 & 4 & -3 \\ 0 & 7 & 12 \\ -1 & 3 & 3 \end{vmatrix} = -39$$

(c) Column by column

$$AB = \begin{vmatrix} 1 & 1 & -1 \\ 2 & 1 & 3 \\ 1 & 0 & 1 \end{vmatrix} \begin{vmatrix} -2 & 1 & 1 \\ 3 & 1 & 0 \\ -1 & 2 & 4 \end{vmatrix} = \begin{vmatrix} 3 & 5 & 5 \\ 1 & 2 & 1 \\ 10 & 4 & 3 \end{vmatrix} = -39$$

34.12 — MATHEMATICAL METHODS

(d) Column by row

$$AB = \begin{vmatrix} 1 & 1 & -1 \\ 2 & 1 & 3 \\ 1 & 0 & 1 \end{vmatrix} \begin{vmatrix} -2 & 1 & 1 \\ 3 & 1 & 0 \\ -1 & 2 & 4 \end{vmatrix} = \begin{vmatrix} 1 & 5 & 7 \\ -1 & 4 & 1 \\ 6 & 0 & 11 \end{vmatrix} = -39$$

(e) $A = 3$, $B = -13$, so $AB = (3)(-13) = -39$

Example 12: Find the derivative of the determinant wrt x (a) using formula (b) by differentiating the value of the (expanded) determinant wrt x .

$$\frac{d}{dx} \begin{vmatrix} x & 1 & 2 \\ x^2 & 2x+1 & x^3 \\ 0 & 3x-2 & x^2+1 \end{vmatrix}$$

Solution: (a) By formula, the derivative = sum of 3 determinants where the 1st, 2nd, 3rd rows are differentiated respectively wrt x . Thus

$$\begin{aligned} \frac{d}{dx} \begin{vmatrix} x & 1 & 2 \\ x^2 & 2x+1 & x^3 \\ 0 & 3x-2 & x^2+1 \end{vmatrix} &= \begin{vmatrix} 1 & 0 & 0 \\ x^2 & 2x+1 & x^3 \\ 0 & 3x-2 & x^2+1 \end{vmatrix} + \\ &+ \begin{vmatrix} x & 1 & 2 \\ 2x & 2 & 3x^2 \\ 0 & 3x-2 & x^2+1 \end{vmatrix} + \begin{vmatrix} x & 1 & 2 \\ x^2 & 2x+1 & x^3 \\ 0 & 3 & 2x \end{vmatrix} \\ &= [(2x+1)(x^2+1) - x^3(3x-2)] + [x^2(x^2+1) - \\ &- 3x^2(3x-2) - 1(2x(x^2+1) - 0)] + \\ &+ 2(2x(3x-2))] + [x((2x+1)2x - 3x^3) - \\ &- x^2(2x-6)] = 1 - 6x + 21x^2 + 12x^3 - 15x^4. \end{aligned}$$

(b) Expanding the given determinant

$$\begin{aligned} &x[(2x+1)(x^2+1) - x^3(3x-2)] - \\ &- 1[x^2(x^2+1) - 0] + 2[x^2(3x-2) - 0] \\ &= -3x^5 + 3x^4 + 7x^3 - 3x^2 + x. \end{aligned}$$

So $\frac{d}{dx}$ of determinant $= \frac{d}{dx} (-3x^5 + 3x^4 + 7x^3 - 3x^2 + x) = -15x^4 + 12x^3 + 21x^2 - 6x + 1$.

Example 13: Determine the values of x for which matrix A is non singular given

$$A = \begin{bmatrix} 3-x & 2 & 2 \\ 2 & 4-x & 1 \\ -2 & -4 & -1-x \end{bmatrix}$$

Solution:

$$|A| = \det A = \begin{vmatrix} 3-x & 2 & 2 \\ 2 & 4-x & 1 \\ -2 & -4 & -1-x \end{vmatrix}$$

Expanding the determinant

$$\begin{aligned} |A| &= (3-x)[(4-x)(-1-x) + 4] \\ &- 2[2(-1-x) + 2] + 2[-8 + 2(4-x)] \\ &= x(x^2 - 6x - 9) = x(x-3)^2 \end{aligned}$$

Then $|A| = 0$ when $x = 0$ or 3 . Thus matrix A is non singular i.e. $|A| \neq 0$ for any x other than zero and 3 .

EXERCISE

1. Evaluate the following determinants

(a) $\begin{vmatrix} 4 & 8 \\ -1 & 2 \end{vmatrix}$ (b) $\begin{vmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{vmatrix}$

(c) $\begin{vmatrix} -1 & 3 & 4 \\ 3 & 4 & -1 \\ 4 & -1 & 3 \end{vmatrix}$ (d) $\begin{vmatrix} 1 & p & p^2 \\ 1 & q & q^2 \\ 1 & r & r^2 \end{vmatrix}$

(e) $\begin{vmatrix} 0 & 1 & 2 & 3 \\ -1 & 0 & 1 & 2 \\ -2 & -1 & 0 & 3 \\ -3 & -2 & -3 & 0 \end{vmatrix}$ (f) $\begin{vmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{vmatrix}$

Ans. (a) 16 (b) 1 (c) -126

(d) $qr(r-q) + rp(p-r) + pq(q-p)$ (e) 4 (f) 1

2. Evaluate the determinants using triangularization.

(a) $\begin{vmatrix} 1 & -2 & 3 & -2 & -2 \\ 2 & -1 & 1 & 3 & 2 \\ 1 & 1 & 2 & 1 & 1 \\ 1 & -4 & -3 & -2 & -5 \\ 3 & -2 & 2 & 2 & -2 \end{vmatrix}$ (b) $\begin{vmatrix} 1 & -2 & 3 & -4 \\ 2 & -1 & 4 & -3 \\ 2 & 3 & -4 & -5 \\ 3 & -4 & 5 & 6 \end{vmatrix}$

(c) $\begin{vmatrix} 21 & 17 & 7 & 10 \\ 24 & 22 & 6 & 10 \\ 6 & 8 & 2 & 3 \\ 6 & 7 & 1 & 2 \end{vmatrix}$ (d) $\begin{vmatrix} 3 & 2 & 2 & 2 \\ 2 & 3 & 2 & 2 \\ 2 & 2 & 3 & 2 \\ 2 & 2 & 2 & 3 \end{vmatrix}$

Ans. (a) 118 (b) -304 (c) 0 (d) 9

3. Determine the values of x for which the determinant is zero

(a) $\begin{vmatrix} x+2 & 2x+3 & 3x+4 \\ 2x+3 & 3x+4 & 4x+5 \\ 3x+5 & 5x+8 & 10x+17 \end{vmatrix}$

$$(b) \begin{vmatrix} 1+x & 2 & 3 & 4 \\ 1 & 2+x & 3 & 4 \\ 1 & 2 & 3+x & 4 \\ 1 & 2 & 3 & 4+x \end{vmatrix}$$

$$(c) \begin{vmatrix} x+1 & 2x+1 & 3x+1 \\ 2x & 4x+3 & 6x+3 \\ 4x+1 & 6x+4 & 8x+4 \end{vmatrix}$$

Ans. (a) $x = -1, -1, -2$ (b) $x = 0, -10$

(c) $x = 0, -\frac{1}{2}$

4. Find the value of the determinant

$$(a) \begin{vmatrix} 1 & a & b+c \\ 1 & b & c+a \\ 1 & c & a+b \end{vmatrix} \quad (b) \begin{vmatrix} a & b & c & d \\ -a & b & c & d \\ -a & -b & c & d \\ -a & -b & -c & d \end{vmatrix}$$

$$(c) \begin{vmatrix} 1 & a & a^2 \\ 1 & b & b^2 \\ 1 & c & c^2 \end{vmatrix} \quad (d) \begin{vmatrix} 1 & a & a^2 & a^3 \\ 1 & b & b^2 & b^3 \\ 1 & c & c^2 & c^3 \\ 1 & d & d^2 & d^3 \end{vmatrix}$$

$$(e) \begin{vmatrix} 1 & a & a^2 & a^3 \\ 1 & b & b^2 & b^3 \\ 1 & c & c^2 & c^3 \\ 1 & d & d^2 & d^3 \end{vmatrix} \quad (f) \begin{vmatrix} 1 & x_1 & x_1^2 & \dots & x_1^{n-1} \\ 1 & x_2 & x_2^2 & \dots & x_2^{n-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_{n-1} & x_{n-1}^2 & \dots & x_{n-1}^{n-1} \\ 1 & x_n & x_n^2 & \dots & x_n^{n-1} \end{vmatrix}$$

Ans. (a) 0 **Hint:** $C_3 \rightarrow C_3 + C_2$, take $(a+b+c)$ common)

(b) $8abcd$

(**Hint:** $R_2 + R_1, R_3 + R_1, R_4 + R_1$, diagonal, product of diagonal elements)

(c) $(a-b)(b-c)(c-a)$

(**Hint:** $a=b, a=c, b=c, \Delta=0$. Assume $\Delta = L(a-b)(b-c)(c-a)$, determine constant $L=1$ by comparing the diagonal element)

(d) $(a-b)(a-c)(a-d)(b-c)(b-d)(c-d)$

(e) $(a-b)(a-c)(a-d)(b-c)(b-d) \times (c-d)(a+b+c+d)$

Hint: By Factor Theorem $\Delta = L(a-b)(a-c)(a-d)(b-c)(b-d)(c-d)$ since at $a=b, a=c, a=d, b=c, b=d, c=d$, the determinant is zero. Since principal diagonal is bc^2d^4 is of 7th degree, introduce a linear factor $(a+b+c+d)$, then determine $L=1$.

(f) $(-1)^{\frac{n(n-1)}{2}} \cdot \pi$ where $\pi =$ product of factors $(x_i - x_j)$ with $i < j (\leq n)$.

Hint: At $x_1 = x_2, x_3, \dots, x_n$, the $\Delta = 0$ so $(x_1 - x_2)(x_1 - x_3) \dots (x_1 - x_n)$ are factors of Δ . Similarly at $x_2 = x_3, x_4, \dots, x_n$, the $\Delta = 0$ so $(x_2 - x_3)(x_2 - x_4) \dots (x_2 - x_n)$ are factors of Δ and so on. At $x_{n-1} = x_n$, the $\Delta = 0$, so $(x_{n-1} - x_n)$ is a factor of Δ . Compare the principal diagonal term to get the value of the constant coefficient.

$$5. \text{ Prove that } \begin{vmatrix} 1+a & 1 & 1 & 1 \\ 1 & 1+b & 1 & 1 \\ 1 & 1 & 1+c & 1 \\ 1 & 1 & 1 & 1+d \end{vmatrix} = abcd \left(1 + \frac{1}{a} + \frac{1}{b} + \frac{1}{c} + \frac{1}{d}\right)$$

Hint: Take a, b, c, d common from R_1, R_2, R_3, R_4 . Add R_2, R_3, R_4 to R_1 , take common $1 + \frac{1}{a} + \frac{1}{b} + \frac{1}{c} + \frac{1}{d}$, subtract C_1 from C_2, C_3, C_4 .

$$6. \text{ Evaluate } \begin{vmatrix} a^2+x & ab & ac & ad \\ ab & b^2+x & bc & bd \\ ac & bc & c^2+x & cd \\ ad & bd & cd & d^2+x \end{vmatrix}$$

Ans. $x^3(a^2 + b^2 + c^2 + d^2 + x)$

Hint: Divide by $abcd$, multiply C_1, C_2, C_3, C_4 by a, b, c, d . Take a, b, c, d common from R_1, R_2, R_3, R_4 . Add C_2, C_3, C_4 to C_1 , subtract R_1 from R_2, R_3, R_4

$$7. \text{ Find } \begin{vmatrix} (b+c)^2 & a^2 & a^2 \\ b^2 & (c+a)^2 & b^2 \\ c^2 & c^2 & (a+b)^2 \end{vmatrix}$$

Ans. $2abc(a+b+c)^3$

Hint: a, b, c , are factors (i.e. $\Delta = 0$ when $a = 0$) $(a+b+c)^2$ is factor since 3 columns are equal, when $a+b+c=0$. Principal diagonal 6th degree so $(a+b+c)$ is also a factor.

$$8. \text{ Show that } \begin{vmatrix} a+b & c & c \\ a & b+c & a \\ b & b & c+a \end{vmatrix} = 4abc$$

Hint: Expand into 8 determinants

34.14 — MATHEMATICAL METHODS

9. Show that

$$\begin{vmatrix} a & -b & -a & b \\ b & a & -b & -a \\ c & -d & c & -d \\ d & c & d & c \end{vmatrix} = 4(a^2 + b^2)(c^2 + d^2)$$

Hint: Add C_1 to C_3 , C_2 to C_4 . Take $2 \cdot 2 = 4$ common. Then subtract C_3 from C_1 , C_4 from C_2 expand

$$\begin{aligned} 10. \text{ Show that } & \begin{vmatrix} 2b_1 + c_1 & c_1 + 3a_1 & 2a_1 + 3b_1 \\ 2b_2 + c_2 & c_2 + 3a_2 & 2a_2 + 3b_2 \\ 2b_3 + c_3 & c_3 + 3a_3 & 2a_3 + 3b_3 \end{vmatrix} \\ &= 31 \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} \end{aligned}$$

Hint: Expand into 8 determinants, $27D + 4D$, remaining six determinants are zeros

11. Find the product of the determinants

$$\begin{vmatrix} -2 & 1 & 1 \\ 3 & 1 & 0 \\ -1 & 2 & 4 \end{vmatrix} \text{ and } \begin{vmatrix} 1 & 3 & 4 \\ 2 & -1 & 0 \\ 0 & 1 & 3 \end{vmatrix}$$

Ans. $(-13)(-13) = 169$

12. If $A = \begin{vmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 0 & -1 & 0 \end{vmatrix}$, $B = \begin{vmatrix} \frac{1}{2} & 0 & -1 \\ -1 & 0 & 1 \\ 1 & 2 & 3 \end{vmatrix}$. Then compute $15A^2 - 2AB - B^2$ without calculating A and B independently

Ans. $15 \cdot 1 - 2 \cdot 1 - 1 = 12$

Hint: $A^2 = \begin{vmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 0 & -1 & 0 \end{vmatrix} \begin{vmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 0 & -1 & 0 \end{vmatrix}$

$$= \begin{vmatrix} 6 & 5 & -1 \\ 5 & 6 & -2 \\ -1 & -2 & 1 \end{vmatrix} = 1$$

Similarly $AB = \begin{vmatrix} 0 & -1 & 7 \\ \frac{1}{2} & 0 & 8 \\ 0 & 0 & -2 \end{vmatrix} = 1$,

$$B^2 = \frac{1}{4} \begin{vmatrix} 5 & -3 & -5 \\ -3 & 2 & 2 \\ -5 & 2 & 14 \end{vmatrix} = 1$$

13. Find the derivatives of $\begin{vmatrix} x^2 & x^3 \\ 2x & 3x+1 \end{vmatrix}$

Ans. $2x + 9x^2 - 8x^3$

14. Find the derivative of $\begin{vmatrix} x^2 & x+1 & 3 \\ 1 & 2x-1 & x^3 \\ 0 & x & -2 \end{vmatrix}$

Ans. $5 + 4x - 12x^2 - 6x^5$

15. Evaluate $\begin{vmatrix} b^2 + ac & bc & c^2 \\ ab & 2ac & bc \\ a^2 & ab & b^2 + ac \end{vmatrix}$

Ans. $4a^2b^2c^2$

Hint: $|A| = \begin{vmatrix} b & c & 0 \\ a & 0 & c \\ 0 & a & b \end{vmatrix}^2$

16. Obtain all solutions of the following equations.

(a) $\begin{vmatrix} -1 & 3 & x \\ 2x-3 & 1-x & 3x+1 \\ 2 & x & -2 \end{vmatrix} = 9x - 28$

(b) $\begin{vmatrix} 1 & x & x+2 & x-2 & 100 \\ 0 & x & x-2 & x+2 & 100 \\ 0 & 0 & x+2 & x-2 & 100 \\ 0 & 0 & 0 & x-2 & x+2 \\ 0 & 0 & 0 & 0 & 100 \end{vmatrix} = 0$

Ans. (a) $x = -1, \pm 3i$ (b) $x = 0, \pm 2$

Chapter 35

Sequences and Series

INTRODUCTION

The study of convergence and divergence of a sequence, which is an ordered list of things, is a prerequisite for infinite series. The unit square in the figure can be expressed as an infinite (geometric) series

$$1 = \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} + \dots$$

Several functions can be expressed as “infinite polynomials” (known as “power series”) using the concept of infinite series. By Fourier series, certain functions can be represented as an infinite sum of trigonometric functions. Using infinite series, differential equations in problems of signal transmission, chemical diffusion, vibration and heat flow can be solved and non elementary integrals evaluated. The infinite process of summing of an infinite series is a puzzle for centuries convergence and divergence of infinite series plays an important role in engineering applications.

| | | |
|---------------|----------------|--|
| | $\frac{1}{2}$ | |
| $\frac{1}{4}$ | $\frac{1}{8}$ | |
| | $\frac{1}{16}$ | |

35.1 SEQUENCES

A *sequence* is a function from the domain set of natural numbers N to any set S .

Real sequence is a function from N to R , the set of real numbers; denoted by $f: N \rightarrow R$. Thus the real sequence f is set of all ordered pairs $\{n, f(n)\} | \{n = 1, 2, 3, \dots\}$ i.e., set of all pairs $(n, f(n))$ with n a positive integer.

Notation: Since the domain of a sequence is always the same (the set of positive integers) a sequence may be written as $\{f(n)\}$ instead of $\{n, f(n)\}$.

Examples:

- $\{n, \frac{1}{n}\} = \{\frac{1}{n}\} = \{1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \dots, \frac{1}{n}, \dots\}$
- $\{n, \frac{1}{2^{n-1}}\} = \{\frac{1}{2^{n-1}}\} = \{1, \frac{1}{2}, \frac{1}{2^2}, \frac{1}{2^3}, \frac{1}{2^4}, \dots, \frac{1}{2^{n-1}}, \dots\}$

constant sequence where range is singleton set $\{c\}$, $c = \text{constant}$.

Example: $\{3, 3, 3, 3, \dots\}$

Null sequence $\{0, 0, 0, \dots, 0, \dots\}$

A sequence is also denoted by $\{a_n\}$ whose ordinate $y = a_n$ at the abscissa $x = n$. Thus in a sequence for each positive integer n , a number a_n is assigned and is denoted as $\langle a_n \rangle$ or (a_n) or

$$\begin{aligned} \{a_n\} &= \{a(1), a(2), a(3), \dots, a(n), \dots\} \\ &= \{a_1, a_2, a_3, \dots, a_n, \dots\} \end{aligned}$$

Here $a_1, a_2, a_3, \dots, a_n$, are known as the first, second, third and n th terms of the sequence.

Infinite sequence is a sequence in which the number of terms is infinite, and is denoted by $\{a_n\}_{n=1}^{\infty}$. On the other hand, finite sequence denoted by $\{a_n\}_{n=1}^m$ contains only a finite number of terms ($m = \text{finite}$).

Bounded sequence A sequence $\{a_n\}$ is said to be bounded if there exists numbers m and M such that $m < a_n < M$ for every n , otherwise it is said to be unbounded.

Monotonic sequence

A sequence $\{a_n\}$ is said to be

- monotonically increasing if $a_{n+1} \geq a_n$ for every n

$$\text{i.e., } a_1 \leq a_2 \leq a_3 \leq \dots \leq a_n \leq a_{n+1} \leq \dots$$

35.2 — ENGINEERING MATHEMATICS

b. monotonically decreasing if $a_{n+1} \leq a_n$ for every n

$$\text{i.e., } a_1 \geq a_2 \geq a_3 \geq \dots \geq a_n \geq a_{n+1} \geq \dots$$

c. monotonic if it is either monotonically increasing or monotonically decreasing.

Example: $\left\{\frac{1}{n}\right\} = \left\{1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \dots\right\}$ bounded since $0 < a_n = \frac{1}{n} < 1$ and monotonically decreasing.

Example: $\{2^n\} = \{2, 2^2, 2^3, 2^4, \dots\}$ unbounded since 2^n becomes larger and larger as n comes large and monotonically increasing.

35.2 LIMIT OF A SEQUENCE

Consider a sequence $\{a_n\} = \left\{3 + \frac{1}{n}\right\}$.

Plotting the values

n : 1 2 4 5 10 50 100 1000 10000 100000...
 a_n : 4 3.5 3.25 3.2 3.1 3.02 3.01 3.001 3.0001 3.00001...

As n increases, $a_n = 3 + \frac{1}{n}$ becomes closer to 3. Thus the difference (or distance) between $3 + \frac{1}{n}$ and 3 becomes smaller and smaller as n becomes larger and larger i.e., we can make $3 + \frac{1}{n}$ and 3 as close as we please, by choosing an appropriately (sufficiently) large value for n , i.e., the terms of a sequence cluster around this (limit) point. However note that $3 + \frac{1}{n} \neq 3$ for any value of n .

Limit: A number L is said to be a limit of a sequence $\{a_n\}$ and is denoted as

$$\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} a_n = L$$

if for every $\epsilon > 0$ there exists N such that

$$|a_n - L| < \epsilon \quad \text{for all } n \geq N.$$

Note: A sequence may have a unique limit or may have more than one limit or may not have a limit at all.

Result: A monotonic sequence always has a limit (may be finite or infinite).

35.3 CONVERGENCE, DIVERGENCE AND OSCILLATION OF A SEQUENCE

Convergent A sequence $\{a_n\}$ is said to be convergent if it has a finite limit i.e., $\lim_{n \rightarrow \infty} a_n = L = \text{finite unique limit value}$.

Divergent If $\lim_{n \rightarrow \infty} a_n = \text{infinite} = \pm\infty$.

Oscillatory If limit of a_n is not unique (oscillates finitely) or $\pm\infty$ (oscillates infinitely).

Examples:

1. $\left\{\frac{1}{n^2}\right\}$ convergent since $\lim_{n \rightarrow \infty} \frac{1}{n^2} = 0 = \text{finite unique}$

2. $\{n\}$ divergent since $\lim_{n \rightarrow \infty} n := \infty$

3. $\{(-1)^n\}$ oscillates finitely, since

$$\lim_{n \rightarrow \infty} (-1)^n = \begin{cases} 1, & n \text{ even} \\ -1, & n \text{ odd.} \end{cases}$$

4. $\{(-1)^n \cdot n^2\}$ oscillates infinitely, since limit $= \pm\infty$.

Result 1: If sequence $\{a_n\}$ converges to limit L and $\{b_n\}$ converges to L^* then

a. $\{a_n + b_n\}$ converges to $L + L^*$

b. $\{ca_n\}$ converges to CL

c. $\{a_n \cdot b_n\}$ converges to $L \cdot L^*$

d. $\left\{\frac{a_n}{b_n}\right\}$ converges to $\frac{L}{L^*}$, provided $L^* \neq 0$.

Result 2: Every convergent sequence is bounded.

Example: $\left\{\frac{1}{n}\right\}$ is convergent and is bounded

$$a_n = \frac{1}{n} < 1, \text{ for every } n.$$

Result 3: The converse is not true i.e., a bounded sequence may not be convergent.

Example: $\{(-1)^n\}$ is oscillatory (has more than one limit but is bounded since $-1 \leq (-1)^n \leq 1$).

Result 4: A bounded monotonic sequence is convergent.

Example: $\left\{\frac{1}{n^2}\right\}$ is bounded since $\frac{1}{n^2} \leq 1$ for every n and monotonically decreasing since $\frac{1}{n^2} > \frac{1}{(n+1)^2}$ for every n . Hence the sequence is convergent because $\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} \frac{1}{n^2} = 0 = \text{finite}$.

Useful Standard Limits

1. a. $\lim_{n \rightarrow \infty} \frac{1}{n} = 0$, b. $\lim_{n \rightarrow \infty} \frac{1}{n^2} = 0$, c. $\lim_{n \rightarrow \infty} \frac{1}{\sqrt{n}} = 0$

2. $\lim_{n \rightarrow \infty} n^{1/n} = 1$

3. $\lim_{n \rightarrow \infty} \frac{\log n}{n} = 0$

4. $\lim_{n \rightarrow \infty} \left(1 + \frac{x}{n}\right)^n = e^x$, for any x

5. $\lim_{n \rightarrow \infty} x^{1/n} = 1$ for $x > 0$

6. (a) $\lim_{n \rightarrow \infty} x^n = 0$ for $|x| < 1$ i.e. $-1 < x < 1$.

(b) $\lim_{n \rightarrow \infty} \frac{x^n}{n!} = 0$ for any x . In formulas (5) and

6(b) x remains fixed as $n \rightarrow \infty$

WORKED OUT EXAMPLES

Determine the nature of the following sequences whose n th term a_n is

Example 1: $a_n = \frac{n^2 - n}{2n^2 + n}$

Solution:

$$\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} \frac{n^2 - n}{2n^2 + n} = \lim_{n \rightarrow \infty} \frac{1 - \frac{1}{n}}{2 + \frac{1}{n}} = \frac{1}{2}$$

sequence is convergent since the limit of the sequence is unique and finite.

Example 2: $a_n = \tanh n$.

Solution:

$$\begin{aligned} \lim_{n \rightarrow \infty} a_n &= \lim_{n \rightarrow \infty} \tanh n = \lim_{n \rightarrow \infty} \frac{\sinh n}{\cosh n} \\ &= \lim_{n \rightarrow \infty} \frac{e^n - e^{-n}}{e^n + e^{-n}} = \lim_{n \rightarrow \infty} \frac{e^{2n} - 1}{e^{2n} + 1} \\ &= \lim_{n \rightarrow \infty} \frac{1 - \frac{1}{e^{2n}}}{1 + \frac{1}{e^{2n}}} = 1 \quad \text{so convergent.} \end{aligned}$$

Example 3: $a_n = e^n$.

Solution: $\lim_{n \rightarrow \infty} e^n = \infty$ so divergent.

Example 4: $a_n = 2 + (-1)^n$.

Solution:

$$\lim_{n \rightarrow \infty} a_{2n} = \lim_{n \rightarrow \infty} \{2 + (-1)^{2n}\} = 2 + 1 = 3$$

$$\lim_{n \rightarrow \infty} a_{2n-1} = \lim_{n \rightarrow \infty} \{2 + (-1)^{2n-1}\} = 2 - 1 = 1$$

sequence oscillates finitely since it has more than one finite (two) limits.

EXERCISE

1. $\frac{2n+1}{1-3n}$ *Ans.* convergent, limit = $\frac{-2}{3}$

2. $1 + \frac{(-1)^n}{n}$ *Ans.* convergent, limit = 1

3. $\frac{1+(-1)^n}{n}$ *Ans.* convergent, limit = 0

4. $\sin n$ *Ans.* divergent, limit = ∞

5. $\frac{\ln n}{n}$ *Ans.* convergent, limit = 0

Hint: Apply L' Hospital's rule.

6. $\frac{1}{3^n}$ *Ans.* convergent, limit = $\frac{3}{2}$

7. $\frac{(-1)^{n-1}n}{3^n}$ *Ans.* convergent

8. $\left(\frac{n}{n+1}\right)^2$ *Ans.* convergent

9. $\frac{(n+1)^2}{(n+1)!}$ *Ans.* convergent

10. $2n$ *Ans.* divergent, limit = ∞

11. $1 + \frac{1}{n}$ *Ans.* convergent, limit = 1

12. $[n + (-1)^n]^{-1}$ *Ans.* convergent.

35.4 INFINITE SERIES

Differential Equations are frequently solved by using infinite series. Fourier series, Fourier-Bessel series, etc. expansions involve infinite series. Transcendental functions (trigonometric, exponential, logarithmic, hyperbolic, etc.) can be expressed conveniently in terms of infinite series. Many problems that cannot be solved in terms of elementary (algebraic and transcendental) functions can also be solved in terms of infinite series.

Series

Given a sequence of numbers $u_1, u_2, u_3, \dots, u_n, \dots$ the expression

$$u_1 + u_2 + u_3 + \dots + u_n + \dots \quad (1)$$

which is the sum of the terms of the sequence, is known as a numerical series or simply "series". The numbers $u_1, u_2, u_3, \dots, u_n$ are known as the first, second, third, ..., n th term of the series (1).

Infinite Series

If the number of terms in the series (1) is infinite, then the series is called an infinite series (otherwise finite series when the number of terms is finite). Infinite series (1) is usually denoted as

$$\sum_{n=1}^{\infty} u_n \quad \text{or} \quad \sum u_n \quad (1)$$

The main aim of this chapter is to study the nature (or behaviour) of convergence, divergence or oscillation of a given infinite series. For this purpose, define $\{S_n\}$

35.4 — ENGINEERING MATHEMATICS

the sequence of partial sums as

$$\begin{aligned} S_1 &= u_1 \\ S_2 &= u_1 + u_2 \\ S_3 &= u_1 + u_2 + u_3 \\ &\vdots \\ S_n &= u_1 + u_2 + u_3 + \cdots + u_n = \sum_{k=1}^n u_k \end{aligned}$$

Here S_n is known as the n th partial sum of the series, i.e., it is the sum of the first n terms of the series (1).

Convergence

An infinite series $\sum_{n=1}^{\infty} u_n$ is said to be convergent if

$$\sum_{n=1}^{\infty} u_n = \lim_{n \rightarrow \infty} \left(\sum_{k=1}^n u_k \right) = \lim_{n \rightarrow \infty} S_n = \text{finite limit value} = S$$

Here S is known as the sum (value) of the series (1).

Divergence

If $\lim_{n \rightarrow \infty} S_n$ does not exist (i.e., $\lim_{n \rightarrow \infty} S_n = \pm\infty$) then series (1) is said to be divergent.

Oscillation

When $\lim_{n \rightarrow \infty} S_n$ tends to more than one limit (non unique) or to $\pm\infty$ then series (1) is said to be oscillatory. Thus the behaviour of convergence, divergence or oscillation of a series is the behaviour of its sequence of partial sums $\{S_n\}$.

Example: $1 + \frac{1}{4} + \frac{1}{16} + \frac{1}{64} + \cdots$

Here $u_n = \frac{1}{4^{n-1}}$ so $\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \frac{1 - \frac{1}{4^n}}{1 - \frac{1}{4}} =$

$$\lim_{n \rightarrow \infty} \frac{4}{3} \left(1 - \frac{1}{4^n} \right) = \frac{4}{3} = \text{finite,}$$

series converges.

Example: $1^2 + 2^2 + 3^2 + \cdots + n^2 + \cdots$
 $\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \frac{n(n+1)(2n+1)}{6} = \infty$, series diverges.

Example: $7 - 4 - 3 + 7 - 4 - 3 + 7 - 4 - 3 + \cdots$
 $\lim_{n \rightarrow \infty} S_n = 0$ or 7 or 3 according as the number of terms is $3m$, $3m + 1$ or $3m + 2$.

Since the limit is not unique, series oscillates (finitely).

Example: $1 - 2 + 3 - 4 + \cdots + (-1)^{n-1}n + \cdots$

$$\lim_{n \rightarrow \infty} S_n = -\frac{n}{2} = -\infty \quad \text{if } n \text{ is even}$$

$$\lim_{n \rightarrow \infty} S_n = \frac{n+1}{2} = +\infty \quad \text{if } n \text{ is odd}$$

series oscillates (infinitely).

Some General Properties of Series

1. If a series $\sum u_n$ converges to a sum s then the series $c \sum u_n$ also converges to the sum cs , where c is a constant.
2. If the series $\sum u_n$ and $\sum v_n$ converges to the sums s' and s'' respectively then the series $\sum(u_n + v_n)$ and $\sum(u_n - v_n)$ also converge to $s' + s''$ and $s' - s''$ respectively. Addition or subtraction of two series is done by termwise addition or termwise subtraction.
3. The convergence of a series is not affected by the suppression (deletion) or addition of a finite number of its terms, since the deletion or addition of the sum of these finite number of terms (which is a finite quantity) does not alter the behaviour of the sum of the series.

35.5 NECESSARY CONDITION FOR CONVERGENCE

Necessary condition for convergence of a series $\sum u_n$ is that, its n th term u_n approaches zero as n becomes infinite i.e.,

$$\text{If series converges, then } \lim_{n \rightarrow \infty} u_n = 0.$$

Important Note: This is not a test for convergence.

Proof: Let s be the sum of this convergent series. Also let S_n and S_{n-1} be the n th and $(n-1)$ th partial sums of the given series so that

$$u_n = S_n - S_{n-1}$$

Taking limit, we have

$$\begin{aligned} \lim_{n \rightarrow \infty} u_n &= \lim_{n \rightarrow \infty} (S_n - S_{n-1}) = \lim_{n \rightarrow \infty} S_n - \lim_{n \rightarrow \infty} S_{n-1} \\ &= s - s = 0. \end{aligned}$$

Note 1: The converse of the above result is not true, i.e., the above result is not a sufficient condition. From the fact that the n th term u_n approaches zero,

it does not follow that the series converges, for the series may diverge.

If $\lim_{n \rightarrow \infty} u_n = 0$, then the series may converge or may diverge.

Example: $1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots + \frac{1}{n} + \cdots$ is a divergent series although its n th term approaches zero i.e.,

$$\lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} \frac{1}{n} = 0$$

Note 2: Preliminary test for divergence.

If the n th term of a series does not tend to zero as $n \rightarrow \infty$, then the series diverges i.e.,

if $\lim_{n \rightarrow \infty} u_n \neq 0$ then series diverges.

Example:

$$\frac{1}{2} + \frac{2}{3} + \frac{3}{4} + \frac{4}{5} + \cdots + \frac{n}{n+1} + \cdots$$

Since $\lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} \frac{n}{n+1} = 1 \neq 0$ by the above preliminary test, the given series diverges.

35.6 STANDARD INFINITE SERIES: GEOMETRIC SERIES AND HARMONIC SERIES

Geometric Series Test

$$\sum_{n=0}^{\infty} ar^n = a + ar + ar^2 + ar^3 + \cdots + ar^{n-1} + \cdots,$$

with $a \neq 0$ (1)

is a geometric series, whose terms form a geometric progression with the first term a and the common ratio r . For this series

$$S_n = \frac{a - ar^n}{1 - r} = \frac{a}{1 - r} - \frac{ar^n}{1 - r}$$

Case 1: When $|r| < 1$ then $\lim_{n \rightarrow \infty} r^n = 0$ so that

$$\begin{aligned} \lim_{n \rightarrow \infty} S_n &= \lim_{n \rightarrow \infty} \left(\frac{a}{1 - r} - \frac{ar^n}{1 - r} \right) = \frac{a}{1 - r} - \frac{a}{1 - r} \cdot 0 \\ &= \frac{a}{1 - r} = \text{finite} \end{aligned}$$

Hence geometric series (1) converges to the sum $\frac{a}{1-r}$ when $|r| < 1$ i.e., in the interval $-1 < r < 1$.

Case 2: When $|r| > 1$ then $\lim_{n \rightarrow \infty} r^n = \infty$ so that

$$\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left(\frac{a}{1 - r} - \frac{ar^n}{1 - r} \right) = \pm \infty$$

Thus series (1) diverges when $|r| > 1$ i.e., when $r > 1$ or $r < -1$.

Case 3: If $r = 1$, the series (1) reduces to

$$a + a + a + \cdots$$

consequently $\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} (na) = \infty$ so series diverges.

Case 4: If $r = -1$, the series (1) reduces to

$$a - a + a - a + \cdots$$

In this case,

$$S_n = \begin{cases} 0, & \text{when } n \text{ is even} \\ a, & \text{when } n \text{ is odd} \end{cases}$$

Thus $\lim_{n \rightarrow \infty} S_n$ is not unique (more than one limit) hence the series diverges.

Hence the geometric series converges only when $|r| < 1$ and diverges for all other values of r .

Example: A ball is dropped from a height b feet from a flat surface. Each time the ball hits the ground after falling a distance h it rebounds a distance rh where $0 < r < 1$ (Fig. 35.1).

Fig. 35.1

Find the total distance the ball travels if $b = 4$ ft and $r = \frac{3}{4}$.

35.6 — ENGINEERING MATHEMATICS

Solution: The total distance travelled by the ball is given by the infinite geometric series

$$s = b + 2br + 2br^2 + 2br^3 + \dots$$

$$s = b + \frac{2br}{1-r} = b \frac{(1+r)}{(1-r)}$$

For $b=4$, and $r=\frac{3}{4}$, the distances $= 4 \left(\frac{1+\frac{3}{4}}{1-\frac{3}{4}} \right) = 28$ ft.

Harmonic Series of Order p or p -Harmonic Series or p -Series Test

$$\sum_{n=1}^{\infty} \frac{1}{n^p} = \frac{1}{1^p} + \frac{1}{2^p} + \frac{1}{3^p} + \dots + \frac{1}{n^p} + \dots$$

This series converges for $p > 1$ and diverges for $p \leq 1$. An easy proof of this test is postponed and is given in section (1.9) using Integral test.

35.7 TESTS FOR CONVERGENCE AND DIVERGENCE

Although the behaviour of a series is found from the behaviour of its sequence of partial sums $\{S_n\}$, most often it is not possible to find S_n , the n th partial sum and even if it is found, the evaluation of its limit is cumbersome. Instead simple, practical and useful test for convergence of a series are presented here which depending on the individual terms of the series rather than their sums.

A given infinite series is classified as

- series of positive terms or positive series
- alternating series
- plus- and -minus series
- power series

In the sections 1.8 to 1.14, only series of positive terms are considered i.e.,

$u_1 + u_2 + u_3 + \dots + u_n + \dots$ with $u_n > 0$ for every $n > N$ where N is a fixed positive integer (barring few finite negative terms at the beginning of the series).

Example:

$$-8 - 6 - 3 - 2 + 1 + 2 + 3 + 4 + 5 + \dots + n + \dots$$

Note: Positive series either converge or diverge (becomes infinite) but do not oscillate.

35.8 COMPARISON TEST: ONLY FOR SERIES WITH POSITIVE TERMS

Comparison test consists of “comparison” between a given (unknown) series

$$\sum_{n=1}^{\infty} u_n = u_1 + u_2 + u_3 + \dots + u_n + \dots \quad (1)$$

and a (known) auxiliary series

$$\sum_{n=1}^{\infty} v_n = v_1 + v_2 + v_3 + \dots + v_n + \dots \quad (2)$$

whose nature (of convergence or divergence) is known. Let the two series be with positive terms i.e.,

$$u_n > 0 \quad \text{and} \quad v_n > 0 \quad \text{for every } n = 1, 2, 3, 4, \dots$$

Comparison Test for Convergence

If $u_n \leq v_n$ for every n and $\sum v_n$ converges then $\sum u_n$ also converges.

Proof: Let $S_n = \sum_{k=1}^n u_k$ and $\sigma_n = \sum_{k=1}^n v_k$ then

$$S_n \leq \sigma_n$$

since $u_n \leq v_n$ for every n taking limit

$$\lim_{n \rightarrow \infty} S_n \leq \lim_{n \rightarrow \infty} \sigma_n = \sigma = \text{finite sum}$$

since $\sum v_n$ converges. Hence $\lim_{n \rightarrow \infty} S_n$ has a finite limit value $s \leq \sigma$ and therefore the series $\sum u_n$ converges.

Example:

$$\begin{aligned} \sum u_n &= \sum_{n=1}^{\infty} \frac{1}{n!} = \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} + \dots \\ &= \frac{1}{1} + \frac{1}{2} + \frac{1}{6} + \frac{1}{24} + \dots \end{aligned}$$

$$\text{choose } \sum v_n = \sum \frac{1}{2^n} = \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \dots$$

which is a convergent geometric series with common ratio $r = \frac{1}{2}$ since

$$u_n = \frac{1}{n!} < v_n = \frac{1}{2^n} \text{ for every } n,$$

by comparison test $\sum u_n$ also converges.

Comparison Test for Divergence

If $u_n \geq v_n$ for every n and $\sum v_n$ diverges then $\sum u_n$ also diverges.

Proof: From the condition $u_n \geq v_n$, it follows that $S_n \geq \sigma_n$. Taking the limit $\lim_{n \rightarrow \infty} S_n \geq \lim_{n \rightarrow \infty} \sigma_n = \infty$ since $\sum v_n$ is a divergent series. Hence $\lim_{n \rightarrow \infty} S_n = \infty$ and therefore $\sum u_n$ also diverges.

Example: Since every term of the series

$$1 + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \frac{1}{\sqrt{4}} + \cdots + \frac{1}{\sqrt{n}} + \cdots$$

is greater than the corresponding term of the divergent harmonic series (with $p = 1$) namely

$$1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n} + \cdots$$

the original given series $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ also diverges.

Limit form of the comparison test

Let $\sum u_n$ and $\sum v_n$ be two series of positive terms only. Then the series $\sum u_n$ and $\sum v_n$ either both converge or both diverge together if

$$\lim_{n \rightarrow \infty} \frac{u_n}{v_n} = \text{finite value} = m \neq 0.$$

Note 1: The above comparison tests for convergence and divergence are valid only when both the series $\sum u_n$ and $\sum v_n$ are series with positive terms.

Note 2: Most often the geometric series

$$\sum_{n=0}^{\infty} ar^n$$

and the p -harmonic series

$$\sum_{n=1}^{\infty} \frac{1}{n^p}$$

are chosen as $\sum v_n$ (known) auxiliary series for “comparison”.

Note 3: For the comparison test in the “limit form” which is most useful, the n th term v_n of the (known) auxiliary series is chosen equal to the term of u_n which is of highest degree in $\frac{1}{n}$.

Note 4: Although comparison test is most useful basic test from which other tests are derived, it is more often difficult, without experience, to find a suitable known series for “comparison”.

Example: $u_n = \frac{n^2 + 3n + 1}{n^3}$, choose $v_n = \frac{n^2}{n^3} = \frac{1}{n}$.

WORKED OUT EXAMPLES

Test for convergence of the following series (1 to 4):

Example 1: $\sum \frac{1}{(n2^n)}$

Solution: Since $n2^n \geq 2^n$ so that $\frac{1}{n2^n} \leq \frac{1}{2^n}$ for all $n \geq 1$. As the geometric series (with $a = 1$, $r = \frac{1}{2}$) $\sum (\frac{1}{2})^n$ is convergent so is the given series by comparison of series.

Example 2: $\sum (n+1)^{-1} n^{-\frac{1}{2}}$

Solution: For $n \geq 1$, $n^{\frac{3}{2}} + n^{\frac{1}{2}} > n^{\frac{3}{2}}$

$$\text{so that } \frac{1}{(n+1)n^{\frac{1}{2}}} < \frac{1}{n^{\frac{3}{2}}} \text{ for all } n \geq 1$$

Thus the given series converges since the series compared $\sum \frac{1}{n^{3/2}}$ is a convergent p -series with $p = \frac{3}{2} > 1$.

Example 3: $\sum_{n=1}^{\infty} \frac{1}{n!}$

Solution: For $n > 3$, $2^n < n!$ so $\frac{1}{n!} < \frac{1}{2^n}$.

Since $\sum (\frac{1}{2})^n$ is convergent geometric series (with $a = 1$ and $r = \frac{1}{2}$) by comparison the given series is also convergent.

Example 4: $\sum_{n=1}^{\infty} \left(\frac{2^n + 3}{3^n + 1} \right)^{\frac{1}{2}}$

Solution: Here the n th term is

$$u_n = \left(\frac{2^n + 3}{3^n + 1} \right)^{\frac{1}{2}}$$

For comparison choose a series with n th term

$$v_n = \left(\frac{2^n}{3^n} \right)^{\frac{1}{2}}$$

35.8 — ENGINEERING MATHEMATICS

so

$$\lim_{n \rightarrow \infty} \frac{u_n}{v_n} = \lim_{n \rightarrow \infty} \left(\frac{2^n + 3}{3^n + 1} \cdot \frac{3^n}{2^n} \right)^{\frac{1}{2}} = \lim_{n \rightarrow \infty} \left(\frac{1 + \frac{3}{2^n}}{1 + \frac{1}{3^n}} \right)^{\frac{1}{2}} = 1$$

Thus both the series $\sum u_n$ and $\sum v_n$ have the same nature of convergence i.e., both converge or both diverge. Since $v_n = \sum \left(\sqrt{\frac{2}{3}}\right)^n$ is a geometric series with $a = 1$ and $r = \sqrt{\frac{2}{3}} < 1$ is convergent so the given series is also convergent.

Example 5: $\sum_{n=1}^{\infty} \sqrt{n^4 + 1} - \sqrt{n^4 - 1}$

Solution: Since $(n^4 + 1) - (n^4 - 1) = 2$, we have

$$\left[\sqrt{n^4 + 1} + \sqrt{n^4 - 1} \right] \left[\sqrt{n^4 + 1} - \sqrt{n^4 - 1} \right] = 2$$

Thus the n th term of the given series is

$$u_n = \left(\sqrt{n^4 + 1} - \sqrt{n^4 - 1} \right) = \frac{2}{\left(\sqrt{n^4 + 1} + \sqrt{n^4 - 1} \right)}$$

For comparison, choose the series with n th term $v_n = \frac{2}{n^2}$. Then

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_n}{v_n} &= \frac{2}{\left(\sqrt{n^4 + 1} + \sqrt{n^4 - 1} \right)} \cdot \frac{n^2}{2} \\ &= \lim_{n \rightarrow \infty} \frac{1}{\sqrt{1 + \frac{1}{n^4}} + \sqrt{1 - \frac{1}{n^4}}} = \frac{1}{2} < 1 \end{aligned}$$

so both the series either converge or diverge.

Since $\sum v_n = 2 \sum \frac{1}{n^2}$ is a convergent p -series (with $p = 2 > 1$) so the given series $\sum u_n$ also converges.

Example 6: $\sum_{n=1}^{\infty} \frac{1}{(a+n)^p(b+n)^q}$ where a, b, p, q are all positive.

Solution: Choose the auxiliary harmonic series $\sum v_n = \sum \frac{1}{n^{p+q}}$

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_n}{v_n} &= \lim_{n \rightarrow \infty} \frac{1}{(a+n)^p(b+n)^q} \cdot n^{p+q} \\ &= \lim_{n \rightarrow \infty} \frac{1}{\left(\frac{a}{n} + 1\right)^p \left(\frac{b}{n} + 1\right)^q} = 1 \end{aligned}$$

Hence $\sum u_n$ and $\sum v_n$ both converge or diverge together. But $\sum v_n$ is convergent for $p + q > 1$ and divergent for $p + q \leq 1$.

EXERCISE

Test for convergence of the following series (1 to 5) whose n th term is:

1. $1/(n(n+2))$ **Hint:** Compare $\sum \frac{1}{n^2}$

Ans. convergent

2. $(n+1)/(n(n+2))$ **Hint:** Compare $\sum \frac{1}{n+2}$

Ans. divergent

3. $1/(2n)^n$ **Hint:** Compare $\sum \frac{1}{2^n}$

Ans. convergent

4. $1/\sqrt{2n}$ **Hint:** Compare $\sum \frac{1}{\sqrt{n}}$

Ans. divergent

5. $1/\ln n$ **Hint:** Compare $\sum \frac{1}{n}$

Ans. divergent

6. $\sum_{n=3}^{\infty} \frac{\sqrt{2n^2-5n+1}}{4n^3-7n^2+2}$ **Hint:** Compare $\sum_{n=3}^{\infty} \frac{1}{n^2}$

Ans. convergent

7. $\sum_{n=1}^{\infty} \frac{\sin^2 n}{2^n}$ **Hint:** Compare $\sum \frac{1}{2^n}$

Ans. convergent

8. $\sum \frac{n^2+1}{n^3+1}$ **Hint:** Compare $\sum \frac{1}{n}$

Ans. divergent

9. $\sum_{n=1}^{\infty} \frac{1}{n^n}$ **Hint:** Compare $\sum \frac{1}{2^n}$

Ans. convergent

10. $\sum_{n=1}^{\infty} \tan\left(\frac{1}{n}\right)$ **Hint:** Compare $\sum \frac{1}{n}$

Ans. divergent

11. $\sum \left(\sqrt{n^2+1} - \sqrt{n^2-1} \right)$

Hint: Compare $\sum \frac{1}{n}$

Ans. divergent

12. $\sum_{n=1}^{\infty} \frac{1}{2^n + 3^n}$ **Hint:** Compare $\sum \left(\frac{1}{3}\right)^n$

Ans. convergent

$$13. \sum_{n=2}^{\infty} \frac{\log n}{2n^3-1} \quad \text{Hint: Compare } \sum \frac{1}{n^2}$$

Ans. convergent

$$14. \sum_{n=1}^{\infty} \frac{1}{\sqrt{n}+\sqrt{n+1}} \quad \text{Hint: Compare } \sum \frac{1}{\sqrt{n}}$$

Ans. divergent

$$15. \sum_{n=1}^{\infty} \frac{1}{x^n+x^{-n}} \quad \text{Hint: Compare } \sum x^n$$

Ans. when $x < 1$ series is convergent; compare $\sum x^{-n}$ when $x > 1$ series is convergent; For $x = 1$ the series is divergent

$$16. \sum \frac{n^p}{(n+1)^q} \quad \text{Hint: Compare } \sum \frac{n^p}{n^q}$$

Ans. convergent when $q > p + 1$ and divergent when $q \leq p + 1$

$$17. \frac{1.2}{3.4.5} + \frac{2.3}{4.5.6} + \frac{3.4}{5.6.7} + \frac{4.5}{6.7.8} + \dots$$

$$\text{Hint: } u_n = \frac{n(n+1)}{(n+2)(n+3)(n+4)}, \text{ compare } \sum \frac{1}{n}$$

Ans. divergent

$$18. \sum_{n=1}^{\infty} \frac{(n^{1/3}+1)^p}{(n^{7/3}+n^{5/2}+1)^{13/11}}$$

$$\text{Hint: Compare } \sum n^{\frac{p}{3}-\frac{65}{22}}$$

Ans. convergent if $p < \frac{129}{22}$

$$19. \sum_{n=1}^{\infty} \frac{x^n}{\sqrt{n}} \quad \text{Hint: Compare } \sum n^{-1/2},$$

Ans. for $x = 1$, series is divergent; for $x < 1$ convergent, for $x > 1$, divergent.

$$20. \sum_{n=1}^{\infty} \left[\sqrt[3]{n^3+1} - n \right]$$

$$\text{Hint: Compare } \sum n^{-2}$$

Ans. convergent.

35.9 CAUCHY'S INTEGRAL TEST

Theorem:

$$\text{Let } \sum u_n = u_1 + u_2 + u_3 + \dots + u_n + \dots \quad (1)$$

be series with positive and non-increasing terms

$$\text{i.e., } u_1 \geq u_2 \geq u_3 \geq \dots \quad (2)$$

Let $f(x)$ be a continuous non-increasing function such that

$$f(1) = u_1, f(2) = u_2, f(3) = u_3, \dots, f(n) = u_n \quad (3)$$

Then the improper integral

$$\int_1^{\infty} f(x) dx \quad (4)$$

and the infinite series (1) are both finite (in which case series (1) is convergent) or both infinite (in which case series (1) is divergent).

Proof: Plot the terms $u_1, u_2, u_3, \dots$ of the series (1) on the y -axis so that the first escribed rectangle is of area u_2 while the first inscribed rectangle is of area u_1 .

Fig. 35.2

Thus the area under the curve $y = f(x)$, above the x -axis and between any two ordinates $x = a$ and $x = b$ lies between the sum of the set of inscribed (solid) and escribed (dotted) rectangles formed by the ordinates at $x = 1, 2, 3, \dots$, as shown in Fig. 35.2. Hence,

$$(S_{n+1} - u_1) \leq \int_1^{n+1} f(x) dx \leq S_n$$

As $n \rightarrow \infty$ the first inequality becomes

$$\lim_{n \rightarrow \infty} S_{n+1} \leq \lim_{n \rightarrow \infty} \int_1^{n+1} f(x) dx + u_1 = \int_1^{\infty} f(x) dx + u_1$$

So if the integral on the R.H.S. is finite, then $\lim_{n \rightarrow \infty} S_{n+1}$ is finite, therefore series (1) converges.

As $n \rightarrow \infty$, from the second inequality

$$\lim_{n \rightarrow \infty} \int_1^{n+1} f(x) dx = \int_1^{\infty} f(x) dx \leq \lim_{n \rightarrow \infty} S_n$$

35.10 — ENGINEERING MATHEMATICS

It follows that if the integral on the L.H.S. is infinite then $\lim_{n \rightarrow \infty} S_n = \text{infinite}$ therefore series (1) diverges.

***p*-Series Test: Nature of *p*-harmonic Series Using Integral Test**

Consider the *p*-harmonic series

$$\sum_{n=1}^{\infty} \frac{1}{n^p} = \frac{1}{1^p} + \frac{1}{2^p} + \frac{1}{3^p} + \cdots + \frac{1}{n^p} + \cdots$$

To apply integral test consider $f(x) = \frac{1}{x^p}$ then the improper integral is

$$\begin{aligned} \int_1^{\infty} f(x) dx &= \int_1^{\infty} \frac{dx}{x^p} = \lim_{n \rightarrow \infty} \int_1^n \frac{dx}{x^p} \\ &= \begin{cases} \lim_{n \rightarrow \infty} \frac{1}{1-p} \cdot x^{1-p} \ln x \Big|_1^n & \text{when } p \neq 1 \\ \lim_{n \rightarrow \infty} \ln x \Big|_1^n & \text{when } p = 1 \end{cases} \\ &= \begin{cases} \frac{1}{p-1} = \text{finite} & \text{when } p > 1 \\ \infty = \text{infinite} & \text{when } p < 1 \\ \infty = \text{infinite} & \text{when } p = 1 \end{cases} \end{aligned}$$

Thus the *p*-harmonic series by integral test is convergent when $p > 1$ and divergent when $p \leq 1$.

Note 1: Integral test is used when the terms of the series are positive and non increasing and when the evaluation of the integral is easy.

Note 2: The lower limit in the improper integral (4) need not be 1 but any number *N* at which the integral is finite.

WORKED OUT EXAMPLES

Using integral test, determine the convergence of the series:

Example 1: $1 + \frac{1}{3} + \frac{1}{5} + \cdots + \frac{1}{2n-1} + \cdots$

Solution: Take $f(x) = \frac{1}{2x-1}$

Applying integral test

$$\int_1^{\infty} \frac{dx}{2x-1} = \frac{1}{2} \ln(2x-1) \Big|_1^{\infty} = \infty, \text{ so divergent.}$$

Example 2: $\sin \pi + \frac{1}{4} \sin \frac{\pi}{2} + \frac{1}{9} \sin \frac{\pi}{3} + \cdots$

Solution: Here $u_n = \frac{1}{n^2} \sin \frac{\pi}{n} \cdots$

Taking $f(x) = \frac{1}{x^2} \sin \frac{\pi}{x}$ and applying integral test

$$\begin{aligned} \int_1^{\infty} \frac{\sin \pi/x}{x^2} dx &= \int_0^{\pi} \sin t dt \quad \text{where } \frac{\pi}{x} = t \\ &= -\cos t \Big|_0^{\pi} = 1 + 1 = 2 \text{ so convergent.} \end{aligned}$$

Example 3: $\frac{1}{2} + \frac{4}{9} + \frac{9}{28} + \cdots$

Solution: Here the *n*th term is $n^2/(n^3 + 1)$ so take $f(x) = \frac{x^2}{x^3+1}$ using integral test.

$$\int_1^{\infty} \frac{x^2}{x^3+1} dx = \frac{1}{3} \ln(x^3+1) \Big|_1^{\infty} = \infty \text{ so divergent.}$$

Example 4: $e^{-1} + 2e^{-2} + 3e^{-3} + \cdots + ne^{-n} + \cdots$

Solution: with $f(x) = xe^{-x}$, Integral Test gives

$$\begin{aligned} \int_1^{\infty} xe^{-x} dx &= -xe^{-x} - e^{-x} \text{ by integration by parts} \\ &= 0 + e^{-1} + 0 + e^{-1} = \frac{2}{e}, \text{ so convergent} \end{aligned}$$

since $\lim_{x \rightarrow \infty} xe^{-x} = \lim_{x \rightarrow \infty} \frac{x}{e^x} = 0$, by L' Hospital's rule and $\lim_{x \rightarrow \infty} \frac{1}{e^x} = 0$.

EXERCISE

Apply integral test to test for convergence of the following series:

$$1. 1 + \frac{1}{\sqrt{2}} + \cdots + \frac{1}{\sqrt{n}} + \cdots$$

Ans. $f(x) = \sqrt{x}$, divergent

$$2. \frac{1}{2} + \frac{1}{6} + \frac{1}{12} + \cdots + \frac{1}{n(n+1)} + \cdots$$

Ans. $f(x) = \frac{1}{x(x+1)}$ convergent

$$3. \frac{1}{3} + \frac{1}{15} + \frac{1}{35} + \cdots + \cdots$$

$$\begin{aligned} \text{Hint: } u_n &= \frac{1}{4n^2-1} = \frac{1}{(2n-1)(2n+1)}, \text{ so } f(x) \\ &= \frac{1}{4x^2-1} \end{aligned}$$

Ans. convergent

$$4. \sum_{n=1}^{\infty} \frac{n}{n^2+1}$$

Ans. divergent

$$5. \sum_{n=1}^{\infty} \frac{2n^3}{n^4+3} \quad \text{Ans. divergent}$$

$$6. \sum_{n=2}^{\infty} \frac{1}{n \log n} \quad \text{Ans. divergent}$$

$$7. \sum_{n=1}^{\infty} \frac{1}{n^2+1} \quad \text{Ans. convergent}$$

$$8. \sum_{n=1}^{\infty} \frac{1}{n^2} \quad \text{Ans. convergent}$$

$$9. \sum_{n=1}^{\infty} \frac{1}{n\sqrt{n^2-1}} \quad \text{Ans. convergent}$$

$$10. \sum_{n=2}^{\infty} \frac{1}{n(\log n)}$$

Hint: Integral = $\frac{1}{(p-1)(\log 2)^{p-1}}$ for $p > 1$
 $= \infty$ for $0 \leq p \leq 1$.

Ans. convergent for $p > 1$
 divergent for $0 \leq p \leq 1$.

$$11. \sum_{n=1}^{\infty} \frac{e^n}{e^{2n+9}} \quad \text{Ans. convergent}$$

$$12. \sum_{n=1}^{\infty} \frac{1}{\sqrt{n^2+9}} \quad \text{Ans. divergent}$$

$$13. \sum_{n=3}^{\infty} \frac{1}{n^2-4} \quad \text{Ans. convergent}$$

$$14. \sum_{n=1}^{\infty} \frac{1}{10n} \quad \text{Ans. divergent}$$

$$15. \sum_{n=0}^{\infty} e^{-n^2}$$

Hint: Since $\int_0^{\infty} e^{-x^2} dx$ cannot be evaluated, show that it is finite by comparing it with $\int_0^{\infty} e^{-x} dx$.

Ans. convergent

$$16. \frac{50}{1.2} + \frac{50}{2.3} + \frac{50}{3.4} + \frac{50}{4.5} + \dots$$

Hint: $f(x) = \frac{50}{x(x+1)}$, limit: $50 \ln 2$

Ans. convergent.

35.10 D'ALEMBERT'S* RATIO TEST

Theorem:

$$\text{Let } \sum u_n = u_1 + u_2 + u_3 + \dots + u_n + \dots \quad (1)$$

be a series with positive terms. The ratio $\frac{u_{n+1}}{u_n}$ measures the rate or growth of the terms of the series (1),

$$\text{Let } \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} = m \quad (2)$$

Then

- a. the series (1) converges if $m < 1$
- b. the series (1) diverges if $m > 1$
- c. the ratio test fails when $m = 1$

i.e., series may converge or diverge. Use a different test.

Proof:

- a. Let $m < 1$ and consider a number q such that $m < q < 1$. For $n \geq N$, where N is a large integer,

$$\frac{u_{n+1}}{u_n} < q, \quad \begin{array}{c} \text{---} m \quad \frac{u_{n+1}}{u_n} \quad q \quad 1 \text{---} \end{array}$$

so that $u_{N+1} < qu_N$, $u_{N+2} < qu_{N+1} < q^2 u_N$, $u_{N+3} < qu_{N+2} < q^3 u_N$, etc. Thus for $n \geq N$, the given series reduces to (leaving the first N terms)

$$\begin{aligned} &= u_N + u_{N+1} + u_{N+2} + u_{N+3} + \dots \\ &= u_N \left(1 + \frac{u_{N+1}}{u_N} + \frac{u_{N+2}}{u_N} + \frac{u_{N+3}}{u_N} + \dots \right) \\ &< u_N (1 + q + q^2 + q^3 + \dots) \quad (\text{since } q < 1) \\ &= \frac{u_N}{1 - q} = \text{finite quantity.} \end{aligned}$$

Hence $\sum u_n$ is convergent.

- b. Let $m > 1$, from limit (2) for $n \geq N$,

$$\frac{u_{n+1}}{u_n} > 1, \quad \begin{array}{c} \text{---} 1 \quad \frac{u_{n+1}}{u_n} \quad m \text{---} \end{array}$$

so that $u_{n+1} > u_n$ for all $n \geq N$, which means that the terms of the series increase after the $N + 1$ th term. For this reason, the general term u_n of the series does not tend to zero. Hence the series diverges.

- c. When $m = 1$, ratio test fails.

*Jean le-Rond d'Alembert (1717–1783) French Mathematician.

35.12 — ENGINEERING MATHEMATICS

Counter Example: For the convergent series

$$\sum_{n=1}^{\infty} \frac{1}{n^2}, \quad \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} = \lim_{n \rightarrow \infty} \frac{1}{(n+1)^2} n^2 = 1$$

Also for the divergent series

$$\sum_{n=1}^{\infty} \frac{1}{n}, \quad \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} = \lim_{n \rightarrow \infty} \frac{1}{n+1} \cdot n = 1$$

Thus ratio test can not be used to distinguish between convergent and divergent series when $m = 1$

Important Note 1: Ratio test fails when the limit (2) does not exist or equals to 1. When ratio test fails, Raabe's test may be used.

Note 2: Series diverges when $\lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} = \infty$ since $\frac{u_{n+1}}{u_n} > 1$ for $n \geq N$.

Note 3: Ratio test is concerned only with value of limit (2) without any reference to the magnitude of the ratio $\frac{u_{n+1}}{u_n}$.

Even if $\lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} = 1$ but $\frac{u_{n+1}}{u_n} > 1$ for $n \geq N$

then series diverges because general term does not approach zero as $n \rightarrow \infty$.

Note 4: Even though $\frac{u_{n+1}}{u_n} < 1$ for all n , the series $\sum u_n$ is not convergent unless $\lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} < 1$

Example: Although $\frac{u_{n+1}}{u_n} = \frac{n}{n+1} < 1$ for all n the series $\sum u_n = \sum \frac{1}{n}$, diverges since $n \rightarrow \infty \frac{u_{n+1}}{u_n} = \lim_{n \rightarrow \infty} \frac{n}{n+1} = 1$.

WORKED OUT EXAMPLES

Use D' Alembert's ratio test to test for convergence of the following series whose n th term is:

Example 1: $(n+3)!/(3!n!3^n)$

Solution:

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} &= \lim_{n \rightarrow \infty} \frac{(n+4)!}{3!(n+1)!3^{n+1}} \cdot \frac{3!n!3^n}{(n+3)!} \\ &= \lim_{n \rightarrow \infty} \frac{n+4}{(n+1) \cdot 3} = \frac{1}{3} \lim_{n \rightarrow \infty} \frac{1 + \frac{4}{n}}{\frac{1}{n} + 1} = \frac{1}{3} < 1 \end{aligned}$$

series is convergent.

Example 2: $(2n)!/(n!)^2$

Solution:

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} &= \lim_{n \rightarrow \infty} \frac{(2n+2)!}{[(n+1)!]^2} \cdot \frac{(n!)^2}{(2n)!} \\ &= \lim_{n \rightarrow \infty} \frac{(2n+1)(2n+2)}{(n+1)^2} \\ &= \lim_{n \rightarrow \infty} 2 \cdot \left(\frac{2n+1}{n+1} \right) = 2 \lim_{n \rightarrow \infty} \left(\frac{2 + \frac{1}{n}}{1 + \frac{1}{n}} \right) \\ &= 2.2 = 4 > 1 \end{aligned}$$

series is divergent.

Example 3: $\frac{n^3+a}{2^n+a}$

Solution:

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} &= \lim_{n \rightarrow \infty} \frac{(n+1)^3+a}{2^{n+1}+a} \cdot \frac{2^n+a}{n^3+a} \\ &= \lim_{n \rightarrow \infty} \frac{\left(1 + \frac{1}{n}\right)^3 + \frac{a}{n^3}}{\left(2 + \frac{a}{2^n}\right)} \cdot \frac{\left(1 + \frac{a}{2^n}\right)}{\left(1 + \frac{a}{n^3}\right)} \\ &= \frac{1}{2} < 1 \end{aligned}$$

series is convergent.

Example 4: $(4n^2 - 1)^{-1}$

Solution: Here the n th term $u_n = (4n^2 - 1)^{-1} = \frac{1}{(2n-1)(2n+1)}$

Applying ratio test, we have

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} &= \frac{1}{(2n+1)(2n+3)} \cdot \frac{(2n-1)(2n+1)}{1} \\ &= \lim_{n \rightarrow \infty} \frac{2 - \frac{1}{n}}{2 + \frac{3}{n}} = 1 \end{aligned}$$

so ratio test fails

Comparison test:

since $n^2 \leq 4n^2 - 1$ for any $n > 0$

$$\frac{1}{n^2} \geq \frac{1}{4n^2 - 1}$$

since $\sum \frac{1}{n^2}$ is a harmonic series (with $p = 2$) which is convergent, so is the series $\sum \frac{1}{4n^2 - 1}$.

Example 5: $[x^{2n} \cdot n/(n^2 + 1)]^{\frac{1}{2}}$

Solution: Applying ratio test,

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} &= \lim_{n \rightarrow \infty} x^{n+1} \cdot \left(\frac{n+1}{(n+1)^2+1} \right)^{\frac{1}{2}} \left(\frac{n^2+1}{n} \right)^{\frac{1}{2}} \cdot \frac{1}{x^n} \\ &= \lim_{n \rightarrow \infty} x \cdot \left(\frac{\left(1+\frac{1}{n}\right)}{\left(1+\frac{1}{n}\right)^2+\frac{1}{n}} \cdot \left(1+\frac{1}{n^2}\right) \right)^{\frac{1}{2}} = x. \end{aligned}$$

For $x < 1$ series converges, while it diverges for $x > 1$.

When $x = 1$, the n th term of the series $\sqrt{\frac{n}{n^2+1}}$ choose the series $v_n = \frac{1}{n}$ which is divergent.

Since $n^3 > n^2 + 1$ or $\frac{n}{n^2+1} > \frac{1}{n^2}$ or

$$\sqrt{\frac{n}{n^2+1}} > \sqrt{\frac{1}{n^2}} = \frac{1}{n} \text{ for every } n > 1.$$

Thus the series with n th term $\sqrt{\frac{n}{n^2+1}}$ is divergent.

Hence series converges for $x < 1$ and diverges for $x \geq 1$.

Example 6: $\frac{(1+\alpha)(1+2\alpha)(1+3\alpha)+\dots+(1+n\alpha)}{(1+\beta)(1+2\beta)(1+3\beta)+\dots+(1+n\beta)}$

Solution: Applying ratio test,

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} &= \frac{(1+\alpha)(1+2\alpha)(1+3\alpha)+\dots+(1+n\alpha)(1+(n+1)\alpha)}{(1+\beta)(1+2\beta)(1+3\beta)+\dots+(1+n\beta)(1+(n+1)\beta)} \\ &\quad \times \frac{(1+\beta)\dots(1+n\beta)}{(1+\alpha)\dots(1+n\alpha)} \\ &= \lim_{n \rightarrow \infty} \frac{1+(n+1)\alpha}{1+(n+1)\beta} = \frac{\alpha}{\beta} \end{aligned}$$

For $\frac{\alpha}{\beta} < 1$ series converges

$\frac{\alpha}{\beta} > 1$ series diverges

For $\frac{\alpha}{\beta} = 1$ i.e., $\alpha = \beta$, the n th term of the series is $u_n = 1$

$$\lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} 1 = 1 \neq 0$$

so the series diverges for $\alpha = \beta$.

Thus the given series converges for $\beta > \alpha > 0$ and diverges for $\alpha \geq \beta > 0$.

EXERCISE

Use D'Alembert's ratio test to test for the convergence of the following series whose n th term is:

1. $10^n/(n!)^2$ Ans. convergent
2. $\frac{1 \cdot 2 \cdot 3 \cdots n}{3 \cdot 5 \cdot 7 \cdots (2n+1)}$ Ans. convergent
3. $n^2/3^n$ Ans. convergent
4. $n!/n^n$ Ans. convergent
5. $2^n/n^2$ Ans. divergent
6. $n/(n+1)$ Ans. divergent
7. $1/(1 \cdot 2 \cdot 3 \cdots n)$ Ans. convergent
8. $n!/(2n)!$ Ans. convergent
9. $n!/100^n$ Ans. divergent
10. $(n+1)/(n \cdot 4^{n-1})$ Ans. convergent
11. $3^{2n}/2^{3n}$ Ans. divergent
12. $(n!)^3 e^{3n}/(3n)!$ Ans. convergent
13. $\sqrt{2n!}/n!$ Ans. divergent
14. $n!/(1 \cdot 3 \cdot 5 \cdots (2n-1))$ Ans. convergent
15. $n!/10^{2n-1}$ Ans. divergent

In case, ratio test fails use other methods (say comparison test)

16. $1/(n(n+1))$ **Hint:** $S_n = 1 - \frac{1}{n+1}$
Ans. convergent
17. $(n^2+1)/(n^3+1)$ **Hint:** Compare $\frac{1}{n}$
Ans. divergent
18. $1/(1+e^{\frac{1}{n}})$ **Hint:** $\lim_{n \rightarrow \infty} u_n = \frac{1}{2}$
Ans. divergent
19. $\frac{1}{(1+n^2)}$ **Hint:** Compare $\frac{1}{n^2}$
Ans. convergent
20. $(n+6)^{-\frac{1}{3}}$ **Hint:** Compare $n^{\frac{1}{3}}$
Ans. divergent
21. $\sqrt{n}/(n^2+1)$ **Hint:** Compare $n^{-\frac{3}{2}}$
Ans. convergent

35.14 — ENGINEERING MATHEMATICS

22. $x^{2n-2}/((n+1)\sqrt{n})$ **Hint:** Compare $n^{-\frac{3}{2}}$

Ans. converges for $x^2 \leq 1$ and diverges for $x^2 > 1$

23. $(2^{n+1} - 2)x^n/(2^{n+1} + 1)$

Ans. converges for $x < 1$ and diverges for $x \geq 1$

24. $1 \cdot 3 \cdot 5 \cdots (2n-1) \cdot x^{n-1}/(2 \cdot 4 \cdot 6 \cdots 2n)$
with $x > 0$

Ans. converges for $x < 1$ and diverges for $x \geq 1$

25. $n^2 \cdot x^{n-1}$ with $x > 0$

Hint: For $x = 1$, the series $\sum n^2$ is divergent

Ans. convergent when $x < 1$ and divergent when $x \geq 1$

26. $x^n/(n(n+1))$

Hint: For $x = 1$, compare with $\sum n^{-2}$ which is convergent

Ans. convergent when $x \leq 1$ and divergent when $x > 1$

27. $x^n/(n(n+1)(n+2))$ with $x > 0$

Ans. convergent if $x \leq 1$ and divergent if $x > 1$

28. $(\sqrt{n^2+1} - n)x^{2n}$

Ans. convergent if $x^2 < 1$ and divergent if $x^2 \geq 1$

29. $[(n+1)/(n+2)]^n x^n$

Ans. convergent if $x < 1$ and divergent if $x \geq 1$

30. $x^{2n-1}/(2n-1)$

Ans. converges for $|x| < 1$.

35.11 CAUCHY'S* n th ROOT TEST

Theorem: For a positive series

$$\sum_{n=1}^{\infty} u_n = u_1 + u_2 + u_3 + \cdots + u_n + \cdots \quad (1)$$

Let $\lim_{n \rightarrow \infty} \sqrt[n]{u_n} = \text{finite value} = m$

Then

- series converges when $m < 1$
- series diverges when $m > 1$
- test fails when $m = 1$, use a different test

Note: Cauchy's root test is applied when u_n involves the n th power of itself as a whole.

WORKED OUT EXAMPLES

Use Cauchy's n th root test to test for convergence of the following series:

Example 1: $\sum \left(\frac{n+1}{2n+5}\right)^n$

Solution: Here $u_n = \left(\frac{n+1}{2n+5}\right)^n$
Applying Cauchy's n th root test,

$$\begin{aligned} \lim_{n \rightarrow \infty} u_n^{1/n} &= \lim_{n \rightarrow \infty} \left[\left(\frac{n+1}{2n+5} \right)^n \right]^{\frac{1}{n}} = \lim_{n \rightarrow \infty} \frac{n+1}{2n+5} \\ &= \lim_{n \rightarrow \infty} \left(\frac{1 + \frac{1}{n}}{2 + \frac{5}{n}} \right) = \frac{1}{2} < 1 \end{aligned}$$

series is convergent.

Example 2: $\sum \frac{\left(1 + \frac{1}{n}\right)^{2n}}{e^n}$

Solution: $u_n = \frac{\left(1 + \frac{1}{n}\right)^{2n}}{e^n}$

$$\begin{aligned} \lim_{n \rightarrow \infty} u_n^{1/n} &= \lim_{n \rightarrow \infty} \left[\frac{\left(1 + \frac{1}{n}\right)^{2n}}{e^n} \right]^{\frac{1}{n}} = \lim_{n \rightarrow \infty} \frac{\left(1 + \frac{1}{n}\right)^2}{e} \\ &= \frac{1}{e} \cdot 1 = 0.3678796 < 1 \end{aligned}$$

series convergent.

Example 3: $1 + \frac{x}{2} + \frac{x^2}{3^2} + \frac{x^3}{4^3} + \cdots \infty$ where $x > 0$

Solution: Here the n th term $u_n = \frac{x^n}{(n+1)^n}$

$$\begin{aligned} \lim_{n \rightarrow \infty} u_n^{1/n} &= \lim_{n \rightarrow \infty} \left[\frac{x^n}{(n+1)^n} \right]^{\frac{1}{n}} \\ &= \lim_{n \rightarrow \infty} \frac{x}{(n+1)} = x \cdot 0 = 0 < 1 \end{aligned}$$

for any x . So series is convergent for any x .

Example 4: $\sum \frac{x^{2n}}{2^n}$ with $x > 0$

*Augustin-Louis Cauchy (1789–1857) French mathematician.

Solution: $u_n = \frac{x^{2n}}{2^n}$

$$\lim_{n \rightarrow \infty} u_n^{\frac{1}{n}} = \lim_{n \rightarrow \infty} \left(\frac{x^{2n}}{2^n} \right)^{\frac{1}{n}} = \lim_{n \rightarrow \infty} \frac{x^2}{2} = \frac{x^2}{2}$$

series is convergent if $\frac{x^2}{2} < 1$, i.e., $x < \sqrt{2} = 1.4142$
and divergent if $\frac{x^2}{2} > 1$, i.e., $x > \sqrt{2}$.

If $x = \sqrt{2}$, $u_n = 1$ for any n , so $\lim_{n \rightarrow \infty} u_n = 1 \neq 0$.
Series is divergent.

EXERCISE

Use Cauchy's n th root test to test for convergence of the following series whose n th term is:

1. $2^n/n^3$ **Ans.** limit: 2, divergent
2. $(1 + \frac{1}{n})^{-n^2}$ **Ans.** limit: $\frac{1}{e}$, convergent
3. $(\log n)^{-n}$ **Ans.** converges for $n > e^2$
4. n^{-n} **Ans.** limit 0; convergent
5. $(\frac{n+1}{n+2} \cdot x)^n$

Ans. convergent for $x < 1$ and divergent for $x \geq 1$

6. $(1 + \frac{1}{\sqrt{n}})^{-\frac{3}{e}}$ **Ans.** limit e^{-1} ; convergent
7. $(\frac{nx}{1+n})^n$ with $x > 0$

Ans. limit: x , convergent for $x < 1$ and divergent for $x \geq 1$

8. $[(n+1)x]^n/n^{n+1}$ with $x > 0$

Ans. limit: x , convergent for $x < 1$ and divergent for $x \geq 1$

9. $\left[\left(\frac{n+1}{n} \right)^{n+1} - \left(\frac{n+1}{n} \right) \right]^{-n}$

Ans. limit: $\frac{1}{e-1}$, convergent

10. ne^{-n^2} **Ans.** limit: $\frac{1}{e^2}$, convergent

35.12 RAABE'S* TEST (Higher Ratio Test)

Theorem: Let $\sum u_n$ be a positive series and let

$$\lim_{n \rightarrow \infty} \left(\frac{u_n}{u_{n+1}} - 1 \right) = m$$

Then the given series converges when $m > 1$ and diverges when $m < 1$. Test fails for $m = 1$.

Note: When Raabe's test fails, Logarithmic ratio test or De Morgan's and Bertrand's tests may be used.

WORKED OUT EXAMPLES

Example 1: Test for convergence of the series

$$1 + a + \frac{a(a+1)}{1 \cdot 2} + \frac{a(a+1)(a+2)}{1 \cdot 2 \cdot 3} + \dots$$

Solution: The n th term of this series is

$$u_n = \frac{a(a+1)(a+2)(a+3) \cdots (a+n)}{1 \cdot 2 \cdot 3 \cdots (n+1)}$$

Applying ratio test, we have

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_n}{u_{n+1}} &= \lim_{n \rightarrow \infty} \frac{a(a+1)(a+2) \cdots (a+n)}{(n+1)!} \\ &\quad \times \frac{(n+2)!}{a(a+1)(a+2) \cdots (a+n)(a+n+1)} \\ &= \lim_{n \rightarrow \infty} \frac{(n+2)}{(a+n+1)} = \lim_{n \rightarrow \infty} \left[\frac{1 + \frac{2}{n}}{1 + \left(\frac{a+1}{n} \right)} \right] \\ &= 1 \end{aligned}$$

so ratio test fails.

Apply Raabe's test,

$$\begin{aligned} \lim_{n \rightarrow \infty} n \left[\frac{n+2}{(a+n+1)} - 1 \right] &= \lim_{n \rightarrow \infty} \frac{n(1-a)}{(n+a+1)} \\ &= \lim_{n \rightarrow \infty} \frac{(1-a)}{\left(1 + \frac{a+1}{n} \right)} = 1-a \end{aligned}$$

series converges if $1-a > 1$ i.e., $a < 0$ and diverges if $1-a < 1$ i.e., $a > 0$.

When $a = 0$, limit = 1. So series converges. Thus series converges for $a \leq 0$ and diverges for $a > 0$.

Example 2: $\frac{2}{5}x + \frac{2 \cdot 4}{5 \cdot 8}x^2 + \frac{2 \cdot 4 \cdot 6}{5 \cdot 8 \cdot 11}x^3 + \dots$ with $x > 0$

Solution: Here the n th term of the series is

$$u_n = \frac{2 \cdot 4 \cdot 6 \cdots (2n)}{5 \cdot 8 \cdot 11 \cdots (3n+2)} \cdot x^n$$

*Joseph Ludwig Raabe (1801–1859) Swiss mathematician.

35.16 — ENGINEERING MATHEMATICS

Applying ratio test,

$$\begin{aligned}\lim_{n \rightarrow \infty} \frac{u_n}{u_{n+1}} &= \lim_{n \rightarrow \infty} \frac{2 \cdot 4 \cdot 6 \cdots (2n)}{5 \cdot 8 \cdot 11 \cdots (3n+2)} \cdot x^n \\ &\quad \times \frac{5 \cdot 8 \cdot 11 \cdots (3n+2)(3n+5)}{2 \cdot 4 \cdot 6 \cdots (2n)(2n+2)x^{n+1}} \\ &= \frac{1}{2x} \lim_{n \rightarrow \infty} \left(\frac{3n+5}{n+1} \right) = \frac{3}{2x}\end{aligned}$$

so series is convergent for $\frac{3}{2x} > 1$ and diverges for $\frac{3}{2x} < 1$. For $x = \frac{3}{2}$, ratio test fails.

Applying Raabe's test,

$$\begin{aligned}\lim_{n \rightarrow \infty} n \left(\frac{u_n}{u_{n+1}} - 1 \right) &= \lim_{n \rightarrow \infty} n \left(\frac{1}{3} \frac{(3n+5)}{(n+1)} - 1 \right) \\ &= \lim_{n \rightarrow \infty} \frac{2n}{3(n+1)} = \frac{2}{3} < 1\end{aligned}$$

series diverges.

Thus the given series converges for $x < \frac{3}{2}$ and diverges for $x \geq \frac{3}{2}$.

Example 3: $1 + \frac{1}{2} + \frac{1 \cdot 3}{2 \cdot 4} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6} + \cdots$

Solution: Here $u_n = \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)}$

Applying ratio test,

$$\begin{aligned}\lim_{n \rightarrow \infty} \frac{u_n}{u_{n+1}} &= \lim_{n \rightarrow \infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \\ &\quad \times \frac{2 \cdot 4 \cdot 6 \cdots (2n)(2n+2)}{1 \cdot 3 \cdot 5 \cdots (2n-1)(2n+1)} \\ &= \lim_{n \rightarrow \infty} \frac{2(n+1)}{2n+1} = 1\end{aligned}$$

Ratio test fails

Applying Raabe's test,

$$\begin{aligned}\lim_{n \rightarrow \infty} n \left(\frac{u_n}{u_{n+1}} - 1 \right) &= \lim_{n \rightarrow \infty} n \left(\frac{2n+2}{2n+1} - 1 \right) \\ &= \lim_{n \rightarrow \infty} \frac{n}{2n+1} = \frac{1}{2} < 1\end{aligned}$$

series is divergent.

EXERCISE

Test for convergence of the following series with $x > 0$ and whose n th term is:

$$1. \frac{1 \cdot 3 \cdot 5 \cdots (2n-3)}{2 \cdot 4 \cdot 6 \cdots (2n-2)} \cdot \frac{a(a+1)(a+2) \cdots (a+n-2)}{b(b+1)(b+2) \cdots (b+n-2)} \text{ with } a > 0, b > 0$$

Hint: Ratio test fails

By Raabe's test, limit $= b - a + \frac{1}{2}$.

Ans. series is convergent for $b > a + \frac{1}{2}$

$$2. [1^2 \cdot 5^2 \cdot 9^2 \cdots (4n-3)^2] / [4^2 \cdot 8^2 \cdot 12^2 \cdots (4n)^2]$$

Ans. convergent

$$3. \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \cdot \frac{1}{(2n+1)}$$

Hint: Raabe's test, limit $= \frac{6}{4} > 1$.

Ans. convergent

$$4. [4 \cdot 7 \cdots (3n+1) \cdot x^n] / n!$$

Hint: For $x = \frac{1}{3}$, ratio test fails.

In Raabe's test, limit $= -\frac{1}{3}$.

Ans. convergent for $x < \frac{1}{3}$ and divergent for $x \geq \frac{1}{3}$.

$$5. [2^2 \cdot 4^2 \cdot 6^2 \cdots (2n)^2 x^{2n+2}] / [3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdots 8 \cdots (2n+1)(2n+2)]$$

Hint: For $x^2 = 1$ (ratio test fails).

By Raabe's test, limit $= \frac{3}{2}$

Ans. convergent for $x^2 \leq 1$ and divergent for $x^2 > 1$

$$6. [1 \cdot 3 \cdot 5 \cdots (2n-3)x^{2n-1}] / [2 \cdot 4 \cdot 6 \cdots (2n-2) \cdot (2n-1)]$$

Ans. convergent for $x^2 \leq 1$ and divergent for $x^2 > 1$

$$7. \frac{a(a+1)(a+2) \cdots (a+n-1)b(b+1)(b+2) \cdots (b+n-1) \cdot x^n}{1 \cdot 2 \cdot 3 \cdots n \cdot c(c+1)(c+2) \cdots (c+n-1)}$$

Ans. convergent for $x < 1$ and divergent for $x > 1$

when $x = 1$, convergent for $c > a + b$ and divergent for $c \leq a + b$

$$8. [1 \cdot 3 \cdot 5 \cdots (2n-1)(x^{2n+1})] / [2 \cdot 4 \cdot 6 \cdots (2n) \cdot (2n+1)]$$

Ans. convergent for $|x| \leq 1$ and divergent for $|x| > 1$

$$9. [3 \cdot 6 \cdot 9 \cdots (3n)]x^n / [7 \cdot 10 \cdot 13 \cdots (3n+4)]$$

Hint: When $x = 1$, by Raabe's test, $\lim$

$n \left(\frac{u_n}{u_{n+1}} - 1 \right) = \frac{4}{3} > 1$ therefore series is convergent.

Ans. convergent for $x \leq 1$ and divergent for $x > 1$

$$10. [1 \cdot 3 \cdot 5 \cdots (2n-1) \cdot x^n] / [2 \cdot 4 \cdot 6 \cdots 2n]$$

Ans. convergent for $x < 1$ and divergent for $x \geq 1$

$$11. x^n \log(nx)$$

Ans. convergent if $x < 1$ and divergent if $x \geq 1$

$$12. (n! x^n) / (3 \cdot 5 \cdot 7 \cdots (2n+1))$$

Hint: For $x = 2$ (ratio test fails), by Raabe's test, limit = $\frac{1}{2}$.

Ans. converges for $x < 2$ and diverges for $x \geq 2$

$$13. (n!)^2 x^n / (2n)!$$

Hint: For $x = 4$, (Ratio test fails), by Raabe's test, limit = $-\frac{1}{2}$.

Ans. convergent for $x < 4$ and diverges for $x \geq 4$

35.13 LOGARITHMIC TEST

Theorem: Let $\sum u_n$ be a positive series with $\lim_{n \rightarrow \infty} \left\{ n \cdot \log \left(\frac{u_n}{u_{n+1}} \right) \right\} = m$. Then the series $\sum u_n$ converges if $m > 1$ and diverges if $m < 1$ and test fails when $m = 1$.

Proof: Let $m > 1$ and p be such that $m > p > 1$. Consider the convergent p -series $\sum v_n = \sum \frac{1}{n^p}$ with $p > 1$. Then by comparison test the given series $\sum u_n$ converges if

$$\frac{u_n}{u_{n+1}} > \frac{v_n}{v_{n+1}} = \left(\frac{n+1}{n} \right)^p = \left(1 + \frac{1}{n} \right)^p$$

Taking log and expanding R.H.S. by log series

$$\log \frac{u_n}{u_{n+1}} > p \log \left(1 + \frac{1}{n} \right) = p \left(\frac{1}{n} - \frac{1}{2n^2} + \frac{1}{3n^3} + \cdots \right)$$

$$\text{or } n \left(\log \frac{u_n}{u_{n+1}} \right) > p \left(1 - \frac{1}{2n} + \frac{1}{3n^2} + \cdots \right).$$

Taking limit

$$\lim_{n \rightarrow \infty} n \left(\log \frac{u_n}{u_{n+1}} \right) > p(1 - 0 - 0 \cdots) = p > 1$$

A similar proof can be obtained when $m < 1$.

Note 1: Generally logarithmic test is used when Raabe's test fails. Logarithmic test is used when either n occurs as an exponent in $\frac{u_n}{u_{n+1}}$ or evaluation of limit becomes easier by taking logarithm.

Note 2: If $\frac{u_n}{u_{n+1}}$ does not involve n as an exponent or a logarithm, the series $\sum u_n$ diverges.

WORKED OUT EXAMPLES

Test for convergence of the following series:

$$\text{Example: } (a+1)\frac{x}{1!} + (a+2)^2\frac{x^2}{2!} + (a+3)^2\frac{x^3}{3!} + \cdots$$

Solution: The n th term of this series is

$$u_n = \frac{(a+n)^n}{n!} x^n \quad \text{so} \quad u_{n+1} = \frac{(a+n+1)^{n+1}}{(n+1)!} x^{n+1}$$

Applying ratio test,

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_n}{u_{n+1}} &= \lim_{n \rightarrow \infty} \frac{(a+n)^n}{n!} x^n \cdot \frac{(n+1)!}{(a+n+1)^{n+1}} \cdot \frac{1}{x^{n+1}} \\ &= \frac{1}{x} \lim_{n \rightarrow \infty} (n+1) \frac{(a+n)^n}{(a+n+1)^{n+1}} \\ &= \frac{1}{x} \lim_{n \rightarrow \infty} \frac{(n+1)n^n \left(1 + \frac{a}{n}\right)^n}{(n+1)^{n+1} \left(1 + \frac{a}{n+1}\right)^{n+1}} \\ &= \frac{1}{x} \lim_{n \rightarrow \infty} \frac{1}{\left(1 + \frac{1}{n}\right)^n} \frac{\left[\left(1 + \frac{a}{n}\right)^{\frac{n}{a}}\right]^{\frac{1}{a}}}{\left[\left(1 + \frac{a}{n+1}\right)^{\frac{n+1}{a}}\right]^{\frac{1}{a}}} \\ &= \frac{1}{x} \cdot \frac{1}{e} \cdot \frac{e^{\frac{1}{a}}}{e^{\frac{1}{a}}} = \frac{1}{xe} \end{aligned}$$

series is convergent for $\frac{1}{xe} > 1$ and divergent for $\frac{1}{xe} < 1$.

Ratio test fails for $xe = 1$

Apply logarithmic test with $x = \frac{1}{e}$ consider

$$\ln \frac{u_n}{u_{n+1}} = \ln \left[e \cdot \frac{1}{\left(1 + \frac{1}{n}\right)^n} \frac{\left(1 + \frac{a}{n}\right)^n}{\left(1 + \frac{a}{n+1}\right)^{n+1}} \right]$$

$$\begin{aligned} \ln \frac{u_n}{u_{n+1}} &= \ln e + n \ln \left(1 + \frac{a}{n} \right) - n \ln \left(1 + \frac{1}{n} \right) - (n+1) \\ &\quad \times \ln \left(1 + \frac{a}{n+1} \right) \end{aligned}$$

Expanding, $\ln(1+b) = b - \frac{b^2}{2} + \frac{b^3}{3} + \dots$

$$\begin{aligned} \ln \frac{u_n}{u_{n+1}} &= 1 + n \left\{ \frac{a}{n} - \frac{1}{2} \frac{a^2}{n^2} + \frac{1}{3} \frac{a^3}{n^3} + \dots \right\} \\ &\quad - n \left\{ \frac{1}{n} - \frac{1}{2} \frac{1}{n^2} + \frac{1}{3} \frac{1}{n^3} + \dots \right\} \\ &\quad - (n+1) \left\{ \frac{a}{(n+1)} - \frac{1}{2} \frac{a^2}{(n+1)^2} \right. \\ &\quad \left. + \frac{1}{3} \frac{a^3}{(n+1)^3} + \dots \right\} \end{aligned}$$

Multiplying by n ,

$$\begin{aligned} n \ln \frac{u_n}{u_{n+1}} &= \left\{ -\frac{a^2}{2} + \frac{a^3}{3n} + \dots \right\} + \left\{ \frac{1}{2} - \frac{1}{3} \frac{1}{n} + \dots \right\} \\ &\quad + \left\{ \frac{a^2}{2} \frac{n}{n+1} - \frac{na^3}{3(n+1)^2} + \dots \right\} \end{aligned}$$

where the terms after $+\dots$ contain $\frac{1}{n^2}, \frac{1}{n^3}$ etc. i.e., are of the order $\left(\frac{1}{n^2}\right)$

Applying logarithmic test,

$$\begin{aligned} \lim_{n \rightarrow \infty} n \ln \frac{u_n}{u_{n+1}} &= \left\{ -\frac{a^2}{2} + 0 + 0 + \dots \right\} \\ &\quad + \left\{ \frac{1}{2} + 0 + 0 + \dots \right\} \\ &\quad + \left\{ \frac{a^2}{2} + 0 + 0 + \dots \right\} = \frac{1}{2} < 1 \end{aligned}$$

series diverges

Thus the given series converges for $xe < 1$ and diverges for $xe \geq 1$.

EXERCISE

Test for convergence of the following series:

$$1. x + \frac{2^2 x^2}{2!} + \frac{3^3 x^3}{3!} + \frac{4^4 x^4}{4!} + \frac{5^5 x^5}{5!} + \dots$$

Hint: By ratio test, limit $\frac{u_{n+1}}{u_n} = ex$, converges for $ex < 1$ and diverges for $ex > 1$

For $ex > 1$ by log test: limit $= \frac{1}{2} < 1$, therefore diverges.

$$2. 1 + \frac{x}{2} + \frac{2!}{3^2} x^2 + \frac{3!}{4^3} x^3 + \frac{4!}{5^4} x^4 + \dots$$

Hint: By ratio test, limit $= x/e$ then for $x < e$ convergent and divergent for $x > e$.

For $x = e$, by log test, limit $= -\frac{1}{2} < 1$, diverges.

$$3. \frac{a+x}{1} + \frac{(a+2x)^2}{2!} + \frac{(a+3x)^3}{3!} + \frac{(a+4x)^4}{4!} + \dots$$

Hint: By ratio test, limit $\frac{u_{n+1}}{u_n} = ex$

converges for $ex < 1$ and diverges for $ex > 1$.

For $ex = 1$, by log test, limit $= \frac{1}{2} < 1$, divergent.

$$4. 1 + \frac{2x}{2!} + \frac{3^2 x^2}{3!} + \frac{4^3 x^3}{4!} + \frac{5^4 x^4}{5!} + \dots$$

Hint: By ratio test, limit $\frac{u_{n+1}}{u_n} = xe$.

Series is convergent for $xe < 1$ and divergent for $xe > 1$.

For $xe = 1$, limit $= \frac{3}{2} > 1$ series is convergent.

$$5. \frac{1}{2^2} + \frac{2^2}{3^3} + \frac{3^3}{4^4} + \frac{4^4}{5^5} + \frac{5^5}{6^6} + \dots$$

Hint: By Logarithmic test, $\lim_{n \rightarrow \infty} n \log \frac{u_n}{u_{n+1}} =$

$$\lim_{n \rightarrow \infty} n \left[\left(-1 + \frac{1}{n} - \frac{2}{2n} + \dots \right) + \log \left(1 + \frac{1}{n} \right)^n + \left(\frac{1}{n} - \frac{1}{2n^2} + \dots \right) \right] = \frac{3}{2} > 1 \text{ series is convergent.}$$

35.14 DeMORGAN'S AND BERTRAND'S TEST

Theorem: The series of positive terms $\sum u_n$ converges or diverges as

$$\lim_{n \rightarrow \infty} \left\{ \left[n \left(\frac{u_n}{u_{n+1}} - 1 \right) - 1 \right] \log n \right\} \text{ is } > 1 \text{ or } < 1.$$

Note: When Raabe's test fails, DeMorgan's test may be tried.

WORKED OUT EXAMPLES

Example 1: Test for convergence of

$$\frac{1^2}{2^2} + \frac{1^2 \cdot 3^2}{2^2 \cdot 4^2} + \frac{1^2 \cdot 3^2 \cdot 5^2}{2^2 \cdot 4^2 \cdot 6^2} + \dots$$

Solution: The n th term of this series is

$$u_n = \frac{1^2 \cdot 3^2 \cdot 5^2 \dots (2n-1)^2}{2^2 \cdot 4^2 \cdot 6^2 \dots (2n)^2}$$

Applying ratio test,

$$\begin{aligned}\lim_{n \rightarrow \infty} \frac{u_n}{u_{n+1}} &= \lim_{n \rightarrow \infty} \frac{1^2 \cdot 3^2 \cdot 5^2 \cdots (2n-1)^2}{2^2 \cdot 4^2 \cdot 6^2 \cdots (2n)^2} \\ &\quad \times \frac{2^2 \cdot 4^2 \cdot 6^2 \cdots (2n)^2 (2n+2)^2}{1^2 \cdot 3^2 \cdot 5^2 \cdots (2n-1)^2 (2n+1)^2} \\ &= \lim_{n \rightarrow \infty} \left(\frac{2n+2}{2n+1} \right)^2 = 1\end{aligned}$$

the ratio test fails.

Apply Raabe's test

$$\begin{aligned}\lim_{n \rightarrow \infty} \left\{ n \left(\frac{u_n}{u_{n+1}} - 1 \right) \right\} &= \lim_{n \rightarrow \infty} \left\{ n \left[\left(\frac{2n+2}{2n+1} \right)^2 - 1 \right] \right\} \\ &= \lim_{n \rightarrow \infty} \left\{ n \frac{(4n+3)}{(2n+1)^2} \right\} = 1\end{aligned}$$

So the Raabe's test also fails.

Apply DeMorgan's and Bertrand's test,

$$\begin{aligned}\lim_{n \rightarrow \infty} \left[\left\{ n \left(\frac{u_n}{u_{n+1}} - 1 \right) - 1 \right\} \log n \right] \\ &= \lim_{n \rightarrow \infty} \left\{ \frac{n(4n+3)}{(2n+1)^2} - 1 \right\} \log n \\ &= \lim_{n \rightarrow \infty} \frac{-(n+1)}{(2n+1)^2} \cdot \log n \\ &= - \lim_{n \rightarrow \infty} \frac{1}{4} \frac{\log n}{n} = 0 < 1, \text{ (by L' Hospital's rule)}\end{aligned}$$

So by DeMorgan's and Bertrand's test the given series is divergent.

Example 2: $\frac{1}{1^2} + \frac{1+2}{1^2+2^2} + \frac{1+2+3}{1^2+2^2+3^2} + \cdots$

Solution: The n th term of this series is

$$\begin{aligned}u_n &= \frac{1+2+3+4+\cdots+n}{1^2+2^2+3^2+\cdots+n^2} \\ &= \frac{n(n+1)}{2} \cdot \frac{6}{n(n+1)(2n+1)} = \frac{3}{(2n+1)}\end{aligned}$$

Applying ratio test,

$$\begin{aligned}\lim_{n \rightarrow \infty} \frac{u_n}{u_{n+1}} &= \lim_{n \rightarrow \infty} \frac{3}{(2n+1)} \cdot \frac{2n+3}{3} \\ &= \lim_{n \rightarrow \infty} \left(\frac{2n+3}{2n+1} \right) = 1\end{aligned}$$

the ratio test fails.

Applying Raabe's test,

$$\begin{aligned}\lim_{n \rightarrow \infty} n \left(\frac{u_n}{u_{n+1}} - 1 \right) &= \lim_{n \rightarrow \infty} n \left(\frac{2n+3}{2n+1} - 1 \right) \\ &= \lim_{n \rightarrow \infty} \frac{2n}{2n+1} = 1\end{aligned}$$

the Raabe's test also fails.

Apply DeMorgan's test,

$$\begin{aligned}\lim_{n \rightarrow \infty} \left[n \left(\frac{u_n}{u_{n+1}} - 1 \right) - 1 \right] \log n \\ &= \lim_{n \rightarrow \infty} \left[\frac{2n}{2n+1} - 1 \right] \log n \\ &= \lim_{n \rightarrow \infty} - \frac{\log n}{2n+1} = \frac{\infty}{\infty} \text{ (By L' Hospital's rule)} \\ &= \lim_{n \rightarrow \infty} - \frac{1}{n} \cdot \frac{1}{2} = 0 < 1\end{aligned}$$

So the series is divergent by DeMorgan's test.

EXERCISE

Test for convergence of the following series:

$$1. \frac{a}{b} + \frac{a(a+1)}{b(b+1)} + \frac{a(a+1)(a+2)}{b(b+1)(b+2)} + \cdots$$

Hint: Ratio test fails. Apply Raabe's test

Ans. Convergent if $b-a > 1$ and divergent if $b-a < 1$. For $b-a = 1$, the Raabe's test fails. By applying DeMorgan's test, series is divergent for $b-a = 1$.

$$2. 1 + \frac{2^2}{3^2} + \frac{2^2 \cdot 4^2}{3^2 \cdot 5^2} + \frac{2^2 \cdot 4^2 \cdot 6^2}{3^2 \cdot 5^2 \cdot 7^2} + \cdots$$

Hint: Ratio test fails, Raabe's test also fails.

By DeMorgan's test, limit $= 0 < 1$ so series is divergent.

Ans. divergent.

35.15 ALTERNATING SERIES LEIBNITZ'S* THEOREM

All the series considered so far contained only positive terms. However a series may contain some positive and some negative terms.

*Gottfried Wilhelm Leibnitz (1646–1716), German mathematician.

35.20 — ENGINEERING MATHEMATICS

Alternating series is a series whose terms are alternately positive and negative, i.e., series whose terms have alternating (positive and negative) signs in the form

$$u_1 - u_2 + u_3 - u_4 + \cdots + (-1)^n u_n + \cdots$$

where $u_1, u_2, \dots, u_n, \dots$ are all positive (i.e., $u_n > 0$, for every n).

A simple test for convergence of alternating series is given by *Leibnitz's theorem* (rule) which states that in the alternating series

$$u_1 - u_2 + u_3 - u_4 + \cdots + (-1)^n u_n + \cdots \quad (\text{with } u_n > 0) \quad (1)$$

if (i) the terms are such that each term is numerically greater than its succeeding term

$$\text{i.e., } u_1 > u_2 > u_3 > u_4 > \cdots > u_n > u_{n+1} > \cdots \quad (2)$$

and (ii)

$$\lim_{n \rightarrow \infty} u_n = 0 \quad (3)$$

Then the alternating series (1) converges. Its sum is positive, and does not exceed the first term.

Proof: Consider

$$S_{2m} = (u_1 - u_2) + (u_3 - u_4) + \cdots + (u_{2m-1} - u_{2m}) \quad (4)$$

which is the sum of the first $n = 2m$ even number of terms of the series (1).

The expression in each of the parentheses in (4) is positive (i.e., $(u_1 - u_2) > 0, (u_3 - u_4) > 0 \dots$, etc.) because of the condition (2). Hence $S_{2m} > 0$ and increases with increasing m as more positive values are added. Rewriting (4) as

$$S_{2m} = u_1 - (u_2 - u_3) - (u_4 - u_5) - \cdots - (u_{2m-2} - u_{2m-1}) - u_{2m}$$

and again using the condition (2), note that

$$S_{2m} < u_1$$

since positive quantities (in each bracket) are subtracted from u_1 . Thus S_{2m} increases with increasing m and is bounded above, hence the sequence of even partial sums has a limit say s ,

$$\text{i.e., } \lim_{m \rightarrow \infty} S_{2m} = s \quad (\text{with } 0 < s < u_1)$$

Now consider the sum of the first $n = 2m + 1$, odd number of terms of the series (1) as

$$S_{2m+1} = S_{2m} + u_{2m+1}$$

Taking the limit,

$$\begin{aligned} \lim_{m \rightarrow \infty} S_{2m+1} &= \lim_{m \rightarrow \infty} S_{2m} + \lim_{m \rightarrow \infty} u_{2m+1} \\ &= s + 0 = s \end{aligned}$$

since $\lim_{m \rightarrow \infty} u_{2m+1} = 0$ follows from condition (3). Therefore the given alternating series (1) converges because $\lim_{n \rightarrow \infty} = s$ both for even n and for odd n .

Note: Leibnitz's theorem holds good even if the inequalities (2) are true from some N onwards.

WORKED OUT EXAMPLES

Test for convergence of the following series:

Example 1: $1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16} + \cdots$

Solution: The given series is an alternating series since the terms of the series are alternately positive and negative n with $u_n = \frac{1}{2^n}$, so that $u_{n+1} = \frac{1}{2^{n+1}}$. Since $u_n - u_{n+1} = \frac{1}{2^n} - \frac{1}{2^{n+1}} = \frac{1}{2^{n+1}} > 0$ i.e., $u_{n+1} < u_n$ for every n , each term is numerically less than its preceding term.

$$\text{Also } \lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} \frac{1}{2^n} = 0$$

By Leibnitz's rule, the given series is convergent.

Example 2: $1 - \frac{x}{1^2} + \frac{x^2}{2^2} - \frac{x^3}{3^2} + \frac{x^4}{4^2} \dots$

Solution: Here $u_n - u_{n+1} = \frac{x^n}{n^2} - \frac{x^{n+1}}{(n+1)^2} = \frac{x^n [n^2(1-x) + 2n + 1]}{n^2(n+1)^2}$

For $|x| \leq 1$, $u_n - u_{n+1} > 0$ for every $n \geq 1$

$$\text{Also } \lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} \frac{x^n}{n^2} = 0 \quad \text{whenever } |x| \leq 1$$

Given alternative series is convergent for $|x| \leq 1$.

[For $|x| > 1$, $\lim_{n \rightarrow \infty} \frac{x^n}{n^2} = \lim_{n \rightarrow \infty} \frac{n \cdot x^{n-1}}{2n} = \infty$ by L' Hospital's rule and therefore the series diverges for $|x| > 1$].

Example 3: $\frac{1}{6} - \frac{2}{11} + \frac{3}{16} - \frac{4}{21} + \frac{5}{26} + \dots$

Solution: Here $u_n = \frac{n}{5n+1}$

$$\text{Since } \lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} \frac{n}{5n+1} = \frac{1}{5} \neq 0$$

By Leibnitz's rule, series is divergent.

Example 4: $\frac{x}{1+x} - \frac{x^2}{1+x^2} + \frac{x^3}{1+x^3} - \frac{x^4}{1+x^4} + \dots$

Solution: For this alternating series

$$\begin{aligned} u_n - u_{n+1} &= \frac{x^n}{1+x^n} - \frac{x^{n+1}}{1+x^{n+1}} \\ &= \frac{x^n(1-x)}{(1+x^n)(1+x^{n+1})} > 0 \text{ for } 0 < x < 1 \end{aligned}$$

$$\begin{aligned} \text{Also } \lim_{n \rightarrow \infty} u_n &= \lim_{n \rightarrow \infty} \frac{x^n}{1+x^n} = \frac{0}{1+0} = 0 \\ &\quad (\text{since for } x < 1, \lim_{n \rightarrow \infty} x^n = 0) \end{aligned}$$

By Leibnitz's rule the series is convergent whenever $0 < x < 1$.

EXERCISE

Test for convergence of the following series:

1. $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$ *Ans. convergent*

2. $1 - \frac{1}{2!} + \frac{1}{3!} - \frac{1}{4!} + \dots$ *Ans. convergent*

3. $\sum_{n=2}^{\infty} \frac{(-1)^{n-1}}{\ln n}$ *Ans. convergent*

4. $\frac{5}{2} - \frac{7}{4} + \frac{9}{6} - \frac{11}{8} + \dots$ **Hint:** limit = 1.
Ans. oscillatory

5. $\sum_{n=1}^{\infty} \frac{\cos n\pi}{n^2+1}$ *Ans. convergent*

6. $\sum (-1)^{n-1} \frac{1}{n^p}$ when $0 < p \leq 1$
Ans. convergent

7. $1 - \frac{1}{2!} + \frac{1}{4!} - \frac{1}{6!} + \dots$ *Ans. convergent*

8. $\sum_{n=1}^{\infty} (-1)^{n+1} (\sqrt{n+1} - \sqrt{n})$
Ans. convergent

9. $\frac{1}{1.2} - \frac{1}{3.4} + \frac{1}{5.6} - \frac{1}{7.8} + \dots$
Ans. convergent

10. $\sum_{n=1}^{\infty} \frac{(-1)^{n-1} \cdot n}{(2n-1)}$ **Hint:** limit = $\frac{1}{2}$.
Ans. oscillatory

11. $\sum_{n=1}^{\infty} (-1)^{n+1} \cdot \frac{1}{\sqrt{n}}$ *Ans. convergent*

12. $\sum_{n=1}^{\infty} (-1)^{n-1} \cdot \frac{n}{n^2+1}$ *Ans. convergent*

13. $\frac{1}{\sqrt{2}-1} - \frac{1}{\sqrt{2}+1} + \frac{1}{\sqrt{3}-1} - \frac{1}{\sqrt{3}+1} + \dots$
Ans. divergent

14. $\sum_{n=1}^{\infty} (-1)^{n-1} \cdot \frac{n}{n+1}$ *Ans. not convergent*

15. $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{\sqrt{n(n+1)(n+2)}}$ *Ans. convergent*

16. $\sum_{n=1}^{\infty} \frac{(-2)^n}{n^2}$ *Ans. divergent*

17. $\sum_{n=1}^{\infty} \frac{(-3)^n}{n!}$ *Ans. convergent*

18. $\sum_{n=1}^{\infty} \frac{(-1)^n n}{5+n}$ *Ans. divergent*

19. $\sum_{n=1}^{\infty} \frac{(-1)^n \sqrt{10n}}{n+2}$ *Ans. convergent*

20. $\sum_{n=0}^{\infty} (-1)^n (n+1)x^n$ with $x < \frac{1}{2}$
Ans. convergent

21. $\sum_{n=2}^{\infty} \frac{(-1)^{n-1} x^n}{n(n-1)}$, with $0 < x < 1$
Ans. convergent

22. $\sum_{n=1}^{\infty} (-1)^{n-1} \frac{1}{(x+n)}$ *Ans. convergent*

23. $\sum_{n=0}^{\infty} (-1)^n \frac{x^n}{1+n^a}$ *Ans. convergent for $|x| < 1$*

24. $\sum_{n=1}^{\infty} \frac{(-1)^{n-1} x^n}{\sqrt{n}}$ *Ans. convergent if $|x| < 1$*

35.22 — ENGINEERING MATHEMATICS

$$25. \frac{3}{2} - \frac{5}{4} + \frac{9}{8} - \frac{17}{16} + \dots$$

Hint: $\lim u_n = (1 + \frac{1}{2^n}) = 1 \neq 0$,

$$\lim S_{2n} = \frac{1}{3} \left[1 - \left(\frac{1}{2} \right)^{2n} \right] = \frac{1}{3} \text{ and } \lim S_{2n+1} =$$

$$\lim 1 + \frac{1}{3} \left\{ 1 + \left(\frac{1}{2} \right)^{2n+1} \right\} \rightarrow \frac{4}{3}.$$

Ans. oscillatory.

35.16 ABSOLUTE CONVERGENCE AND CONDITIONAL CONVERGENCE

Plus- and -minus series (also known as series of positive and negative terms) is a series containing both positive and negative terms in any order. In such a series, any term may be either positive or negative. Thus the alternating series considered earlier is a special case of plus- and -minus series with alternating positive and negative terms.

Absolute and conditional convergence

$$\text{Let } u_1 + u_2 + u_3 + \dots + u_n + \dots = \sum u_n \quad (1)$$

be a plus- and -minus series with the assumption that here onwards the members $u_1, u_2, \dots, u_n, \dots$ can be either positive or negative i.e., some terms may be positive and others negative (not necessarily alternative). Let us form a series made up of the absolute values of the terms of the series (1) i.e.,

$$|u_1| + |u_2| + |u_3| + \dots + |u_n| + \dots = \sum |u_n| \quad (2)$$

Each term of the series (2) is positive and numerically equal to the corresponding term of series (1).

Absolute Convergence

The plus- and -minus series $\sum_{n=1}^{\infty} u_n$ is said to be absolutely convergent if the corresponding series with absolute terms $\sum |u_n|$ is convergent.

Example: $1 - \frac{1}{2!} + \frac{1}{3!} - \frac{1}{4!} + \dots$ is absolutely convergent because the series formed with absolute values $1 + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} + \dots$ is convergent.

Conditional Convergence

If $\sum u_n$ is convergent while $\sum |u_n|$ is divergent then $\sum u_n$ is said to be conditionally convergent.

Example: $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$ is conditionally convergent because the given series is convergent (by Leibnitz's rule) while $1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \dots$ is a divergent harmonic series (with $p = 1$).

Sufficient Condition for Convergence

Theorem: Every absolutely convergent series is necessarily a convergent series.

Note 1: The converse is not true i.e., a series $\sum u_n$ of positive and negative terms may converge while the corresponding series $\sum |u_n|$ of absolute terms may diverge. See example under conditional convergence.

Note 2: Any convergent series of positive terms is also absolutely convergent.

Test for Absolute Convergence

A series $\sum u_n$ is absolutely convergent if

$$\lim_{n \rightarrow \infty} \left| \frac{u_{n+1}}{u_n} \right| < 1$$

and divergent if

$$\lim_{n \rightarrow \infty} \left| \frac{u_{n+1}}{u_n} \right| > 1$$

and test fails when the limit value is unity.

WORKED OUT EXAMPLES

Examine the following series for absolute or conditional convergence:

Example 1: $1 - \frac{1}{3!} + \frac{1}{5!} - \frac{1}{7!} + \dots$ (JNTU 2001/S)

Solution: This is an alternating series with n th term $u_n = \frac{1}{(2n+1)!}$ also $u_{n+1} = \frac{1}{(2n+3)!}$ so that

$$\begin{aligned} u_n - u_{n+1} &= \frac{1}{(2n+1)!} - \frac{1}{(2n+3)!} = \frac{(2n+3)! - (2n+1)!}{(2n+1)!(2n+3)!} \\ &= \frac{(2n+2)(2n+3) - 1}{(2n+3)!} > 0 \end{aligned}$$

$$\text{Also } \lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} \frac{1}{(2n+1)!} = 0$$

So by Leibnitz's rule the given alternating series is absolutely convergent and hence is convergent because every absolutely convergent series is necessarily convergent.

Example 2: $\frac{1}{\sqrt[5]{2}} - \frac{1}{\sqrt[5]{3}} + \frac{1}{\sqrt[5]{4}} + \dots + (-1)^n \frac{1}{\sqrt[5]{n}} + \dots$

Solution: The given series is an alternating series with the n th term $u_n = \frac{1}{\sqrt[5]{n}} = \frac{1}{n^{1/5}}$.

Here $u_n = \frac{1}{n^{1/5}} > u_{n+1} = \frac{1}{(n+1)^{1/5}}$ for all n and

$$\lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} \frac{1}{n^{1/5}} = 0.$$

Thus by Leibnitz's rule the given series is convergent. However the series with absolute values

$$\text{i.e., } \frac{1}{\sqrt[5]{2}} + \frac{1}{\sqrt[5]{3}} + \frac{1}{\sqrt[5]{4}} + \dots + \frac{1}{\sqrt[5]{n}} + \dots$$

is p series $\sum \frac{1}{n^p}$ with $p = \frac{1}{5} < 1$ and therefore is divergent. Hence the given series is conditionally convergent.

EXERCISE

Examine the following series for absolute convergence (A.C.) or conditional convergence (C.C.)

$$1. 1 - \frac{1}{3^2} + \frac{1}{5^2} - \frac{1}{7^2} + \frac{1}{9^2} + \dots + (-1)^{n+1} \frac{1}{(2n-1)^2} + \dots$$

Hint: Compare with $\sum \frac{1}{n^p}$ series with say $p = 10$.

Ans. A.C.

$$2. \frac{1}{2} - \frac{4}{2^3+1} + \frac{9}{3^3+1} - \frac{16}{4^3+1} + \dots + (-1)^{n+1} \frac{n^2}{n^3+1} + \dots$$

Hint: Use integral test to prove divergence.

Ans. C.C.

$$3. 1 - \frac{2}{3} + \frac{3}{3^2} - \frac{4}{3^3} + \dots$$

Ans. A.C.

$$4. \frac{2}{3} - \frac{3}{4} \cdot \frac{1}{2} + \frac{4}{5} \cdot \frac{1}{3} - \frac{5}{6} \cdot \frac{1}{4} + \dots$$

Ans. C.C.

$$5. 1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16} - \dots + (-1)^n \frac{1}{2^n} + \dots$$

Ans. A.C.

$$6. 1 - \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} - \frac{1}{\sqrt{4}} + \dots + (-1)^{n+1} \frac{1}{\sqrt{n}} + \dots$$

Ans. C.C.

$$7. \frac{1}{1^2+1} - \frac{2}{2^2+1} + \frac{3}{3^2+1} - \frac{4}{4^2+1} + \dots + (-1)^{n-1} \frac{n}{n^2+1} + \dots$$

Ans. C.C.

$$8. 1 + \frac{1}{2^2} - \frac{1}{3^2} - \frac{1}{4^2} + \frac{1}{5^2} + \frac{1}{6^2} - \frac{1}{7^2} - \frac{1}{8^2} + \dots$$

Ans. A.C. (JNTU 1998)

$$9. \frac{1}{2(\log n)^2} - \frac{1}{3(\log 3)^2} + \frac{1}{4(\log 4)^2} - \frac{1}{5(\log 5)^2} + \dots + \frac{(-1)^n}{n(\log n)^2} + \dots$$

Ans. A.C.

$$10. \sum_{n=1}^{\infty} (-1)^n n^p$$

Ans. (i) A.C. for $p < -1$ (ii) C.C. for $-1 \leq p < 0$ (iii) divergent, for $p > 0$

$$11. \sum_{n=2}^{\infty} (-1)^n \frac{n \log \log n}{\sqrt{\log n}} \quad \text{Ans. C.C.}$$

$$12. \sum_{n=3}^{\infty} \frac{(-1)^n \log n}{n \log \log n} \quad \text{Ans. C.C.}$$

$$13. \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} \quad \text{Ans. C.C. (JNTU 1997)}$$

$$14. \sum_{n=0}^{\infty} \frac{(-1)^{n-1}}{n \sqrt{n}} \quad \text{Ans. A.C.}$$

$$15. \sum_{n=1}^{\infty} \frac{(-1)^{n+1}(n+1)}{n^2} \quad \text{Ans. C.C.}$$

$$16. \sum_{n=1}^{\infty} \frac{(-1)^{n+1} 2^{2n-1}}{(2n-1)!} \quad \text{Ans. A.C.}$$

Hint: Use ratio test for convergency.

$$17. \sum_{n=1}^{\infty} (-1)^{n+1} \frac{n}{n^3+1} \quad \text{Ans. A.C.}$$

$$18. \sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n \cdot 2^n} \quad \text{Ans. A.C.}$$

Hint: Use geometric series with $r = \frac{1}{2}$ to test for convergency.

$$19. \sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n} \quad \text{Ans. C.C.}$$

Hint: Compare with harmonic series with $p = 1$.

$$20. \sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n!} \quad \text{Ans. A.C.}$$

35.17 POWER SERIES

We have considered so far, series whose terms are constants. Now we consider, series whose terms are functions of x , more specifically series in which n th term is a constant times x^n or constant times $(x - b)^n$ where b is a constant. A **power series** is a series of the form $\sum_{n=0}^{\infty} a_n x^n = a_0 + a_1 x + a_2 x^2 + \dots + a_n x^n + \dots$ where $a_0, a_1, a_2 \dots a_n \dots$ are all constants known as coefficients of the series or $\sum_{n=0}^{\infty} a_n (x - b)^n = a_0 + a_1 (x - b) + a_2 (x - b)^2 + \dots + a_n (x - b)^n + \dots$

Interval of convergence of a power series is the interval of x say $-L < x < L$ such that the series converges for values of x in this interval $(-L, L)$ and diverges for values of x outside this interval.

Test for Convergence of Power Series

$$\lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} = \lim_{n \rightarrow \infty} \frac{a_{n+1} x^{n+1}}{a_n x^n} = x \cdot \lim_{n \rightarrow \infty} \frac{a_{n+1}}{a_n} = x \cdot L$$

series converges if $|xL| < 1$ i.e., $\frac{-1}{L} < x < \frac{1}{L}$ or $-L < x < L$. Series diverges if $|xL| > 1$.

WORKED OUT EXAMPLES

Determine for what values of x , the following series are convergent:

Example 1: $\sum_{n=1}^{\infty} \frac{(-1)^{n+1} x^{2n-1}}{(2n-1)!}$

Solution: Applying the ratio test

$$\begin{aligned} \lim_{n \rightarrow \infty} \left| \frac{u_{n+1}}{u_n} \right| &= \lim_{n \rightarrow \infty} \left| \frac{(-1)^{n+2} x^{2n+1}}{(2n+1)!} \cdot \frac{(2n-1)!}{(-1)^{n+1} x^{2n-1}} \right| \\ &= \lim_{n \rightarrow \infty} \left| \frac{x^2}{2n(2n+1)} \right| = 0 < 1, \text{ for any } x. \end{aligned}$$

So the given series converges for all x i.e., $-\infty < x < \infty$.

Example 2: $\frac{1}{1-x} + \frac{1}{2(1-x)^2} + \frac{1}{3(1-x)^3} + \dots$

Solution: Here $u_n = \frac{1}{n(1-x)^n}$.

Applying ratio test,

$$\begin{aligned} \lim_{n \rightarrow \infty} \left| \frac{u_{n+1}}{u_n} \right| &= \lim_{n \rightarrow \infty} \left| \frac{1}{(n+1)(1-x)^{n+1}} \cdot n(1-x)^n \right| \\ &= \left| \frac{1}{1-x} \right| \lim_{n \rightarrow \infty} \frac{n}{n+1} = \left| \frac{1}{1-x} \right| \end{aligned}$$

series converges when $\left| \frac{1}{1-x} \right| < 1$ i.e., $|1-x| > 1$ or $x < 0$ and $x > 2$

Test for convergence at the end points $x=0$ and $x=2$.

For $x = 0$, the given series reduces to

$$1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \dots + \frac{1}{n} + \dots$$

which is a divergent harmonic series with $p = 1$

For $x = 2$, the given series becomes

$$-1 + \frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \frac{1}{5} + \dots + \frac{(-1)^n}{n} + \dots$$

This alternating series is convergent by Leibnitz's rule because

- i. $u_n = \frac{1}{n} > u_{n+1} = \frac{1}{n+1}$ i.e., $n+1 > n$ true for all n
- ii. $\lim_{n \rightarrow \infty} u_n = \lim_{n \rightarrow \infty} \frac{1}{n} = 0$

Thus the given series converges for $x \geq 2$ and $x < 0$.

Example 3: Find the interval of convergence of

- i. exponential series
- ii. logarithmic series and
- iii. binomial series.

Solution:

- i. Exponential series

$$\sum_{n=0}^{\infty} \frac{x^n}{n!} = 1 + x + \frac{x^2}{2!} + \dots + \frac{x^n}{n!} + \dots$$

converges for all values of x i.e., $-\infty < x < \infty$ since by ratio test,

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} &= \lim_{n \rightarrow \infty} \left(\frac{x^{n+1}}{(n+1)!} \cdot \frac{n!}{x^n} \right) = x \cdot \lim_{n \rightarrow \infty} \frac{1}{n+1} \\ &= 0 \text{ for any } x \end{aligned}$$

Interval of convergence is $(-\infty, \infty)$

ii. The logarithmic series is given by $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^n}{n}$.

By ratio test,

$$\begin{aligned}\lim_{n \rightarrow \infty} \frac{u_{n+1}}{u_n} &= \lim_{n \rightarrow \infty} (-1)^{n+2} \frac{x^{n+1}}{n+1} \cdot \frac{n}{(-1)^{n+1} x^n} \\ &= (-x) \lim_{n \rightarrow \infty} \frac{n}{n+1} = -x \cdot 1 = -x.\end{aligned}$$

Series is convergent for $|x| < 1$ and divergent for $|x| > 1$. When $x = 1$, the series reduces to $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$, which is convergent.

When $x = -1$, the series reduces to $-(1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \dots)$ which is divergent.

Thus the interval of convergence of the logarithmic series is $(-1, 1]$ (i.e., $(-1 < x \leq 1)$).

iii. The binomial series is

$$\begin{aligned}1 + nx + \frac{n(n-1)}{2!}x^2 + \dots \\ + \frac{n(n-1) \cdots (n-(r-1))}{r!}x^r + \dots\end{aligned}$$

By ratio test,

$$\begin{aligned}\lim_{r \rightarrow \infty} \frac{u_{r+1}}{u_r} &= \lim_{r \rightarrow \infty} \frac{n(n-1) \cdots (n-(r-1))}{r!} x^r \\ &\quad \times \frac{(r-1)!}{n(n-1) \cdots (n-r)} \cdot \frac{1}{x^{r-1}} \\ &= x \cdot \lim_{r \rightarrow \infty} \left(\frac{n-r+1}{r} \right) \\ &= x \cdot \lim_{r \rightarrow \infty} \left(\frac{n+1}{r} - 1 \right) \\ &= -x \text{ for } r > n+1\end{aligned}$$

Thus the interval of convergence of the binomial series is $(-1, 1)$ (i.e., $-1 < x < 1$).

EXERCISE

Determine the interval of convergence i.e., for what values of x , the following series are convergent. Investigate convergence at the end points of the interval also.

1. $\sum_{n=1}^{\infty} \frac{x^n}{(n!)^2}$ Ans. All x

2. $\sum_{n=0}^{\infty} (-1)^n x^n$ Ans. $|x| < 1$

3. $\sum_{n=1}^{\infty} \frac{(-1)^n x^n}{n(n+1)}$ Ans. $|x| \leq 1$

4. $\sum_{n=1}^{\infty} \frac{x^{2n}}{2^n n^2}$ Ans. $|x| \leq \sqrt{2}$

5. $\sum_{n=0}^{\infty} \frac{(x+2)^n}{\sqrt{n+1}}$ Ans. $-3 \leq x < -1$

6. $\sum_{n=1}^{\infty} \frac{x^n}{n}$ Ans. $-1 \leq x < 1$

7. $\sum_{n=1}^{\infty} n x^{n-1}$ Ans. $-1 < x < 1$

8. $\sum_{n=1}^{\infty} (-1)^n n^3 x^n$ Ans. $|x| < 1$

9. $\sum_{n=1}^{\infty} \frac{1}{n} \left(\frac{x}{5} \right)^n$ Ans. $-5 \leq x < 5$

10. $\sum_{n=1}^{\infty} \frac{(-2)^n (2x+1)^n}{n^2}$ Ans. $-\frac{3}{4} \leq x \leq -\frac{1}{4}$

11. $\sum_{n=1}^{\infty} \frac{(x-2)^n}{3^n}$ Ans. $-1 < x < 5$

12. $\sum_{n=1}^{\infty} \frac{(-1)^n x^{2n}}{(2n)^{3/2}}$ Ans. $-1 \leq x \leq 1$

13. $\sum_{n=1}^{\infty} (-1)^n \frac{x^n}{\log(n+1)}$ Ans. $|x| < 1$

14. $\sum_{n=0}^{\infty} (-1)^n \frac{x^n}{1+n^a}$ Ans. $|x| < 1$

15. $\sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{n}$ Ans. $|x| < 1$

16. $\sum_{n=0}^{\infty} (-1)^n x^n$ Ans. $0 < x < 1$

17. $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{(2x)^n}{n}$ Ans. $-\frac{1}{2} < x \leq \frac{1}{2}$

18. $\sum_{n=0}^{\infty} (nx)^n$ Ans. only for $x = 0$

19. $\sum_{n=1}^{\infty} 3^{n^2} x^{n^2}$ Ans. $|x| < \frac{1}{3}$

20. $\sum_{n=1}^{\infty} \frac{n! x^n}{n^n}$ Ans. $-e < x < e$

21. $\sum_{n=1}^{\infty} \frac{(n!)^2}{(2n)!} x^n$ Ans. $|x| < 4$

22. $\sum_{n=1}^{\infty} n!(x-1)^n$ Ans. only for $x = 1$

23. $\sum_{n=1}^{\infty} \frac{(x+1)^n}{\sqrt{n}}$ *Ans.* $-2 \leq x < 0$

24. $\sum_{n=1}^{\infty} \frac{(x+3)^{n-1}}{n}$ *Ans.* $-4 \leq x < -2$

25. $\sum_{n=0}^{\infty} \frac{(3x+6)^n}{n!}$ *Ans.* All x

26. $\sum_{n=0}^{\infty} (-2)^n (n+1)(x-1)^n$

Ans. $\frac{1}{2} < x < \frac{3}{2}$

27. Hypergeometric series

$$\sum_{n=0}^{\infty} \frac{a(a+1)\cdots(a+n-1)b(b+1)\cdots(b+n-1)}{1\cdot 2\cdot 3\cdots n\cdot c(c+1)\cdots(c+n-1)} \cdot x^n$$

Ans. i. Absolutely convergent if $|x| < 1$ and divergent if $|x| > 1$

ii. For $x = 1$, converges if $c > a + b$

iii. For $x = -1$, converges if $c + 1 > a + b$

$$28. \sum_{n=0}^{\infty} \frac{a(a+1)\cdots(a+n-1)b(b+1)\cdots(b+n-1)}{c(c+1)\cdots(c+n-1)d(d+1)\cdots(d+n-1)} \cdot x^n$$

Ans. i. convergent if $|x| < 1$ and divergent if $|x| > 1$

ii. For $x = 1$ and convergent if $c+d-a-b>1$
and divergent if $c + d - a - b \leq 1$

iii. For $x = -1$ and convergent if $c+d>a+b$.

35.18 SUMMARY

1. An infinite sequence $\{a_n\}$ is convergent, divergent or oscillates finitely (or infinitely) according as the limit a_n as $n \rightarrow \infty$ is finite, infinite, or not unique ($\pm\infty$).

2. If an infinite series is convergent then necessarily its n th term approaches zero as $n \rightarrow \infty$, although the converse is not true i.e., when $\lim_{n \rightarrow \infty} u_n = 0$, the series may converge or diverge, so further investigation is required. However, when $\lim_{n \rightarrow \infty} u_n \neq 0$, the series is divergent.

3. Given an infinite series, classify it as (a) series of positive terms (b) alternating series (c) plus and minus series (d) power series.

4. For positive series, check whether $\lim_{n \rightarrow \infty} u_n = 0$. If so, compare it with the standard geometric series $\sum ar^n$ or p -harmonic series $\sum \frac{1}{n^p}$ where $p =$ difference between the degree of the numerator and denominators of u_n .

5. Otherwise try ratio test. When ratio test fails, apply Raabe's or Logarithmic or DeMorgan's and Bertrand's tests.

6. Prefer Cauchy's n th root test when u_n involves n th powers of itself as a whole.

7. Integral test is used when the terms of the series are positive and non-increasing and the evaluation of the integral is easy.

8. Use Leibnitz's theorem to test for convergence of an alternating series.

9. In a plus- and -minus series (includes alternating series) if the series of absolute terms converges then the series is absolutely convergent and is therefore also (ordinarily) convergent. If not i.e., when the series of absolute terms diverges and original series is convergent then series is conditionally convergent.

10. Use ratio test, to find the interval of convergence of a power series. Examine the series at the end points of the interval also.

Chapter 36

Analytical Solid Geometry

36.1 INTRODUCTION

In 1637, Rene Descartes* represented geometrical figures (configurations) by equations and vice versa. Analytical Geometry involves algebraic or analytic methods in geometry. Analytical geometry in three dimensions also known as Analytical solid** geometry or solid analytical geometry, studies geometrical objects in space involving three dimensions, which is an extension of coordinate geometry in plane (two dimensions).

Fig. 36.1

Rectangular Cartesian Coordinates

The position (location) of a point in space can be determined in terms of its perpendicular distances (known as rectangular cartesian coordinates or simply *rectangular coordinates*) from three mutually perpendicular planes (known as **coordinate planes**). The lines of intersection of these three coordinate planes are known as *coordinate axes* and their point of intersection the *origin*.

The three axes called x-axis, y-axis and z-axis are marked positive on one side of the origin. The positive sides of axes OX , OY , OZ form a right handed system. The coordinate planes divide entire space into eight parts called *octants*. Thus a point P with coordinates x, y, z is denoted as $P(x, y, z)$. Here x, y, z are respectively the perpendicular distances of P from the YZ , ZX and XY planes. Note that a line perpendicular to a plane is perpendicular to every line in the plane.

Distance between two points $P_1(x_1, y_1, z_1)$ and $P_2(x_2, y_2, z_2)$ is $\sqrt{(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2}$.

Distance from origin $O(0, 0, 0)$ is $\sqrt{x_2^2 + y_2^2 + z_2^2}$.

Divisions of the line joining two points P_1, P_2 : The coordinates of $Q(x, y, z)$, the point on P_1P_2 dividing the line segment P_1P_2 in the ratio $m : n$ are $\left(\frac{nx_1+mx_2}{m+n}, \frac{ny_1+my_2}{m+n}, \frac{nz_1+mz_2}{m+n}\right)$ or putting k for $\frac{m}{n}$, $\left(\frac{x_1+kx_2}{1+k}, \frac{y_1+ky_2}{1+k}, \frac{z_1+kz_2}{1+k}\right)$; $k \neq -1$. Coordinates of mid point are $\left(\frac{x_1+x_2}{2}, \frac{y_1+y_2}{2}, \frac{z_1+z_2}{2}\right)$.

* Rene Descartes (1596–1650) French philosopher and mathematician, latinized name for Renatus Cartesius.

** Not used in the sense of “non-hollowness”. By a sphere or cylinder we mean a hollow sphere or cylinder.

36.2 — ENGINEERING MATHEMATICS

Direction of a line: A line in space is said to be directed if it is taken in a definite sense from one extreme (end) to the other (end).

Angle between Two Lines

Two straight lines in space may or may not intersect. If they intersect, they form a plane and are said to be coplanar. If they do not intersect, they are called *skew lines*.

Angle between two intersecting (coplanar) lines is the angle between their positive directions.

Angle between two non-intersecting (non-coplanar or skew) lines is the angle between two intersecting lines whose directions are same as those of given two lines.

36.2 DIRECTION COSINES AND DIRECTION RATIOS

Direction Cosines of a Line

Let L be a directed line OP from the origin $O(0, 0, 0)$ to a point $P(x, y, z)$ and of length r (Fig. 36.2). Suppose OP makes angles α, β, γ with the positive directions of the coordinate axes. Then α, β, γ are known as the *direction angles* of L . The cosines of these angles $\cos \alpha, \cos \beta, \cos \gamma$ are known as the *direction cosines* of the line $L(OP)$ and are in general denoted by l, m, n respectively.

Thus

$$l = \cos \alpha = \frac{x}{r}, \quad m = \cos \beta = \frac{y}{r}, \quad n = \cos \gamma = \frac{z}{r}.$$

where $r = \sqrt{x^2 + y^2 + z^2}.$

Fig. 36.2

Corollary 1: Lagrange's identity: $l^2 + m^2 + n^2 = 1$ i.e., sum of the squares of the direction cosines of any line is one, since $l^2 + m^2 + n^2 = \cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = \frac{x^2}{r^2} + \frac{y^2}{r^2} + \frac{z^2}{r^2} = 1.$

Corollary 2: Direction cosines of the coordinate axes OX, OY, OZ are $(1, 0, 0), (0, 1, 0), (0, 0, 1)$ respectively.

Corollary 3: The coordinates of P are (lr, mr, nr) where l, m, n are the direction cosines of OP and r is the length of OP .

Note: Direction cosines is abbreviated as DC's.

Direction Ratios

(abbreviated as DR's:) of a line L are any set of three numbers a, b, c which are proportional to l, m, n the DC's of the line L . DR's are also known as direction numbers of L . Thus $\frac{l}{a} = \frac{m}{b} = \frac{n}{c} = k$ (proportionality constant) or $l = ak, m = bk, n = ck$. Since $l^2 + m^2 + n^2 = 1$ or $(ak)^2 + (bk)^2 + (ck)^2 = 1$ or $k = \frac{\pm 1}{\sqrt{a^2 + b^2 + c^2}}$. Then the actual direction cosines are $\cos \alpha = l = ak = \pm \frac{a}{\sqrt{a^2 + b^2 + c^2}}, \cos \beta = m = bk = \pm \frac{b}{\sqrt{a^2 + b^2 + c^2}}, \cos \gamma = n = ck = \pm \frac{c}{\sqrt{a^2 + b^2 + c^2}}$ with $a^2 + b^2 + c^2 \neq 0$. Here +ve sign corresponds to positive direction and -ve sign to negative direction.

Note 1: Sum of the squares of DR's need not be one.

Note 2: Direction of line is $[a, b, c]$ where a, b, c are DR's.

Direction cosines of the line joining two points $P_1(x_1, y_1, z_1)$ and $P_2(x_2, y_2, z_2)$:

$$l = \cos \alpha = \frac{PQ}{r} = \frac{LM}{r} = \frac{OM - OL}{r} = \frac{x_2 - x_1}{r}.$$

Similarly, $m = \cos \beta = \frac{y_2 - y_1}{r}$ and $n = \cos \gamma = \frac{z_2 - z_1}{r}$. Then the DR's of $P_1 P_2$ are $x_2 - x_1, y_2 - y_1, z_2 - z_1$

Fig. 36.3

Projections

Projection of a point P on line L is Q , the foot of the perpendicular from P to L .

Fig. 36.4

Projection of line segment

P_1P_2 on a line L is the line segment MN where M and N are the feet of the perpendiculars from P and Q on to L . If θ is the angle between P_1P_2 and line L , then projection of P_1P_2 on $L = MN = PR = P_1P_2 \cos \theta$. Projection of line segment P_1P_2 on line L with (whose) DC's l, m, n is

$$l(x_2 - x_1) + m(y_2 - y_1) + n(z_2 - z_1)$$

Fig. 36.5

Angle between Two Lines

Let θ be the angle between the two lines OP_1 and OP_2 . Let $OP_1 = r_1$, $OP_2 = r_2$. Let l_1, m_1, n_1 be DC's of OP_1 and l_2, m_2, n_2 are DC's of OP_2 . Then the coordinates of P_1 are l_1r_1, m_1r_1, n_1r_1 and of P_2 are l_2r_2, m_2r_2, n_2r_2 .

Fig. 36.6

From $\triangle OP_1P_2$, we have

$$\begin{aligned} P_1P_2^2 &= OP_1^2 + OP_2^2 - 2OP_1 \cdot OP_2 \cdot \cos \theta \\ (l_2r_2 - l_1r_1)^2 + (m_2r_2 - m_1r_1)^2 + (n_2r_2 - n_1r_1)^2 \\ &= [(l_1r_1)^2 + (m_1r_1)^2 + (n_1r_1)^2] \\ &\quad + [(l_2r_2)^2 + (m_2r_2)^2 + (n_2r_2)^2] - 2 \cdot r_1r_2 \cos \theta. \end{aligned}$$

Using $l_1^2 + m_1^2 + n_1^2 = 1$ and $l_2^2 + m_2^2 + n_2^2 = 1$,

$$\begin{aligned} r_1^2 + r_2^2 - 2r_1r_2(l_1l_2 + m_1m_2 + n_1n_2) \\ = r_1^2 + r_2^2 - 2r_1r_2 \cos \theta. \end{aligned}$$

Then

$$\cos \theta = l_1l_2 + m_1m_2 + n_1n_2$$

Corollary 1:

$$\begin{aligned} \sin^2 \theta &= 1 - \cos^2 \theta = 1 - (l_1l_2 + m_1m_2 + n_1n_2)^2 \\ &= (l_1^2 + m_1^2 + n_1^2)(l_2^2 + m_2^2 + n_2^2) \\ &\quad - (l_1l_2 + m_1m_2 + n_1n_2)^2 \\ &= (l_1m_2 - m_1l_2)^2 + (m_1n_2 - n_1m_2)^2 \\ &\quad + (n_1l_2 - l_1n_2)^2 \end{aligned}$$

using the Lagrange's identity. Then

$$\begin{aligned} (l_1^2 + m_1^2 + n_1^2)(l_2^2 + m_2^2 + n_2^2) - (l_1l_2 + m_1m_2 + n_1n_2)^2 \\ = (l_1m_2 - l_2m_1)^2 + (m_1n_2 - m_2n_1)^2 + (n_1l_2 - n_2l_1)^2. \end{aligned}$$

36.4 — ENGINEERING MATHEMATICS

$$\text{Thus } \sin \theta = \sqrt{\sum (l_1 m_2 - m_1 l_2)^2}$$

$$\text{Corollary 2: } \tan \theta = \frac{\sin \theta}{\cos \theta} = \frac{\sqrt{\sum (l_1 m_2 - m_1 l_2)^2}}{l_1 l_2 + m_1 m_2 + n_1 n_2}.$$

Corollary 3: If a_1, b_1, c_1 and a_2, b_2, c_2 are DR's of OP_1 and OP_2

$$\text{Then } l_1 = \frac{a_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}}, \quad m_1 = \frac{b_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}}, \quad n_1 = \frac{c_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} \text{ etc.}$$

$$\text{Then } \cos \theta = \frac{a_1 a_2 + b_1 b_2 + c_1 c_2}{\sqrt{a_1^2 + b_1^2 + c_1^2} \sqrt{a_2^2 + b_2^2 + c_2^2}},$$

$$\sin \theta = \frac{\sqrt{(a_1 b_2 - a_2 b_1)^2 + (b_1 c_2 - b_2 c_1)^2 + (c_1 a_2 - c_2 a_1)^2}}{\sqrt{a_1^2 + b_1^2 + c_1^2} \sqrt{a_2^2 + b_2^2 + c_2^2}}.$$

Corollary: Condition for perpendicularity:

The two lines are perpendicular if $\theta = 90^\circ$. Then

$$\cos \theta = \cos 90 = 0$$

$$\text{Thus } l_1 l_2 + m_1 m_2 + n_1 n_2 = 0$$

$$\text{or } a_1 a_2 + b_1 b_2 + c_1 c_2 = 0$$

Corollary: Condition for parallelism:

If the two lines are parallel then $\theta = 0$. So $\sin \theta = 0$.

$$(l_1 m_2 - m_1 l_2)^2 + (m_1 n_2 - m_2 n_1)^2 + (n_1 l_2 - n_2 l_1)^2 = 0$$

$$\text{or } \frac{l_1}{l_2} = \frac{m_1}{m_2} = \frac{n_1}{n_2} = \frac{\sqrt{l_1^2 + m_1^2 + n_1^2}}{\sqrt{l_2^2 + m_2^2 + n_2^2}} = \frac{1}{1}.$$

$$\text{Thus } l_1 = l_2, \quad m_1 = m_2, \quad n_1 = n_2$$

$$\text{or } \frac{a_1}{a_2} = \frac{b_1}{b_2} = \frac{c_1}{c_2}.$$

WORKED OUT EXAMPLES

Example 1: Find the angle between the lines $A(-3, 2, 4)$, $B(2, 5, -2)$ and $C(1, -2, 2)$, $D(4, 2, 3)$.

Solution: DR's of AB : $2 - (-3), 5 - 2, -2 - 4 = 5, 3, -6$

DR's of CD : $3, 4, 1$. Then DC's of AB are $l_1 = \cos \alpha_1 = \frac{5}{\sqrt{5^2 + 3^2 + 6^2}} = \frac{5}{\sqrt{25 + 9 + 36}} = \frac{5}{\sqrt{70}}$ and $m_1 =$

$\cos \beta_1 = \frac{3}{70}, n_1 = \cos \gamma_1 = \frac{-6}{\sqrt{70}}$. Similarly, $l_2 = \cos \alpha_2 = \frac{3}{\sqrt{3^2 + 4^2 + 1^2}} = \frac{3}{\sqrt{9 + 16 + 1}} = \frac{3}{\sqrt{26}}$, and $m_2 = \cos \beta_2 = \frac{4}{\sqrt{26}}, n_2 = \cos \gamma_2 = \frac{1}{\sqrt{26}}$. Now

$$\begin{aligned} \cos \theta &= \cos \alpha_1 \cdot \cos \alpha_2 + \cos \beta_1 \cdot \cos \beta_2 + \cos \gamma_1 \cdot \cos \gamma_2 \\ &= l_1 l_2 + m_1 m_2 + n_1 n_2 \\ \cos \theta &= \frac{5}{\sqrt{70}} \cdot \frac{3}{\sqrt{26}} + \frac{3}{\sqrt{70}} \cdot \frac{4}{\sqrt{26}} - \frac{6}{\sqrt{70}} \cdot \frac{1}{\sqrt{26}} \\ &= 0.49225 \end{aligned}$$

$$\therefore \theta = \cos^{-1}(0.49225) = 60^\circ 30.7'$$

Example 2: Find the DC's of the line that is $\perp^r$ to each of the two lines whose directions are $[2, -1, 2]$ and $[3, 0, 1]$.

Solution: Let $[a, b, c]$ be the direction of the line. Since this line is $\perp^r$ to the line with direction $[2, -1, 2]$, by orthogonality

$$2a - b + 2c = 0$$

Similarly, direction $[a, b, c]$ is $\perp^r$ to direction $[3, 0, 1]$. So

$$3a + 0 + c = 0.$$

Solving $c = -3a, b = -4a$ or

direction $[a, b, c] = [a, -4a, -3a] = [1, -4, -3]$.

$\therefore$ DC's of the line: $\frac{1}{\sqrt{1^2 + 4^2 + 3^2}} = \frac{1}{\sqrt{26}}, \frac{-4}{\sqrt{26}}, \frac{-3}{\sqrt{26}}$.

Example 3: Show that the points $A(1, 0, -2)$, $B(3, -1, 1)$ and $C(7, -3, 7)$ are collinear.

Solution: DR's of AB : $[2, -1, 3]$, DR's of AC : $[6, -3, 9]$, DR's of BC : $[4, -2, 6]$. Thus DR's of AB, AC, BC are same. Hence A, B, C are collinear.

Example 4: Find the coordinates of the foot of the perpendicular from $A(1, 1, 1)$ on the line joining $B(1, 4, 6)$ and $C(5, 4, 4)$.

Solution: Suppose D divides BC in the ratio $k : 1$. Then the coordinates of D are $(\frac{5k+1}{k+1}, \frac{4k+4}{k+1}, \frac{4k+6}{k+1})$.

DR's of AD : $\frac{4k}{k+1}, 3, \frac{3k+5}{k+1}$, DR's of BC : $4, 0, -2$. AD is $\perp^r$ BC : $16k - 6k - 10 = 0$, or $k = 1$.

Coordinates of the foot of perpendicular are (3, 4, 5).

Example 5: Show that the points $A(1, 0, 2)$, $B(3, -1, 3)$, $C(2, 2, 2)$, $D(0, 3, 1)$ are the vertices of a parallelogram.

Fig. 36.7

Solution: DR's of AB are $[3 - 1, -1 - 0, 3 - 2] = [2, -1, 1]$. Similarly, DR's of BC are $[-1, 3, -1]$, of CD $[-2, 1, -1]$ of DA $[-1, 3, -1]$. Since DR's of AB and CD are same, they are parallel. Similarly BC and DA are parallel since DR's are same. Further AB is not $\perp$ to AD because

$$2(+1) + (-1)(-3) + 1(+1) = 6 \neq 0$$

Similarly, AD is not $\perp$ to BC because

$$2(-1) + (-1)3 + 1(-1) = -6 \neq 0.$$

Hence $ABCD$ is a parallelogram.

EXERCISE

- Show that the points $A(7, 0, 10)$, $B(6, -1, 6)$, $C(9, -4, 6)$ form an isosceles right angled triangle.

Hint: $AB^2 = BC^2 = 18$, $CA^2 = 36$,
 $AB^2 + BC^2 = CA^2$

- Prove that the points $A(3, -1, 1)$, $B(5, -4, 2)$, $C(11, -13, 5)$ are collinear.

Hint 1: $AB^2 = 14$, $BC^2 = 126$, $CA^2 = 224$,
 $AB + BC = 4\sqrt{14} = CA$

Hint 2: DR's of $AB = 2, -3, 1$; $BC: 6, -9, 3$;
 $AB \parallel$ to BC

- Determine the internal angles of the triangle ABC where $A(2, 3, 5)$, $B(-1, 3, 2)$, $C(3, 5, -2)$.

Hint: $AB^2 = 18$, $BC^2 = 36$, $AC^2 = 54$. DC's
 $AB: -\frac{1}{\sqrt{2}}, 0, -\frac{1}{\sqrt{2}}$; $BC: \frac{2}{3}, \frac{1}{3}, \frac{-2}{3}$; $AC: \frac{1}{3\sqrt{6}}, \frac{2}{3\sqrt{6}}, \frac{-7}{3\sqrt{6}}$.

Ans. $\cos A = \frac{1}{\sqrt{3}}$, $\cos B = 0$ i.e., $B = 90^\circ$, $\cos C = \frac{\sqrt{6}}{3}$.

- Show that the foot of the perpendicular from $A(0, 9, 6)$ on the line joining $B(1, 2, 3)$ and $C(7, -2, 5)$ is $D(-2, 4, 2)$.

Hint: D divides BC in $k : 1$, $D\left(\frac{7k+1}{k+1}, \frac{-2k+2}{k+1}, \frac{5k+3}{k+1}\right)$. DR's $AD: (7k+1, -11k-7, -k-3)$,
 DR's $BC: 6, -4, 2$. $AD \perp BC: k = -\frac{1}{3}$.

- Find the condition that three lines with DC 's $l_1, m_1, n_1; l_2, m_2, n_2; l_3, m_3, n_3$ are concurrent.

Hint: Line with DC 's l, m, n through point of concurrency will be $\perp$ to all three lines, $ll_i + mm_i + nn_i = 0, i = 1, 2, 3$.

Ans.
$$\begin{vmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{vmatrix} = 0$$

- Show that $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma + \cos^2 \delta = \frac{4}{3}$ where $\alpha, \beta, \gamma, \delta$ are the angles which a line makes with the four diagonals of a cube.

Hint: DC's of four diagonals are (k, k, k) , $(-k, k, k)$, $(k, -k, k)$, $(k, k, -k)$ where $k = \frac{1}{\sqrt{3}}$; l, m, n are DC's of line. $\cos \alpha = l.k$, $+mk + nk$, $\cos \beta = (-l + m + n)k$, $\cos \gamma = (l - m + n)k$, $\cos \delta = (l + m - n)k$.

- Show that the points $A(-1, 1, 3)$, $B(1, -2, 4)$, $C(4, -1, 1)$ are vertices of a right triangle.

Hint: DR's $AB: [2, -3, 1]$, $BC: [3, 1, -3]$,
 $CA: [5, -2, -2]$. AB is $\perp$ to BC .

36.6 — ENGINEERING MATHEMATICS

8. Prove that $A(3, 1, -2)$, $B(3, 0, 1)$, $C(5, 3, 2)$, $D(5, 4, -1)$ form a rectangle.

Hint: DR's: $AB: [0, -1, 3]$; $AC: [2, 2, 4]$, $CD[0, 1, -3]$; $AD[2, 3, 1]$; $BC[2, 3, 1]$; $AB \parallel CD$, $AD \parallel BC$, $AD \perp AB: 0 - 3 + 3 = 0$, $BC \perp DC: 0 + 3 - 3 = 0$.

9. Find the interior angles of the triangle

$A(3, -1, 4)$, $B(1, 2, -4)$, $C(-3, 2, 1)$.

Hint: DC's of $AB: (-2, 3, -8)k_1$, $BC: (-4, 0, 5)k_2$, $AC: (-6, 3, -3)k_3$ where $k_1 = \frac{1}{\sqrt{77}}$, $k_2 = \frac{1}{\sqrt{41}}$, $k_3 = \frac{1}{\sqrt{54}}$.

Ans. $\cos A = \frac{15}{\sqrt{462}}$, $\cos B = \frac{32}{\sqrt{3157}}$, $\cos C = \frac{3}{\sqrt{246}}$.

10. Determine the DC's of a line $\perp^r$ to a triangle formed by $A(2, 3, 1)$, $B(6, -3, 2)$, $C(4, 0, 3)$.

Ans. $(3, 2, 0)k$ where $k = \frac{1}{\sqrt{13}}$.

Hint: DR: $AB: [4, -6, 1]$, $BC: [-2, 3, 1]$, $CA: [2, -3, 2]$. $[a, b, c]$ of $\perp^r$ line: $4a - 6b + c = 0$, $-2a + 3b + c = 0$, $2a - 3b + 2c = 0$.

36.3 THE PLANE

Surface is the locus of a point moving in space satisfying a single condition.

Example: Surface of a sphere is the locus of a point that moves at a constant distance from a fixed point.

Surfaces are either plane or curved. Equation of the locus of a point is the analytical expression of the given condition(s) in terms of the coordinates of the point.

Exceptional cases: Equations may have locus other than a surface. Examples: (i) $x^2 + y^2 = 0$ is z-axis (ii) $x^2 + y^2 + z^2 = 0$ is origin (iii) $y^2 + 4 = 0$ has no locus.

Plane is a surface such that the straight line PQ , joining any two points P and Q on the plane, lies completely on the plane.

General equation of first degree in x, y, z is of the form

$$Ax + By + Cz + D = 0$$

Here A, B, C, D are given real numbers and A, B, C are not all zero (i.e., $A^2 + B^2 + C^2 \neq 0$)

Book Work: Show that every equation of the first degree in x, y, z represents a plane.

Proof: Let

$$Ax + By + Cz + D = 0 \quad (1)$$

be the equation of first degree in x, y, z with the condition that not all A, B, C are zero (i.e., $A^2 + B^2 + C^2 \neq 0$). Let $P(x_1, y_1, z_1)$ and $Q(x_2, y_2, z_2)$ be any two points on the surface represented by (1). Then

$$Ax_1 + By_1 + Cz_1 + D_1 = 0 \quad (2)$$

$$Ax_2 + By_2 + Cz_2 + D_2 = 0 \quad (3)$$

Multiplying (3) by k and adding to (2), we get

$$A(x_1 + kx_2) + B(y_1 + ky_2) + C(z_1 + kz_2) + D(1 + k) = 0 \quad (4)$$

Assuming that $1 + k \neq 0$, divide (4) by $(1 + k)$.

$$A \left(\frac{x_1 + kx_2}{1 + k} \right) + B \left(\frac{y_1 + ky_2}{1 + k} \right) + C \left(\frac{z_1 + kz_2}{1 + k} \right) + D = 0$$

i.e., the point $R \left(\frac{x_1 + kx_2}{1 + k}, \frac{y_1 + ky_2}{1 + k}, \frac{z_1 + kz_2}{1 + k} \right)$ which is point dividing the line PQ in the ratio $k : 1$, also lies on the surface (1). Thus any point on the line joining P and Q lies on the surface i.e., line PQ completely lies on the surface. Therefore the surface by definition must be a plane.

General form of the equation of a plane is

$$Ax + By + Cz + D = 0$$

Special cases:

- (i) Equation of plane passing through origin is

$$Ax + By + Cz = 0 \quad (5)$$

- (ii) Equations of the coordinate planes XOY, YOZ and ZOX are respectively $z = 0, x = 0$ and $y = 0$
- (iii) $Ax + By + D = 0$ plane $\perp^r$ to xy -plane
 $Ax + Cz + D = 0$ plane $\perp^r$ to xz -plane
 $Ay + Cz + D = 0$ plane $\perp^r$ to yz -plane.

Similarly, $Ax + D = 0$ is $\parallel^l$ to yz -plane, $By + D = 0$ is $\parallel^l$ to xz -plane, $Cz + D = 0$ is $\parallel^l$ to xy -plane.

One point form

Equation of a plane through a fixed point $P_1(x_1, y_1, z_1)$ and whose normal CD has DC's proportional to (A, B, C) : For any point $P(x, y, z)$ on the given plane, the DR's of the line P_1P are $(x - x_1, y - y_1, z - z_1)$. Since a line perpendicular to a plane is perpendicular to every line in the plane, so ML is perpendicular to P_1P . Thus

$$A(x - x_1) + B(y - y_1) + C(z - z_1) = 0 \quad (6)$$

Fig. 36.8

Note 1: Rewriting (6), we get the general form of plane

$$Ax + By + Cz + D = 0 \quad (1)$$

where $D = -ax_1 - by_1 - cz_1$

Note 2: The real numbers A, B, C which are the coefficients of x, y, z respectively in (1) are proportional to DC's of the normal of the plane (1).

Note 3: Equation of a plane parallel to plane (1) is

$$Ax + By + Cz + D^* = 0 \quad (7)$$

x -intercept of a plane is the point where the plane cuts the x -axis. This is obtained by putting $y = 0,$

$z = 0$. Similarly, y -, z -intercepts. Traces of a plane are the lines of intersection of plane with coordinate axis.

Example: xy -trace is obtained by putting $z = 0$ in equation of plane.

Intercept form

Suppose $P(a, 0, 0), Q(0, b, 0), R(0, 0, c)$ are the x -, y -, z -intercepts of the plane. Then P, Q, R lies on the plane. From (1)

$$Aa + 0 + 0 + D = 0$$

or
$$A = -\frac{D}{a}.$$

Fig. 36.9

similarly, $0 + bB + 0 + D = 0$ or $B = -\frac{D}{b}$ and $C = -\frac{D}{c}.$

Eliminating A, B, C the equation of the plane in the intercept form is

$$-\frac{D}{a}x - \frac{D}{b}y - \frac{D}{c}z + D = 0$$

or
$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1 \quad (8)$$

Normal form

Let $P(x, y, z)$ be any point on the plane. Let ON be the perpendicular from origin O to the given plane. Let $ON = p$. (i.e., length of the perpendicular ON is p). Suppose l, m, n are the DC's of ON . Now ON is perpendicular to PN . Projection of OP on ON is ON itself i.e., p .

Fig. 36.10

Also the projection OP joining origin $(0, 0, 0)$ to $P(x, y, z)$ on the line ON with DC's l, m, n is

$$l(x - 0) + m(y - 0) + n(z - 0)$$

$$\text{or} \quad lx + my + nz \quad (9)$$

Equating the two projection values from (8) & (9)

$$lx + my + nz = p \quad (10)$$

Note 1: p is always positive, since p is the perpendicular distance from origin to the plane.

Note 2: Reduction from general form.

Transpose constant term to R.H.S. and make it positive (if necessary by multiplying throughout by -1). Then divide throughout by $\pm\sqrt{A^2 + B^2 + C^2}$. Thus the general form $Ax + By + Cz + D = 0$ takes the following normal form

$$\frac{Ax}{\pm\sqrt{A^2+B^2+C^2}} + \frac{By}{\pm\sqrt{A^2+B^2+C^2}} + \frac{Cz}{\pm\sqrt{A^2+B^2+C^2}} = \frac{-D}{\pm\sqrt{A^2+B^2+C^2}} \quad (11)$$

The sign before the radical is so chosen to make the R.H.S. in (11) positive.

Three point form

Equation of a plane passing through three given points $P_1(x_1, y_1, z_1)$, $P_2(x_2, y_2, z_2)$, $P_3(x_3, y_3, z_3)$:

Since the three points P_1, P_2, P_3 lie on the plane

$$Ax + By + Cz + D = 0 \quad (1)$$

$$\text{we have} \quad Ax_1 + By_1 + Cz_1 + D = 0 \quad (12)$$

$$Ax_2 + By_2 + Cz_2 + D = 0 \quad (13)$$

$$Ax_3 + By_3 + Cz_3 + D = 0 \quad (14)$$

Eliminating A, B, C, D from (1), (12), (13), (14) (i.e., a non trivial solution A, B, C, D for the homogeneous system of 4 equations exist if the determinant coefficient is zero)

$$\begin{vmatrix} x & y & z & 1 \\ x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \end{vmatrix} = 0 \quad (15)$$

Equation (15) is the required equation of the plane through the 3 points P_1, P_2, P_3 .

Corollary 1: Coplanarity of four given points:

The four points $P_1(x_1, y_1, z_1)$, $P_2(x_2, y_2, z_2)$, $P_3(x_3, y_3, z_3)$, $P_4(x_4, y_4, z_4)$ are coplanar (lie in a plane) if

$$\begin{vmatrix} x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \\ x_4 & y_4 & z_4 & 1 \end{vmatrix} = 0 \quad (16)$$

Angle between Two Given Planes

The angle between two planes

$$A_1x + B_1y + C_1z + D_1 = 0 \quad (17)$$

$$A_2x + B_2y + C_2z + D_2 = 0 \quad (18)$$

is the angle θ between their normals. Here A_1, B_1, C_1 and A_2, B_2, C_2 are the DR's of the normals respectively to the planes (17) and (18). Then

$$\cos \theta = \frac{A_1A_2 + B_1B_2 + C_1C_2}{\sqrt{A_1^2 + B_1^2 + C_1^2} \sqrt{A_2^2 + B_2^2 + C_2^2}}$$

Condition for perpendicularity

If $\theta = 0$ then the two planes are $\perp^r$ to each other. Then

$$A_1A_2 + B_1B_2 + C_1C_2 = 0 \quad (19)$$

Condition for parallelism

If $\theta = 0$, the two planes are $\parallel^l$ to each other. Then

$$\frac{A_1}{A_2} = \frac{B_1}{B_2} = \frac{C_1}{C_2} \quad (20)$$

Note: Thus parallel planes differ by a constant.

Although there are four constants A, B, C, D in the equation of plane, essentially three conditions are

required to determine the three ratios of A, B, C, D , for example plane passing through:

- three non-collinear points
- two given points and $\perp^r$ to a given plane
- a given point and $\perp^r$ to two given planes etc.

Coordinate of the Foot of the Perpendicular from a Point to a Given Plane

Let $Ax + By + Cz + D = 0$ be the given plane and $P(x_1, y_1, z_1)$ be a given point. Let PN be the perpendicular from P to the plane. Let the coordinates of the foot of the perpendicular PN be $N(\alpha, \beta, \gamma)$. Then DR's of $PN(x_1 - \alpha, y_1 - \beta, z_1 - \gamma)$ are proportional to the coefficients A, B, C i.e.,

$$\begin{aligned} x_1 - \alpha &= kA, & y_1 - \beta &= kB, & z_1 - \gamma &= kC \\ \text{or } \alpha &= x_1 - kA, & \beta &= y_1 - kB, & \gamma &= z_1 - kC \end{aligned}$$

Fig. 36.11

Since N lies in the plane

$$A\alpha + B\beta + C\gamma + D = 0$$

Substituting α, β, γ ,

$$A(x_1 - kA) + b(y_1 - kB) + c(z_1 - kC) + D = 0$$

$$\text{Solving } k = \frac{Ax_1 + By_1 + Cz_1 + D}{A^2 + B^2 + C^2}$$

Thus the coordinates of $N(\alpha, \beta, \gamma)$ the foot of the perpendicular from $P(x_1, y_1, z_1)$ to the plane are

$$\begin{aligned} \alpha &= x_1 - \frac{A(Ax_1 + By_1 + Cz_1 + D)}{A^2 + B^2 + C^2}, \\ \beta &= y_1 - \frac{B(Ax_1 + By_1 + Cz_1 + D)}{A^2 + B^2 + C^2}, \\ \gamma &= z_1 - \frac{C(Ax_1 + By_1 + Cz_1 + D)}{A^2 + B^2 + C^2} \end{aligned} \quad (21)$$

Corollary 1: Length of the perpendicular from a given point to a given plane:

$$\begin{aligned} PN^2 &= (x_1 - \alpha)^2 + (y_1 - \beta)^2 + (z_1 - \gamma)^2 \\ &= (kA)^2 + (kB)^2 + (kC)^2 \end{aligned}$$

$$\begin{aligned} &= k^2(A^2 + B^2 + C^2) \\ &= \left[\frac{Ax_1 + By_1 + Cz_1 + D}{A^2 + B^2 + C^2} \right]^2 (A^2 + B^2 + C^2) \\ &= \frac{(Ax_1 + By_1 + Cz_1 + D)^2}{A^2 + B^2 + C^2} \end{aligned}$$

$$\text{or } PN = \frac{Ax_1 + By_1 + Cz_1 + D}{\pm \sqrt{A^2 + B^2 + C^2}}.$$

The sign before the radical is chosen as positive or negative according as D is positive or negative. Thus the numerical values of the length of the perpendicular PN is

$$PN = \left| \frac{Ax_1 + By_1 + Cz_1 + D}{\sqrt{A^2 + B^2 + C^2}} \right| \quad (22)$$

Note: PN is obtained by substituting the coordinates (x_1, y_1, z_1) in the L.H.S. of the Equation (1) and dividing it by $\sqrt{A^2 + B^2 + C^2}$.

Equation of a plane passing through the line of intersection of two given planes $u \equiv A_1x + B_1y + C_1z + D_1 = 0$ and $v \equiv A_2x + B_2y + C_2z + D_2 = 0$ is $u + kv = 0$ where k is any constant.

Equations of the two planes bisecting the angles between two planes are

$$\frac{A_1x + B_1y + C_1z + D_1}{\sqrt{A_1^2 + B_1^2 + C_1^2}} = \pm \frac{A_2x + B_2y + C_2z + D_2}{\sqrt{A_2^2 + B_2^2 + C_2^2}}.$$

WORKED OUT EXAMPLES

Example 1: Find the equation of the plane which passes through the point $(2, 1, 4)$ and is

- Parallel to plane $2x + 3y + 5z + 6 = 0$
- Perpendicular to the line joining $(3, 2, 5)$ and $(1, 6, 4)$
- Perpendicular to the two planes $7x + y + 2z = 6$ and $3x + 5y - 6z = 8$
- Find intercept points and traces of the plane in case c.

Solution:

- Any plane parallel to the plane $2x + 3y + 5z + 6 = 0$

36.10 — ENGINEERING MATHEMATICS

is given by $2x + 3y + 5z + k = 0$ (1) (differs by a constant). Since the point $(2, 1, 4)$ lies on the plane (1), $2(2) + 3(1) + 5(4) + k = 0$, $k = -27$. Required equation of plane is $2x + 3y + 5z - 27 = 0$.

- b. Any plane through the point $(2, 1, 4)$ is (one point form)

$$A(x - 2) + B(y - 1) + C(z - 4) = 0 \quad (2)$$

DC's of the line joining $M(3, 2, 5)$ and $N(1, 6, 4)$ are proportional to $2, -4, 1$. Since MN is perpendicular to (2), A, B, C are proportional to $2, -4, 1$. Then $2(x - 2) - 4(y - 1) + 1(z - 4) = 0$. The required equation of plane is $2x - 4y + z - 4 = 0$.

- c. The plane through $(2, 1, 4)$ is

$$A(x - 2) + B(y - 1) + C(z - 4) = 0. \quad (2)$$

This plane (2) is perpendicular to the two planes $7x + y + 2z = 6$ and $3x + 5y - 6z = 8$.

Using $A_1A_2 + B_1B_2 + C_1C_2 = 0$, we have

$$7a + b + 2c = 0$$

$$3a + 5b - 6c = 0$$

$$\text{Solving } \frac{a}{-6-10} = \frac{-b}{-42-8} = \frac{c}{35-3} \quad \text{or} \quad \frac{a}{1} = \frac{b}{-3} = \frac{c}{-2}.$$

Required equation of plane is

$$1(x - 4) - 3(y - 1) - 2(z - 4) = 0$$

$$\text{or} \quad x - 3y - 2z + 7 = 0$$

- d. x -intercept: Put $y = z = 0$, $\therefore x = -7$ or $(-7, 0, 0)$ is the x -intercept. Similarly, y -intercept is $(0, \frac{7}{3}, 0)$ and z -intercept is $(0, 0, \frac{7}{2})$. xy -trace is obtained by putting $z = 0$. It is $x - 3y + 7 = 0$. Similarly, yz -trace is $3y + 2z - 7 = 0$ and zx -trace is $x - 2z + 7 = 0$.

Example 2: Find the equation of the plane containing the points $P(3, -1, -4)$, $Q(-2, 2, 1)$, $R(0, 4, -1)$.

Solution: Equation of plane through the point $P(3, -1, -4)$ is

$$A(x + 3) + B(y + 1) + C(z + 4) = 0. \quad (1)$$

DR's of PQ : $-5, 3, 5$; DR's of PR : $-3, 5, 3$. Since line PQ and PR completely lies in the plane (1), normal to (1) is perpendicular to PQ and PR . Then

$$-5A + 3B + 5C = 0$$

$$-3A + 5B + 3C = 0$$

$$\text{Solving } A = C = 1, \quad B = 0$$

$$(x - 3) + 0 + (z + 4) = 0$$

Equation of the plane is

$$x + z + 1 = 0$$

Aliter: Equation of the plane by 3-point form is

$$\begin{vmatrix} x & y & z & 1 \\ 3 & -1 & -4 & 1 \\ -2 & 2 & 1 & 1 \\ 0 & 4 & -1 & 1 \end{vmatrix} = 0$$

Expanding $D_1x - D_2y + D_3z - 1.D_4 = 0$ where

$$D_1 = \begin{vmatrix} -1 & -4 & 1 \\ 2 & 1 & 1 \\ 4 & -1 & 1 \end{vmatrix} = -16, \quad D_2 = \begin{vmatrix} 3 & -4 & 1 \\ -2 & 1 & 1 \\ 0 & -1 & 1 \end{vmatrix} = 0 = 0$$

$$D_3 = \begin{vmatrix} 3 & -1 & 1 \\ -2 & 2 & 1 \\ 0 & 4 & 1 \end{vmatrix} = -16, \quad D_4 = \begin{vmatrix} 3 & -1 & -4 \\ -2 & 2 & 1 \\ 0 & 4 & -1 \end{vmatrix} = 16$$

or required equation is $x + z + 1 = 0$.

Example 3: Find the perpendicular distance between (a) The Point $(3, 2, -1)$ and the plane $7x - 6y + 6z + 8 = 0$ (b) between the parallel planes $x - 2y + 2z - 8 = 0$ and $x - 2y + 2z + 19 = 0$ (c) find the foot of the perpendicular in case (a).

Solution:

$$\text{Perpendicular distance} = \left(\frac{Ax_1 + By_1 + Cz_1 + D}{\sqrt{A^2 + B^2 + C^2}} \right)$$

- a. Point $(3, 2, -1)$, plane is $7x - 6y + 6z + 8 = 0$. So perpendicular distance from $(3, 2, -1)$ to plane is

$$= \frac{7(3) - 6(2) + 6(-1) + 8}{\sqrt{7^2 + 6^2 + 6^2}} = \frac{11}{-11} = |-1| = 1$$

- b. x -intercept point of plane $x - 2y + 2z - 8 = 0$ is $(8, 0, 0)$ (obtained by putting $y = 0, z = 0$ in the equation). Then perpendicular distance from

the point $(8, 0, 0)$ to the second plane $x - 2y + 2z + 19 = 0$ is $\frac{1.8-2.0+2.0+19}{\sqrt{1^2+2^2+2^2}} = \frac{27}{3} = 9$

- c. Let $N(\alpha, \beta, \gamma)$ be the foot of the perpendicular from $P(3, 2, -1)$. DR's of PN: $3 - \alpha, 2 - \beta, -1 - \gamma$. DR's of normal to plane are $7, -6, 6$. These are proportional. $\frac{3-\alpha}{7} = \frac{2-\beta}{-6} = \frac{-1-\gamma}{6}$ or $\alpha = 3 - 7k, \beta = 2 + 6k, \gamma = -1 - 6k$. Now (α, β, γ) lies on the plane. $7(3 - 7k) - 6(2 + 6k) + 6(-1 - 6k) + 8 = 0$ or $k = \frac{1}{11}$. $\therefore$ the coordinates of the foot of perpendicular are $(\frac{26}{11}, \frac{28}{11}, \frac{-17}{11})$.

Example 4: Are the points $(2, 3, -5)$ and $(3, 4, 7)$ on the same side of the plane $x + 2y - 2z = 9$?

Solution: Perpendicular distance of the point $(2, 3, -5)$ from the plane $x + 2y - 2z - 9 = 0$ or $-x - 2y + 2z + 9 = 0$ is $\frac{-1.2-2(3)-2(-5)+9}{\sqrt{1^2+2^2+2^2}} = -\frac{9}{3} = -3$.

$\perp^r$ distance of $(3, 4, 7)$ is $\frac{-1.3-2.4+2.7+9}{\sqrt{1^2+2^2+2^2}} = \frac{12}{3} = 6$

$\perp^r$ distance from origin $(0, 0, 0)$ is $\frac{0+0+0+9}{3} = 3$

So points $(2, 3, -5)$ and $(3, 4, 7)$ are on opposite sides of the given plane.

Example 5: Find the angle between the planes $4x - y + 8z = 9$ and $x + 3y + z = 4$.

Solution: DR's of the planes are $[4, -1, 8]$ and $[1, 3, 1]$. Now

$$\begin{aligned}\cos \theta &= \frac{A_1 A_2 + B_1 B_2 + C_1 C_2}{\sqrt{A_1^2 + B_1^2 + C_1^2} \sqrt{A_2^2 + B_2^2 + C_2^2}} \\ &= \frac{4.1 + 3 \cdot (-1) + 1.8}{\sqrt{16 + 1 + 64} \sqrt{1 + 9 + 1}} \\ &= \frac{9}{\sqrt{81} \sqrt{11}} = \frac{1}{\sqrt{11}} \quad \text{or} \quad \theta = \cos^{-1} \frac{1}{\sqrt{11}}.\end{aligned}$$

Example 6: Find the equation of a plane passing through the line of intersection of the planes.

- a. $3x + y - 5z + 7 = 0$ and $x - 2y + 4z - 3 = 0$ and passing through the point $(-3, 2, -4)$

- b. $2x - 5y + z = 3$ and $x + y + 4z = 5$ and parallel to the plane $x + 3y + 6z = 1$.

Solution:

- a. Equation of plane is $u + kv = 0$ i.e.,

$$(3x + y - 5z + 7) + k(x - 2y + 4z - 3) = 0.$$

Since point $(-3, 2, -4)$ lies on the intersection plane

$$\begin{aligned}3(-3) + 1(2) - 5(-4) + 7 \\ + k[1(-3) - 2(2) + 4(-4) - 3] = 0.\end{aligned}$$

So $k = \frac{10}{13}$. Then the required plane is

$$49x - 7y - 25z + 61 = 0.$$

- b. Equation of plane is $u + kv = 0$ i.e.,

$$(2x - 5y + z - 3) + k(x + y + 4z - 5) = 0$$

$$\text{or } (2+k)x + (-5+k)y + (1+4k)z + (-3-5k) = 0.$$

Since this intersection plane is parallel to $x + 3y + 6z - 1 = 0$

$$\text{So } \frac{2+k}{1} = \frac{-5+k}{3} = \frac{1+4k}{6} \quad \text{or} \quad k = -\frac{11}{2}.$$

Required equation of plane is $7x + 21y + 42z - 49 = 0$.

Example 7: Find the planes bisecting the angles between the planes $x + 2y + 2z = 9$ and $4x - 3y + 12z + 13 = 0$. Specify the angle θ between them.

Solution: Equations of the bisecting planes are

$$\begin{aligned}\frac{x + 2y + 2z - 9}{\sqrt{1 + 2^2 + 2^2}} &= \pm \frac{4x - 3y + 12z + 13}{\sqrt{4^2 + 3^2 + 12^2}} \\ \frac{x + 2y + 2z - 9}{3} &= \pm \frac{4x - 3y + 12z + 13}{13}\end{aligned}$$

$$\begin{aligned}\text{or } 25x + 17y + 62z - 78 &= 0 \quad \text{and} \\ x + 35y - 10z - 156 &= 0.\end{aligned}$$

$$\cos \theta = \frac{25 \cdot 1 + 17 \cdot 35 - 62 \times 10}{\sqrt{25^2 + 17^2 + 62^2} \sqrt{1 + 35^2 + 10^2}} = 0$$

$$\therefore \theta = \frac{\pi}{2}$$

i.e., angle between the bisecting planes is $\frac{\pi}{2}$.

36.12 — ENGINEERING MATHEMATICS

Example 8: Show that the planes

$$7x + 4y - 4z + 30 = 0 \quad (1)$$

$$36x - 51y + 12z + 17 = 0 \quad (2)$$

$$14x + 8y - 8z - 12 = 0 \quad (3)$$

$$12x - 17y + 4z - 3 = 0 \quad (4)$$

form four faces of a rectangular parallelopiped.

Solution: (1) and (3) are parallel since $\frac{7}{14} = \frac{4}{8} = \frac{-4}{-8} = \frac{1}{2}$. (2) and (4) are parallel since $\frac{36}{12} = \frac{-51}{-17} = \frac{12}{4} = 3$. Further (1) and (2) are $\perp^r$ since

$$7 \cdot 36 + 4(-51) - 4(12) = 252 - 204 - 48 = 0.$$

EXERCISE

- Find the equation of the plane through $P(4, 3, 6)$ and perpendicular to the line joining $P(4, 3, 6)$ to the point $Q(2, 3, 1)$.

Hint: DR's PQ: $[2, 0, 5]$, DR of plane through $(4, 3, 6) : x - 4, y - 3, z - 6; \perp^r : 2(x - 4) + 0(y - 3) + 5(z - 6) = 0$

Ans. $2x + 5z - 38 = 0$

- Find the equation of the plane through the point $P(1, 2, -1)$ and parallel to the plane $2x - 3y + 4z + 6 = 0$.

Hint: Eq. $2x - 3y + 4z + k = 0, (1, 2, -1)$ lies, $k = 8$.

Ans. $2x - 3y + 4z + 8 = 0$

- Find the equation of the plane that contains the three points $P(1, -2, 4), Q(4, 1, 7), R(-1, 5, 1)$.

Hint: $A(x - 1) + B(y + 2) + C(z - 4) = 0$, DR: $PQ: [3, 3, 3], PR: [-2, 7, -3]. \perp^r 3A + 3B + 3C = 0, -2A + 7B - 3C = 0, A = -10B, C = 9B$.

Aliter:

$$\begin{vmatrix} x & y & z & 1 \\ 1 & -2 & 4 & 1 \\ 4 & 1 & 7 & 1 \\ -1 & 5 & 1 & 1 \end{vmatrix} = 0,$$

$$D_1x - D_2y + D_3z - D_4 = 0$$

where $D_1 = \begin{vmatrix} -2 & 4 & 1 \\ 1 & 7 & 1 \\ 5 & 1 & 1 \end{vmatrix}$ etc.

Ans. $10x - y - 9z + 24 = 0$

- Find the equation of the plane
 - passing through $(1, -1, 2)$ and $\perp^r$ to each of the planes $2x + 3y - 2z = 5$ and $x + 2y - 3z = 8$
 - passing through $(-1, 3, -5)$ and parallel to the plane $6x - 3y - 2z + 9 = 0$
 - passing through $(2, 0, 1)$ and $(-1, 2, 0)$ and $\perp^r$ to the plane $2x - 4y - z = 7$.

Ans. a. $5x - 4y - z = 7$
 b. $6x - 3y - 2z + 5 = 0$
 c. $6x + 5y - 8z = 4$

- Find the perpendicular distance between
 - the point $(-2, 8, -3)$ and plane $9x - y - 4z = 0$
 - the two planes $x - 2y + 2z = 6, 3x - 6y + 6z = 2$
 - the point $(1, -2, 3)$ and plane $2x - 3y + 2z - 14 = 0$.

Ans. (a) $\sqrt{2}$ (b) $\frac{-16}{9}$ (c) 0 i.e., lies on the plane.

- Find the angle between the two planes
 - $x + 4y - z = 5, y + z = 2$
 - $x - 2y + 3z + 4 = 0, 2x + y - 3z + 7 = 0$

Ans. (a) $\cos \theta = \frac{1}{2}, \theta = 60^\circ$ (b) $\cos \theta = \frac{-9}{14}$.

- Prove that the planes $5x - 3y + 4z = 1, 8x + 3y + 5z = 4, 18x - 3y + 13z = 6$ contain a common line.

Hint: $u + kv = 0$ substitute in $w = 0, k = \frac{1}{2}$

- Find the coordinates of N , the foot of the perpendicular from the point $P(-3, 0, 1)$ on the plane $4x - 3y + 2z = 19$. Find the length of this perpendicular. Find also the image of P in the plane.

Hint: $PN = NQ$ i.e., N is the mid point.

Ans. $N(1, -3, 3), \sqrt{29}$, image of P is $Q(5, -6, 5)$

- Find the equation of the plane through the line of intersection of the two planes $x - 3y + 5z - 7 = 0$ and $2x + y - 4z + 1 = 0$ and $\perp^r$ to the plane $x + y - 2z + 4 = 0$.

Ans. $3x - 2y + z - 6 = 0$

10. A variable plane passes through the fixed point (a, b, c) and meets the coordinate axes in P, Q, R . Prove that the locus of the point common to the planes through P, Q, R parallel to the coordinate plane is $\frac{a}{x} + \frac{b}{y} + \frac{c}{z} = 1$.

Hint: $OP = x_1, OQ = y_1, OR = z_1, \frac{x}{x_1} + \frac{y}{y_1} + \frac{z}{z_1} = 1, (a, b, c)$ lies, $\frac{a}{x_1} + \frac{b}{y_1} + \frac{c}{z_1} = 1$.

36.4 THE STRAIGHT LINE

Two surfaces will in general intersect in a curve. In particular two planes, which are not parallel, intersect in a straight line.

Example: The coordinate planes ZOX and XOY , whose equations are $y = 0$ and $z = 0$ respectively, intersect in a line the x -axis.

Straight line

The locus of two simultaneous equations of first degree in x, y, z

$$\begin{aligned} A_1x + B_1y + C_1z + D_1 &= 0 \\ A_2x + B_2y + C_2z + D_2 &= 0 \end{aligned} \quad (1)$$

is a straight line, provided $A_1 : B_1 : C_1 \neq A_2 : B_2 : C_2$ (i.e., not parallel). Equation (1) is known as the **general form** of the equation of a straight line. Thus the equation of a straight line or simply line is the pair of equations taken together i.e., equations of two planes together represent the equation of a line. However this representation is not unique, because many planes can pass through a given line. Thus a given line can be represented by different pairs of first degree equations.

Projecting planes

Of the many planes passing through a given line, those that are perpendicular to the coordinate planes are known as projecting planes and their traces give the **projections** of the line on the coordinate planes.

Symmetrical Form

The equation of line passing through a given point $P_1(x_1, y_1, z_1)$ and having direction cosines l, m, n is given by

$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n} \quad (2)$$

since for any point $P(x, y, z)$ on the line, the DR's of PP_1 : $x - x_1, y - y_1, z - z_1$ be proportional to l, m, n . Equation (2) represent two independent linear equations and are called the symmetrical (or symmetric) form of the equation of a line.

Corollary: Any point P on the line (2) is given by

$$x = x_1 + lr, \quad y = y_1 + mr, \quad z = z_1 + nr \quad (3)$$

for different values of r , where $r = PP_1$.

Corollary: Lines perpendicular to one of the coordinate axes:

- $x = x_1, \frac{y - y_1}{m} = \frac{z - z_1}{n}$, ($\perp^r$ to x -axis i.e., $\parallel^l$ to yz -plane)
- $y = y_1, \frac{x - x_1}{l} = \frac{z - z_1}{n}$, ($\perp^r$ to y -axis i.e., $\parallel^l$ to xz -plane)
- $z = z_1, \frac{x - x_1}{l} = \frac{y - y_1}{m}$, ($\perp^r$ to z -axis i.e., $\parallel^l$ to xy -plane)

Corollary: Lines perpendicular to two axes

- $x = x_1, y = y_1$ ($\perp^r$ to x - & y -axis i.e., $\parallel^l$ to z -axis):
- $x = x_1, z = z_1$ ($\perp^r$ to x - & z -axis i.e., $\parallel^l$ to y -axis)
- $y = y_1, z = z_1$ ($\perp^r$ to y - & z -axis i.e., $\parallel^l$ to x -axis)

Corollary: Projecting planes: (containing the given line)

$$(a) \frac{x - x_1}{l} = \frac{y - y_1}{m} \quad (b) \frac{x - x_1}{l} = \frac{z - z_1}{n} \quad (c) \frac{y - y_1}{m} = \frac{z - z_1}{n}.$$

Note: When any of the constants l, m, n are zero, the Equation (2) are equivalent to equations

$$\frac{l}{x - x_1} = \frac{m}{y - y_1} = \frac{n}{z - z_1}.$$

36.14 — ENGINEERING MATHEMATICS

Example: $\frac{x}{0} = \frac{y}{2} = \frac{z}{0}$ means $\frac{0}{x} = \frac{2}{y} = \frac{0}{z}$.

Corollary: If a, b, c are the DR's of the line, then (2) takes the form $\frac{x-x_1}{a} = \frac{y-y_1}{b} = \frac{z-z_1}{c}$.

Corollary: Two point form of a line passing through two given points $P_1(x_1, y_1, z_1)$ and $P_2(x_2, y_2, z_2)$ is

$$\frac{x-x_1}{x_2-x_1} = \frac{y-y_1}{y_2-y_1} = \frac{z-z_1}{z_2-z_1} \quad (4)$$

since the DR's of P_1P_2 are $x_2-x_1, y_2-y_1, z_2-z_1$.

Transformation of General Form to Symmetrical Form

The general form also known as unsymmetrical form of the equation of a line can be transformed to symmetrical form by determining

- one point on the line, by putting say $z = 0$ and solving the simultaneous equations in x and y .
- the DC's of the line from the fact that this line is $\perp^r$ to both normals of the given planes.

For example,

- by putting $z = 0$ in the general form

$$\begin{aligned} A_1x + B_1y + C_1z + D_1 &= 0 \\ A_2x + B_2y + C_2z + D_2 &= 0 \end{aligned} \quad (2)$$

and solving the resulting equations

$$\begin{aligned} A_1x + B_1y + D_1 &= 0 \\ A_2x + B_2y + D_2 &= 0, \end{aligned}$$

we get a point on the line as

$$\left(\frac{B_1D_2 - B_2D_1}{A_1B_2 - A_2B_1}, \frac{A_2D_1 - A_1D_2}{A_1B_2 - A_2B_1}, 0 \right) \quad (5)$$

- Using the orthogonality of the line with the two normals of the two planes, we get

$$\begin{aligned} lA_1 + mB_1 + nC_1 &= 0 \\ lA_2 + mB_2 + nC_2 &= 0 \end{aligned}$$

where (l, m, n) , (A_1, B_1, C_1) and (A_2, B_2, C_2) are DR's of the line, normal to first plane, normal to second plane respectively. Solving, we get the

DR's l, m, n of the line as

$$\frac{l}{B_1C_2 - B_2C_1} = \frac{m}{C_1A_2 - C_2A_1} = \frac{n}{A_1B_2 - A_2B_1} \quad (6)$$

Using (5) and (6), thus the given general form (2) of the line reduces to the symmetrical form

$$\begin{aligned} \frac{x - \frac{(B_2D_1 - B_1D_2)}{A_1B_2 - A_2B_1}}{B_1C_2 - B_2C_1} &= \frac{y - \frac{(A_2D_1 - A_1D_2)}{A_1B_2 - A_2B_1}}{C_1A_2 - C_2A_1} \\ &= \frac{z - 0}{A_1B_2 - A_2B_1} \end{aligned} \quad (7)$$

Note 1: In finding a point on the line, one can put $x = 0$ or $y = 0$ instead of $z = 0$ and get similar results.

Note 2: General form (2) can also be reduced to the two point form (4) (special case of symmetric form) by determining two points on the line.

Angle between a Line and a Plane

Let π be the plane whose equation is

$$Ax + By + Cz + D = 0 \quad (8)$$

Fig. 36.12

and L be the straight line whose symmetrical form is

$$\frac{x-x_1}{l} = \frac{y-y_1}{m} = \frac{z-z_1}{n} \quad (2)$$

Let θ be the angle between the line L and the plane π . Let ψ be the angle between L and the normal to the plane π . Then

$$\begin{aligned} \cos \psi &= \frac{lA + mB + nC}{\sqrt{l^2 + m^2 + n^2} \sqrt{A^2 + B^2 + C^2}} \\ &= \cos(90 - \theta) = \sin \theta \end{aligned} \quad (9)$$

since $\psi = 90 - \theta$. The angle between a line L and plane π is the complement of the angle between the

line L and the normal to the plane). Thus θ is determined from (9).

Corollary: Line is $\parallel^l$ to the plane if $\theta = 0$ then $\sin \theta = 0$ i.e.,

$$\boxed{lA + mB + nC = 0} \quad (10)$$

Corollary: Line is $\perp^r$ to the plane if $\theta = \frac{\pi}{2}$, then $\sin \theta = 1$ i.e.,

$$\boxed{\frac{l}{A} = \frac{m}{B} = \frac{n}{C}} \quad (11)$$

(i.e., DR's of normal and the line are same).

Conditions for a Line L to Lie in a Plane π

If every point of line L is a point of plane π , then line L lies in plane π . Substituting any point of the line $L : (x_1 + lr, y_1 + mr, z_1 + nr)$ in the equation of the plane (8), we get

$$\begin{aligned} A(x_1 + lr) + B(y_1 + mr) + C(z_1 + nr) + D &= 0 \\ \text{or } (Al + Bm + Cn)r + (Ax_1 + By_1 + Cz_1 + D) &= 0 \end{aligned} \quad (12)$$

This Equation (12) is satisfied for all values of r if the coefficient of r and constant term in (12) are both zero i.e.,

$$\boxed{\begin{aligned} Al + Bm + Cn &= 0 \quad \text{and} \\ Ax_1 + By_1 + Cz_1 + D &= 0 \end{aligned}} \quad (13)$$

Thus the two conditions for a line L to lie in a plane π are given by (13) which geometrically mean that (i) line L is $\perp^r$ to the normal of the plane and (ii) a (any one) point of line L lies on the plane.

Corollary: General equation of a plane containing line L (2) is

$$A(x - x_1) + B(y - y_1) + C(z - z_1) = 0 \quad (14)$$

subject to

$$Al + Bm + Cn = 0$$

Corollary: Equation of any plane through the line of intersection of the two planes

$$\begin{aligned} u &\equiv A_1x + B_1y + C_1z + D_1 = 0 \quad \text{and} \\ v &\equiv A_2x + B_2y + C_2z + D_2 = 0 \end{aligned}$$

is $u + kv = 0$ or $(A_1x + B_1y + C_1z + D_1) + k(A_2x + B_2y + C_2z + D_2) = 0$ where k is a constant.

Coplanar Lines

Consider two given straight lines L_1

$$\frac{x - x_1}{l_1} = \frac{y - y_1}{m_1} = \frac{z - z_1}{n_1} \quad (15)$$

and line L_2

$$\frac{x - x_2}{l_2} = \frac{y - y_2}{m_2} = \frac{z - z_2}{n_2} \quad (16)$$

From (14), equation of any plane containing line L_1 is

$$A(x - x_1) + B(y - y_1) + C(z - z_1) = 0 \quad (17)$$

subject to

$$Al_1 + Bm_1 + Cn_1 = 0 \quad (18)$$

If the plane (17) contains line L_2 also, then the point (x_2, y_2, z_2) of L_2 should also lie in the plane (17). Then

$$A(x_2 - x_1) + B(y_2 - y_1) + C(z_2 - z_1) = 0 \quad (19)$$

But the line L_2 is $\perp^r$ to the normal to the plane (17). Thus

$$Al_2 + Bm_2 + Cn_2 = 0 \quad (20)$$

Therefore the two lines L_1 and L_2 will lie in the same plane if (17), (18), (20) are simultaneously satisfied. Eliminating A, B, C from (19), (18), (20) (i.e., homogeneous system consistent if coefficient determinant is zero), we have

$$\begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = 0 \quad (21)$$

Thus (21) is the condition for coplanarity of the two lines L_1 and L_2 . Now the equation of the plane containing lines L_1 and L_2 is

$$\begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = 0 \quad (22)$$

which is obtained by eliminating A, B, C from (17), (18), (20).

Corollary: Condition for the two lines L_1

$$\begin{aligned} u_1 &\equiv A_1x + B_1y + C_1z + D_1 = 0, \\ u_2 &\equiv A_2x + B_2y + C_2z + D_2 = 0 \end{aligned} \quad (23)$$

and Line L_2 $u_3 \equiv A_3x + B_3y + C_3z + D_3 = 0$,

$$u_4 \equiv A_4x + B_4y + C_4z + D_4 = 0$$

to be coplanar is

$$\begin{vmatrix} A_1 & B_1 & C_1 & D_1 \\ A_2 & B_2 & C_2 & D_2 \\ A_3 & B_3 & C_3 & D_3 \\ A_4 & B_4 & C_4 & D_4 \end{vmatrix} = 0 \quad (24)$$

If $P(\alpha, \beta, \gamma)$ is the point of intersection of the two lines, then P should satisfy the four Equations (23): u_i at $(\alpha, \beta, \gamma) = 0$ for $i = 1, 2, 3, 4$. Elimination of (α, β, γ) from these four equations leads to (24).

Corollary: The general form of equations of a line L_3 intersecting the lines L_1 and L_2 given by (23) are

$$u_1 + k_1u_2 = 0 \quad \text{and} \quad u_3 + k_2u_4 = 0 \quad (25)$$

where k_1 and k_2 are any two numbers.

Foot and length of the perpendicular from a point $P_1(\alpha, \beta, \gamma)$ to a given line L : $\frac{x-x_1}{l} = \frac{y-y_1}{m} = \frac{z-z_1}{n}$

Fig. 36.13

Any point on the line L be $(x_1 + lr, y_1 + mr, z_1 + nr)$. The DR's of PN are $x_1 + lr - \alpha, y_1 + mr - \beta, z_1 + nr - \gamma$. Since PN is $\perp^r$ to line L , then

$$l(x_1 + lr - \alpha) + m(y_1 + mr - \beta) + n(z_1 + nr - \gamma) = 0.$$

Solving

$$r = \frac{l(\alpha - x_1) + m(\beta - y_1) + n(\gamma - z_1)}{l^2 + m^2 + n^2} \quad (26)$$

The coordinates of N , the foot of the perpendicular PN is $(x_1 + lr - \alpha, y_1 + mr - \beta, z_1 + nr - \gamma)$ where r is given by (26).

The length of the perpendicular PN is obtained by distance formula between P (given) and N (found).

Line of greatest slope in a plane

Let ML be the line of intersection of a horizontal plane I with slant plane II. Let P be any point on plane II. Draw $PN \perp^r$ to the line ML . Then the line of greatest slope in plane II is the line PN , because no other line in plane II through P is inclined to the horizontal plane I more steeply than PN .

Fig. 36.14

WORKED OUT EXAMPLES

Example 1: Find the points where the line $x - y + 2z = 2$, $2x - 3y + 4z = 0$ pierces the coordinate planes.

Solution: Put $z = 0$ to find the point at which the line pierces the xy -plane: $x - y = 2$ and $2x - 3y = 0$ or $x = 6, y = 4$. $\therefore (6, 4, 0)$.

Put $x = 0$, $-y + 2z = 2$, $-3y + 4z = 0$ or $y = 4, z = 3$. $\therefore (0, 4, 3)$ is piercing point.

Put $y = 0$, $x + 2z = 2$, $2x + 4z = 0$ no unique solution.

Note that DR's of the line are $[2, 0, -1]$. So this line is $\perp^r$ to y -axis whose DR's are $[0, 1, 0]$ (i.e., $2 \cdot 0 + 0 \cdot 1 + (-1) \cdot 0 = 0$). Hence the given line does not pierce the xz -plane.

Example 2: Transfer the general (unsymmetrical) form $x + 2y + 3z = 1$ and $x + y + 2z = 0$ to the symmetrical form.

Solution: Put $x = 0$, $2y + 3z = 1$, $y + 2z = 0$. Solving $z = -1$, $y = 2$. So $(0, 2, -1)$ is a point on the line. Let l, m, n be the DR's of the line. Since this line is $\perp^r$ to both normals of the given two planes, we have

$$1 \cdot l + 2 \cdot m + 3 \cdot n = 0$$

$$1 \cdot l + 1 \cdot m + 2 \cdot n = 0$$

$$\text{Solving } \frac{l}{4-3} = -\frac{m}{2-3} = \frac{n}{1-2} \text{ or } \frac{l}{1} = \frac{m}{1} = -\frac{n}{1}$$

Equation of the line passing through the point $(0, 2, -1)$ and having DR's $1, 1, -1$ is

$$\frac{x-0}{1} = \frac{y-2}{1} = \frac{z+1}{-1}$$

Aliter: Two point form.

Put $y = 0$, $x + 3z = 1$, $x + 2z = 0$. Solving $z = 1$, $x = -2$ or $(-2, 0, 1)$ is another point on the line. Now DR's of the line joining the two points $(0, 2, -1)$ and $(-2, 0, 1)$ are $-2, -2, 2$. Hence the equation of the line in the two point form is

$$\frac{x-0}{-2} = \frac{y-2}{-2} = \frac{z+1}{2} \text{ or } \frac{x}{1} = \frac{y-2}{1} = \frac{z+1}{-1}.$$

Example 3: Find the acute angle between the lines $\frac{x}{2} = \frac{y}{2} = \frac{z}{1}$ and $\frac{x}{5} = \frac{y}{4} = \frac{z}{-3}$.

Solution: DR's are $[2, 2, 1]$ and $[5, 4, -3]$. If θ is the angle between the two lines, then

$$\begin{aligned} \cos \theta &= \frac{l_1 l_2 + m_1 m_2 + n_1 n_2}{\sqrt{l_1^2 + m_1^2 + n_1^2} \sqrt{l_2^2 + m_2^2 + n_2^2}} \\ &= \frac{2 \cdot 5 + 2 \cdot 4 + 1 \cdot (-3)}{\sqrt{4 + 4 + 1} \sqrt{25 + 16 + 9}} = \frac{15}{3\sqrt{50}} = \frac{1}{\sqrt{2}} \end{aligned}$$

$$\therefore \theta = 45^\circ$$

Example 4: Find the equation of the plane containing the line $x = y = z$ and passing through the point $(1, 2, 3)$.

Solution: General form of the given line is

$$x - y = 0 \quad \text{and} \quad x - z = 0.$$

Equation of a plane containing this line is

$$(x - y) + k(x - z) = 0$$

Since point $(1, 2, 3)$ lies on this line, it also lies on the above plane. Then

$$(1 - 2) + k(1 - 3) = 0 \quad \text{or} \quad k = -\frac{1}{2}$$

Equation of required plane is

$$(x - y) - \frac{1}{2}(x - z) = 0$$

or

$$x - 2y + z = 0.$$

Example 5: Show that the lines $\frac{x}{1} = \frac{y+3}{2} = \frac{z+1}{3}$ and $\frac{x-3}{2} = \frac{y}{1} = \frac{z-1}{-1}$ intersect. Find the point of intersection.

Solution: Rewriting the equation in general form, we have

$$2x - y = 3, \quad 3x - z = 1$$

and

$$x - 2y = 3, \quad x + 2z = 5$$

If these four equations have a common solution, then the given two lines intersect. Solving, $y = -1$, then $x = 1$, $z = 2$. So the point of intersection is $(1, -1, 2)$.

Example 6: Find the acute angle between the lines $\frac{x}{3} = \frac{y}{1} = \frac{z}{0}$ and the plane $x + 2y - 7 = 0$.

Solution: DR's of the line: $[3, 1, 0]$. DR's of normal to the plane is $[1, 2, 0]$. If ψ is the angle between the line and the normal, then

$$\begin{aligned} \cos \psi &= \frac{3 \cdot 1 + 1 \cdot 2 + 0 \cdot 0}{\sqrt{3^2 + 1^2 + 0^2} \sqrt{1^2 + 2^2 + 0^2}} \\ &= \frac{5}{\sqrt{10}\sqrt{5}} = \frac{1}{\sqrt{2}} \quad \text{so} \quad \psi = 45^\circ. \end{aligned}$$

Angle θ between the line and the plane is the complement of the angle ψ i.e., $\theta = 90 - \psi = 90 - 45 = 45^\circ$.

Example 7: Show that the lines $x + y - 3z = 0$, $2x + 3y - 8z = 1$ and $3x - y - z = 3$, $x + y - 3z = 5$ are parallel.

Solution: DR's of the first line are

$$\begin{array}{ccc} l_1 & m_1 & n_1 \\ 1 & 1 & -3 \\ 2 & 3 & -8 \end{array} \quad \text{or} \quad \frac{l_1}{1} = \frac{m_1}{2} = \frac{n_1}{1}$$

36.18 — ENGINEERING MATHEMATICS

Similarly, DR's of the second line are

$$\begin{array}{ccc} l_2 & m_2 & n_2 \\ 3 & -1 & -1 \end{array} \quad \text{or} \quad \frac{l_2}{4} = \frac{m_2}{8} = \frac{n_2}{4} \quad \text{i.e.,} \quad \frac{l_2}{1} = \frac{m_2}{2} = \frac{n_2}{1}$$

Since the DR's of the two lines are same, they are parallel.

Example 8: Find the acute angle between the lines $2x - y + 3z - 4 = 0$, $3x + 2y - z + 7 = 0$ and $x + y - 2z + 3 = 0$, $4x - y + 3z + 7 = 0$.

Solution: The line represented by the two planes is perpendicular to both the normals of the two planes. If l_1, m_1, n_1 are the DR's of this line, then

$$\begin{array}{ccc} l_1 & m_1 & n_1 \\ 2 & -1 & 3 \\ 3 & 2 & -1 \end{array} \quad \text{or} \quad \frac{l_1}{-5} = \frac{m_1}{11} = \frac{n_1}{7}$$

Similarly, DR's of the 2nd line are

$$\begin{array}{ccc} l_2 & m_2 & n_2 \\ 1 & +1 & -2 \\ 4 & -1 & -3 \end{array} \quad \text{or} \quad \frac{l_2}{-1} = \frac{m_2}{11} = \frac{n_2}{5}$$

If θ is the angle between the lines, then

$$\begin{aligned} \cos \theta &= \frac{l_1 l_2 + m_1 m_2 + n_1 n_2}{\sqrt{l_1^2 + m_1^2 + n_1^2} \sqrt{l_2^2 + m_2^2 + n_2^2}} \\ &= \frac{5 + 121 + 35}{\sqrt{195} \sqrt{147}} = \frac{23}{3\sqrt{65}} \end{aligned}$$

$$\therefore \quad \text{So} \quad \theta = 180^\circ 1.4'$$

Example 9: Prove that the line $\frac{x-4}{2} = \frac{y-2}{3} = \frac{z-3}{6}$ lies in the plane $3x - 4y + z = 7$.

Solution: The point of the line (4, 2, 3) should also lie in the plane. So $3 \cdot 4 - 4 \cdot 2 + 1 \cdot 3 = 7$ satisfied. The line and normal to the plane are perpendicular. So $2 \cdot 3 + 3 \cdot (-4) + 6 \cdot 1 = 6 - 12 + 6 = 0$. Thus the given line completely lies in the given plane.

Example 10: Show that the lines $\frac{x-2}{2} = \frac{y-3}{-1} = \frac{z+4}{3}$ and $\frac{x-3}{1} = \frac{y+1}{3} = \frac{z-1}{-2}$ are coplanar. Find their common point and determine the equation of the plane containing the two given lines.

Solution: Here first line passes through (2, 3, -4) and has DR's $l_1, m_1, n_1 : 2, -1, 3$. The second line

passes through (3, -1, 1) and has DR's $l_2, m_2, n_2 : 1, 3, -2$. Condition for coplanarity:

$$\begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = \begin{vmatrix} 3-2 & -1-3 & 1+4 \\ 2 & -1 & 3 \\ 1 & 3 & 2 \end{vmatrix} = 7+28-35 = 0 \text{ satisfied.}$$

Point of intersection: Any point on the first line is $(2 + 2r_1, 3 - r_1 - 4 + 3r_1)$ and any point on the second line is $(3 + r_2, -1 + 3r_2, 1 - 2r_2)$. When the two lines intersect in a common point then co-ordinates on line (1) and line (2) must be equal, i.e., $2 + 2r_1 = 3 + r_2$, $3 - r_1 = -1 + 3r_2$ and $-4 + 3r_1 = 1 - 2r_2$. Solving $r_1 = r_2 = 1$. Therefore the point of intersection is $(2 + 2 \cdot 1, 3 - 1, -4 + 3 \cdot 1) = (4, 2, -1)$.

Equation of plane containing the two lines:

$$\begin{vmatrix} x-x_1 & y-y_1 & z-z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = \begin{vmatrix} x-2 & y-3 & z+4 \\ 2 & -1 & 3 \\ 1 & 3 & -2 \end{vmatrix} = 0$$

Expanding $-7(x-2) - (-7)(y-3) + 7(z+4) = 0$ or $x - y - z + 3 = 0$.

Example 11: Find the coordinates of the foot of the perpendicular from $P(1, 0, 2)$ to the line $\frac{x+1}{3} = \frac{y-2}{-2} = \frac{z+1}{-1}$. Find the length of the perpendicular and its equation.

Solution: Any point N on the given line is $(3r - 1, 2 - 2r, -1 - r)$. DR's of PN are $(3r - 2, 2 - 2r, -3 - r)$. Now PN is normal to line if $3(3r - 2) + (-2)(2 - 2r) + (-1)(-3 - r) = 0$ or $r = \frac{1}{2}$. So the coordinates of N the foot of the perpendicular from P to the line are $(3 \cdot \frac{1}{2} - 1, 2 - 2 \cdot \frac{1}{2}, -1 - \frac{1}{2})$ or $(\frac{1}{2}, 1, -\frac{3}{2})$.

Length of the perpendicular

$$PN = \sqrt{\left(\frac{1}{2} - 1\right)^2 + (1 - 0)^2 + \left(-\frac{3}{2} - 2\right)^2}$$

$$= \sqrt{\frac{1}{4} + 1 + \frac{49}{4}} = \sqrt{\frac{54}{4}} = \frac{3}{2}\sqrt{6}.$$

DR's of PM with $r = \frac{1}{2}$ are $[3 \cdot \frac{1}{2} - 2, 2 - 2 \cdot \frac{1}{2}, -3 - \frac{1}{2}]$ i.e., DR's of PM are $\frac{1}{2}, -1, \frac{7}{2}$. And PM passes through $P(1, 0, 2)$. Therefore the equation of the perpendicular PM

$$\frac{x-1}{\frac{1}{2}} = \frac{y-0}{-1} = \frac{z-2}{\frac{7}{2}} \quad \text{or} \quad x-1 = \frac{y}{-2} = \frac{z-2}{7}.$$

Example 12: Find the equation of the line of the greatest slope through the point $(2, 1, 1)$ in the slant plane $2x + y - 5z = 0$ to the horizontal plane $4x - 3y + 7z = 0$.

Solution: Let l_1, m_1, n_1 be the DR's of the line of intersection ML of the two given planes. Since ML is $\perp^r$ to both normals,

$$2l_1 + m_1 - 5n_1 = 0, \quad 4l_1 - 3m_1 + 7n_1 = 0.$$

Solving $\frac{l_1}{4} = \frac{m_1}{17} = \frac{n_1}{5}$. Let PN be the line of greatest slope and let l_2, m_2, n_2 be its DR's. Since PN and ML are perpendicular

$$4l_2 + 17m_2 + 5n_2 = 0$$

Also PN is perpendicular to normal of the slant plane $2x + y - 5z = 0$. So

$$2l_2 + m_2 - 5n_2 = 0$$

Solving $\frac{l_2}{3} = \frac{m_2}{-1} = \frac{n_2}{1}$.

Therefore the equation of the line of greatest slope PN having DR's $3, -1, 1$ and passing through $P(2, 1, 1)$ is

$$\frac{x-2}{3} = \frac{y-1}{-1} = \frac{z-1}{1}.$$

EXERCISE

- Find the points where the line $x + y + 4z = 6$, $2x - 3y - 2z = 2$ pierce the coordinate planes.

Ans. $(0, -2, 2), (4, 2, 0), (2, 0, 1)$

- Transform the general form $3x + y - 2z = 7$, $6x - 5y - 4z = 7$ to symmetrical form and two point form.

Hint: $(0, 1, -3), (2, 1, 0)$ are two points on the line.

Ans. $\frac{x-2}{2} = \frac{y-1}{0} = \frac{z-0}{3}$

- Show that the lines $x = y = z + 2$ and $\frac{x-1}{1} = \frac{y}{0} = \frac{z}{2}$ intersect and find the point of intersection.

Hint: Solve $x - y = 0$, $y - z = 2$, $y = 0$, $2x - z = 2$ simultaneously.

Ans. $(0, 0, -2)$

- Find the equation plane containing the line $x = y = z$ and

a. Passing through the line $x + 1 = y + 1 = z$

b. Parallel to the line $\frac{x+1}{3} = \frac{y}{2} = \frac{z}{-1}$.

Ans. (a) $x - y = 0$; (b) $3x - 4y + z = 0$

- Show that the line $\frac{x+1}{1} = \frac{y}{-1} = \frac{z-2}{2}$ is in the plane $2x + 4y + z = 0$.

Hint: $2(1) + 4(-1) + 1(2) = 0$, $2(-1) + 4(0) + 2 = 0$

- Find the equation of the plane containing line $\frac{x-1}{3} = \frac{y-1}{4} = \frac{z-2}{2}$ and parallel to the line $x - 2y + 3z = 4$, $2x - 3y + 4z = 5$.

Hint: Eq. of 2nd line $\frac{x-0}{1} = \frac{y-1}{1} = \frac{z-2}{1}$, contains 1st line: $3A + 4B + 2C = 0$. Parallel to 2nd line $A + 2B + C = 0$, $A = 0$, $B = -\frac{1}{2}C$, $D = -\frac{3}{2}C$.

Ans. $y - 2z + 3 = 0$

- Show that the lines $x + 2y - z = 3$, $3x - y + 2z = 1$ and $2x - 2y + 3z = 2$, $x - y + z + 1 = 0$ are coplanar. Find the equation of the plane containing the two lines.

Hint: $\frac{x-0}{3} = \frac{y-7}{-5} = \frac{z-5}{-7}$, $\frac{x-0}{1} = \frac{y-5}{+1} = \frac{z-4}{0}$.

$$\begin{vmatrix} x-0 & y-5 & z-4 \\ 3 & -5 & -7 \\ 1 & 1 & 0 \end{vmatrix} = 0, \quad \text{Expand.}$$

36.20 — ENGINEERING MATHEMATICS

Ans. $7x - 7y + 8z + 3 = 0$

8. Prove that the equation of the plane through the origin containing the line $\frac{x-1}{5} = \frac{y-2}{4} = \frac{z-3}{5}$ is $x - 5y + 3z = 0$.

Hint: $A(x-1) + B(y-2) + C(z-3) = 0$,
 $5A + 2B + 3C = 0$, $A + 2B + 3C = 0$,
 Expand $\begin{vmatrix} x-1 & y-2 & z-3 \\ 5 & 4 & 5 \\ 1 & 2 & 3 \end{vmatrix} = 0$

9. Find the image of the point $P(1, 3, 4)$ in the plane $2x - y + z + 3 = 0$.

Hint: Line through P and $\perp$ to plane: $\frac{x-1}{2} = \frac{y-3}{-1} = \frac{z-4}{1}$. Image $Q: (2r+1, -r+3, r+4)$. Mid point L of PQ is $(r+1, -\frac{1}{2}r+3, \frac{1}{2}r+4)$. L lies on plane, $r = -2$.

Ans. $(-3, 5, 2)$

10. Determine the point of intersection of the lines

$$\frac{x-4}{1} = \frac{y+3}{-4} = \frac{z+1}{7}, \quad \frac{x-1}{2} = \frac{y+1}{-3} = \frac{z+10}{8}$$

Hint: General points: $(r_1 + 4, -4r_1 - 3, 7r_1 - 1)$, $(2r_2 + 1, -3r_2 - 1, 8r_2 - 10)$, Equating $r_1 + 4 = 2r_2 + 1$, $-4r_1 - 3 = -3r_2 - 1$, solving $r_1 = 1$, $r_2 = 2$.

Ans. $(5, -7, 6)$

11. Show that the lines $\frac{x+3}{2} = \frac{y+5}{3} = \frac{z-7}{-3}$, $\frac{x+1}{4} = \frac{y+1}{5} = \frac{z+1}{-1}$ are coplanar. Find the equation of the plane containing them.

Ans. $6x - 5y - z = 0$

12. Find the equation of the line which passes through the point $(2, -1, 1)$ and intersect the lines $2x + y = 4$, $y + 2z = 0$, and $x + 3z = 4$, $2x + 5z = 8$.

Ans. $x + y + z = 2$, $x + 2z = 4$

13. Find the coordinates of the foot of the perpendicular from $P(5, 9, 3)$ to the line $\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4}$. Find the length of the perpendicular and its equations.

Ans. $(3, 5, 7)$, Length: 6, Equation $\frac{x-5}{-2} = \frac{y-9}{-4} = \frac{z-3}{4}$.

14. Find the equation of the line of greatest slope in the slant plane $2x + y - 5z = 12$ and passing through the point $(2, 3, -1)$ given that the line $\frac{x}{4} = \frac{y}{-3} = \frac{z}{7}$ is vertical.

Ans.

15. Find the angle between the line $\frac{x+1}{2} = \frac{y}{3} = \frac{z-3}{6}$ and the plane $3x + y + z = 7$.

Hint: DR's of line: 2, 3, 6; DR's of normal to plane 3, 1, 1

$$\cos(90^\circ - \theta) = \sin \theta = \frac{2 \cdot 3 + 3 \cdot 1 + 6 \cdot 1}{\sqrt{4+9+36}\sqrt{9+1+1}}.$$

Ans. $\sin \theta = \frac{15}{7\sqrt{11}}$

16. Find the angle between the line $x + y - z = 1$, $2x - 3y + z = 2$ and the plane $3x + y - z + 5 = 0$.

Hint: DR's of line 2, 3, 5, DR's of normal: 3, 1, -1

$$\cos(90^\circ - \theta) = \sin \theta = \frac{2 \cdot 3 + 3 \cdot 1 + 5 \cdot (-1)}{\sqrt{4+9+25}\sqrt{9+1+1}}.$$

Ans. $\sin \theta = \frac{4}{\sqrt{38}\sqrt{11}}$

36.5 SHORTEST DISTANCE BETWEEN SKEW LINES

Skew lines: Any two straight lines which do not lie in the same plane are known as skew lines (or non-planar lines). Such lines neither intersect nor are parallel. **Shortest distance between two skew lines:**

Fig. 36.15

Let L_1 and L_2 be two skew lines; L_1 passing through a given point A and L_2 through a given point

B. Shortest distance between the two skew lines L_1 and L_2 is the length of the line segment CD which is perpendicular to **both** L_1 and L_2 . The equation of the shortest distance line CD can be uniquely determined since it intersects both lines L_1 and L_2 at right angles. Now $CD = \text{projection of } AB \text{ on } CD = AB \cos \theta$ where θ is the angle between AB and CD . Since $\cos \theta < 1$, $CD < AB$, thus CD is the shortest distance between the lines L_1 and L_2 .

Magnitude (length) and the equations of the line of shortest distance between two lines L_1 and L_2 :

Suppose the equation of given line L_1 be

$$\frac{x - x_1}{l_1} = \frac{y - y_1}{m_1} = \frac{z - z_1}{n_1} \quad (1)$$

and of line L_2 be

$$\frac{x - x_2}{l_2} = \frac{y - y_2}{m_2} = \frac{z - z_2}{n_2} \quad (2)$$

Assume the equation of shortest distance line CD as

$$\frac{x - \alpha}{l} = \frac{y - \beta}{m} = \frac{z - \gamma}{n} \quad (3)$$

where (α, β, γ) and (l, m, n) are to be determined. Since CD is perpendicular to both L_1 and L_2 ,

$$ll_1 + mm_1 + nn_1 = 0$$

$$ll_2 + mm_2 + nn_2 = 0$$

Solving

$$\begin{aligned} \frac{l}{m_1 n_2 - m_2 n_1} &= \frac{m}{n_1 l_2 - n_2 l_1} = \frac{n}{l_1 m_2 - l_2 m_1} \\ &= \frac{\sqrt{l^2 + m^2 + n^2}}{\sqrt{(m_1 n_2 - m_2 n_1)^2 + (n_1 l_2 - n_2 l_1)^2 + (l_1 m_2 - l_2 m_1)^2}} \\ &= \frac{1}{\sqrt{\sum (m_1 n_2 - m_2 n_1)^2}} = \frac{1}{k} \end{aligned}$$

$$\text{where } k = \sqrt{\sum (m_1 n_2 - m_2 n_1)^2}$$

$$\begin{aligned} \text{or } l &= \frac{m_1 n_2 - m_2 n_1}{k}, \quad m = \frac{n_1 l_2 - n_2 l_1}{k}, \\ n &= \frac{l_1 m_2 - l_2 m_1}{k} \end{aligned} \quad (4)$$

Thus the DC's l, m, n of the shortest distance line CD are determined by (4).

Magnitude of shortest distance $CD = \text{projection of } AB \text{ on } CD$ where $A(x_1, y_1, z_1)$ is a point on L_1 and $B(x_2, y_2, z_2)$ is a point on L_2 .

$\therefore$ shortest distance $CD =$

$$= l(x_2 - x_1) + m(y_2 - y_1) + n(z_2 - z_1) \quad (5)$$

In the determinant form,

$$\text{Shortest distance } CD = \frac{1}{k} \begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} \quad (5')$$

Note: If shortest distance is zero, then the two lines L_1 and L_2 are coplanar.

Equation of the line of shortest distance CD : Observe that CD is coplanar with both L_1 and L_2 . Let P_1 be the plane containing L_1 and CD . Equation of plane P_1 containing coplanar lines L_1 and CD is

$$\begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ l_1 & m_1 & n_1 \\ l & m & n \end{vmatrix} = 0 \quad (6)$$

Fig. 36.16

Similarly, equation of plane P_2 containing L_2 and CD is

$$\begin{vmatrix} x - x_2 & y - y_2 & z - z_2 \\ l_2 & m_2 & n_2 \\ l & m & n \end{vmatrix} = 0 \quad (7)$$

36.22 — ENGINEERING MATHEMATICS

Equations (6) and (7) together give the equation of the line of shortest distance.

Points of intersection C and D with L_1 and L_2 :

Any general point C^* on L_1 is

$$(x_1 + l_1 r_1, \quad y_1 + m_1 r_1, \quad z_1 + n_1 r_1)$$

and any general point D^* on L_2 is

$$(x_2 + l_2 r_2, \quad y_2 + m_2 r_2, \quad z_2 + n_2 r_2)$$

$$\text{DR's of } C^*D^*: (x_2 - x_1 + l_2 r_2 - l_1 r_1, \quad y_2 - y_1$$

$$+ m_2 r_2 - m_1 r_1, \quad z_2 - z_1 + n_2 r_2 - n_1 r_1)$$

If C^*D^* is $\perp^r$ to both L_1 and L_2 , we get two equations for the two unknowns r_1 and r_2 . Solving and knowing r_1 and r_2 , the coordinates of C and D are determined. Then the magnitude of CD is obtained by length formula, and equation of CD by two point formula.

Parallel planes: Shortest distance CD = perpendicular distance from any point on L_1 to the plane parallel to L_1 and containing L_2 .

WORKED OUT EXAMPLES

Example 1: Find the magnitude and equation of the line of shortest distance between the lines

$$\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4},$$

$$\frac{x-2}{3} = \frac{y-4}{4} = \frac{z-5}{5}.$$

Solution: Point $A(x_1, y_1, z_1)$ on first line is (1, 2, 3) and $B(x_2, y_2, z_2)$ on second line is (2, 4, 5). Also (l_1, m_1, n_1) are (2, 3, 4) and $(l_2, m_2, n_2) = (3, 4, 5)$. Then

$$\begin{aligned} k^2 &= (m_1 n_2 - m_2 n_1)^2 + (n_1 l_2 - n_2 l_1)^2 + (l_1 m_2 - l_2 m_1)^2 \\ &= (15 - 16)^2 + (12 - 10)^2 + (8 - 9)^2 \\ &= 1 + 4 + 1 = 6 \quad \text{or} \quad k = \sqrt{6}. \end{aligned}$$

So DR's is of line of shortest of distance: $-\frac{1}{\sqrt{6}}, \frac{2}{\sqrt{6}}, -\frac{1}{\sqrt{6}}$.

$$\text{Shortest distance} = \frac{1}{k} \begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix}$$

$$\begin{aligned} &= \begin{vmatrix} 1 & 2 & 2 \\ 2 & 3 & 4 \\ 3 & 4 & 5 \end{vmatrix} \frac{1}{\sqrt{6}} \\ &= \frac{(15 - 16) - 2(10 - 12) + 2(8 - 9)}{\sqrt{6}} \\ &= \frac{-1 + 4 - 2}{\sqrt{6}} = \frac{1}{\sqrt{6}}. \end{aligned}$$

Equation of shortest distance line:

$$\begin{vmatrix} x-1 & y-2 & z-3 \\ 2 & 3 & 4 \\ -\frac{1}{\sqrt{6}} & \frac{2}{\sqrt{6}} & -\frac{1}{\sqrt{6}} \end{vmatrix} = 0 \quad \text{or} \quad 11x + 2y - 7z + 6 = 0$$

and

$$\begin{vmatrix} x-1 & y-4 & z-5 \\ 2 & 3 & 4 \\ -\frac{1}{\sqrt{6}} & \frac{2}{\sqrt{6}} & -\frac{1}{\sqrt{6}} \end{vmatrix} = 0 \quad \text{or} \quad 7x + y - 5z + 7 = 0.$$

Example 2: Determine the points of intersection of the line of shortest distance with the two lines

$$\frac{x-3}{3} = \frac{y-8}{-1} = \frac{z-3}{1}; \quad \frac{x+3}{-3} = \frac{y+7}{2} = \frac{z-6}{4}.$$

Also find the magnitude and equation of shortest distance.

Solution: Any general point C^* on first line is $(3 + 3r_1, 8 - r_1, 3 + r_1)$ and any general point D^* on the second line is $(-3 - 3r_2, -7 + 2r_2, 6 - 4r_2)$. DR's of C^*D^* are $(6 + 3r_1 + 3r_2, 15 - r_1 - 2r_2, -3 + r_1 - 4r_2)$. If C^*D^* is $\perp^r$ to both the given lines, then

$$3(6 + 3r_1 + 3r_2) - 1(15 - r_1 - 2r_2) + 1(-3 + r_1 - 4r_2) = 0$$

$$-3(6 + 3r_1 + 3r_2) + 2(15 - r_1 - 2r_2) + 4(-3 + r_1 - 4r_2) = 0$$

Solving for r_1 and r_2 , $11r_1 - 7r_2 = 0$, $+7r_1 + 29r_2 = 0$ so $r_1 = r_2 = 0$. Then the points of intersection of shortest distance line CD with the given two lines are $C(3, 8, 3)$, $D(-3, -7, 6)$.

$$\begin{aligned} \text{Length of } CD &= \sqrt{(-6)^2 + (-15)^2 + (3)^2} \\ &= \sqrt{270} = 3\sqrt{30} \end{aligned}$$

$$\text{Equation } CD: \frac{x-3}{-3-3} = \frac{y-8}{-7-8} = \frac{z-3}{6-3}$$

$$\text{i.e.,} \quad \frac{x-3}{-6} = \frac{y-8}{-15} = \frac{z-3}{3}.$$

Example 3: Calculate the length and equation of line of shortest distance between the lines

$$5x - y - z = 0, \quad x - 2y + z + 3 = 0 \quad (1)$$

$$7x - 4y - 2z = 0, \quad x - y + z - 3 = 0 \quad (2)$$

Solution: Any plane containing the second line (2) is

$$(7x - 4y - 2z) + \mu(x - y + z - 3) = 0$$

$$\text{or } (7 + \mu)x + (-4 - \mu)y + (-2 + \mu)z - 3\mu = 0 \quad (3)$$

DR's of first line (1) are $(l, m, n) = (-3, -6, -9)$ obtained from:

$$\begin{array}{ccc} l & m & n \\ 5 & -1 & -1 \\ l & -2 & 1 \end{array}$$

The plane (3) will be parallel to the line (1) with $l = -3, m = -6, n = -9$ if

$$-3(7 + \mu) + 6(4 + \mu) + 9(2 - \mu) = 0 \quad \text{or} \quad \mu = \frac{7}{2}$$

Substituting μ in (3), we get the equation of a plane containing line (2) and parallel to line (1) as

$$7x - 5y + z - 7 = 0 \quad (4)$$

To find an arbitrary point on line (1), put $x = 0$. Then $-y - z = 0$ or $y = -z$ and $-2y + z + 3 = 0, z = -1, y = 1$. $\therefore (0, 1, -1)$ is a point on line (1). Now the length of the shortest distance = perpendicular distance of $(0, 1, -1)$ to plane (4)

$$= \frac{0 - 5(1) + (-1) - 7}{\sqrt{49 + 25 + 1}} = \left| \frac{-13}{\sqrt{75}} \right| = \frac{13}{\sqrt{75}} \quad (5)$$

Equation of any plane through line (1) is

$$5x - y - z + \lambda(x - 2y + z + 3) = 0$$

$$\text{or } (5 + \lambda)x + (-y - 2\lambda)y + (-1 + \lambda)z + 3\lambda = 0 \quad (6)$$

DR's of line (2) are $(l, m, n) = (2, 3, 1)$ obtained from

$$\begin{array}{ccc} l & m & n \\ 7 & -4 & -2 \\ 1 & -1 & 1 \end{array}$$

plane (6) will be parallel to line (2) if

$$2(5 + \lambda) + 3(-y - 2\lambda) + 1(-1 + \lambda) = 0 \quad \text{or} \quad \lambda = 2.$$

Thus the equation of plane containing line (1) and parallel to line (2) is

$$7x - 5y + z + 6 = 0 \quad (7)$$

Hence equation of the line of shortest distance is given by (6) and (7) together.

Aliter: A point on line (2) is $(0, -1, 2)$ obtained by putting $x = 0$ and solving (2). Then the length of shortest distance = perpendicular distance of $(0, -1, 2)$ to the plane (7) $= \frac{0 + 5 + 2 + 6}{\sqrt{75}} = \frac{13}{\sqrt{75}}$

Note: By reducing (1) and (2) to symmetric forms

$$\begin{aligned} \frac{x - \frac{1}{3}}{1} &= \frac{y - \frac{5}{3}}{2} = \frac{z}{3} \\ \frac{x + 4}{1} &= \frac{y + 7}{\frac{3}{2}} = \frac{z}{\frac{1}{2}} \end{aligned}$$

The problem can be solved as in above worked Example 1.

Example 4: Show that the lines $\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4}$, $\frac{x-2}{3} = \frac{y-3}{4} = \frac{z-4}{5}$ are coplanar.

Solution: Shortest distance between the two lines is

$$\begin{vmatrix} 2-1 & 3-2 & 4-3 \\ 2 & 3 & 4 \\ 3 & 4 & 5 \end{vmatrix} = \begin{vmatrix} 1 & 1 & 1 \\ 2 & 3 & 4 \\ 3 & 4 & 5 \end{vmatrix} = (-1) - (-2) + (-1) = 0$$

$\therefore$ Lines are coplanar.

Example 5: If a, b, c are the lengths of the edges of a rectangular parallelepiped, show that the shortest distance between a diagonal and an edge not meeting the diagonal is $\frac{bc}{\sqrt{b^2+c^2}}$ (or $\frac{ca}{\sqrt{c^2+a^2}}$ or $\frac{ab}{\sqrt{a^2+b^2}}$).

Solution: Choose coterminus edges OA, OB, OC along the X, Y, Z axes. Then the coordinates are $A(a, 0, 0), B(0, b, 0), C(0, 0, c), E(a, b, 0), D(0, b, c), G(a, 0, c), F(a, b, c)$ etc. so that $OA = a, OB = b, OC = c$.

To find the shortest distance between a diagonal OF and an edge GC . Here GC does not intersect OF

$$\begin{aligned} \text{Equation of the line } OF: \frac{x-0}{a-0} &= \frac{y-0}{b-0} = \frac{z-0}{c-0} \\ \text{or} \quad \frac{x}{a} &= \frac{y}{b} = \frac{z}{c} \quad (1) \end{aligned}$$

$$\begin{aligned} \text{Equation of the line } GC: \frac{x-0}{a-0} &= \frac{y-0}{b-0} = \frac{z-c}{c-c} \\ \text{or} \quad \frac{x}{1} &= \frac{y}{0} = \frac{z-c}{0} \quad (2) \end{aligned}$$

Fig. 36.17

Equation of a plane containing line (1) and parallel to (2) is

$$\begin{vmatrix} x & y & z \\ a & b & c \\ 1 & 0 & 0 \end{vmatrix} = 0 \quad \text{or} \quad cy - bz = 0 \quad (3)$$

Shortest distance = Length of perpendicular drawn from

a point say $C(0, 0, c)$ to the plane (3)

$$= \frac{c \cdot 0 - b \cdot c}{\sqrt{0^2 + c^2 + b^2}} = \frac{bc}{\sqrt{c^2 + b^2}}.$$

In a similar manner, it can be proved that the shortest distance between the diagonal OF and non-intersecting edges AN and AM are respectively

$$\frac{ca}{\sqrt{c^2 + a^2}}, \frac{ab}{\sqrt{a^2 + b^2}}.$$

EXERCISE

- Determine the magnitude and equation of the line of shortest distance between the lines. Find the points of intersection of the shortest distance line, with the given lines

$$\frac{x-8}{3} = \frac{y+9}{-16} = \frac{z-10}{7}, \quad \frac{x-15}{3} = \frac{y-29}{8} = \frac{z-5}{-5}.$$

Ans. $14, 117x + 4y - 41z - 490 = 0, 9x - 4y - z = 14$, points of intersection $(5, 7, 3), (9, 13, 15)$.

- Calculate the length, points of intersection, the equations of the line of shortest distance between the two lines

$$\frac{x+1}{2} = \frac{y+1}{3} = \frac{z+1}{4}, \quad \frac{x+1}{3} = \frac{y}{4} = \frac{z}{5}.$$

$$\text{Ans. } \frac{1}{\sqrt{6}}, \frac{x-5}{\frac{1}{6}} = \frac{y-3}{-\frac{1}{2}} = \frac{z-\frac{15}{2}}{\frac{1}{6}}, \left(\frac{5}{3}, 3, \frac{13}{3}\right), \left(\frac{3}{2}, \frac{10}{3}, \frac{25}{6}\right).$$

- Find the magnitude and equations of shortest distance between the two lines

$$\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4}, \quad \frac{x-2}{3} = \frac{y-4}{4} = \frac{z-5}{5}.$$

$$\text{Ans. } \frac{1}{\sqrt{6}}, 11x + 2y - 7z + 6 = 0, 7x + y - 5z + 7 = 0.$$

- Show that the shortest distance between the lines $\frac{x}{2} = \frac{y}{-3} = \frac{z}{1}$ and $\frac{x-2}{3} = \frac{y-1}{-5} = \frac{z+2}{2}$ is $\frac{1}{\sqrt{3}}$ and its equations are $4x + y - 5z = 0, 7x + y - 8z = 31$.

- Determine the points on the lines $\frac{x-6}{3} = \frac{y-7}{-1} = \frac{z-4}{1}$, $\frac{x}{-3} = \frac{y+9}{2} = \frac{z-2}{4}$ which are nearest to each other. Hence find the shortest distance between the lines and find its equations.

$$\text{Ans. } (3, 8, 3), (-3, -7, 6), 3\sqrt{30}, \frac{x-3}{2} = \frac{y-8}{5} = \frac{z-3}{-1}.$$

- Prove that the shortest distance between the two lines $\frac{x-1}{3} = \frac{y-4}{2} = \frac{z-4}{-2}$, $\frac{x+1}{2} = \frac{y-1}{-4} = \frac{z+2}{1}$ is $\frac{120}{\sqrt{341}}$.

Hint: Equation of a plane passing through the first lines and parallel to the second line is $6x + 7y + 16z = 98$. A point on second line is $(-1, 1, -2)$. Perpendicular distance = $\frac{6(-1)+7(1)+16(-2)}{\sqrt{6^2+7^2+16^2}}.$

- Find the length and equations of shortest distance between the lines $x - y + z = 0, 2x - 3y + 4z = 0$; and $x + y + 2z - 3 = 0, 2x + 3y + 3z - 4 = 0$.

Hint: Equations of two lines in symmetric form are $\frac{x}{1} = \frac{y}{2} = \frac{z}{1}, \frac{x-5}{-3} = \frac{y+2}{1} = \frac{z}{1}.$

$$\text{Ans. } \frac{13}{\sqrt{66}}, 3x - y - z = 0, x + 2y + z - 1 = 0.$$

- Determine the magnitude and equations of the line of shortest distance between the lines $\frac{x-3}{2} = \frac{y+15}{-7} = \frac{z-9}{5}$ and $\frac{x+1}{2} = \frac{y-1}{1} = \frac{z-9}{-3}.$

$$\text{Ans. } 4\sqrt{3}, -4x + y + 3z = 0, 4x - 5y + z = 0 \text{ (or } x = y = z).$$

9. Obtain the coordinates of the points where the line of shortest distance between the lines $\frac{x-23}{-6} = \frac{y-19}{-4} = \frac{z-25}{3}$ and $\frac{x-12}{-9} = \frac{y-1}{4} = \frac{z-5}{2}$ meets them. Hence find the shortest distance between the two lines.

Ans. (11, 11, 31), (3, 5, 7), 26

10. Find the shortest distance between any two opposite edges of a tetrahedron formed by the planes $x + y = 0$, $y + z = 0$, $z + x = 0$, $x + y + z = a$. Also find the point of intersection of three lines of shortest distances.

Hint: Vertices are $(0, 0, 0)$, $(a, -a, a)$, $(-a, a, a)$, $(a, a, -a)$.

Ans. $\frac{2a}{\sqrt{6}}$, $(-a, -a, -a)$.

11. Find the shortest distance between the lines PQ and RS where $P(2, 1, 3)$, $Q(1, 2, 1)$, $R(-1, -2, -2)$, $S(-1, 4, 0)$.

Ans. $3\sqrt{2}$

36.6 THE RIGHT CIRCULAR CONE

Cone

A **cone** is a surface generated by a straight line (known as **generating line or generator**) passing through a fixed point (known as **vertex**) and satisfying a condition, for example, it may intersect a given curve (known as **guiding curve**) or touches a given surface (say a sphere). Thus cone is a set of points on its generators. Only cones with second degree equations known as quadratic cones are considered here. In particular, quadratic cones with vertex at origin are homogeneous equations of second degree.

Equation of cone with vertex at (α, β, γ) and the conic $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$, $z = 0$ as the guiding curve:

The equation of any line through vertex (α, β, γ) is

$$\frac{x-\alpha}{l} = \frac{y-\beta}{m} = \frac{z-\gamma}{n} \quad (1)$$

(1) will be generator of the cone if (1) intersects the given conic

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0, \quad z = 0 \quad (2)$$

Since (1) meets $z = 0$, put $z = 0$ in (1), then the point

$\left(\alpha - \frac{l\gamma}{n}, \beta - \frac{m\gamma}{n}, 0\right)$ will lie on the conic (2), if

$$a\left(\alpha - \frac{l\gamma}{n}\right)^2 + 2h\left(\alpha - \frac{l\gamma}{n}\right)\left(\beta - \frac{m\gamma}{n}\right) + b\left(\beta - \frac{m\gamma}{n}\right)^2 + 2g\left(\alpha - \frac{l\gamma}{n}\right) + 2f\left(\beta - \frac{m\gamma}{n}\right) + c = 0 \quad (3)$$

From (1)

$$\frac{l}{n} = \frac{x-\alpha}{z-\gamma}, \quad \frac{m}{n} = \frac{y-\beta}{z-\gamma} \quad (4)$$

Eliminate l, m, n from (3) using (4),

$$\begin{aligned} & a\left(\alpha - \frac{x-\alpha}{z-\gamma} \cdot \gamma\right)^2 + \\ & + 2h\left(\alpha - \frac{x-\alpha}{z-\gamma} \cdot \gamma\right)\left(\beta - \frac{y-\beta}{z-\gamma} \cdot \gamma\right) + \\ & + b\left(\beta - \frac{y-\beta}{z-\gamma} \cdot \gamma\right)^2 + 2g\left(\alpha - \frac{x-\alpha}{z-\gamma} \cdot \gamma\right) + \\ & + 2f\left(\beta - \frac{y-\beta}{z-\gamma} \cdot \gamma\right) + c = 0 \end{aligned}$$

or

$$\begin{aligned} & a(\alpha z - x\gamma)^2 + 2h(\alpha z - x\gamma)(\beta z - y\gamma) + \\ & + b(\beta z - y\gamma)^2 + 2g(\alpha z - x\gamma)(z - \gamma) + \\ & + 2f(\beta z - y\gamma)(z - \gamma) + c(z - \gamma)^2 = 0 \end{aligned}$$

or

$$\begin{aligned} & a(x - \alpha)^2 + b(y - \beta)^2 + c(z - \gamma)^2 + \\ & + 2f(z - \gamma)(y - \beta) + 2g(x - \alpha)(z - \gamma) + \\ & + 2h(x - \alpha)(y - \beta) = 0 \end{aligned} \quad (5)$$

Thus (5) is the equation of the quadratic cone with vertex at (α, β, γ) and guiding curve as the conic (2).

Special case: Vertex at origin $(0, 0, 0)$. Put $\alpha = \beta = \gamma = 0$ in (5). Then (5) reduces to

$$ax^2 + by^2 + cz^2 + 2fzy + 2gxz + 2hxy = 0 \quad (6)$$

Equation (6) which is a homogeneous and second degree in x, y, z is the equation of cone with vertex at origin.

Right circular cone

A right circular cone is a surface generated by a line (**generator**) through a fixed point (**vertex**) making a

constant angle θ (**semi-vertical angle**) with the fixed line (**axis**) through the fixed point (**vertex**). Here the guiding curve is a circle with centre at c . Thus every section of a right circular cone by a plane perpendicular to its axis is a circle.

Fig. 36.18

Equation of a right circular cone: with vertex at (α, β, γ) , semi vertical angle θ and equation of axis

$$\frac{x - \alpha}{l} = \frac{y - \beta}{m} = \frac{z - \gamma}{n} \quad (1)$$

Let $P(x, y, z)$ be any point on the generating line VB . Then the DC's of VB are proportional to $(x - \alpha, y - \beta, z - \gamma)$. Then

$$\cos \theta = \frac{l(x - \alpha) + m(y - \beta) + n(z - \gamma)}{\sqrt{(l^2 + m^2 + n^2)} \sqrt{(x - \alpha)^2 + (y - \beta)^2 + (z - \gamma)^2}}$$

Rewriting, the required equation of cone is

$$\begin{aligned} & [l(x - \alpha) + m(y - \beta) + n(z - \gamma)]^2 = \\ & (l^2 + m^2 + n^2) [(x - \alpha)^2 + (y - \beta)^2 + (z - \gamma)^2] \cos^2 \theta \quad (2) \end{aligned}$$

Case 1: If vertex is origin $(0, 0, 0)$ then (2) reduces

$$(lx + my + nz)^2 = (l^2 + m^2 + n^2)(x^2 + y^2 + z^2) \cos^2 \theta \quad (3)$$

Case 2: If vertex is origin and axis of cone is z -axis (with $l = 0, m = 0, n = 1$) then (2) becomes

$$\begin{aligned} z^2 &= (x^2 + y^2 + z^2) \cos^2 \theta \quad \text{or} \quad z^2 \sec^2 \theta = x^2 + y^2 + z^2 \\ z^2 (1 + \tan^2 \theta) &= x^2 + y^2 + z^2 \\ \text{i.e.,} \quad x^2 + y^2 &= z^2 \tan^2 \theta \quad (4) \end{aligned}$$

Similarly, with y -axis as the axis of cone

$$x^2 + z^2 = y^2 \tan^2 \theta$$

with x -axis as the axis of cone

$$y^2 + z^2 = x^2 \tan^2 \theta.$$

If the right circular cone admits sets of three mutually perpendicular generators then the semi-vertical angle $\theta = \tan^{-1} \sqrt{2}$ (since the sum of the coefficients of x^2, y^2, z^2 in the equation of such a cone must be zero i.e., $1 + 1 - \tan^2 \theta = 0$ or $\tan \theta = \sqrt{2}$).

WORKED OUT EXAMPLES

Example 1: Find the equation of cone with base curve $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, z = 0$ and vertex (α, β, γ) . Deduce the case when base curve is $\frac{x^2}{16} + \frac{y^2}{9} = 1, z = 0$ and vertex at $(1, 1, 1)$.

Solution: The equation of any generating line through the vertex (α, β, γ) is

$$\frac{x - \alpha}{l} = \frac{y - \beta}{m} = \frac{z - \gamma}{n} \quad (1)$$

This generator (1) meets $z = 0$ in the point

$$\left(x = \alpha - \frac{l\gamma}{n}, \quad y = \beta - \frac{m\gamma}{n}, \quad z = 0 \right) \quad (2)$$

Point (2) lies on the generating curve

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad (3)$$

Substituting (2) in (3)

$$\frac{\left(\alpha - \frac{l\gamma}{n} \right)^2}{a^2} + \frac{\left(\beta - \frac{m\gamma}{n} \right)^2}{b^2} = 1 \quad (4)$$

Eliminating l, m, n from (4) using (1),

$$\begin{aligned} & \frac{\left[\alpha - \left(\frac{x - \alpha}{z - \gamma} \right) \gamma \right]^2}{a^2} + \frac{\left[\beta - \left(\frac{y - \beta}{z - \gamma} \right) \gamma \right]^2}{b^2} = 1 \\ & b^2 \left[\alpha(z - \gamma) - \gamma(x - \alpha) \right]^2 + a^2 \left[\beta(z - \gamma) - \gamma(y - \beta) \right]^2 \\ & = a^2 b^2 (z - \gamma)^2 \end{aligned}$$

Deduction: When $a=4, b=3, \alpha=1, \beta=1, \gamma=1$,

$$9[(z-1)-(x-1)]^2 + 16[(z-1)-(y-1)]^2 = 144(z-1)^2$$

$$9x^2 + 16y^2 - 119z^2 - 18xz - 32yz + 288z - 144 = 0.$$

Example 2: Find the equation of the cone with vertex at $(1, 0, 2)$ and passing through the circle $x^2 + y^2 + z^2 = 4, x + y - z = 1$.

Solution: Equation of generator is

$$\frac{x-1}{l} = \frac{y-0}{m} = \frac{z-2}{n} \quad (1)$$

Any general point on the line (1) is

$$(1+lr, \quad mr, \quad 2+nr). \quad (2)$$

Since generator (1) meets the plane

$$x + y - z = 1 \quad (3)$$

substitute (2) in (3)

$$(1+lr) + (mr) - (2+nr) = 1$$

$$\text{or} \quad r = \frac{2}{l+m-n}. \quad (4)$$

Since generator (1) meets the sphere

$$x^2 + y^2 + z^2 = 4 \quad (5)$$

substitute (2) in (5)

$$(1+lr)^2 + (mr)^2 + (2+nr)^2 = 4$$

$$\text{or} \quad r^2(l^2 + m^2 + n^2) + 2r(l + 2n) + 1 = 0 \quad (6)$$

Eliminate r from (6) using (4), then

$$\frac{4}{(l+m-n)^2}(l^2+m^2+n^2) + 2\frac{2}{(l+m-n)}(l+2n) + 1 = 0$$

$$9l^2 + 5m^2 - 3n^2 + 6lm + 2ln + 6nm = 0 \quad (7)$$

Eliminate l, m, n from (7) using (1), then

$$9\left(\frac{x-1}{r}\right)^2 + 5\left(\frac{y}{r}\right)^2 - 3\left(\frac{z-2}{r}\right)^2 + 6\left(\frac{x-1}{r}\right)\left(\frac{y}{r}\right) + 2\left(\frac{x-1}{r}\right)\left(\frac{z-2}{r}\right) + 6\left(\frac{z-2}{r}\right)\left(\frac{y}{r}\right) = 0$$

$$\text{or} \quad 9(x-1)^2 + 5y^2 - 3(z-2)^2 + 6y(x-1) + 2(x-1)(x-2) + 6(z-2)y = 0$$

Vertex $(0, 0, 0)$:

Example 3: Determine the equation of a cone with vertex at origin and base curve given by

- a. $ax^2 + by^2 = 2z, \quad lx + my + nz = p$
 b. $ax^2 + by^2 + cz^2 = 1, \quad lx + my + nz = p$
 c. $x^2 + y^2 + z^2 = 25, \quad x + 2y + 2z = 9$

Solution: We know that the equation of a quadratic cone with vertex at origin is a homogeneous equation of second degree in x, y, z . By eliminating the non-homogeneous terms in the base curve, we get the required equation of the cone.

- a. $2z$ is the term of degree one and is non homogeneous. Solving

$$\frac{lx + my + nz}{p} = 1$$

rewrite the equation

$$ax^2 + by^2 = 2 \cdot z(1) = 2z \left(\frac{lx + my + nz}{p} \right)$$

$$apx^2 + bpy^2 - 2nz^2 - 2lzx - 2myz = 0$$

which is the equation of cone.

- b. Except the R.H.S. term 1, all other terms are of degree 2 (and homogeneous). Rewriting, the required equation of cone as

$$ax^2 + by^2 + cz^2 = (1)^2 = \left(\frac{lx + my + nz}{p} \right)^2$$

$$(ap^2 - l^2)x^2 + (bp^2 - m^2)y^2 + (cp^2 - n^2)z^2 - 2lmxy - 2mnyz - 2lnxz = 0$$

- c. On similar lines

$$x^2 + y^2 + z^2 = 25 = 25(1)^2 = 25 \left(\frac{x + 2y + 2z}{9} \right)^2$$

$$56x^2 - 19y^2 - 19z^2 - 100xy - 200yz - 100xz = 0$$

Right circular cone:

Example 4: Find the equation of a right circular cone with vertex at $(2, 0, 0)$, semi-vertical angle $\theta = 30^\circ$ and axis is the line $\frac{x-2}{3} = \frac{y}{4} = \frac{z}{6}$.

36.28 — ENGINEERING MATHEMATICS

Solution: Here $\alpha = 2, \beta = 0, \gamma = 0, l = 3, m = 4, n = 6$

$$\frac{\sqrt{3}}{2} = \cos 30 = \cos \theta$$

$$= \frac{l(x - \alpha) + m(y - \beta) + n(z - \gamma)}{\sqrt{(l^2 + m^2 + n^2)[(x - \alpha)^2 + (y - \beta)^2 + (z - \gamma)^2]}}$$

$$\frac{\sqrt{3}}{2} = \frac{3(x - 2) + 4y + 6z}{\sqrt{9 + 16 + 36}\sqrt{(x - 2)^2 + y^2 + z^2}}$$

$$183[(x - 2)^2 + y^2 + z^2] = 4[3(x - 2) + 4y + 6z]^2$$

$$147x^2 + 119y^2 + 39z^2 - 192yz - 144zx - 96xy - 588x + 192y + 288z + 588 = 0$$

Vertex (0, 0, 0):

Example 5: Find the equation of the right circular cone which passes through the line $2x = 3y = -5z$ and has $x = y = z$ as its axis.

Solution: DC's of the generator $2x = 3y = -5z$ are $\frac{1}{2}, \frac{1}{3}, -\frac{1}{5}$. DC's of axis are $\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}$. Point of intersection of the generator and axis is (0, 0, 0). Now

$$\cos \theta = \frac{\frac{1}{2} \cdot \frac{1}{\sqrt{3}} + \frac{1}{3} \cdot \frac{1}{\sqrt{3}} - \frac{1}{5} \cdot \frac{1}{\sqrt{3}}}{\sqrt{\frac{1}{3} + \frac{1}{3} + \frac{1}{3}} \sqrt{\frac{1}{4} + \frac{1}{9} + \frac{1}{25}}} = \frac{\frac{19}{30}}{\sqrt{\frac{361}{900}}} \cdot \frac{1}{\sqrt{3}} = \frac{1}{\sqrt{3}}$$

Equation of cone with vertex at origin

$$\frac{1}{\sqrt{3}} = \cos \theta = \frac{\frac{1}{\sqrt{3}}(x + y + z)}{1\sqrt{x^2 + y^2 + z^2}}$$

$$x^2 + y^2 + z^2 = (x + y + z)^2$$

$$xy + yz + zx = 0.$$

Example 6: Determine the equation of a right circular cone with vertex at origin and the guiding curve circle passing through the points (1, 2, 2), (1, -2, 2), (2, -1, -2).

Solution: Let l, m, n be the DC's of OL the axis of the cone. Let θ be the semi-vertical angle. Let $A(1, 2, 2), B(1, -2, 2), C(2, -1, -2)$ be the three points on the guiding circle. Then the lines OA, OB, OC make the same angle θ with the axis OL . The DC's of OA, OB, OC are proportional to

(1, 2, 2)(1, -2, 2)(2, -1, -2) respectively. Then

$$\cos \theta = \frac{l(1) + m(2) + n(2)}{\sqrt{l^2 + m^2 + n^2} \sqrt{1 + 4 + 4}} = \frac{l + 2m + 2n}{3} \quad (1)$$

Fig. 36.19

Similarly,

$$\cos \theta = \frac{l(1) + m(-2) + n(2)}{\sqrt{l^2 + m^2 + n^2} \sqrt{1 + 4 + 4}} = \frac{l - 2m + 2n}{3} \quad (2)$$

$$\cos \theta = \frac{2l - m - 2n}{3} \quad (3)$$

From (1) and (2), $4m = 0$ or $m = 0$.

From (2) and (3), $l + m - 4n = 0, l - 4n = 0$ or $l = 4n$.

$$\text{DC's} \quad \frac{l}{4} = \frac{m}{0} = \frac{n}{1} \quad \text{or} \quad \frac{l}{4} = \frac{m}{0} = \frac{n}{\frac{1}{\sqrt{17}}}$$

$$\text{From (1)} \quad \cos \theta = \frac{\frac{4}{\sqrt{17}} + 2 \cdot 0 + 2 \cdot \frac{1}{\sqrt{17}}}{3} = \frac{2}{\sqrt{17}}.$$

Equation of right circular cone is

$$(l^2 + m^2 + n^2)(x^2 + y^2 + z^2) \cos^2 \theta = (lx + my + nz)^2$$

$$\left(\frac{16}{17} + 0 + \frac{1}{17}\right)(x^2 + y^2 + z^2) \frac{4}{17} = \left(\frac{4}{\sqrt{17}}x + 0 + \frac{1}{\sqrt{17}}z\right)^2$$

$$4(x^2 + y^2 + z^2) = (4x + z)^2$$

$$12x^2 - 4y^2 - 3z^2 + 8xz = 0$$

is the required equation of the cone.

EXERCISE

- Find the equation of the cone whose vertex is (3, 1, 2) and base circle is $2x^2 + 3y^2 = 1, z = 1$.

Ans. $2x^2 + 3y^2 + 20z^2 - 6yz - 12xz + 12x + 6y - 38z + 17 = 0$

2. Find the equation of the cone whose vertex is origin and guiding curve is $\frac{x^2}{4} + \frac{y^2}{9} + \frac{z^2}{1} = 1$, $x + y + z = 1$.

Ans. $27x^2 + 32y^2 + 72(xy + yz + zx) = 0$.

3. Determine the equation of the cone with vertex at origin and guiding curve $x^2 + y^2 + z^2 - x - 1 = 0$, $x^2 + y^2 + z^2 + y - z = 0$.

Hint: Guiding curve is circle in plane $x + y = 1$. Rewrite $x^2 + y^2 + z^2 - x(x + y) - (x + y)^2 = 0$.

Ans. $x^2 + 3xy - z^2 = 0$

4. Show that the equation of cone with vertex at origin and base circle $x = a$, $y^2 + z^2 = b^2$ is $a^2(y^2 + z^2) = b^2x^2$. Further prove that the section of the cone by a plane parallel to the XY -plane is a hyperbola.

Ans. $b^2x^2 - a^2y^2 = a^2c^2$, $z = c$ (put $z = c$ in equation of cone)

5. Find the equation of a cone with vertex at origin and guiding curve is the circle passing through the X, Y, Z intercepts of the plane $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$.

Ans. $a(b^2 + c^2)yz + b(c^2 + a^2)zx + c(a^2 + b^2)xy = 0$

6. Write the equation of the cone whose vertex is $(1, 1, 0)$ and base is $y^2 + z^2 = 9$, $x = 0$.

Hint: Substitute $(0, 1 - \frac{m}{l}, -\frac{n}{l})$ in base curve and eliminate $\frac{m}{l} = \frac{y-1}{x-1}$, $\frac{n}{l} = \frac{z}{x-1}$.

Ans. $x^2 + y^2 + z^2 - 2xy = 0$

Right circular cone (R.C.C.)

7. Find the equation of R.C.C. with vertex at $(2, 3, 1)$, axis parallel to the line $-x = \frac{y}{2} = z$ and one of its generators having DC's proportional to $(1, -1, 1)$.

Hint: $\cos \theta = \frac{-1-2+1}{\sqrt{6}\sqrt{3}}$, $l = -1, m = 2, n = 1$, $\alpha = 2, \beta = 3, \gamma = 1$.

Ans. $x^2 - 8y^2 + z^2 + 12xy - 12yz + 6zx - 46x + 36y + 22z - 19 = 0$

8. Determine the equation of R.C.C. with vertex at origin and passes through the point $(1, 1, 2)$ and axis line $\frac{x}{2} = \frac{-y}{4} = \frac{z}{3}$.

Hint: $\cos \theta = \frac{2-4+6}{\sqrt{6}\sqrt{29}}$, DC's of generator: 1, 1, 2, axis: 2, -4, 3

Ans. $4x^2 + 40y^2 + 19z^2 - 48xy - 72yz + 36xz = 0$

9. Find the equation of R.C.C. whose vertex is origin and whose axis is the line $\frac{x}{1} = \frac{y}{2} = \frac{z}{3}$ and which has semi-vertical angle of 30° .

Hint: $\cos 30 = \frac{\sqrt{3}}{2} = \frac{x(1+y(2)+z(3))}{\sqrt{(x^2+y^2+z^2)}\sqrt{1+4+9}}$

Ans. $19x^2 + 13y^2 + 3z^2 - 8xy - 24yz - 12zx = 0$

10. Obtain the equation of R.C.C. generated when the straight line $2y + 3z = 6$, $x = 0$ revolves about z -axis.

Hint: Vertex $(0, 0, 2)$, generator $\frac{x}{0} = \frac{y}{3} = \frac{z-2}{-2}$, $\cos \theta = -\frac{2}{\sqrt{13}}$.

Ans. $4x^2 + 4y^2 - 9z^2 + 36z - 36 = 0$

11. Lines are drawn from the origin with DC's proportional to $(1, 2, 2)$, $(2, 3, 6)$, $(3, 4, 12)$. Find the equation of R.C.C.

Hint: $\cos \alpha = \frac{l+2m+2n}{3} = \frac{2l+3m+6n}{7} = \frac{3l+4m+12n}{13}$
 $\frac{l}{-1} = \frac{m}{1} = \frac{n}{1}$, $\cos \alpha = \frac{1}{\sqrt{3}}$, DC's of axis: -1, 1, 1.

Ans. $xy - yz + zx = 0$

12. Determine the equation of the R.C.C. generated by straight lines drawn from the origin to cut the circle through the three points $(1, 2, 2)$, $(2, 1, -2)$, and $(2, -2, 1)$.

Hint: $\cos \alpha = \frac{l+2m+2n}{3} = \frac{2l+m-2n}{3} = \frac{2l-2m+n}{3}$
 $\frac{l}{5} = \frac{m}{1} = \frac{n}{1}$, $\cos \alpha = \frac{5+2+2}{3\sqrt{27}} = \frac{1}{\sqrt{3}}$.

Ans. $8x^2 - 4y^2 - 4z^2 + 5xy + 5zx + yz = 0$

36.7 THE RIGHT CIRCULAR CYLINDER

A cylinder is the surface generated by a straight line (known as **generator**) which is parallel to a fixed straight line (known as **axis**) and satisfies a condition; for example, it may intersect a fixed curve (known as the **guiding curve**) or touch a given surface. A **right circular cylinder** is a cylinder whose surface is generated by revolving the generator at a fixed distance (known as the **radius**) from the axis; i.e., the guiding curve in this case is a circle. In fact, the

36.30 — ENGINEERING MATHEMATICS

intersection of the right circular cylinder with any plane perpendicular to axis of the cylinder is a circle.

Equation of a cylinder with generators parallel to the line $\frac{x}{l} = \frac{y}{m} = \frac{z}{n}$ and guiding curve conic $ax^2 + by^2 + 2hxy + 2gx + 2fy + c = 0, z = 0$.

Let $P(x_1, y_1, z_1)$ be any point on the cylinder. The equation of the generator through $P(x_1, y_1, z_1)$ which is parallel to the given line

$$\frac{x}{l} = \frac{y}{m} = \frac{z}{n} \quad (1)$$

is
$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n} \quad (2)$$

Since (2) meets the plane $z = 0$,

$$\therefore \frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{0 - z_1}{n}$$

or
$$x = x_1 - \frac{l}{n}z_1, y = y_1 - \frac{m}{n}z_1 \quad (3)$$

Since this point (3) lies on the conic

$$ax^2 + by^2 + 2hxy + 2gx + 2fy + c = 0 \quad (4)$$

substitute (3) in (4). Then

$$\begin{aligned} & a \left(x_1 - \frac{l}{n}z_1 \right)^2 + b \left(y_1 - \frac{m}{n}z_1 \right)^2 + \\ & + 2h \left(x_1 - \frac{l}{n}z_1 \right) \left(y_1 - \frac{m}{n}z_1 \right) + 2g \left(x_1 - \frac{l}{n}z_1 \right) + \\ & + 2f \left(y_1 - \frac{m}{n}z_1 \right) + c = 0. \end{aligned}$$

The required equation of the cylinder is

$$\begin{aligned} & a(nx - lz)^2 + b(ny - mz)^2 + 2h(nx - lz)(ny - mz) + \\ & + 2ng(nx - lz) + 2nf(ny - mz) + cn^2 = 0 \end{aligned} \quad (5)$$

where the subscript 1 is dropped because (x_1, y_1, z_1) is any general point on the cylinder.

Corollary 1: The equation of a cylinder with axis parallel to z-axis is obtained from (5) by putting $l = 0, m = 0, n = 1$ which are the DC's of z-axis: i.e.,

$$ax^2 + by^2 + 2hxy + 2gx + 2fy + c = 0$$

which is **free** from z .

Thus the equation of a cylinder whose axis is parallel to x-axis (y-axis or z-axis) is obtained by eliminating the variable x (y or z) from the equation of the conic.

Equation of a right circular cylinder:

a. Standard form: with z-axis as axis and of radius a . Let $P(x, y, z)$ be any point on the cylinder. Then M the foot of the perpendicular PM has $(0, 0, z)$ and $PM = a$ (given). Then

$$\begin{aligned} a = PM &= \sqrt{(x - 0)^2 + (y - 0)^2 + (z - z)^2} \\ x^2 + y^2 &= a^2 \end{aligned}$$

Fig. 36.20

Corollary 2: Similarly, equation of right circular cylinder with y-axis is $x^2 + z^2 = a^2$, with x-axis is $y^2 + z^2 = a^2$.

b. General form with the line $\frac{x-\alpha}{l} = \frac{y-\beta}{m} = \frac{z-\gamma}{n}$ as axis and of radius a .

Axis AB passes through the point (α, β, γ) and has DR's l, m, n . Its DC's are $\frac{l}{k}, \frac{m}{k}, \frac{n}{k}$ where $k = \sqrt{l^2 + m^2 + n^2}$.

Fig. 36.21

From the right angled triangle APM

$$\begin{aligned} AP^2 &= PM^2 + AM^2 \\ (x - \alpha)^2 + (y - \beta)^2 + (z - \gamma)^2 \\ &= a^2 + \left[l(x - \alpha) + m(y - \beta) + n(z - \gamma) \right]^2 \end{aligned}$$

which is the required equation of the cylinder (Here AM is the projection of AP on the line AB is equal to $l(x - \alpha) + m(y - \beta) + n(z - \gamma)$).

Enveloping cylinder of a sphere is the locus of the tangent lines to the sphere which are parallel to a given line. Suppose

$$x^2 + y^2 + z^2 = a^2 \quad (1)$$

is the sphere and suppose that the generators are parallel to the given line

$$\frac{x}{l} = \frac{y}{m} = \frac{z}{n} \quad (2)$$

Then for any point $P(x_1, y_1, z_1)$ on the cylinder, the equation of the generating line is

$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n} \quad (3)$$

Any general point on (3) is

$$(x_1 + lr, y_1 + mr, z_1 + nr) \quad (4)$$

By substituting (4) in (1), we get the points of intersection of the sphere (1) and the generating line (3) i.e.,

$$(x_1 + lr)^2 + (y_1 + mr)^2 + (z_1 + nr)^2 = a^2$$

Rewriting as a quadratic in r , we have

$$(l^2 + m^2 + n^2)r^2 + 2(lx_1 + my_1 + nz_1)r + (x_1^2 + y_1^2 + z_1^2 - a^2) = 0 \quad (5)$$

If the roots of (5) are equal, then the generating line (3) meets (touches) the sphere in a single point i.e., when the discriminant of the quadratic in r is zero.

$$\begin{aligned} \text{or } 4(lx_1 + my_1 + nz_1)^2 - 4(l^2 + m^2 + n^2) \times \\ \times (x_1^2 + y_1^2 + z_1^2 - a^2) = 0 \end{aligned}$$

Thus the required equation of the enveloping cylinder is

$$(lx + my + nz)^2 = (l^2 + m^2 + n^2)(x^2 + y^2 + z^2 - a^2)$$

where the subscript 1 is dropped to indicate that (x, y, z) is a general point on the cylinder.

WORKED OUT EXAMPLES

Example 1: Find the equation of the quadratic cylinder whose generators intersect the curve $ax^2 +$

$by^2 + cz^2 = k$, $lx + my + nz = p$ and parallel to the y -axis. Deduce the case for $x^2 + y^2 + z^2 = 1$ and $x + y + z = 1$ and parallel to y -axis

Solution: Eliminate y between

$$ax^2 + by^2 + cz^2 = k \quad (1)$$

$$\text{and } lx + my + nz = p \quad (2)$$

Solving (2) for y , we get

$$y = \frac{p - lx - nz}{m} \quad (3)$$

Substitute (3) in (1), we have

$$ax^2 + b\left(\frac{p - lx - nz}{m}\right)^2 + cz^2 = k.$$

The required equation of the cylinder is

$$\begin{aligned} (am^2 + l^2)x^2 + (bn^2 + m^2c)z^2 - 2pblx \\ - 2npbz + 2blnxz + (bp^2 - m^2k) = 0. \end{aligned}$$

Deduction: Put $a = 1, b = 1, c = 1, k = 1, l = m = n = p = 1$

$$2x^2 + 2z^2 - 2x - 2z + 2xz = 0$$

$$\text{or } x^2 + z^2 + xz - x - z = 0.$$

Example 2: If l, m, n are the DC's of the generators and the circle $x^2 + y^2 = a^2$ in the XY -plane is the guiding curve, find the equation of the cylinder. Deduce the case when $a = 4, l = 1, m = 2, n = 3$.

Solution: For any point $P(x_1, y_1, z_1)$ on the cylinder, the equation of the generating line through P is

$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n} \quad (1)$$

Since the line (1) meets the guiding curve $x^2 + y^2 = a^2, z = 0$,

$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{0 - z_1}{n}$$

$$\text{or } x = x_1 - \frac{lz_1}{n}, \quad y = y_1 - \frac{mz_1}{n} \quad (2)$$

This point (2) lies on the circle $x^2 + y^2 = a^2$ also. Substituting (2) in the equation of circle, we have

$$\left(x_1 - \frac{lz_1}{n}\right)^2 + \left(y_1 - \frac{mz_1}{n}\right)^2 = a^2$$

$$\text{or } (nx - lz)^2 + (ny - mz)^2 = n^2a^2$$

is the equation of the cylinder.

36.32 — ENGINEERING MATHEMATICS

Deduction: Equation of cylinder whose generators are parallel to the line $\frac{x}{1} = \frac{y}{2} = \frac{z}{3}$ and pass through the curve $x^2 + y^2 = 16, z = 0$. With $a = 4, l = 1, m = 2, n = 3$, the required equation of the cylinder is

$$(3x - z)^2 + (3y - 2z)^2 = 9(16) = 144$$

$$\text{or } 9x^2 + 9y^2 + 5z^2 - 6zx - 12yz - 144 = 0.$$

Example 3: Find the equation of the right circular cylinder of radius 3 and the line $\frac{x-1}{2} = \frac{y-3}{2} = \frac{z-5}{-1}$ as axis.

Solution: Let $A(1, 3, 5)$ be the point on the axis and DR's of AB are $2, 2, -1$ or DC's of AB are $\frac{2}{3}, \frac{2}{3}, -\frac{1}{3}$. Radius $PM = 3$ given. Since AM is the projection of AP on AB , we have

$$AM = \frac{2}{3}(x-1) + \frac{2}{3}(y-3) - \frac{1}{3}(z-5)$$

Fig. 36.22

From the right angled triangle APM

$$AP^2 = AM^2 + MP^2$$

$$(x-1)^2 + (y-3)^2 + (z-5)^2 = \left[2\frac{(x-1)}{3} + 2\frac{(y-3)}{3} - 1\frac{(z-5)}{3} \right]^2 + 9$$

$$9[x^2 + 1 - 2x + y^2 + 9 - 6y + z^2 + 25 - 10z] = [2x + 2y - z - 3]^2 + 81$$

$$9[x^2 + y^2 + z^2 - 2x - 6y - 10z + 35] = [4x^2 + 4y^2 + z^2 + 9 + 8xy - 4xz - 12x - 4yz - 12y + 6z] + 81$$

is the required equation of the cylinder.

Example 4: Find the equation of the enveloping cylinder of the sphere $x^2 + y^2 + z^2 - 2y - 4z - 11 = 0$ having its generators parallel to the line $x = -2y = 2z$.

Solution: Let $P(x_1, y_1, z_1)$ be any point on the cylinder. Then the equation of the generating line

through P and parallel to the line $x = -2y = 2z$ or $\frac{x}{1} = \frac{y}{-1} = \frac{z}{2}$ is

$$\frac{x - x_1}{1} = \frac{y - y_1}{-1} = \frac{z - z_1}{2} \quad (1)$$

Any general point on (1) is

$$\left(x_1 + r, \quad y_1 - \frac{1}{2}r, \quad z_1 + \frac{1}{2}r \right) \quad (2)$$

The points of intersection of the line (1) and the sphere

$$x^2 + y^2 + z^2 - 2y - 4z - 11 = 0 \quad (3)$$

are obtained by substituting (2) in (3).

$$(x_1 + r)^2 + \left(y_1 - \frac{1}{2}r \right)^2 + \left(z_1 + \frac{1}{2}r \right)^2 - 2\left(y_1 - \frac{1}{2}r \right) - 4\left(z_1 + \frac{1}{2}r \right) - 11 = 0$$

Rewriting this as a quadratic in r

$$\frac{3}{2}r^2 + (2x_1 - y_1 + z_1 - 1)r + (x_1^2 + y_1^2 + z_1^2 - 2y_1 - 4z_1 - 11) = 0 \quad (4)$$

The generator touches the sphere (3) if (4) has equal roots i.e., discriminant is zero or

$$(2x_1 - y_1 + z_1 - 1)^2 = 4 \cdot \frac{3}{2} \cdot (x_1^2 + y_1^2 + z_1^2 - 2y_1 - 4z_1 - 11).$$

The required equation of the cylinder is

$$2x^2 + 5y^2 + 5z^2 + 4xy - 4xz + 2yz + 4x - 14y - 22z - 67 = 0.$$

EXERCISE

- Find the equation of the quadratic cylinder whose generators intersect the curve
 - $ax^2 + by^2 = 2z, lx + my + nz = p$ and are parallel to z -axis.
 - $ax^2 + by^2 + cz^2 = 1, lx + my + nz = p$ and are parallel to x -axis.

Hint: Eliminate z

Ans. **a.** $n(ax^2 + by^2) + 2lx + 2my - 2p = 0$

Hint: Eliminate x .

Ans. **b.** $(bl^2 + am^2)y^2 + (cl^2 + an^2)z^2 + 2amnyz - 2ampy - 2anpz + (ap^2 - l^2) = 0$

2. If l, m, n are the DC's of the generating line and the circle $x^2 + z^2 = a^2$ in the zx -plane is the guiding curve, find the equation of the sphere.

Ans. $(mx - ly)^2 + (mz - ny)^2 = a^2m^2$

Find the equation of a right circular cylinder (4 to 9)

4. Whose axis is the line $\frac{x-1}{2} = \frac{y+3}{-1} = \frac{z-2}{5}$ and radius is 2 units.

Ans. $26x^2 + 29y^2 + 5z^2 + 4xy + 10yz - 20zx + 150y + 30z + 75 = 0$

5. Having for its base the circle $x^2 + y^2 + z^2 = 9, x - y + z = 3$.

Ans. $x^2 + y^2 + z^2 + xy + yz - zx - 9 = 0$

6. Whose axis passes through the point $(1, 2, 3)$ and has DC's proportional to $(2, -3, 6)$ and of radius 2.

Ans. $45x^2 + 40y^2 + 13z^2 + 36yz - 24zx + 12xy - 42x - 280y - 126z + 294 = 0$.

7. Whose axis is the line $\frac{x-1}{2} = \frac{y-2}{1} = \frac{z-3}{2}$ and radius 2 units.

Ans. $5x^2 + 8y^2 + 5z^2 - 4yz - 8zx - 4xy + 22x - 16y - 14z - 10 = 0$

8. The guiding curve is the circle through the three points $(1, 0, 0), (0, 1, 0), (0, 0, 1)$.

Ans. $x^2 + y^2 + z^2 - xy - yz - zx = 1$

9. The directing curve is $x^2 + z^2 - 4x - 2z + 4 = 0, y = 0$ and whose axis contains the point $(0, 3, 0)$. Also find the area of the section of the cylinder by a plane parallel to xz -plane.

Hint: Centre of circle $(2, 0, 1)$ radius: 1

Ans. $9x^2 + 5y^2 + 9z^2 + 12xy + 6yz - 36x - 30y - 18z + 36 = 0, \pi$

10. Find the equation of the enveloping cylinder of the sphere $x^2 + y^2 + z^2 - 2x + 4y = 1$, having its generators parallel to the line $x = y = z$.

Ans. $x^2 + y^2 + z^2 - xy - yz - zx - 2x + 7y + z - 2 = 0$.

Chapter 37

Calculus of Variations

37.1 INTRODUCTION

Calculus of variations deals with certain kinds of “external problems” in which expressions involving integrals are optimized (maximized or minimized). Euler and Lagrange in the 18th century laid the foundations, with the classical problems of determining a closed curve in the plane enclosing maximum area subject to fixed length and the brachistochrone problem of determining the path between two points in minimum time. The present day problems include the maximization of the entropy integral in third law of thermodynamics, minimization of potential and kinetic energies integral in Hamilton’s principle in mechanics, the minimization of energy integral in the problems in elastic behaviour of beams, plates and shells. Thus calculus of variations deals with the study of extrema of “functionals”.

Functional: A real valued function f whose domain is the set of real functions $\{y(x)\}$ is known as a functional (or functional of a single independent variable). Thus the domain of definition of a functional is a set of **admissible functions**. In ordinary functions the values of the independent variables are numbers. Whereas with functionals, the values of the independent variables are functions.

Example: The length L of a curve, c whose equation is $y = f(x)$, passing through two given points $A(x_1, y_1)$ and $B(x_2, y_2)$ is given by

$$L = \int_{x_1}^{x_2} \sqrt{1 + y'^2} dx$$

where y' denotes derivative of y w.r.t. x .

Now the length L of the curve passing through A and B depends on $y(x)$ (the curve). Then L is a

function of the independent variable $y(x)$, which is a function. Thus

$$L\{y(x)\} = \int_{x_1}^{x_2} \sqrt{1 + y'^2} dx$$

Fig. 37.1

defines a functional which associates a real number L uniquely to each $y(x)$ (the independent variable). Further suppose we wish to determine the curve having shortest (least) distance between the two given points A and B , i.e., curve with minimum length L . This is a classical example of a variational problem in which we wish to determine, the particular curve $y = y(x)$ which minimizes the functional $L\{y(x)\}$ given by (1). Here the two conditions $y(x_1) = y_1$ and $y(x_2) = y_2$, which are imposed on the curve $y(x)$ are known as *end conditions* of the problem. Thus variational problems involves determination of maximum or minimum or stationary values of a functional. The term extremum is used to include maximum or minimum or stationary values.

37.2 VARIATIONAL PROBLEM

Consider the general integral (a functional)

$$I\{y(x)\} = \int_{x_1}^{x_2} f(x, y, y') dx \quad (1)$$

37.2 — MATHEMATICAL METHODS

Extremal: A function $y = y(x)$ which extremizes (1) and satisfies the end conditions $y(x_1) = y_1$ and $y(x_2) = y_2$ is known as an extremal or extremizing function of the functional I (given by (1)). A variational problem is to find such an extremal function $y(x)$.

Variation of a Function and a Functional

When the independent variable x changes to $x + \Delta x$ then the dependent variable y of the function $y = f(x)$ changes to $y + \Delta y$. Thus Δy is the change of the function, the differential dy provides the variation in y . Consider a function $f(x, y, y')$ which for a fixed x , becomes a functional defined on a set of functions $\{y(x)\}$.

For a fixed value of x , if $y(x)$ is changed to $y(x) + \epsilon \eta(x)$, where ϵ is independent of x , then $\epsilon \eta(x)$ is known as the *variation* of y and is denoted by δy . Similarly, variation of y' is $\epsilon \eta'(x)$ and is denoted by $\delta y'$. Now the change in f is given by

$$\Delta f = f(x, y + \epsilon \eta, y' + \epsilon \eta') - f(x, y, y')$$

Expanding the first term on R.H.S. by Maclaurin's series in powers of ϵ , we get

$$\begin{aligned} \Delta f = & f(x, y, y') + \left(\frac{\partial f}{\partial y} \eta + \frac{\partial f}{\partial y'} \eta' \right) \epsilon + \\ & + \left(\frac{\partial^2 f}{\partial y^2} \eta^2 + \frac{2\partial^2 f}{\partial y \partial y'} \eta \eta' + \frac{\partial^2 f}{\partial y'^2} \eta'^2 \right) \frac{\epsilon^2}{2!} + \\ & + \dots - F(x, y, y') \end{aligned}$$

or approximately, neglecting higher powers of ϵ .

$$\Delta f = \frac{\partial f}{\partial y} \eta \epsilon + \frac{\partial f}{\partial y'} \eta' \epsilon = \frac{\partial f}{\partial y} \delta y + \frac{\partial f}{\partial y'} \delta y'$$

Thus the *variation of a functional* f is denoted by δf and is given by

$$\delta f = \frac{\partial f}{\partial y} \delta y + \frac{\partial f}{\partial y'} \delta y'$$

which is analogous to the differential of a function.

Result: (a) $\delta(f_1 \pm f_2) = \delta f_1 \pm \delta f_2$
 (b) $\delta(f_1 f_2) = f_1 \delta f_2 + f_2 \delta f_1$
 (c) $\delta(f^\eta) = \eta f^{\eta-1} \delta f$

$$\begin{aligned} \text{(d)} \quad \delta \left(\frac{f_1}{f_2} \right) &= \frac{f_2 \delta f_1 - f_1 \delta f_2}{f_2^2} \\ \text{(e)} \quad \frac{d}{dx} (\delta y) &= \frac{d}{dx} (\epsilon \eta) = \epsilon \frac{d\eta}{dx} = \epsilon \eta' = \\ &\delta y' = \delta \left(\frac{dy}{dx} \right). \end{aligned}$$

Thus taking the variation of a functional and differentiating w.r.t. the independent variable x are commutative operations.

Result: The necessary condition for the functional I to attain an extremum is that its variation vanish i.e., $\delta I = 0$.

37.3 EULER'S EQUATION

A necessary condition for the integral

$$I = \int_{x_1}^{x_2} f(x, y, y') dx \quad (1)$$

to attain an extreme value is that the extremizing function $y(x)$ should satisfy

$$\boxed{\frac{\partial f}{\partial y} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) = 0} \quad (2)$$

for $x_1 \leq x \leq x_2$.

Note 1: The second order differential equation (2) is known as Euler-Lagrange or simply Euler's equation for the integral (1).

Note 2: The solutions (integral curves) of Euler's equation are known as *extremals* (or stationary functions) of the functional. Extremum for a functional can occur only on extremals.

Proof: Assume that the function $y = y(x)$, is twice-differentiable on $[x_1, x_2]$, satisfies the end (boundary) conditions $y(x_1) = y_1$ and $y(x_2) = y_2$ and extremizes (maximizes or minimizes) the integral I given by (1). To determine such a function $y(x)$, construct the class of *comparison functions* $Y(x)$ defined by

$$Y(x) = y(x) + \epsilon \eta(x) \quad (2)$$

on the interval $[x_1, x_2]$. For any function $\eta(x)$, $y(x)$ is a member of this class of functions $\{Y(x)\}$ for $\epsilon = 0$. Assume that

$$\eta(x_1) = \eta(x_2) = 0 \quad (3)$$

Differentiating (2),

$$Y'(x) = y'(x) + \epsilon \eta'(x) \quad (4)$$

Replacing y and y' in (1) Y and Y' from (2) and (4), we obtain the integral

$$I(\epsilon) = \int_{x_1}^{x_2} f(x, Y, Y') dx \quad (5)$$

which is a function of the parameter ϵ . Thus the problem of determining $y(x)$ reduces to finding the extremum of $I(\epsilon)$ at $\epsilon = 0$ which is obtained by solving $I'(\epsilon = 0) = 0$. For this, differentiate (5) w.r.t. ϵ , we get

$$\begin{aligned} \frac{dI}{d\epsilon} &= I'(\epsilon) = \int_{x_1}^{x_2} \left(\frac{\partial f}{\partial Y} \frac{\partial Y}{\partial \epsilon} + \frac{\partial f}{\partial Y'} \frac{\partial Y'}{\partial \epsilon} \right) dx \\ &= \int_{x_1}^{x_2} \left(\frac{\partial f}{\partial Y} \eta + \frac{\partial f}{\partial Y'} \eta' \right) dx \end{aligned}$$

putting $\epsilon = 0$,

$$I'(0) = \int_{x_1}^{x_2} \left(\frac{\partial f}{\partial y} \eta + \frac{\partial f}{\partial y'} \eta' \right) dx \quad (6)$$

because for $\epsilon = 0$, we have from (2) $Y = y$ and $Y' = y'$. Integrating the second integral in R.H.S. of (6) by parts, we have

$$I'(0) = \int_{x_1}^{x_2} \frac{\partial f}{\partial y} \eta + \left[\frac{\partial f}{\partial y'} \eta \right]_{x_1}^{x_2} - \int_{x_1}^{x_2} \eta \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) dx$$

Since by (3), $\eta(x_1) = \eta(x_2) = 0$, the second term vanishes and using $I'(0) = 0$, we get

$$I'(0) = \int_{x_1}^{x_2} \left[\frac{\partial f}{\partial y} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) \right] \eta dx = 0 \quad (7)$$

Since $\eta(x)$ is arbitrary, equation (7) holds good only when the integrand is zero

$$\text{i.e.,} \quad \boxed{\frac{\partial f}{\partial y} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) = 0} \quad (2)$$

Note: Equation (2) is not sufficient condition. Solution of (2) may be maximum or minimum or a horizontal inflexion. Thus $y(x)$ is known as extremizing function or extremal and the term extremum includes maximum or minimum or stationary value.

EQUIVALENT FORMS OF EULER'S EQUATION:

(I) Differentiating f , which is a function of x, y, y' , w.r.t. x , we get

$$\begin{aligned} \frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} \frac{dy}{dx} + \frac{\partial f}{\partial y'} \frac{dy'}{dx} \\ \frac{df}{dx} &= \frac{\partial f}{\partial x} + y' \frac{\partial f}{\partial y} + y'' \frac{\partial f}{\partial y'} \end{aligned} \quad (8)$$

Consider

$$\frac{d}{dx} \left(y' \frac{\partial f}{\partial y'} \right) = y' \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) + \frac{\partial f}{\partial y'} y'' \quad (9)$$

Subtracting (9) from (8), we have

$$\frac{df}{dx} - \frac{d}{dx} \left(y' \frac{\partial f}{\partial y'} \right) = \frac{\partial f}{\partial x} + y' \frac{\partial f}{\partial y} - y' \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right)$$

Rewriting this

$$\frac{d}{dx} \left\{ f - y' \frac{\partial f}{\partial y'} \right\} - \frac{\partial f}{\partial x} = y' \left\{ \frac{\partial f}{\partial y} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) \right\} \quad (10)$$

Since by Euler's Equation (2), the R.H.S. of (10) is zero, we get another form of Euler's equation

$$\boxed{\frac{d}{dx} \left\{ f - y' \frac{\partial f}{\partial y'} \right\} - \frac{\partial f}{\partial x} = 0} \quad (11)$$

(II) Since $\frac{\partial f}{\partial y'}$ is also function ϕ of x, y, y' say $\frac{\partial f}{\partial y'} = \phi(x, y, y')$. Differentiating w.r.t. x

$$\begin{aligned} \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) &= \frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y} \frac{dy}{dx} + \frac{\partial \phi}{\partial y'} \frac{dy'}{dx} \\ &= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y'} \right) + y' \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y'} \right) + y'' \frac{\partial}{\partial y'} \left(\frac{\partial f}{\partial y'} \right) \\ \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) &= \frac{\partial^2 f}{\partial x \partial y'} + y' \frac{\partial^2 f}{\partial y \partial y'} + y'' \frac{\partial^2 f}{\partial y'^2} \end{aligned} \quad (12)$$

Substituting (12) in the Euler's equation (2), we have

$$\boxed{\frac{\partial f}{\partial y} - \frac{\partial^2 f}{\partial x \partial y'} - y' \frac{\partial^2 f}{\partial y \partial y'} - y'' \frac{\partial^2 f}{\partial y'^2} = 0} \quad (13)$$

General case: the necessary condition for the occurrence of extremum of the general integral

$$\int_{x_1}^{x_2} f(x, y_1, y_2, \dots, y_n, y'_1, y'_2, \dots, y'_n) dx$$

involving n functions $y_1, y_2, \dots, y_n$, is given by the

37.4 — MATHEMATICAL METHODS

set of η Euler's equations

$$\frac{\partial f}{\partial y_i} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'_i} \right) = 0$$

for $i = 1, 2, 3, \dots, \eta$.

First integrals of the Euler-Lagrang's equation:

Degenerate cases: Euler's equation is readily integrable in the following cases:

Case (a): If f is independent of x , then $\frac{\partial f}{\partial x} = 0$ and equivalent form of Euler's Equation (11) reduces to

$$\frac{d}{dx} \left(f - y' \frac{\partial f}{\partial y'} \right) = 0$$

Integrating, we get the first integral of Euler's equation

$$f - y' \frac{\partial f}{\partial y'} = \text{constant} \quad (14)$$

Thus the extremizing function y is obtained as the solution of a first-order differential equation (14) involving y and y' only.

Case (b): If f is independent of y , then $\frac{\partial f}{\partial y} = 0$, and the Euler's Equation (2) reduces to

$$\frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) = 0$$

Integrating, we get the first integral of the Euler's equation as,

$$\frac{\partial f}{\partial y'} = \text{constant} \quad (15)$$

which is a first order differential equation involving y' and x only.

Case (c): If f is independent of x and y then the partial derivative $\frac{\partial f}{\partial y'}$ is independent of x and y and is therefore function of y' alone. Now (15) of case (b) $\frac{\partial f}{\partial y'} = \text{constant}$ has the solution.

$$y' = \text{constant} = c_1$$

Integrating, the extremizing function is a linear function of x given by

$$y = c_1 x + c_2$$

Case (d): If f is independent of y' , then $\frac{\partial f}{\partial y'} = 0$ and the Euler's Equation (2) reduces to

$$\frac{\partial f}{\partial y} = 0$$

Integrating, we get $f = f(x)$, i.e., function of x alone.

Geodesics: A geodesic on a surface is a curve on the surface along which the distance between any two points of the surface is a minimum.

37.4 STANDARD VARIATIONAL PROBLEMS

Shortest distance

Example 1: Find the shortest smooth plane curve joining two distinct points in the plane.

Fig. 37.2

Solution: Assume that the two distinct points be $P_1(x_1, y_1)$ and $P_2(x_2, y_2)$ lie in the XY -Plane. If $y = f(x)$ is the equation of any plane curve c in XY -Plane and passing through the points P_1 and P_2 , then the length L of curve c is given by

$$L[y(x)] = \int_{x_1}^{x_2} \sqrt{1 + (y')^2} dx \quad (1)$$

The variational problem is to find the plane curve whose length is shortest i.e., to determine the function $y(x)$ which minimizes the functional (1). The condition for extrema is the Euler's equation

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) = 0$$

Here $f = \sqrt{1 + y'^2}$ so $\frac{\partial f}{\partial y} = 0$, $\frac{\partial f}{\partial y'} = \frac{1}{2} \frac{2y'}{\sqrt{1 + y'^2}}$

Then

$$0 - \frac{d}{dx} \left(\frac{y'}{\sqrt{1 + y'^2}} \right) = 0$$

or $y' = k\sqrt{1 + y'^2}$ where $k = \text{constant}$

Squaring $y'^2 = k^2(1 + y'^2)$

$$\text{i.e., } y' = \sqrt{\frac{k^2}{1-k^2}} = m = \text{constant.}$$

Integrating, $y = mx + c$, where c is the constant of integration. Thus the straight line joining the two points P_1 and P_2 is the curve with shortest length (distance).

Brachistochrone (shortest time) problem

Example 2: Determine the plane curve down which a particle will slide without friction from the point $A(x_1, y_1)$ to $B(x_2, y_2)$ in the shortest time.

Fig. 37.3

Solution: Assume the positive direction of the y -axis is vertically downward and let $x_1 < x_2$. Let $P(x, y)$ be the position of the particle at any time t , on the curve c . Since energy is conserved, the speed v of the particle sliding along any curve is given by

$$v = \sqrt{2g(y - y^*)}$$

where $y^* = y_1 - \left(\frac{v_1^2}{2g}\right)$. Here g is acceleration due to gravity, v_1 is the initial speed. Choose the origin at A so that $x_1 = 0$, $y_1 = 0$ and assume that $v_1 = 0$. Then

$$\frac{ds}{dt} = v = \sqrt{2gy}$$

Integrating this, we get the time taken by the particle moving under gravity (and neglecting friction along the curve and neglecting resistance of the medium) from $A(0, 0)$ to $B(x_2, y_2)$ is

$$t[y(x)] = \int \frac{ds}{\sqrt{2gy}} = \frac{1}{\sqrt{2g}} \int_{x=0}^{x=x_2} \frac{\sqrt{1+y'^2}}{\sqrt{y}} dx \quad (1)$$

subject to the boundary conditions $y(0) = 0$ and $y(x_2) = y_2$. Integral (1) is convergent although it is improper. Here

$$f = \frac{\sqrt{1+y'^2}}{\sqrt{y}}$$

which is independent of x . Now

$$\frac{\partial f}{\partial y'} = \frac{1}{\sqrt{y}} \cdot \frac{1}{\sqrt{1+y'^2}} \cdot \frac{1}{2} \cdot 2y' = \frac{y'}{\sqrt{y}\sqrt{1+y'^2}}$$

The Euler's equation

$$\frac{d}{dx} \left[f - y' \frac{\partial f}{\partial y'} \right] = 0$$

reduces to

$$\frac{d}{dx} \left[\frac{\sqrt{1+y'^2}}{\sqrt{y}} - \frac{y'^2}{\sqrt{y}\sqrt{1+y'^2}} \right] = 0$$

Integrating

$$\frac{\sqrt{1+y'^2}\sqrt{1+y'^2} - y'^2}{\sqrt{y}\sqrt{1+y'^2}} = k_1 = \text{constant}$$

$$\text{or } y(1+y'^2) = k_2 \quad (1)$$

where $k_2 = \left(\frac{1}{k_1}\right)^2$, put $y' = \cot \theta$ where θ is a parameter. Then from (1)

$$y = \frac{k_2}{1+y'^2} = \frac{k_2}{1+\cot^2 \theta} = k_2 \sin^2 \theta = \frac{k_2}{2}(1 - \cos 2\theta) \quad (2)$$

Now

$$\begin{aligned} dx &= \frac{dy}{y'} = \frac{\frac{k_2}{2}(-2 \sin 2\theta)d\theta}{\cot \theta} \\ &= \frac{k_2 2 \cdot \sin \theta \cdot \cos \theta d\theta}{\cot \theta} = 2k_2 \sin^2 \theta d\theta \\ dx &= k_2 \cdot (1 - \cos 2\theta)d\theta. \end{aligned}$$

Integrating, $x = k_2 \left(\theta - \frac{\sin 2\theta}{2}\right) + k_3$, where k_3 is constant of integration. So

$$x - k_3 = \frac{k_2}{2}(2\theta - \sin 2\theta) \quad (2)$$

Since $y = 0$ at $x = 0$, we have $k_3 = 0$. Put $2\theta = \phi$ in (1) and (2), then

$$x = \frac{k_2}{2}(\phi - \sin \phi), \quad y = \frac{k_2}{2}(1 - \cos 2\phi) \quad (3)$$

37.6 — MATHEMATICAL METHODS

Equation (3) represents a one parameter family of cycloids with $\frac{k_2}{2}$ as the radius of the rolling circle. Using the condition that the curve (cycloid) passes through $B(x_2, y_2)$, the value of the constant k_2 can be determined.

Note: A curve having this property of shortest time is known as “brachistochrone” with Greek words ‘brachistos’ meaning shortest and ‘chronos’ meaning time. In 1696 John Bernoulli advanced this ‘brachistochrone’ problem, although it was also studied by Leibnitz, Newton and L’Hospital.

Minimal surface area

Example 3: Find the curve c passing through two given points $A(x_1, y_1)$ and $B(x_2, y_2)$ such that the rotation of the curve c about x-axis generates a surface of revolution having minimum surface area.

Fig. 37.4

Solution: The surface area S generated by revolving the curve c defined by $y(x)$ about x-axis is

$$S[y(x)] = \int_A^B 2\pi y \, ds = \int_{x=x_1}^{x_2} 2\pi y \sqrt{1 + y'^2} \, dx \quad (1)$$

To find the extremal $y(x)$ which minimizes (1). Here $f = y\sqrt{1 + y'^2}$ which is independent of x . The Euler's equation is

$$\frac{d}{dx} \left(f - y' \frac{\partial f}{\partial y'} \right) = 0 \quad \text{or} \quad f - y' \frac{\partial f}{\partial y'} = \text{constant} = c_1$$

Substituting f and $\frac{\partial f}{\partial y'}$, we have

$$y\sqrt{1 + y'^2} - y' \frac{y}{2} \frac{1}{\sqrt{1 + y'^2}} \cdot 2y' = c_1$$

$$\frac{y\{(1 + y'^2) - y'^2\}}{\sqrt{1 + y'^2}} = \frac{y}{\sqrt{1 + y'^2}} = c_1 \quad (2)$$

Put $y' = \sinh t$, then from (2)

$$\frac{y}{\sqrt{1 + \sinh^2 t}} = \frac{y}{\cosh t} = c_1 \quad \text{or} \quad y = c_1 \cosh t \quad (3)$$

$$\text{So } dx = \frac{dy}{y'} = \frac{c_1 \sinh t \, dt}{\sinh t} = c_1 \, dt$$

$$\text{Integrating } x = c_1 t + c_2 \quad (4)$$

where c_2 is the constant of integration. Eliminating ‘ t ’ between (3) and (4)

$$t = \frac{x - c_2}{c_1}$$

$$\text{therefore } y = c_1 \cosh t = c_1 \cosh \left(\frac{x - c_2}{c_1} \right) \quad (5)$$

Equation (5) represents a two parameter family of catenaries. The two constants C_1 and C_2 are determined using the end (boundary) conditions $y(x_1) = y_1$ and $y(x_2) = y_2$.

Solid of revolution with least resistance

Example 4: Determine the shape of solid of revolution moving in a flow of gas with least resistance.

Fig. 37.5

Solution: The total resistance experienced by the body is

$$F[y(x)] = 4\pi\rho v^2 \int_0^L y y'^3 \, dx$$

with boundary conditions $y(0) = 0$, $y(L) = R$. Here ρ is the density, v is the velocity of gas relative to solid. Here $f = yy'^3$ is independent of x . The Euler's equation is

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) = y'^3 - \frac{d}{dx} (3yy'^2) = 0 \quad (1)$$

Multiplying (1) by y' , we get

$$\frac{d}{dx} (yy'^3) = 0$$

Integrating

$$yy'^3 = c_1^3 \quad \text{or} \quad y' = \frac{c_1}{y^{\frac{1}{3}}}$$

Integrating $y^{\frac{1}{3}} dy = c_1 dx$ yields

$$\frac{y^{\frac{4}{3}}}{\frac{4}{3}} = c_1 x + c_2$$

$$\text{or} \quad y(x) = (c_3 x + c_4)^{\frac{3}{4}} \quad (2)$$

Using boundary conditions

$$0 = y(0) = 0 + c_4 \quad \therefore c_4 = 0$$

$$R = y(L) = (c_3 L)^{\frac{3}{4}} \quad \therefore c_3 = \frac{R^{\frac{4}{3}}}{L}$$

The the required function $y(x)$ is given by

$$y(x) = R \left(\frac{x}{L} \right)^{\frac{3}{4}}.$$

Geodesics

Example 5: Find the geodesics on a sphere of radius ' a '.

Solution: In spherical coordinates r, θ, ϕ , the differential of arc length on a sphere is given by

$$(ds)^2 = (dr)^2 + (r d\theta)^2 + (r \sin \theta d\phi)^2$$

Since $r = a = \text{constant}$, $dr = 0$. So

$$\left(\frac{ds}{d\theta} \right)^2 = a^2 + a^2 \sin^2 \theta \left(\frac{d\phi}{d\theta} \right)^2$$

Integrating w.r.t. θ between θ_1 and θ_2 ,

$$s = \int_{\theta_1}^{\theta_2} a \sqrt{1 + \sin^2 \theta \left(\frac{d\phi}{d\theta} \right)^2} d\theta$$

Here $f = a \sqrt{1 + \sin^2 \theta \cdot \left(\frac{d\phi}{d\theta} \right)^2}$ is independent of ϕ , but is a function of θ and $\frac{d\phi}{d\theta}$. Denoting $\frac{d\phi}{d\theta} = \phi'$, the Euler's equation reduces to

$$\frac{d}{d\theta} \left(\frac{\partial f}{\partial \phi'} \right) = 0 \quad \text{or} \quad \frac{\partial f}{\partial \phi'} = \text{constant}.$$

$$\text{i.e., } a \cdot \frac{1}{\sqrt{1 + \sin^2 \theta \phi'^2}} \cdot \frac{1}{2} \cdot 2 \cdot \sin^2 \theta \cdot \phi' = k = \text{constant}$$

$$\text{Squaring } a^2 \sin^4 \theta \cdot \phi'^2 = k^2 (1 + \sin^2 \theta \cdot \phi'^2)$$

$$\text{or } \frac{d\phi}{d\theta} = \phi' = \frac{k}{\sin \theta \cdot \sqrt{\sin^2 \theta - k^2}} = \frac{k \operatorname{cosec}^2 \theta}{\sqrt{1 - c^2 \operatorname{cosec}^2 \theta}}$$

Integrating, we get

$$\phi(\theta) = \int \frac{k \operatorname{cosec}^2 \theta d\theta}{\sqrt{(1 - k^2) - (k \cot \theta)^2}} + c_2$$

$$\phi(\theta) = \cos^{-1} \left\{ \frac{k \cot \theta}{\sqrt{1 - k^2}} \right\} + c_2$$

where c_2 is constant of integration. Rewriting

$$\frac{k \cot \theta}{\sqrt{1 - k^2}} = \cos(\phi - c_2) = \cos \phi \cdot \cos c_2 + \sin \phi \cdot \sin c_2$$

$$\text{or } \cot \theta = A \cos \phi + B \sin \phi$$

$$\text{where } A = \frac{(\cos c_2)(\sqrt{1 - k^2})}{k},$$

$$B = (\sin c_2) \frac{(\sqrt{1 - k^2})}{k}$$

Multiplying by $a \sin \theta$, we have

$$a \cos \theta = A \cdot a \cdot \sin \theta \cdot \cos \phi + B \cdot a \cdot \sin \theta \cdot \sin \phi$$

Since $r = a$, the spherical coordinates are $x = a \sin \theta \cos \phi$, $y = a \sin \theta \sin \phi$, $z = a \cos \theta$, so

$$z = Ax + By$$

which is the equation of plane, passing through origin $(0, 0, 0)$ (since no constant term) the centre of sphere. This plane cuts the sphere along a great circle. Hence the great circle is the geodesic on the sphere.

WORKED OUT EXAMPLES

Variational problems.

f is dependent on x, y, y'

Example 1: Find a complete solution of the Euler-Lagrange equation for

$$\int_{x_1}^{x_2} [y^2 - (y')^2 - 2y \cosh x] dx \quad (1)$$

Solution: Here $f(x, y, y') = y^2 - (y')^2 - 2y \cosh x$, which is a function of x, y, y' . The Euler-Lagrange equation is

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) = 0 \quad (2)$$

Differentiating (1) partially w.r.t. y and y' , we get

$$\frac{\partial f}{\partial y} = 2y - 2 \cosh x \quad (3)$$

$$\frac{\partial f}{\partial y'} = -2y' \quad (4)$$

Substituting (3) and (4) in (2), we have

$$2y - 2 \cosh x - \frac{d}{dx}(-2y') = 0$$

$$y'' + y = \cosh x \quad (5)$$

The complimentary function of (5) is

$$y_c = c_1 \cos x + c_2 \sin x$$

and particular integral of (5) is

$$y = \frac{1}{2} \cosh x.$$

Thus the complete solution Euler-Lagrange Equation (5) is

$$y(x) = c_1 \cos x + c_2 \sin x + \frac{1}{2} \cosh x.$$

f is independent of x

Example 1: Find the extremals of the functional

$$I[y(x)] = \int_{x_1}^{x_2} \frac{(1+y^2)}{y^2} dx$$

Solution: Here $f = \frac{1+y^2}{y^2}$ which is independent of x . So the Euler's equation becomes

$$\frac{d}{dx} \left(f - y' \frac{\partial f}{\partial y'} \right) = 0 \quad (1)$$

$$\text{Here } \frac{\partial f}{\partial y'} = \frac{\partial}{\partial y'} \left(\frac{1+y^2}{y^2} \right) = -\frac{2(1+y^2)}{y^3} \quad (2)$$

Substituting (2) in (1), we have

$$\frac{d}{dx} \left(\frac{1+y^2}{y^2} - y' \frac{(-2)(1+y^2)}{y^3} \right) = 3 \frac{d}{dx} \left(\frac{1+y^2}{y^2} \right) = 0$$

$$\frac{y'^2(2yy') - (1+y^2)2y'y''}{y^4} = 0$$

$$\text{or } (1+y^2)y'' - yy'^2 = 0 \quad (3)$$

Put $y' = p$, then $y'' = \frac{dp}{dx} y' = \frac{dp}{dx} p = \frac{dp}{dy} \frac{dy}{dx} = y' \frac{dp}{dy} = p \frac{dp}{dy}$. Putting these values in (3),

$$(1+y^2)p \frac{dp}{dy} - yp^2 = 0 \quad \text{or} \quad \frac{dp}{dy} = \frac{py}{1+y^2}$$

$$\text{Integrating } \frac{dp}{p} = \frac{y dy}{1+y^2} = \frac{1}{2} \frac{d(1+y^2)}{(1+y^2)}$$

$$p^2 = c_1^2(1+y^2).$$

$$\text{so } p = c_1 \sqrt{(1+y^2)} \quad \text{or} \quad \frac{dy}{dx} = c \sqrt{1+y^2}$$

$$\text{Integrating } \frac{dy}{\sqrt{1+y^2}} = c_1 dx \quad \text{we get}$$

$$\sinh^{-1} y = c_1 x + c_2$$

Thus the required extremal function is

$$y(x) = \sinh(c_1 x + c_2)$$

where c_1 and c_2 are two arbitrary constant.

f is independent of y

Example 3: If the rate of motion $v = \frac{ds}{dt}$ is equal to x then the time t spent on translation along the curve $y = y(x)$ from one point $P_1(x_1, y_1)$ to another point $P_2(x_2, y_2)$ is a functional. Find the extremal of this functional, when $P(1, 0)$ and $P_2(2, 1)$.

$$\text{Solution: Given } \frac{ds}{dt} = x \quad \text{or} \quad \frac{ds}{x} = dt.$$

$$\text{But } ds = \sqrt{1+y'^2} dx \quad \text{so} \quad \sqrt{1+y'^2} \frac{dx}{x} = dt.$$

Integrating from P_1 to P_2

$$\int_{x_1}^{x_2} dt = \int_{x_1}^{x_2} \frac{\sqrt{1+y'^2}}{x} dx. \text{ The functional is}$$

$$t[y(x)] = \int_{x_1}^{x_2} \frac{\sqrt{1+y'^2}}{x} dx$$

Here $f = \frac{\sqrt{1+y'^2}}{x}$ which is independent of y . Euler's equation is $\frac{d}{dx} \left\{ \frac{\partial f}{\partial y'} \right\} = 0$

$$\frac{d}{dx} \left\{ \frac{1}{x} \cdot \frac{1}{2} \cdot \frac{1}{\sqrt{1+y'^2}} \cdot 2y' \right\} = 0$$

$$\frac{x\sqrt{(1+y'^2)y''} - y' \left\{ (1+y'^2) + xy'y'' \right\}}{x^2(1+y'^2)^{\frac{3}{2}}} = 0$$

$$\text{or } xy'' - y'(1+y'^2) = 0.$$

Put $y' = u$, then $x \frac{du}{dx} - u(1+u^2) = 0$

$$\frac{du}{u(1+u^2)} = \frac{du}{u} - \frac{udu}{1+u^2} = \frac{dx}{x}$$

Integrating $\left(\frac{u}{x}\right)^2 = c_1^2(1+u^2)$

$$y'^2 = c_1^2 x^2 (1+y'^2)$$

$$\text{or } y' = c_1 x \sqrt{(1+y'^2)}.$$

Put $y' = \tan v$, then $\sqrt{1+y'^2} = \sqrt{1+\tan^2 v} = \sec v$

$$\text{so } x = \frac{y'}{c_1(1+y'^2)} = \frac{1}{c_1} \frac{\tan v}{\sec v} = \frac{1}{c_1} \sin v \quad (1)$$

$$\text{and } dx = \frac{1}{c_1} \cos v dv$$

$$\text{Now } \frac{dy}{dx} = y' = \tan v$$

$$dy = \tan v dx = \tan v \cdot \frac{1}{c_1} \cdot \cos v dv =$$

$$= \frac{1}{c_1} \sin v dv$$

Integrating $y = -c_2 \cos v + c_3$ (2)

where $c_2 = \frac{1}{c_1}$ or $y - c_3 = -c_2 \cos v$ (3)

Squaring (1) and (3) and adding

$$\begin{aligned} x^2 + (y - c_3)^2 &= (c_2 \sin v)^2 + (-c_2 \cos v)^2 \\ &= c_2^2 = c_4 \end{aligned} \quad (4)$$

Equation (4) represents a two-parameter family of circles. If (4) passes through $P_1(1, 0)$ Then $y(0) = 1$. Then (4) becomes

$$1 + (0 - c_3)^2 = c_4 \quad \text{or} \quad 1 + c_3^2 = c_4$$

If (4) passes through $P_2(2, 1)$ then $y(2) = 1$. So from (4),

$$4 + (1 - c_3)^2 = c_4 = 1 + c_3^2 \quad \therefore c_3 = -2$$

and $c_4 = 5$. Thus the required extremal satisfying the end points P_1 and P_2 is

$$x^2 + (y + 2)^2 = 5.$$

Invalid variational problem

Example 4: Test for an extremum of the functional

$$I[y(x)] = \int_0^1 (xy + y^2 - 2y^2 y') dx, \text{ with } y(0)=1, y(1)=2.$$

Solution: Here $f = xy + y^2 - 2y^2 y'$. Differentiating partially w.r.t. y and y' , we have

$$\frac{\partial f}{\partial y} = x + 2y - 4yy' \quad \text{and} \quad \frac{\partial f}{\partial y'} = -2y^2.$$

Substituting these in the Euler's equation

$$\begin{aligned} \frac{\partial f}{\partial y} - \frac{d}{dx} \left(\frac{\partial f}{\partial y'} \right) &= (x + 2y - 4yy') - \frac{d}{dx} (-2y^2) = 0 \\ &= x + 2y - 4yy' + 4yy' = 0 \end{aligned}$$

$$\text{or } x + 2y = 0 \quad \text{i.e., } y = -\frac{x}{2}.$$

However, this function $y = f(x)$ does not satisfy the given boundary conditions $y(0) = 1$ and $y(1) = 2$ i.e., $1 = y(0) \neq 0$ and $2 = y(1) \neq -\frac{1}{2}$. Thus an extremum can not be achieved on the class of continuous functions.

Geodesics

Example 5: Determine the equation of the geodesics on a right circular cylinder of radius ' a '.

37.10 — MATHEMATICAL METHODS

Solution: In cylindrical coordinates (r, θ, z) , the differential of arc ds on a cylinder is given by

$$(ds)^2 = (dr)^2 + (rd\theta)^2 + (dz)^2$$

Since radius $r = a = \text{constant}$, $dr = 0$. Then

$$\left(\frac{ds}{d\theta}\right)^2 = a^2 + \left(\frac{dz}{d\theta}\right)^2 \quad \text{or} \quad \frac{ds}{d\theta} = \sqrt{a^2 + \left(\frac{dz}{d\theta}\right)^2}$$

Integrating

$$s = \int_{\theta_1}^{\theta_2} \sqrt{a^2 + \left(\frac{dz}{d\theta}\right)^2} d\theta.$$

Since geodesic is curve with minimum length, we have to find minimum of s . Here $f = \sqrt{a^2 + \left(\frac{dz}{d\theta}\right)^2}$ which is independent of the variable z . Now the Euler's equation is

$$\frac{d}{d\theta} \left(\frac{\partial f}{\partial z'} \right) = 0 \quad \text{or} \quad \frac{\partial f}{\partial z'} = \text{constant} = k$$

$$\text{so} \quad \frac{\partial f}{\partial z'} = \left\{ \sqrt{a^2 + \left(\frac{dz}{d\theta}\right)^2} \right\} = \frac{1}{2} \frac{2 \cdot z'}{\sqrt{a^2 + z'^2}} = k$$

$$\text{or} \quad z'^2 = k^2(a^2 + z'^2)$$

$$z'^2 = \frac{k^2 a^2}{1 - k^2}$$

$$\text{i.e.,} \quad z' = \frac{dz}{d\theta} = \frac{ka}{\sqrt{1 - k^2}}$$

Integrating $z(\theta) = \frac{ka\theta}{\sqrt{1 - k^2}} + c_1$. Thus the equation of the geodesics which is a circular helix is

$$z = k^* \theta + c_1 \quad \text{and} \quad r = a$$

$$\text{where} \quad k^* = \frac{ka}{\sqrt{1 - k^2}}.$$

Example 6: Find the geodesics on a right circular cone of semivertical angle α .

Solution: In spherical coordinates (r, θ, ϕ) the differential of an arc ds on a right circular cone is given by

$$(ds)^2 = (dr)^2 + (rd\theta)^2 + (r \sin \alpha d\phi)^2.$$

With vertex of the cone at the origin and z -axis as the axis of the cone, the polar equation of cone is $\theta = \alpha = \text{constant}$ so $d\theta = 0$.

Then

$$\left(\frac{ds}{d\phi}\right)^2 = \left(\frac{dr}{d\phi}\right)^2 + r^2 \sin^2 \alpha$$

Integrating w.r.t., ϕ

$$s = \int_{\phi_1}^{\phi_2} \sqrt{\left(\frac{dr}{d\phi}\right)^2 + r^2 \sin^2 \alpha} d\phi$$

The arc length s of the curve is to be minimized. Here

$f = \sqrt{\left(\frac{dr}{d\phi}\right)^2 + r^2 \sin^2 \alpha}$ is independent of ϕ . Then the integral of Euler's equation is

$$f - r' \frac{\partial f}{\partial r'} = \text{constant} = k$$

$$\text{or} \quad \sqrt{r'^2 + r^2 \sin^2 \alpha} - r' \cdot \frac{1}{2} \frac{2r'}{\sqrt{r'^2 + r^2 \sin^2 \alpha}} = k$$

$$r'^2 + r^2 \sin^2 \alpha - r'^2 = k \sqrt{r'^2 + r^2 \sin^2 \alpha}$$

squaring, $r^4 \sin^4 \alpha = k^2(r'^2 + r^2 \sin^2 \alpha)$

$$r'^2 = \frac{r^2 \sin^2 \alpha (r^2 \sin^2 \alpha - k^2)}{k^2}$$

$$\text{or} \quad \frac{dr}{d\phi} = \frac{r \sin \alpha}{k} \cdot \sqrt{r^2 \sin^2 \alpha - k^2}$$

$$\text{i.e.,} \quad \frac{kdr}{r \sqrt{r^2 \sin^2 \alpha - k^2}} = \sin \alpha \cdot d\phi.$$

$$\text{Integrating} \quad k \cdot \int \frac{dr}{r \sqrt{r^2 \sin^2 \alpha - k^2}} = \sin \alpha \cdot \phi + c_1$$

where c_1 is the constant of integration. Introducing $r = \frac{1}{t}$, $dr = -\frac{1}{t^2} dt$, $t = \frac{1}{r}$, the L.H.S. integral transforms to

$$k \cdot \int \cdot t \frac{1}{\sqrt{\frac{\sin^2 \alpha}{t^2} - k^2}} \cdot \left(-\frac{dt}{t^2}\right) = -k \int \frac{dt}{\sqrt{\sin^2 \alpha - k^2 t^2}} = \cos^{-1} \left(\frac{kt}{\sin \alpha} \right).$$

$$\text{Then} \quad \cos^{-1} \left(\frac{kt}{\sin \alpha} \right) = \phi \sin \alpha + c_1$$

$$\frac{kt}{\sin \alpha} = \cos(\phi \sin \alpha + c_1)$$

$$\text{Thus} \quad \frac{k}{r \sin \alpha} = \cos(\phi \sin \alpha + c_1)$$

and $\theta = \alpha$ are the equations of the geodesics.

EXERCISE
Variational problems

1. Test for extremum of the functional

$$I[y(x)] = \int_0^{\frac{\pi}{2}} (y'^2 - y^2) dx, y(0) = 0, y\left(\frac{\pi}{2}\right) = 1.$$

Hint: Euler's Equation (EE): $y'' + y = 0$, $y = c_1 \cos x + c_2 \sin x$ using B.C, $c_1 = 0$, $c_2 = 1$

Ans. $y = \sin x$

Find the extremal of the following functionals

2. $\int_{x_1}^{x_2} (y^2 + y'^2 - 2y \sin x) dx$

Hint: EE: $2y - 2 \sin x - 2y'' = 0$

Ans. $y = c_1 e^x + c_2 e^{-x} + \frac{\sin x}{2}$

3. $\int_0^1 (y'^2 + 12xy) dx, y(0) = 0, y(1) = 1.$

Hint: EE: $y'' = 6x$, $y = x^3 + c_1 x + C_2$, $C = 0$, $c_2 = 0$

Ans. $y = x^3$

4. $\int_0^{\frac{\pi}{2}} (y'^2 - y^2 + 2xy) dy, y(0) = 0, y\left(\frac{\pi}{2}\right) = 0$

Hint: EE: $y'' + y = x$, $y = c_1 \cos x + c_2 \sin x + x$

Ans. $y = x - \frac{\pi}{2} \sin x$

5. $\int_{x_1}^{x_2} (y^2 + 2xyy') dx, y(x_1) = y_1, y(x_2) = y_2$

Hint: EE: $2y + 2xy' - 2(xy' + y) = 0$ i.e., $0 = 0$

Ans. Invalid problem

6. $\int_1^2 \frac{x^3}{y'^2} dx, y(1) = 1, y(2) = 4$

Ans. $y = x^2$

7. $\int_2^3 \frac{y'^2}{x^3} dx, y(2) = 1, y(3) = 16$

Hint: EE: $\frac{y''}{y'} = \frac{3}{x}$, $y' = cx^3$, $y = c_1 x^4 + c_2$

Ans. $y = \frac{3}{13} x^4 - \frac{35}{13}$

8. $\int_{x_0}^{x_1} (y^2 + y'^2 + 2ye^x) dx$

Ans. $y = Ae^x + Be^{-x} + \frac{1}{2}xe^x$

9. $\int_0^{\pi} (4y \cos x - y^2 + y'^2) dx, y(0) = 0, y(\pi) = 0$

Hint: EE: $y'' + y = 2 \cos x$, $y = c_1 \cos x + c_2 \sin x + x \sin x$, $c_1 = 0$, $c_2 = \text{arbitrary}$

Ans. $y = (C + x) \sin x$.

37.5 ISOPERIMETRIC PROBLEMS

In calculus, in problems of extrema with constraints it is required to find the maximum or minimum of a function of several variables $g(x_1, x_2, \dots, x_n)$ where the variables $x_1, x_2, \dots, x_n$ are connected by some given relation or condition known as a constraint.

The variational problems considered so far find the extremum of a functional in which the argument functions could be chosen arbitrarily except for possible end (boundary) conditions. However, the class of variational problems with subsidiary conditions or constraints imposed on the argument functions, apart from the end conditions, are branded as isoperimetric problems. In the original isoperimetric ("iso" for same, "perimetric" for perimeter) problem it is required to find a closed curve of given length which enclose maximum area. It is known even in ancient Greece that the solution to this problem is circle. This is an example of the extrema of integrals under constraint consists of maximizing the area subject to the constraint (condition) that the length of the curve is fixed.

The simplest isoperimetric problem consists of finding a function $f(x)$ which extremizes the functional

$$I[y(x)] = \int_{x_1}^{x_2} f(x, y, y') dx \quad (1)$$

subject to the constraint (condition) that the second integral

$$J[y(x)] = \int_{x_1}^{x_2} g(x, y, y') dx \quad (2)$$

assumes a given prescribed value and satisfying the prescribed end conditions $y(x_1) = y_1$ and $y(x_2) = y_2$. To solve this problem, use the method of Lagrange's multipliers and form a new function

$$H(x, y, y') = f(x, y, y') + \lambda g(x, y, y') \quad (3)$$

where λ is an arbitrary constant known as the Lagrange multiplier. Now the problem is to find the extremal of the new functional,

37.12 — MATHEMATICAL METHODS

$I^*[y(x)] = \int_{x_1}^{x_2} H(x, y, y')dx$, subject to no constraints (except the boundary conditions). Then the modified Euler's equation is given by

$$\frac{\partial H}{\partial y} - \frac{d}{dx} \left(\frac{\partial H}{\partial y'} \right) = 0 \quad (4)$$

The complete solution of the second order Equation (4) contains, in general, two constants of integration say c_1, c_2 and the unknown Lagrange multiplier λ . These 3 constants c_1, c_2, λ will be determined using the two end conditions $y(x_1) = y_1, y(x_2) = y_2$ and given constraint (2).

Corollary: Parametric form: To find the extremal of the functional

$$I = \int_{t_1}^{t_2} f(x, y, \dot{x}, \dot{y}, t) dt$$

subject to the constraint

$$J = \int_{t_1}^{t_2} g(x, y, \dot{x}, \dot{y}, t) dt = \text{constant}$$

solve the system of two Euler equations given by

$$\frac{\partial H}{\partial x} - \frac{d}{dt} \left(\frac{\partial H}{\partial \dot{x}} \right) = 0 \quad \text{and} \quad \frac{\partial H}{\partial y} - \frac{d}{dt} \left(\frac{\partial H}{\partial \dot{y}} \right) = 0$$

resulting in the solution $x = x(t), y = y(t)$, which is the parametric representation of the required function $y = f(x)$ which is obtained by elimination of t . Here $\dot{x} = \frac{dx}{dt}$ and $\dot{y} = \frac{dy}{dt}$ and

$$H(x, y, \dot{x}, \dot{y}, t) = f(x, y, \dot{x}, \dot{y}, t) + \lambda g(x, y, \dot{x}, \dot{y}, t)$$

The two arbitrary constants c_1, c_2 and λ are determined using the end conditions and the constraint.

37.6 STANDARD ISOPERIMETRIC PROBLEMS

Circle

Example 1: Isoperimetric problem is to determine a closed curve C of given (fixed) length (perimeter) which encloses maximum area.

Solution: Let the parametric equation of the curve C be

$$x = x(t), \quad y = y(t) \quad (1)$$

where t is the parameter. The area enclosed by curve C is given by the integral

$$I = \frac{1}{2} \int_{t_1}^{t_2} (x\dot{y} - \dot{x}y) dt \quad (2)$$

where $\dot{x} = \frac{dx}{dt}, \dot{y} = \frac{dy}{dt}$. We have $x(t_1) = x(t_2) = x_0$ and $y(t_1) = y(t_2) = y_0$, since the curve is closed. Now the total length of the curve C is given by

$$J = \int_{t_1}^{t_2} \sqrt{\dot{x}^2 + \dot{y}^2} dt \quad (3)$$

$$\text{Form} \quad H = \frac{1}{2} (x\dot{y} - \dot{x}y) + \lambda \sqrt{\dot{x}^2 + \dot{y}^2} \quad (4)$$

Here λ is the unknown Lagrangian multiplier. Problem is to find a curve with given perimeter for which area (2) is maximum. Euler equations are

$$\frac{\partial H}{\partial x} - \frac{d}{dt} \left(\frac{\partial H}{\partial \dot{x}} \right) = 0 \quad (5)$$

$$\text{and} \quad \frac{\partial H}{\partial y} - \frac{d}{dt} \left(\frac{\partial H}{\partial \dot{y}} \right) = 0 \quad (6)$$

Differentiating H in (4) w.r.t. $x, \dot{x}, y, \dot{y}$ and substituting them in (5) and (6), we get

$$\frac{1}{2} \dot{y} - \frac{d}{dt} \left(-\frac{1}{2} y + \frac{\lambda \dot{x}}{\sqrt{\dot{x}^2 + \dot{y}^2}} \right) = 0 \quad (7)$$

$$-\frac{1}{2} \dot{x} - \frac{d}{dt} \left(\frac{1}{2} x + \frac{\lambda \dot{y}}{\sqrt{\dot{x}^2 + \dot{y}^2}} \right) = 0 \quad (8)$$

Integrating (7) and (8) w.r.t. ' t ', we get

$$y - \frac{\lambda \dot{x}}{\sqrt{\dot{x}^2 + \dot{y}^2}} = c_1 \quad (9)$$

$$\text{and} \quad x + \frac{\lambda \dot{y}}{\sqrt{\dot{x}^2 + \dot{y}^2}} = c_2 \quad (10)$$

where c_1 and c_2 are arbitrary constants. From (9) and (10) squaring $(y - c_1)$ and $(x - c_2)$ and adding, we get

$$\begin{aligned} (x - c_2)^2 + (y - c_1)^2 &= \left(\frac{-\lambda \dot{y}}{\sqrt{\dot{x}^2 + \dot{y}^2}} \right)^2 + \left(\frac{\lambda \dot{x}}{\sqrt{\dot{x}^2 + \dot{y}^2}} \right)^2 \\ &= \lambda^2 \frac{(\dot{x}^2 + \dot{y}^2)}{(\dot{x}^2 + \dot{y}^2)} = \lambda^2 \end{aligned}$$

$$\text{i.e., } (x - c_2)^2 + (y - c_1)^2 = \lambda^2$$

which is the equation of circle. Thus we have obtained the well-known result that the closed curve of given perimeter for which the enclosed area is a maximum is a circle.

Catenary

Example 2: Determine the shape an absolutely flexible, inextensible homogeneous and heavy rope of given length L suspended at the points A and B

Fig. 37.6

Solution: The rope in equilibrium take a shape such that its centre of gravity occupies the lowest position. Thus to find minimum of y-coordinate of the centre of gravity of the string given by

$$I[y(x)] = \frac{\int_{x_1}^{x_2} y \sqrt{1 + y'^2} dx}{\int_{x_1}^{x_2} \sqrt{1 + y'^2} dx} \quad (1)$$

subject to the constraint

$$J[y(x)] = \int_{x_1}^{x_2} \sqrt{1 + y'^2} dx = L = \text{constant} \quad (2)$$

Thus to minimize the numerator in R.H.S. of (1) subject to (2). Form

$$H = y \sqrt{1 + y'^2} + \lambda \sqrt{1 + y'^2} = (y + \lambda) \sqrt{1 + y'^2} \quad (3)$$

where λ is Lagrangian multiplier. Here H is independent of x . So the Euler equation is

$$H - y' \frac{\partial H}{\partial y'} = \text{constant} = k_1$$

$$\text{i.e., } (y + \lambda) \sqrt{1 + y'^2} - y' (y + \lambda) \cdot \frac{1}{2} \frac{2y'}{\sqrt{1 + y'^2}} = k_1$$

$$(y + \lambda) \left\{ (1 + y'^2) - y'^2 \right\} = k_1 (\sqrt{1 + y'^2})$$

$$\text{or } y + \lambda = k_1 \sqrt{1 + y'^2} \quad (4)$$

Put $y' = \sinh t$, where t is a parameter, in (4)

$$\text{Then } y + \lambda = k_1 \sqrt{1 + \sinh^2 t} = k_1 \cosh t \quad (5)$$

$$\text{Now } dx = \frac{dy}{y'} = \frac{k_1 \sinh t dt}{\sinh t} = k_1 dt$$

$$\text{Integrating } x = k_1 t + k_2 \quad (6)$$

Eliminating ' t ' between (5) and (6), we have

$$y + \lambda = k_1 \cosh t = k_1 \cosh \left(\frac{x - k_2}{k_1} \right) \quad (7)$$

Equation (7) is the desired curve which is a catenary.

Note: The three unknowns λ, k_1, k_2 will be determined from the two boundary conditions (curve passing through A and B) and the constraint (2).

WORKED OUT EXAMPLES

Example 1: Find the extremal of the function $I[y(x)] = \int_0^\pi (y'^2 - y^2) dx$ with boundary conditions $y(0) = 0, y(\pi) = 1$ and subject to the constraint $\int_0^\pi y dx = 1$.

Solution: Here $f = y'^2 - y^2$ and $g = y$. So choose $H = f + \lambda g = (y'^2 - y^2) + \lambda y$ where λ is the unknown Lagrange's multiplier. The Euler's equation for H is

$$\frac{\partial H}{\partial y} - \frac{d}{dx} \left(\frac{\partial H}{\partial y'} \right) = 0$$

Using derivatives of H w.r.t. y and y' , we get

$$(-2y + \lambda) - \frac{d}{dx} (2y') = 0$$

$$\text{or } y'' + y = \lambda$$

whose general solution is

$$y(x) = CF + PI = (c_1 \cos x + c_2 \sin x) + (\lambda) \quad (1)$$

37.14 — MATHEMATICAL METHODS

The three unknowns c_1, c_2, λ in (1) will be determined using the two boundary conditions and the given constraint. From (1)

$$0 = y(0) = c_1 + c_2 \cdot 0 + \lambda \quad \text{or} \quad c_1 + \lambda = 0$$

$$1 = y(\pi) = -c_1 + c_2 \cdot 0 + \lambda \quad \text{or} \quad -c_1 + \lambda = 1$$

Solving $\lambda = \frac{1}{2}, c_1 = -\lambda = -\frac{1}{2}$

Now from the given constraint

$$\int_0^\pi y \, dx = 1, \quad \text{we have}$$

$$\int_0^\pi (c_1 \cos x + c_2 \sin x + \lambda) dx = 1$$

$$c_1 \sin x - c_2 \cos x + \lambda x \Big|_0^\pi = 1$$

$$(0 + c_2 + \lambda\pi) - (0 - c_2 + 0) = 1$$

$$\text{or} \quad 2c_2 = 1 - \pi\lambda = \left(1 - \frac{\pi}{2}\right)$$

Thus the required extremal function $y(x)$ is

$$y(x) = -\frac{1}{2} \cos x + \left(\frac{1}{2} - \frac{\pi}{4}\right) \sin x + \frac{1}{2}.$$

Example 2: Show that the extremal of the isoperimetric problem $I[y(x)] = \int_{x_1}^{x_2} y^2 \, dx$ subject to the condition $J[y(x)] = \int_{x_1}^{x_2} y \, dx = \text{constant} = k$ is a parabola. Determine the equation of the parabola passing through the points $P_1(1, 3)$ and $P_2(4, 24)$ and $k = 36$.

Solution: Here $f = y^2$ and $g = y$. So form

$$H = f + \lambda g = y^2 + \lambda y.$$

The Euler equation for H is

$$\frac{\partial H}{\partial y} - \frac{d}{dx} \left(\frac{\partial H}{\partial y'} \right) = 0$$

$$\lambda - \frac{d}{dx} (2y') = 0$$

$$\text{or} \quad y'' - \frac{\lambda}{2} = 0$$

Integrating twice,

$$y(x) = \frac{\lambda}{2} \frac{x^2}{2} + c_1 x + c_2 \quad (1)$$

which is a parabola. Here c_1 and c_2 are constants of integration. To determine the particular parabola, use

B.C's $y(1) = 3$ and $y(4) = 24$ (i.e., passing through points P_1 and P_2) and the given constraint. From (1)

$$3 = y(1) = \frac{\lambda}{4} + c_1 + c_2 \quad (2)$$

Again from (1)

$$24 = y(4) = 4\lambda + 4c_1 + c_2 \quad (3)$$

Now from the constraint

$$\int_{x_1=1}^{x_2=4} y(x) dx = 36$$

$$\text{or} \quad \int_1^4 \left(\frac{\lambda}{4} x^2 + c_1 x + c_2 \right) dx = 36$$

$$\text{i.e.,} \quad \frac{\lambda}{4} \cdot \frac{x^3}{3} + c_1 \frac{x^2}{2} + c_2 x \Big|_1^4 = 36$$

$$\text{or} \quad 42\lambda + 60c_1 + 24c_2 = 288 \quad (4)$$

From (2) & (3):

$$\lambda - c_2 = 12$$

and from (3) & (4)

$$2\lambda - c_2 = 8$$

Solving $\lambda = -4, c_2 = -16, c_1 = 20$. Thus the specific parabola satisfying the given B.C.'s (passing through P_1 and P_2) is

$$y = -\frac{4}{4}x^2 + 20x - 16$$

$$\text{i.e.,} \quad y = -x^2 + 20x - 16.$$

EXERCISE

1. Find the curve of given length L which joins the points $(x_1, 0)$ and $(x_2, 0)$ and cuts off from the first quadrant the maximum area.

$$\text{Ans.} \quad (x - c)^2 + (y - d)^2 = \lambda^2, \quad c = \frac{x_1 + x_2}{2}, \\ a = \frac{(x_2 - x_1)}{2}, \quad \lambda^2 = d^2 + a^2, \quad \sqrt{d^2 + a^2} \\ \cot^{-1} \left(\frac{d}{a} \right) = \frac{L}{2}.$$

2. Determine the curve of given length L which joins the points $(-a, b)$ and (a, b) and generates the minimum surface area when it is revolved about the x-axis.

$$\text{Ans.} \quad y = c \cosh \frac{x}{c} - \lambda, \quad \text{where} \quad c = \frac{a}{\sinh^{-1} \left(\frac{L}{2} \right)}, \quad \lambda = \\ \frac{c}{2} \sqrt{4 + L^2} - b$$

3. Find the extremal of $I = \int_0^\pi y'^2 dx$ subject to $\int_0^\pi y^2 dx = 1$ and satisfying $y(0) = y(\pi) = 0$

Hint: EE: $y'' - \lambda y = 0$

Ans. $y_\eta(x) = \pm \sqrt{\frac{2}{\pi}} \sin \eta x, \eta = 1, 2, 3 \dots$

4. Show that sphere is the solid of revolution which has maximum volume for a given surface area.

Hint: $H = \pi y^2 + \lambda[(2\pi y)\sqrt{(1 + y'^2)}]$, EE: $y' = \frac{\sqrt{4\lambda^2 - y^2}}{y}$, $(x - 2\lambda)^2 + y^2 = (2\lambda)^2$; circle, solid of revolution sphere.

5. Find the curve of given length L which minimizes the curved surface area of the solid generated by the revolution of the curve about the x-axis.

Ans. Catenary

6. Determine $y(x)$ for which $\int_0^1 (x^2 + y'^2) dx$ is stationary subject to $\int_0^1 y^2 dx = 2, y(0) = 0, y(1) = 0$.

Ans. $y = \pm 2 \sin m\pi x$, where m is an integer.

Chapter 38

Linear Programming

38.1 INTRODUCTION

Optimization problems seek to maximize or minimize a function of a number of variables which are subject to certain constraints. The objective may be to maximize the profit or to minimize the cost. The variables may be products, man-hours, money or even machine hours. Optimal allocation of limited resources to achieve a given object forms programming problems. A programming problem in which all the relations between the variables is linear including the function to be optimized is called a Linear Programming Problem (LPP). G.B. Dantzig, in 1947, first developed and applied general problem of linear programming. Classical examples include transportation problem, activity-analysis problem, diet problems and network problem. The simplex method, developed by GB Dantzig, in 1947, continues to be the most efficient and popular method to solve general LPP. Karmarkar's method developed in 1984 has been found to be upto 50 times as fast as the simplex algorithm. LPP is credited to the works of Kuhn, Tucker, Koopmans, Kantorovich, Charnes Cooper, Hitchcock, Stiegler. LPP has been used to solve problems in banking, education, distribution of goods, approximation theory, forestry, transportation and petroleum.

38.2 FORMULATION OF LPP

In a linear programming problem (LPP) we wish to determine a set of variables known as *decision* vari-

ables. This is done with the objective of maximizing or minimizing a linear function of these variables, known as *objective function*, subject to certain linear inequality or equality constraints. These variables, should also satisfy the nonnegativity restrictions since these physical quantities can not be negative. Here linearity is characterized by proportionality and additivity properties.

Let $x_1, x_2, \dots, x_n$ be the n decision unknown variables and $c_1, c_2, \dots, c_n$ be the associated (constant cost) coefficients. Then the aim of LP is to optimize (extremise) the linear function,

$$z = c_1x_1 + c_2x_2 + \dots + c_nx_n \quad (1)$$

Here (1) is known as the objective function. (O.F.) The variables x_j are subject to the following m linear constraints

$$a_{i1}x_1 + a_{i2}x_2 + \dots + a_{in}x_n \begin{cases} \geq \\ \leq \\ = \end{cases} b_i \quad (2)$$

for $i = 1, 2, \dots, m$. In (2), for each constraint only one of the signs $\geq$ or $\leq$ or $=$ holds. Finally x_i should also satisfy nonnegativity restrictions

$$x_j \geq 0 \text{ for } j = 1 \text{ to } n \quad (3)$$

Thus a general linear programming problem consists of an objective function (1) to be extremized subject to the constraints (2) satisfying the non-negativity restrictions (3).

38.2 — MATHEMATICAL METHODS

Solution

To LPP is any set of values $\{x_1, x_2, \dots, x_n\}$ which satisfies *all* the m constraints (2).

Feasible Solution

To LPP is any solution which would satisfy the non negativity restrictions given by (3).

Optimal Feasible Solution

To LPP is any feasible solution which optimizes (i.e. maximizes or minimizes) the objective function (1).

From among the infinite number of feasible solutions to an LPP, we should find the optimal feasible solution in which the maximum (or minimum) value of z is finite.

Example 1: Suppose Ajanta clock company produces two types of clocks “standard” and “deluxe” using three different inputs A, B, C. From the data given below formulate the LPP to determine the number of standard and deluxe clock to be manufactured to maximize the profit.

Let x_1 and x_2 be the number of “standard” and “deluxe” clocks to be produced.

| Input
(Resource) | Technical coefficients | | Capacity |
|---------------------|------------------------|--------|----------|
| | Standard | Deluxe | |
| A | 2 | 4 | 20 |
| B | 2 | 2 | 12 |
| C | 4 | 0 | 16 |
| Profit (Rs) | 2 | 3 | |

Then the objective function is to maximize the total profit i.e. maximize $z = 2x_1 + 3x_2$, since the profit for one standard clock is Rs 2 and profit for one deluxe and clock is Rs 3. Because of the limited resources, for input A we have the following restriction. Since one standard clock consumes 2 units of resource A, x_1 units of standard clocks consume $2x_1$ units of input A. Similarly $4x_2$ units of input A is required to produce x_2 deluxe clocks. Thus the total requirement of the input A for production of x_1 , standard and x_2 deluxe clocks is

$$2x_1 + 4x_2.$$

However, the total amount of resource A available is 20 units only. Therefore the restriction on resource A is

$$2x_1 + 4x_2 \leq 20$$

Similarly the restriction of resource B is

$$2x_1 + 2x_2 \leq 12$$

and restriction on source C is

$$4x_1 \leq 16.$$

Since x_1, x_2 are physical quantities (the number of clocks produced), they must be non negative i.e.

$$x_1 \geq 0$$

and

$$x_2 \geq 0.$$

Thus the LPP consists of the O.F., three inequality constraints and the non-negativity restrictions.

38.3 GRAPHICAL SOLUTION OF LPP

When the number of decision variables (or products) is two, the solution to linear programming problem involving any number of constraints can be obtained graphically. Consider the first quadrant of the x_1x_2 plane since the two variables x_1 and x_2 should satisfy the nonnegativity restrictions $x_1 \geq 0$ and $x_2 \geq 0$. Now the basic feasible solution space is obtained in the first quadrant by plotting all the given constraints as follows. For a given inequality, the equation with equality sign (replacing the inequality) represents a straight line in x_1x_2 plane dividing it into two open half spaces. By a test reference point, the correct side of the inequality is identified. Say choosing origin $(0, 0)$ as a reference point, if the inequality is satisfied then the correct side of the inequality is the side on which the origin $(0, 0)$ lies. Indicate this by an arrow. When all the inequalities are plotted like this, in general, we get a bounded (or unbounded in case of greater than inequalities) polygon which enclose the feasible solution space, any point of which is a feasible solution.

For $z = z_0$, the objective function $z = c_1x_1 + c_2x_2$ represents an iso-contribution (or iso-profit) straight line say $x_2 = -\frac{c_1}{c_2}x_1 + \frac{z_0}{c_2}$ (or $x_1 = \frac{-c_2}{c_1}x_2 + \frac{z}{c_1}$)

such that for any point on this line, the contribution (Profit) (value of z_0) is same. To determine the optimal solution, in the maximization case, assigning arbitrary values to z , move the iso-contribution line in the increasing direction of z without leaving the feasible region. The optimum solution occurs at a corner (extreme) point of the feasible region. So the iso-profit line attains its maximum value of z and passes through this corner point. If the iso-contribution line (objective function) coincides with one of the edges of the polygon, then any point on this edge gives optimal solution with the same maximum (unique) value of the objective function. Such a case is known as multiple (alternative) optima case. In the minimization case, assigning arbitrary values to z , move the iso-contribution line in the direction of decreasing z until it passes through a corner point (or coincides with an edge of the polygon) in which case the minimum is attained at this corner point.

Range of Optimality

For a given objective function $z = c_1x_1 + c_2x_2$, slope of z changes as the coefficients c_1 and c_2 change which may result in the change of the optimal corner point itself. In order to keep (maintain) the current optimum solution valid, we can determine the *range of optimality* for the ratio $\frac{c_1}{c_2}$ (or $\frac{c_2}{c_1}$) by restricting the variations for both c_1 and c_2 .

Special Cases:

- (a) The feasible region is unbounded and in the case of maximization, has an unbounded solution or bounded solution.
- (b) Feasible region reduces to a single point which itself is the optimal solution. Such a trivial solution is of no interest since this can be neither maximized nor minimized.
- (c) A feasible region satisfying *all* the constraints is *not* possible since the constraints are inconsistent.
- (d) LPP is ill-posed if the non-negativity restriction are not satisfied although all the remaining constraints are satisfied.

Examples:

- (a) $x_1 + 3x_2 \geq 3, x_1 + x_2 \geq 2, x_1, x_2 \geq 0$,
Maximize: $z = 1.5x_1 + 2.5x_2$ unbounded feasible region, unbounded solution (can be maximized indefinitely)

Fig. 38.1

- (b) $x_1 - x_2 \geq 0, -0.5x_1 + x_2 \leq 1, x_1, x_2 \geq 0$
Maximize: $z = x_2 - 0.75x_1$ unbounded feasible region $z_2 = 0.5$ is bounded optimal solution.

Fig. 38.2

- (c) $x_1 + x_2 \leq 2, -x_1, -5x_2 \leq -10$
Maximize: $z = -5x_2, x_1, x_2 \geq 0, (0, 2)$ is *unique* solution, max: $z = -10$.

Fig. 38.3

- (d) $x_1 + x_2 \leq 1, -0.5x_1 - 5x_2 \leq -10$
Maximize: $z = -5x_2, x_1, x_2 \geq 0$. No feasible region. Constraints are inconsistent

Fig. 38.4

- (e) $1.5x_1 + 1.5x_2 \geq 9$, $x_1 + x_2 \leq 2$.
No feasible region.

WORKED OUT EXAMPLES

Example 1: ABC company produces two types of calculators. A business calculator requires 1 hour of wiring, one hour of testing and 3 hours of assembly, while a scientific calculator requires 4 hours of wiring, one hour of testing and one hour of assembly. A total of 24 hours of wiring, 21 hours of assembly and 9 hours of testing are available with the company. If the company makes a profit of Rs 4 on business calculator (BC) and Rs 10 on scientific calculator (SC), determine the best product mix to maximize the profit.

Solution: Let x_1 be the number of business calculators (BC) produced while x_2 be the number of scientific calculators (SC) produced. Then the objective is to maximize the profit $z = 4x_1 + 10x_2$ subject to the following five constraints:

$$\begin{aligned} x_1 + 4x_2 &\leq 24 && \text{(wiring) (I)} \\ x_1 + x_2 &\leq 9 && \text{(testing) (II)} \\ 3x_1 + x_2 &\leq 21 && \text{(assembly) (III)} \\ x_1 &\geq 0 && \left\{ \begin{array}{l} \text{non negative} \\ \text{constraints} \end{array} \right. && \text{(IV)} \\ x_2 &\geq 0 && \text{(V)} \end{aligned}$$

To determine the feasible solution space consider the first quadrant of the x_1x_2 -plane since $x_1 \geq 0$ and $x_2 \geq 0$. Then draw the straight lines $x_1 + 4x_2 =$

24 , $x_1 + x_2 = 9$ and $3x_1 + x_2 = 21$. Note that an inequality divides the x_1x_2 -plane into two open half-space. Choose any reference point in the first quadrant. If this reference point satisfies the inequality then the correct side of the inequality is the side on which the reference point lies. Generally origin $(0, 0)$ is taken as the reference point. The correct side of the inequality is indicated by an arrow. The shaded region is the required feasible solution space satisfying all the five constraints. The five corner points of the feasible region are A(0, 0), B(7, 0), C(6, 3), D(4, 5), E(0, 6). Identify the direction in which z increases without leaving the region. Arbitrarily choosing $z = 0, 28, 54, 60, 66$, observe that the straight lines (profit function) $z = 4x_1 + 10x_2$ or $x_2 = -\frac{2}{5}x_1 + \frac{z}{10}$ passes through the corner points A, B, C, E, D respectively. The optimum solution occurs at the corner point D(4, 5), where the maximum value for $z = 66$ is attained. Thus the best product mix is to produce 4 business and 5 scientific calculator which gives a maximum profit of Rs. 66.

Fig. 38.5

Example 2: (a) Solve the above problems to minimize $z = -4x_1 - 10x_2$.
(b) If $z = c_1x_1 + c_2x_2$, does an alternative optimal solution exists
(c) Determine the range of optimality for the ratio $\frac{c_1}{c_2}$ (or $\frac{c_2}{c_1}$).

Solution: (a) Rewriting, $x_2 = -\frac{2}{5}x_1 - \frac{z}{10}$. Choose $z = 0, -28, -54, -60, -66$, then the objective function passes through the corner points A, B, C, E, D respectively. Thus the minimum value $z = -66$ is attained at the corner point D(4, 5). Observe that maximum of $z = 4x_1 + 10x_2$ is 66 and minimum of $z = -4x_1 - 10x_2$ is -66 i.e., $\max f(x) = -\min(-f(x))$.

(b) If $z = c_1x_1 + c_2x_2$ coincides with the straight line CD: $x_1 + x_2 = 9$, then any point on the line segment CD is an optimal solution to the current problem and thus has multiple (infinite) alternative optima.

(c) Let $z = c_1x_1 + c_2x_2$ be the objective function. Then for $c_2 \neq 0$, we write this as

$$x_2 = \frac{-c_1}{c_2}x_1 + \frac{z}{c_2}$$

The straight line

$x_1 + 4x_2 = 24$ rewritten as $x_2 = -\frac{1}{4}x_1 + \frac{24}{4}$ has slope $-\frac{1}{4}$ and the straight line $x_1 + x_2 = 9$ rewritten as $x_2 = -x_1 + 9$ has slope -1 . Thus range of optimality which will keep the present optimum solution valid is

$$\frac{1}{4} \leq \frac{c_1}{c_2} \leq 1$$

For $c_2 = 4$, $1 \leq c_1 \leq 4$

Similarly for $c_1 \neq 0$, the range of optimality is $1 \leq \frac{c_2}{c_1} \leq 4$. For $c_1 = 2$, $2 \leq c_2 \leq 8$.

Example 3: The minimum fertilizer needed/hector is 120 kgs nitrogen, 100 kgs phosphorous and 80 kgs of potassium. Two brands of fertilizers available have the following composition.

| Fertilizer | Nitrogen | Phos. | Potassium | Price/100 kgs bag |
|------------|----------|-------|-----------|-------------------|
| A | 20% | 10% | 10% | Rs 50 |
| B | 10% | 20% | 10% | Rs 40 |

Determine the number of bags of fertilizer A and B which will meet the minimum requirements such that the total cost is minimum.

Solution: Let X be the number of bags of fertilizer A purchased and Y be the number of bags of fertilizer B purchased. Then the objective is to minimize the total cost $z = 50X + 40Y$ subject to

$$\begin{aligned} 20X + 10Y &\geq 120 && \text{(Nitrogen)} \\ 10X + 20Y &\geq 100 && \text{(Phosphorous)} \end{aligned}$$

$$10S + 10Y \geq 80 \quad \text{(Potassium)}$$

and $X, Y \geq 0$

Draw the straight lines

$$2X + Y = 12 \quad (1)$$

$$X + 2Y = 10 \quad (2)$$

$$X + Y = 8 \quad (3)$$

A(0, 12), B(4, 4), C(6, 2), D(10, 0)

Fig. 38.6

Objective function: iso-profit equation:

$$Y = -\frac{5}{4}X + \frac{z}{40} \quad (4)$$

Choose $z = 500, 480, 380, 360$ then (4) passes through the corner points D, A, C, B respectively. Thus the optimal solution occurs at B(4, 4) i.e. purchase four bags of fertilizer A and 4 bags of fertilizer B with a total minimum cost of Rs 360/-.

EXERCISE

Solve the following LPP graphically:

1. Right Wood Furniture Company manufactures chairs and desks. The time required (in minutes) and the total available time is given below. If company sells a chair for a profit of Rs. 25 and desk

38.6 — MATHEMATICAL METHODS

for a profit of Rs 75/- determine the best product mix that will maximize the profit.

| | Chair | Desk | Available time |
|-------------|-------|-------|----------------|
| Fabrication | 15 | 40 | 27,000 |
| Assembly | 12 | 50 | 27,000 |
| Upholstery | 18.75 | — | 27,000 |
| Linoleum | — | 56.25 | 27,000 |

Ans: Produce 1000 chairs and 300 desks, making a profit of Rs 47,500.

Hint: Corner points are A(0, 0), B(1440, 0), C(1440, 135), D(1000, 300), E(250, 480), F(0, 480): Maximize: $z = 25X + 75Y$. s.t.

$$15X + 40Y \leq 27,000,$$

$$12X + 50Y \leq 27000,$$

$$18.75X \leq 27000, 56.25Y \leq 27000$$

2. Asia paints produces two types of paints with the following requirements.

| | Standard Paint | Delux Paint | Total Available Quantity (in tons) |
|-------------------|----------------|-------------|------------------------------------|
| Base | 6 | 4 | 24 |
| Chemicals | 1 | 2 | 6 |
| Profit (in 100's) | 5 | 4 | |

Determine the optimum (best) product mix of the paints that maximizes the total profit for the company. Demand for deluxe paint can not exceed that of standard paint by more than 1 ton. Also maximum demand of deluxe paint is 2 tons.

Ans: Produce 3 tons of standard and 1.5 tons of deluxe paint, making a profit of Rs 2100.

Hint: Corner points: A(0, 0), B(4, 0), C(3, 1.5), D(2, 2), E(1, 2), F(0, 1); OF: Maximize $z = 5x_1 + 4x_2$ subject to

$$6x_1 + 4x_2 \leq 24, x_1 + 2x_2 \leq 6,$$

$$-x_1 + x_2 \leq 1, x_2 \leq 2, x_1, x_2 \geq 0.$$

3. In an oil refinery, two possible blending processes for which the inputs and outputs per production run are given below.

| | Input | | Output | |
|---------|---------|---------|------------|------------|
| Process | Crude A | Crude B | Gasoline X | Gasoline Y |
| I | 5 | 3 | 5 | 8 |
| II | 4 | 5 | 4 | 4 |

A maximum of 200 units of crude A and 150 units of crude B are available. It is required to produce at least 100 units of gasoline X and 80 units of gasoline Y. The profit from process I is Rs 300 while from process II is Rs 400. Determine the optimal mix of the two processes.

Ans: Produce 30.7 units by process I and 11.5 units from process II, getting a maximum profit of Rs 13,846.20.

Hint: Maximize: $z = 300x_1 + 400x_2$, subject to
 $5x_1 + 4x_2 \leq 200, 3x_1 + 5x_2 \leq 150$
 $5x_1 + 4x_2 \geq 100, 8x_1 + 4x_2 \geq 80$

Corner points: A(20, 0), B(40, 0), D(0, 30), E(0, 25), C($\frac{400}{13}, \frac{150}{13}$)

4. Minimize $z = 0.3x_1 + 0.9x_2$ subject to
 $x_1 + x_2 \geq 800, 0.21x_1 - 0.30x_2 \geq 0, 0.03x_1 - 0.01x_2 \geq 0, x_1, x_2 \geq 0$

Ans: $x_1 = 470.6, x_2 = 329.4$, minimum cost: Rs 437.64.

5. Maximize: $z = 30x_1 + 20x_2$ subject to $x_1 \leq 60, x_2 \leq 75, 10x_1 + 8x_2 \leq 800$.

Ans: $x_1 = 60, x_2 = 25$, Max: profit = Rs 2300

Hint: Corner points: A(0, 0), B(60, 0), C(60, 25), D(20, 75), E(0, 75).

6. Given $x_1 \geq 0, x_2 \geq 0, x_1 + 2x_2 \leq 8, 2x_1 - x_2 \geq -2$ solve to (a) max x_1 (b) max x_2 (c) min x_1 (d) min x_2 (e) max $3x_1 + 2x_2$ (f) min $-3x_1 - 2x_2$ (g) max $2x_1 - 2x_2$

Ans: (a) $x_1 = 8$ (b) $x_2 = \frac{18}{5}$ (c) $x_1 = 0$ (d) $x_2 = 0$ (e) $z = 24, x_1 = 8, x_2 = 0$ (f) $z = -24, x_1 = 8, x_2 = 0$ (g) $z = -\frac{28}{5}, x_1 = \frac{4}{5}, x_2 = \frac{18}{5}$

7. Minimize $z = x_1 + x_2$ s.t. $x_1 \geq 0, x_2 \geq 0, 2x_1 + x_2 \geq 12, 5x_1 + 8x_2 \geq 74, x_1 + 6x_2 \geq 28$.

Ans: $x_1 = 2, x_3 = 8$, min. 10

Hint: Unbounded region with corner points A(0, 12), B(2, 8), C(10, 3), D(28, 0)

- Ans:* $x_1 = 24, x_2 = 14, z = Rs2200$.

 $x_{m+1}, \dots, x_n$ all to zero.

38.8 — MATHEMATICAL METHODS

Basic solution

$\{x_1, x_2, \dots, x_m\}$ is the solution of the system of equations (2) in which $n - m$ variables are set to zero.

Basic variables

are the variables $x_1, x_2, \dots, x_m$ in the basic solution.

Basis

is the set of m basic variables in the basic solution.

Non-basic variables

$x_{m+1}, x_{m+2}, \dots, x_n$ are the $(n - m)$ variables which are equated to zero to solve the m equations (2), (resulting in the basic solution).

Basic feasible solution

is a basic solution which satisfies the nonnegativity restrictions, (3) i.e. all basic variables are non negative. (i.e. $x_j \geq 0$ for $j = 1, 2, 3, \dots, m$)

Nondegenerate basic feasible solution

is a basic feasible solution in which all the basic variables are positive (i.e., $x_j > 0$ for $j = 1, 2, 3, \dots, m$)

Optimal basic feasible solution

is a basic feasible solution which optimizes (in this case minimizes) the objective function (1).

Why Simplex Method

In an LPP with m equality constraints and n variables with $m < n$, the number of basic solutions is $n_c m$. For small n and m , all the basic solutions (corner points) can be enumerated (listed out) and the optimal basic feasible solution can be determined.

Example:

Maximize: $z = 2x_1 + 3x_2$ s.t. $2x_1 + x_2 \leq 4$, $x_1 + 2x_2 \leq 5$. Rewriting $2x_1 + x_2 + x_3 = 4$, $x_1 + 2x_2 + x_4 = 5$. Here $m = 2$, $n = 4$, $n_c m = 4_c 2 = 6$ The six basic solutions are: 1. (0, 0, 4, 5), Feasible (F), Non-degenerate (ND) and $z =$ value of O.F = 0

2. (0, 4, 0, -3), NF (non feasible)

3. (0, 2.5, 1.5, 0), $z = 7.5$ F, ND

4. (2, 0, 0, 3), $z = 4$, F, ND

5. (5, 0, -6, 0), NF

6. (1, 2, 0, 0), $z = 8$,

Feasible nondegenerate and optimal.

However, even for $n = 20$, $m = 10$, the number of basic solutions to be investigated is 1,84,756, a large part of which are infeasible. It is proved that the set of feasible solutions to a LPP form a convex set (the line joining any two points of the set lies in the set) and the corner (extreme) points of the convex set are basic feasible solutions. If there is an optimal solution, it exists at one of these corner points. The simplex method devised by GB Dantzig is a powerful procedure which investigates in a systematic way for optimal solution at these corner points which are finite in number.

For $m = 10$, $n = 20$, simplex method obtains the optimal in 15 steps, thus having an advantage of 92,378 to 1.

38.5 SIMPLEX METHOD

The simplex method is an algebraic iterative procedure which solves any LPP exactly (*not approximately*) or gives an indication of an unbounded solution. Starting at an initial extreme point, it moves in a finite number of steps, between m and $2m$, from one extreme point to the optimal extreme point. Consider the following LPP with ' m ' less than or equal to inequalities in ' n ' variables.

Maximize $z = c_1x_1 + c_2x_2 + \dots + c_nx_n$

subject to $a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n \leq b_1$

$a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n \leq b_2$

.....

$a_{m1}x_{m1} + a_{m2}x_2 + \dots + a_{mn}x_n \leq b_m$

Introducing ' m ' slack variables $s_1, s_2, \dots, s_m$, the less than or equal to in equalities are converted to equations.

$a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n + s_1 = b_1$

$a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n + s_2 = b_2$

.....

$a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n + s_m = b_m$

Here $x_1, x_2, \dots, x_n, s_1, s_2, \dots, s_m$ are all nonnegative i.e. ≥ 0 . The objective function is rewritten as

Maximize: $z = c_1x_1 + \cdots + c_nx_n + 0.s_1 + \cdots + 0.s_m$.

Thus there are m equations in $m + n$ variables. Putting $(m + n) - m = n$ variables zero we get a starting basic feasible solution. Take $x_1 = x_2 = \cdots x_n = 0$. Then the initial solution contains the m basic variables $s_1, s_2, \dots, s_m$. This corresponds to the corner point origin with value of the objective function zero. Since this is a problem of maximization, the value of objective function will increase if we introduce one of non-basic variable x_j ($j = 1$ to n), into the solution forcing out one of the basic variable. The obvious choice is the x_j with the largest c_j . Ties are broken arbitrarily. The objective equation is written as $z - c_1x_1 - c_2x_2 - \cdots - c_nx_n + 0.s_1 + \cdots + 0.s_n = 0$

For efficient use, this data is written in the form of a table known as simplex tableau shown below:

| Remark | Basis | z | x_1 | x_2 | $\vdots$ | x_j | $\vdots$ | x_n | s_1 | s_2 | $\vdots$ | s_m | Solution |
|------------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|
| c_1 -row | z | 1 | $-c_1$ | $-c_2$ | $\vdots$ | $-c_j$ | $\vdots$ | $-c_n$ | 0 | 0 | $\vdots$ | 0 | 0 |
| s_1 -row | s_1 | 0 | a_{11} | a_{12} | $\vdots$ | a_{1j} | $\vdots$ | a_{1n} | 1 | 0 | $\vdots$ | 0 | b_1 |
| s_2 -row | s_2 | 0 | a_{21} | a_{22} | $\vdots$ | a_{2j} | $\vdots$ | a_{2n} | 0 | 1 | $\vdots$ | $\vdots$ | b_2 |
| s_i -row | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | a_{ij} | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |
| s_m -row | s_m | 0 | a_{m1} | a_{m2} | $\vdots$ | a_{mj} | $\vdots$ | a_{mn} | 0 | 0 | $\vdots$ | 1 | b_m |

The first row, z -row contains the coefficients of the objective equation with last element in rectangle indicating the current value of the objective function (In the present case it is zero). The left most (first) column indicates the current basic variables $s_1, s_2, \dots, s_m$. The right most (last) column is the solution column. Thus $s_1 = b_1, s_2 = b_2, \dots, s_m = b_m$ (all resources unused) is the basic solution with the value of the objective function zero.

Test for optimality

If *all* the z -row coefficients of the nonbasic variables are nonnegative, then the current solution is optimal. Stop. Otherwise goto step I.

Step I. Entering variables: Suppose $-c_j$, the z -row coefficient of the non basic variables x_j is the most negative, then the variable x_j will enter the basis. The j th column is known as the pivotal column.

Step II. Leaving variable: Divide the solution column with the corresponding elements of the pivotal column, with strictly positive denominator. Ignore the ratios, when the pivotal column elements are zero or negative.

Suppose $\frac{b_i}{a_{ij}}$ is the smallest non negative ratio among these ratios

$$\frac{b_i}{a_{ij}}, \frac{b_2}{a_{2j}}, \dots, \frac{b_m}{a_{mj}},$$

then the basic variable s_i will leave the basis (and therefore will become a non basic variable). The i th row is known as the pivotal row. The element a_{ij} at the intersection of the pivotal column and pivotal row is known as the pivotal element, which is encircled in the table step III. Compute the new simplex tableau with $(s_1, s_2, \dots, x_j, \dots, s_m)$ as the new basis compute.

Pivot row:

$$\text{New pivot row} = \frac{\text{current pivot row}}{\text{pivotal element}}.$$

All other rows including z :

New row = current row - (Corresponding pivot column coefficient) $\times$ (New pivot row).

The solution-column in the new tableau readily gives the new basic solution with new objective value (last element in the z -row). Now test for optimality. If yes, stop. Otherwise goto step I.

Optimality condition

The *nonbasic* variable having the most negative (positive) coefficient coefficient in the z -row will be the entering variable in a maximization (minimization) problem. Ties are broken arbitrarily. When all the z -row coefficients of the non basic variables are non-negative (nonpositive) then the current solution is optimal.

Feasibility condition

In both the maximization and minimization problems, the *basic* variable associated with the smallest nonnegative ratio (with *strictly positive* denominator) will be the leaving variable.

Thus the simplex method can be summarized as follows:

Step 0. If all the constraints are less than or equal to type, introduce slack variables and determine the starting basic solution.

Step I. Using optimality condition, select the entering variable. If no variable can enter the basis, stop. The current solution is optimal.

Step II. Using feasibility condition determine the leaving variable.

Step III. Compute the new basic solution (new simplex tableau) and go to step I.

Artificial Variable Technique

For a LPP in which all the constraints are less than or equal to type with $b_i \geq 0$, an all-slack, initial basic feasible solution readily exists. However for problems involving $\geq$ inequalities or equality constraints no such solution is possible. To alleviate this, artificial variables are introduced in each of the $\geq$ or $=$ type constraints, and slack variables for the less than or equal to type which will then provide a starting solution. The M-method and the two-phase method are two closely related methods involving artificial variables.

M-Method (also Known as Charne's Method or Big M-Method)

Since artificial variables are undesirable, the coefficient for the artificial variable in the objective function is taken as $-M$ in maximization problem and as $+M$ in minimization problems. Here M is a very large positive (penalty) value. The augmented problem is solved by simplex method, resulting in one of the following cases:

1. When all the artificial variables have left the basis and optimality condition is satisfied, then the current solution is optimal.
2. When one or more artificial variables are present in the basis at zero level and the optimality condition is satisfied, then the solution is optimal with some redundant constraints

3. No feasible solution exists when one or more artificial variables are present in the basis at a positive level although the optimality condition is satisfied. Such a solution is known as *pseudo optimal solution* since it satisfies the constraints but does not optimize the objective function.

Note: Since artificial variables which is forced out of the basis, is never considered for reentry, the column corresponding to the artificial variable may be omitted from the next simplex tableau.

Two-Phase Method

In the M-method, M must be assigned some specific numerical value which creates trouble of roundoff errors especially in computer calculations. The z -coefficient of the artificial variable will be of the form $aM + b$. For large chosen M , b may be lost and for small chosen M and small a , b may be present leading to incorrect results. The two phase method consists of two phases and alleviates the difficulty in the M-method.

Phase I

Exactly as in M-method, introduce necessary artificial variables to get an initial basic feasible solution. Solve this augmented problem, by simplex method to *minimize* r , the sum of the artificial variables. If $r = 0$, then all the artificial variables are forced out of the basis. Goto phase II. If $r > 0$, indicating the presence of artificial variables at non zero level, LP has no feasible solution

Phase II

The feasible solution of phase I forms the initial basic feasible solution to the original problem (without any artificial variables). Apply simplex method to obtain the optimal solution.

WORKED OUT EXAMPLES

Enumeration

Example 1: Solve the following LPP by enumerating all basic feasible solutions. Identify the infeasible

solutions. Find the optimal solution and the value of the objective function.

$$\begin{aligned} \text{Maximize } z &= 2x_1 + 3x_2 + 4x_3 + 7x_4 \text{ subject to} \\ 2x_1 + 3x_2 - x_3 + 4x_4 &= 8 \\ x_1 - 2x_2 + 6x_3 - 7x_4 &= -3 \\ \text{and } x_1, x_2, x_3, x_4 &\geq 0. \end{aligned}$$

Solution: The number of equations $m = 2$. The number of variable $n = 4$. The number of basic variables $= m = 2$. The number of all possible solutions is ${}^4C_2 = 6$.

- Put $x_3 = x_4 = 0$, solving $2x_1 + 3x_2 = 8$, $x_1 - 2x_2 = -3$, we get $x_1 = 1$, $x_2 = 2$, $z = 8$. Basic feasible solution, not optimal, x_1, x_2 are basic variables, x_3, x_4 are non basic variables (which are always zero).
- Put $x_2 = x_4 = 0$. Solving $2x_1 - x_3 = 8$, $x_1 + 6x_3 = -3$, we get $x_1 = \frac{45}{13}$, $x_3 = -\frac{14}{3}$. Since $x_3 < 0$, this is a basic non feasible solution.
- Put $x_1 = x_4 = 0$. Solving $3x_2 - x_3 = 8$, $-2x_2 + 6x_3 = -3$, we get $x_2 = \frac{45}{16}$, $x_3 = \frac{7}{16}$, $z = \frac{163}{16}$. This is a basic feasible solution (not optimal).
- Put $x_3 = x_2 = 0$, solving $2x_1 + 4x_4 = 8$, $x_1 - 7x_4 = -3$, we get $x_1 = \frac{22}{9}$, $x_4 = \frac{7}{9}$, $z = \frac{93}{9}$, basic feasible solution (not optimal).
- Put $x_1 = x_3 = 0$. Solving $3x_2 + 4x_4 = 8$, $2x_2 + 7x_4 = 3$ we get $x_2 = \frac{44}{13}$, $x_4 = \frac{-7}{13}$. This is a basic non feasible solution.
- Put $x_1 = x_2 = 0$. Solving $-x_3 + 4x_4 = 8$, $6x_3 - 7x_4 = -3$, we get $x_3 = \frac{44}{17}$, $x_4 = \frac{45}{17}$. Thus the optimal basic feasible solution with the basic variables $x_3 = \frac{44}{17}$, $x_4 = \frac{45}{17}$ (and obviously the remaining non basic variables x_1, x_2 at zero value) has the maximum value of the objective function as $\frac{491}{17}$.

Simplex Method: Maximization

Example 1: Solve the following LPP by simplex method.

$$\begin{aligned} \text{Maximize } z &= 2x_1 + 3x_2 \\ \text{subject to } 2x_1 + 4x_2 &\leq 20 \\ 2x_1 + 2x_2 &\leq 12 \\ 4x_1 &\leq 16 \\ x_1 \geq 0, x_2 &\geq 0 \end{aligned}$$

Solution: Introducing three slack variables, the given three less than or equal to inequality constraints will be expressed as equations. Assign zero cost to each of these slack variables. Then the standard form of the LPP is to

Maximize $z = 2x_1 + 3x_2 + 0 \cdot s_1 + 0 \cdot s_2 + 0 \cdot s_3$ subject to

$$\begin{aligned} 2x_1 + 4x_2 + s_1 &= 20 \\ 2x_1 + 2x_2 + s_2 &= 12 \\ 4x_1 + s_3 &= 16 \end{aligned}$$

and $x_1, x_2, s_1, s_2, s_3 \geq 0$

Express the objective equation as

$$z - 2x_1 - 3x_2 = 0$$

Then the starting simplex tableau is represented as follows:

| Basis | z | x_1 | x_2 | s_1 | s_2 | s_3 | Solution | Remark |
|-------|---|-------|-------|-------|-------|-------|----------|------------|
| z | 1 | -2 | -3 | 0 | 0 | 0 | 0 | z-row |
| s_1 | 0 | 2 | 4 | 1 | 0 | 0 | 20 | s_1 -row |
| s_2 | 0 | 2 | 2 | 0 | 1 | 0 | 12 | s_2 -row |
| s_3 | 0 | 4 | 0 | 0 | 0 | 1 | 16 | s_3 -row |

Corner points: A(0, 0), B(4, 0), C(4, 2), D(2, 4), E(0, 5). Value of O.F. at these extreme points: $z_A = 0$, $z_B = 8$, $z_C = 14$, $z_D = 16$, $z_E = 15$

Fig. 38.7

The initial basis consists of the three basic variables $s_1 = 20$, $s_2 = 12$, $s_3 = 16$. The two non basic variables are $x_1 = 0$, $x_2 = 0$. Note that non basic variables are always equal to zero. Thus this solution corresponds to the corner (extreme) point A (0, 0) in the graph. In the simplex tableau all the three basic

38.12 — MATHEMATICAL METHODS

variables are listed in the left-most (first) column and their values (including the value of the objective function), in the right-most (last) column. Here the value of OF is 0 since all the resources are unutilized. In the z -row, the value of the objective function in the solution column is enclosed in a square. Since this is a maximization problem, to improve (increase) the value of z , one of the non-basic variables will enter into the basis and there by forcing out one of the current basic variable from the basis (since the number of basic variables in the basis is fixed and equals to $m = 3$ the number of constraints). From the optimality condition, the entering variable is one with the most negative coefficient in the z -row. In the z -row the most negative elements is -3 . Thus the non basic variable x_2 will enter the basis. To determine the leaving variable, calculate the ratios of the right-hand side of the equations (solution-column) to the corresponding constraint coefficients under the entering variable x_2 , as follows:

| Basis | Entering
x_2 | Solution | Ratio |
|-------|-------------------|----------|--|
| s_1 | 4 | 20 | $\frac{20}{4} = 5 \leftarrow \text{minimum}$ |
| s_2 | 2 | 12 | $\frac{12}{2} = 6$ |
| s_3 | 0 | 16 | $\frac{16}{0} = \infty$ (Ignore) |

Therefore s_1 is the leaving variable. The value of the entering variable x_2 in the new solution equals to this minimum ratio 5. Here s_1 -row is the pivot row; x_2 column is the pivot column and the intersection of pivot column and pivot row is the pivot element 4 which is circled in the tableau. The new pivot row is obtained by dividing the current pivot row by the pivot element 4. Thus the new pivot row is

$$\begin{array}{cccccc} \frac{0}{4} & \frac{2}{4} & \frac{4}{4} & \frac{1}{4} & \frac{0}{4} & \frac{0}{4} & \frac{20}{4} \\ \text{i.e.,} & 0 & \frac{1}{2} & 1 & \frac{1}{4} & 0 & 5 \end{array}$$

Recall that for all other rows, including z -row,

New row = current row - (corresponding pivot coefficient) $\times$ (new pivot row)

$$\begin{aligned} \text{New } z\text{-row} &= \text{current } z\text{-row} - (-3) \text{ new pivot row} \\ &= (1, -2, -3, 0, 0, 0, 0) + \\ &\quad + 3 \left(0, \frac{1}{2}, 1, \frac{1}{4}, 0, 0, 5 \right) \\ &= 1, -\frac{1}{2}, 0, \frac{3}{4}, 0, 0, 15 \end{aligned}$$

$$\begin{aligned} \text{New } s_2\text{-row} &= \text{current } s_2\text{-row} - (2) \text{ new pivot row} \\ &= (0, 2, 2, 0, 1, 0, 12) - \end{aligned}$$

$$\begin{aligned} &-2 \left(0, \frac{1}{2}, 1, \frac{1}{4}, 0, 0, 5 \right) = \\ &= (0, 1, 0, -\frac{1}{2}, 1, 0, 2) \end{aligned}$$

$$\begin{aligned} \text{New } s_3\text{-row} &= \text{current } s_3\text{-row} - (0) \times (\text{new pivot row}) \\ &= \text{current } s_3\text{-row itself} \\ &= 0, 4, 0, 0, 0, 1, 16 \end{aligned}$$

Summarizing these results we get the new simplex tableau corresponding to the new basis (x_2, s_2, s_3) as follows. Note that this new basis corresponds to the corner point E(0, 5) with value of OF as 15.

| Basis | z | x_1 | x_2 | s_1 | s_2 | s_3 | solution |
|-------|-----|----------------|-------|----------------|-------|-------|----------|
| z | 1 | $-\frac{1}{2}$ | 0 | $\frac{3}{4}$ | 0 | 0 | 15 |
| x_2 | 0 | $\frac{1}{2}$ | 1 | $\frac{1}{4}$ | 0 | 0 | 5 |
| s_2 | 0 | ① | 0 | $-\frac{1}{2}$ | 1 | 0 | 2 |
| s_3 | 0 | 4 | 0 | 0 | 0 | 1 | 16 |

From the tableau, the solution is

$$x_2 = 5, s_2 = 2, s_3 = 16 \text{ (basic variables)}$$

$$x_1 = 0, s_1 = 0 \text{ (non basic variables), value of OF is 15.}$$

Thus the solution moved from corner point A to corner point E in this one iteration. Optimal solution is not reached since all elements of z -row are not non negative. Since $-\frac{1}{2}$ is the most negative element in the current z -row, the variable x_1 will enter the basis. To determine the leaving variable again calculate the ratios of RHS column with the elements of the entering variable x_1 .

| Basis | Entering
x_1 | Solution | Ratio |
|-------|-------------------|----------|-------------------------------|
| x_2 | $\frac{1}{2}$ | 5 | 10 |
| s_2 | ① | 2 | 2 $\leftarrow \text{minimum}$ |
| s_3 | 4 | 16 | 4 |

Therefore, s_2 will leave the basis. The pivotal element is one; so pivot row remain the same. The

new simplex tableau corresponding to the new basis (x_2, x_1, s_3) is given below.

| Basis | z | x_1 | x_2 | s_1 | s_2 | s_3 | Solution |
|-------|-----|-------|-------|----------------|----------------|-------|----------|
| z | 1 | 0 | 0 | $\frac{1}{2}$ | $\frac{1}{2}$ | 0 | 16 |
| x_2 | 0 | 0 | 1 | $\frac{1}{2}$ | $-\frac{1}{2}$ | 0 | 4 |
| x_1 | 0 | 1 | 0 | $-\frac{1}{2}$ | 1 | 0 | 2 |
| s_3 | 0 | 0 | 0 | 2 | -4 | 1 | 8 |

Here new z -row = current z -row $- (-\frac{1}{2})$ pivot row
 $= (1, -\frac{1}{2}, 0, \frac{3}{4}, 0, 0, 15) \times$

$\times (-(-\frac{1}{2})) (0, 1, 0, -\frac{1}{2}, 1, 0, 2) =$

$= 1, 0, 0, \frac{1}{2}, \frac{1}{2}, 0, 16$

Here new x_2 -row = (current x_2 row) $- \frac{1}{2}$ (pivot row)

$= (0, -\frac{1}{2}, 0, \frac{3}{4}, 0, 0, 15) \times$

$\times - (1) (\frac{1}{2}), (0, 1, 0, -\frac{1}{2}, 1, 0, 2) =$

$= (1, 0, 0, \frac{1}{2}, \frac{1}{2}, 0, 16)$

Here new s_3 -row = current s_3 -row $- 4$ (pivot row)

$= (0, 4, 0, 0, 0, 1, 16)$

$-4 (0, 1, 0, -\frac{1}{2}, 1, 0, 2) =$

$= (0, 0, 0, 2, -4, 1, 8)$

Since all the elements in the current z -row are non-negative, the current solution is optimal. Read the solution from the tableau as

$x_2 = 4, x_1 = 2, s_3 = 8$ (basic variables)

$s_1 = 0, s_2 = 0$ (non basic variables)

value of O. F is 16.

Note that this solution corresponds to the corner point D(2, 4). In this second iteration solution moved from E to D.

Simplex Method: Minimization:

Example 1: Minimize: $z = x_1 + x_2 + x_3$ subject to $x_1 - x_4 - 2x_6 = 5, x_2 + 2x_4 - 3x_5 + x_6 = 3, x_3 + 2x_4 - 5x_5 + 6x_6 = 5.$

Solution: Fortunately the problem contains already a starting basic feasible solution with x_1, x_2, x_3 as the

basic variables.

| Basis | x_1 | x_2 | x_3 | x_4 | x_5 | x_6 | Solution |
|-------|-------|----------------|-----------------|----------------|------------------|-------|------------------|
| z | -1 | -1 | -1 | 0 | 0 | 0 | 13 |
| x_1 | 1 | 0 | 0 | -1 | 0 | -2 | 5 |
| x_2 | 0 | 1 | 0 | 2 | -3 | 1 | 3 |
| x_3 | 0 | 0 | 1 | 2 | -5 | 6 | 5 |
| z | -1 | -1 | -1 | 0 | 0 | 0 | $\frac{53}{6}$ |
| x_1 | 1 | 0 | $\frac{1}{3}$ | $-\frac{1}{3}$ | $-\frac{5}{3}$ | 0 | $\frac{20}{3}$ |
| x_2 | 0 | 1 | $-\frac{1}{6}$ | $\frac{5}{3}$ | $-\frac{13}{6}$ | 0 | $\frac{13}{6}$ |
| x_6 | 0 | 0 | $\frac{1}{6}$ | $\frac{1}{3}$ | $-\frac{5}{6}$ | 1 | $\frac{5}{6}$ |
| z | -1 | -1 | -1 | 0 | 0 | 0 | $\frac{213}{30}$ |
| x_1 | 1 | $\frac{1}{5}$ | $\frac{3}{10}$ | 0 | $-\frac{63}{30}$ | 0 | $\frac{213}{30}$ |
| x_4 | 0 | $\frac{3}{5}$ | $-\frac{1}{10}$ | 1 | $-\frac{13}{10}$ | 0 | $\frac{13}{10}$ |
| x_6 | 0 | $-\frac{1}{5}$ | $+\frac{4}{15}$ | 0 | $-\frac{2}{5}$ | 1 | $\frac{2}{5}$ |

Optimal solution: $x_1 = \frac{213}{30}, x_4 = \frac{13}{10}, x_6 = \frac{2}{5}$ O.F : $\frac{213}{30}$.

Unbounded solution:

Example 1: Solve LPP by simplex method.

Maximize: $z = 2x_1 - 3x_2 + 4x_3 + x_4$ subject to

$x_1 + 5x_2 + 9x_3 - 6x_4 \geq -2$

$3x_1 - x_2 + x_3 + 3x_4 \leq 10$

$-2x_1 - 3x_2 + 7x_3 - 8x_4 \geq 0$

and $x_1, x_2, x_3, x_4 \geq 0.$

Solution: Rewriting in the standard form

$-x_1 - 5x_2 - 9x_3 + 6x_4 \leq 2$

$3x_1 - x_2 + x_3 + 3x_4 \leq 10$

$2x_1 + 3x_2 - 7x_3 + 8x_4 \leq 0$

Introducing 3 slack variables x_5, x_6, x_7 we write the LPP as

maximize: $z = 2x_1 - 3x_2 + 4x_3 + x_4 + 0 \cdot x_5 + 0 \cdot$

$x_6 + 0 \cdot x_7$

subject to

$-x_1 - 5x_2 - 9x_3 + 6x_4 + x_5 = 2$

$3x_1 - x_2 + x_3 + 3x_4 + x_6 = 10$

$2x_1 + 3x_2 - 7x_3 + 8x_4 + x_7 = 0$

38.14 — MATHEMATICAL METHODS

Objective equation is: $z - 2x_1 + 3x_2 - 4x_3 - x_4 = 0$

The first simplex tableau with the 3 basic variables x_5, x_6, x_7 is given below:

| Basis | x_1 | x_2 | x_3 | x_4 | x_5 | x_6 | x_7 | Solution |
|-------|-------|-------|-------|-------|-------|-------|-------|----------|
| z | -2 | 3 | -4 | -1 | 0 | 0 | 0 | 0 |
| x_5 | -1 | -5 | -9 | 6 | 1 | 0 | 0 | 2 |
| x_6 | 3 | -1 | ① | 3 | 0 | 1 | 0 | 10 |
| x_7 | 2 | 3 | -7 | 8 | 0 | 0 | 1 | 0 |

Since -4 is most negative element in the z -row, the associated variable x_3 will enter the basis. Out of the three ratios $\frac{2}{-9}, \frac{10}{-1}, \frac{0}{-7}$, the first and third are ignored (because the denominator is negative). So x_6 will be outgoing variable. The pivotal element is 1. So pivotal row remains same. The next simplex tableau with x_5, x_3, x_7 is given below.

| Basis | x_1 | x_2 | x_3 | x_4 | x_5 | x_6 | x_7 | Solution |
|-------|-------|-------|-------|-------|-------|-------|-------|----------|
| z | 10 | -1 | 0 | 11 | 0 | 4 | 0 | 40 |
| x_5 | 26 | -14 | 0 | 33 | 1 | 9 | 0 | 92 |
| x_6 | 3 | -1 | 1 | 3 | 0 | 1 | 0 | 10 |
| x_7 | 23 | -4 | 0 | 29 | 0 | 7 | 1 | 70 |

In the current z -row, x_2 has the most negative coefficient -1, so normally x_2 should enter the basis. However, all the constraint coefficients under x_2 are negative, meaning that x_2 can be increased indefinitely without violating any of the constraints. Thus the problem has no bounded solution.

M-method:

Example 1: Solve the LPP by M-method

$$\text{minimize } z = 3x_1 + 2.5x_2$$

subject to

$$2x_1 + 4x_2 \geq 40$$

$$3x_1 + 2x_2 \geq 50$$

$$x_1, x_2 \geq 0$$

Solution: Introducing surplus variables x_3, x_4 , the greater than inequations are converted to equations. Minimize $z = 3x_1 + 2.5x_2 + 0 \cdot x_3 + 0 \cdot x_4$

subject to

$$2x_1 + 4x_2 - x_3 = 40$$

$$3x_1 + 2x_2 - x_4 = 50$$

$$x_1, x_2, x_3, x_4 \geq 0$$

In order to have a starting solution, introduce two artificial variables R_1 and R_2 in the first and second equations. In the objective function the cost coefficients for these undesirable artificial variables R_1 and R_2 are taken as a very large penalty value M . Thus the LPP takes the following form:

$$\text{Minimize } z = 3x_1 + 2.5x_2 + 0 \cdot x_3 + 0 \cdot x_4 +$$

$$+ M \cdot R_1 + M \cdot R_2 \quad (1)$$

subject to

$$2x_1 + 4x_2 - x_3 + R_1 = 40 \quad (2)$$

$$3x_1 + 2x_2 - x_4 + R_2 = 50 \quad (3)$$

and $x_1, x_2, x_3, x_4, R_1, R_2 \geq 0$

The z -column is omitted in the tableau for convenience because it does not change in all the iterations. Solving (2) and (3) we get

$$R_1 = 40 - 2x_1 - 4x_2 + x_3 \quad (4)$$

$$\text{and } R_2 = 50 - 3x_1 - 2x_2 + x_4 \quad (5)$$

Substituting (4) and (5) in the objective function (1) we get

$$z = 3x_1 + 2.5x_2 + M(40 - 2x_1 - 4x_2 + x_3) + M(50 - 3x_1 - 2x_2 + x_4)$$

or

$$z = (3 - 5M)x_1 + (2.5 - 6M)x_2 + M \cdot x_3 + M \cdot x_4 + 90 \cdot M$$

which is independent of R_1 and R_2 . Thus the objection equation is

$$z - (3 - 5M)x_1 - (2.5 - 6M)x_2 - Mx_3 - Mx_4 = 90M$$

The simplex tableau with the starting basic solution containing R_1 and R_2 as the basic variables is given below:

| Basis | x_1 | x_2 | x_3 | x_4 | R_1 | R_2 | Solution |
|-------|-------|---------|-------|-------|-------|-------|----------|
| z | -3+5M | -2.5-6M | -M | -M | 0 | 0 | 90M |
| R_1 | 2 | ④ | -1 | 0 | 1 | 0 | 40 |
| R_2 | 3 | 2 | 0 | -1 | 0 | 1 | 50 |

In the z -row, the most positive coefficient is $-2.5 + 6M$. So x_2 will be entering variable. Since $\frac{40}{4} = 10, \frac{50}{2} = 25$, the variable R_1 will leave the

basis. So 4 is the pivotal element. New simplex tableau is given below:

| Basis | x_1 | x_2 | x_3 | x_4 | R_1 | R_2 | Solution |
|-------|---------------------|-------|---------------------|-------|--------------------|-------|--------------------|
| z | $\frac{-3.5+4M}{2}$ | 0 | $\frac{-2.5+2M}{4}$ | $-M$ | $\frac{2.5-6M}{4}$ | 0 | $\frac{25+30M}{4}$ |
| x_2 | $\frac{1}{2}$ | 1 | $-\frac{1}{4}$ | 0 | $\frac{1}{4}$ | 0 | 40 |
| R_2 | ② | 0 | $\frac{1}{2}$ | -1 | $-\frac{1}{2}$ | 1 | 50 |

Since $\frac{-3.5+4M}{2}$ is the most positive element in the z -row, the variable x_1 will enter the basis forcing R_2 out since the minimum of the ratios $\frac{10}{\frac{1}{2}} = 20$, $\frac{30}{\frac{1}{2}} = 15$ is 15. So pivotal element is 2. The next simplex tableau is shown below:

| Basis | x_1 | x_2 | x_3 | x_4 | R_1 | R_2 | Solution |
|-------|-------|-------|-----------------|----------------|-------------------|-------------------|-----------------|
| z | 0 | 0 | $-\frac{3}{16}$ | $-\frac{7}{8}$ | $\frac{3-16M}{8}$ | $\frac{7}{8} - M$ | $\frac{205}{4}$ |
| x_2 | 0 | 1 | $-\frac{3}{8}$ | $\frac{1}{4}$ | $\frac{3}{8}$ | $-\frac{1}{4}$ | $\frac{5}{2}$ |
| x_1 | 1 | 0 | $\frac{1}{4}$ | $-\frac{1}{2}$ | $-\frac{1}{4}$ | $\frac{1}{2}$ | 15 |

Since all the elements in the z -row are non positive, the current solution is optimal given by $x_1 = 15$, $x_2 = \frac{5}{2}$ with value of objective function $\frac{205}{4}$ (observe that the artificial variables R_1 , R_2 and surplus variables x_3 , x_4 are nonbasic variables assuming zero values. Thus R_1 , R_2 have been forced out of the basis).

Two-Phase Method

Example 1: Solve LPP by two-phase method

$$\text{Maximize } z = 2x_1 + 3x_2 - 5x_3$$

subject to

$$x_1 + x_2 + x_3 = 7$$

$$2x_1 - 5x_2 + x_3 \geq 10$$

$$\text{and } x_1, x_2, x_3 \geq 0$$

Solution: **Phase I:** Introducing a surplus variable x_4 and two artificial variables R_1 and R_2 , the Phase I of the LPP takes the following form:

$$\text{Minimize } r = R_1 + R_2 \quad (1)$$

subject to

$$x_1 + x_2 + x_3 + R_1 = 7 \quad (2)$$

$$2x_1 - 5x_2 + x_3 - x_4 + R_2 = 10 \quad (3)$$

$$\text{and } x_1, x_2, x_3, x_4, R_1, R_2 \geq 0.$$

$$\text{From (2), } R_1 = 7 - x_1 - x_2 - x_3 \quad (4)$$

$$\text{From (3), } R_2 = 10 - 2x_1 + 5x_2 - x_3 + x_4 \quad (5)$$

Substituting (4), (5) in (1) we get the objection function as

$$\text{Minimize } r = (7 - x_1 - x_2 - x_3) + (10 - 2x_1 + 5x_2 - x_3 + x_4)$$

$$\text{or Minimize } r = -3x_1 + 4x_2 - 2x_3 + x_4 + 17 \text{ or } r + 3x_1 - 4x_2 + 2x_3 - x_4 = 17$$

The simplex tableau containing the basic solution with R_1 , R_2 as the basic variables is given below.

| Basis | x_1 | x_2 | x_3 | R_1 | R_2 | x_4 | Solution |
|-------|-------|-------|-------|-------|-------|-------|----------|
| r | 3 | -4 | 2 | 0 | 0 | -1 | 17 |
| R_1 | 1 | 1 | 1 | 1 | 0 | 0 | 7 |
| R_2 | ② | -5 | 1 | 0 | 1 | -1 | 10 |

The variable x_1 will enter the basis since 3 is most positive coefficient in the r -row of this minimization problem. The variable R_2 will leave the basis since $\frac{10}{2} = 5$ is less than $\frac{7}{1} = 7$. The pivotal element is 2. Dividing the pivot row by the pivot element 2, we get the new pivot row as $1, -\frac{5}{2}, \frac{1}{2}, 0, \frac{1}{2}, -\frac{1}{2}, 5$.

Here the new r -th-row:

$$= (3 - 4 \ 2 \ 0 \ 0 - 1 \ 17) - 3 \left(1 - \frac{5}{2} \ \frac{1}{2} \ 0 \ \frac{1}{2} - \frac{1}{2} \ 5\right)$$

$$= (0 \ \frac{7}{2} \ \frac{1}{2} \ 0 - \frac{3}{2} \ \frac{1}{2} \ 2)$$

Here the new R_1 -row:

$$= (1 \ 1 \ 1 \ 1 \ 0 \ 0 \ 7) - 1 \left(1 - \frac{5}{2} \ \frac{1}{2} \ 0 \ \frac{1}{2} - \frac{1}{2} \ 5\right)$$

$$= (0 \ \frac{7}{2} \ \frac{1}{2} \ 1 - \frac{1}{2} \ \frac{1}{2} \ 2)$$

The new simplex table with R_1 and x_1 as the basic variables is shown below:

| Basis | x_1 | x_2 | x_3 | R_1 | R_2 | x_4 | Solution |
|-------|-------|----------------------------|---------------|-------|----------------|----------------|----------|
| r | 0 | $\frac{7}{2}$ | $\frac{1}{2}$ | 0 | $-\frac{3}{2}$ | $\frac{1}{2}$ | 2 |
| R_1 | 0 | $\left(\frac{7}{2}\right)$ | $\frac{1}{2}$ | 1 | $-\frac{1}{2}$ | $\frac{1}{2}$ | 7 |
| R_2 | ① | $-\frac{5}{2}$ | $\frac{1}{2}$ | 0 | $\frac{1}{2}$ | $-\frac{1}{2}$ | 5 |

Now x_2 with most positive coefficient $\frac{7}{2}$, will enter

38.16 — MATHEMATICAL METHODS

the basis pushing out R_1 with ratio $\frac{2}{\frac{2}{7}} = \frac{4}{7}$. (The other ratio $\frac{5}{-\frac{5}{2}}$ is ignored since the denominator is negative). The pivotal element is $\frac{7}{2}$. The pivot row is $(0 \ 1 \ \frac{1}{7} \ \frac{2}{7} \ -\frac{1}{7} \ \frac{4}{7})$

Here new r -row:

$$= (0 \ \frac{7}{2} \ \frac{1}{2} \ 0 \ \frac{-3}{2} \ \frac{1}{2} \ 2) - \frac{7}{2} (0 \ 1 \ \frac{1}{7} \ \frac{2}{7} \ -\frac{1}{7} \ \frac{4}{7})$$

$$= (0 \ 0 \ 0 \ -1 \ -1 \ 0 \ 0)$$

Here new x_1 -row:

$$= (1 - \frac{5}{2} \ \frac{1}{2} \ 0 \ \frac{1}{2} - \frac{1}{2} \ 5) -$$

$$(-\frac{5}{2}) (0 \ 1 \ \frac{1}{7} \ \frac{2}{7} - \frac{1}{7} \ \frac{4}{7})$$

$$= (1 \ 0 \ \frac{6}{7} \ \frac{5}{7} \ \frac{1}{7} - \frac{1}{7} \ \frac{45}{7})$$

The next simplex tableau of the second iteration with x_1 and x_2 as the basic variables is given below.

| Basis | x_1 | x_2 | x_3 | R_1 | R_2 | x_4 | Solution |
|-------|-------|-------|---------------|---------------|----------------|----------------|----------------|
| r | 0 | 0 | 0 | -1 | -1 | 0 | 0 |
| x_2 | 0 | 1 | $\frac{1}{7}$ | $\frac{2}{7}$ | $-\frac{1}{7}$ | $\frac{1}{7}$ | $\frac{4}{7}$ |
| x_1 | 1 | 0 | $\frac{6}{7}$ | $\frac{5}{7}$ | $\frac{1}{7}$ | $-\frac{1}{7}$ | $\frac{45}{7}$ |

The phase I is complete since r is minimized attaining value 0, producing the basic *feasible solution* $x_1 = \frac{45}{7}$, $x_2 = \frac{4}{7}$. Note that both the artificial variables R_1 and R_2 have been forced out of the (starting) basis. Therefore the columns of R_1 and R_2 can altogether be ignored in the future simplex tableau.

Phase II: Having deleted the artificial variables R_1 and R_2 and having obtained a basic feasible solution x_1, x_2 we solve the *original problem* given by maximization of $z = 2x_1 + 3x_2 - 5x_3$

subject to

$$x_2 + \frac{1}{7}x_3 + \frac{1}{7}x_4 = \frac{4}{7}$$

$$x_1 + \frac{6}{7}x_3 - \frac{1}{7}x_4 = \frac{45}{7}$$

and $x_1, x_2, x_3, x_4 \geq 0$

The tableau associated with this phase II is

| Basis | x_1 | x_2 | x_3 | x_4 | Solution |
|-------|-------|-------|---------------|----------------|---|
| z | -2 | -3 | 5 | 0 | $\frac{90}{7} + \frac{12}{7} = \frac{102}{7}$ |
| x_2 | 0 | 1 | $\frac{1}{7}$ | $\frac{1}{7}$ | $\frac{4}{7}$ |
| x_1 | 1 | 0 | $\frac{6}{7}$ | $-\frac{1}{7}$ | $\frac{45}{7}$ |

Since x_2 with most negative element in the z -row is

already in the basis, the current solution is optimal. The basic feasible solution is $x_1 = \frac{45}{7}$, $x_2 = \frac{4}{7}$ and the maximum value of the objective function is $\frac{102}{7}$.

38.6 LINEAR PROGRAMMING PROBLEM

EXERCISE

Enumeration:

- If a person requires 3000 calories and 100 gms of protein per day find the optimal product mix of food items whose contents and costs are given below such that the total cost is minimum. Formulate this as an LPP. Enumerate all possible solutions. Identify basic, feasible, nonfeasible, degenerate, non degenerate solutions and optimal solution.

| | Bread
x_1 | Meat
x_2 | Potatoes
x_3 | Cabbage
x_4 | Milk
x_5 |
|-----------|----------------|---------------|-------------------|------------------|---------------|
| Calories | 2500 | 3000 | 600 | 100 | 600 |
| Protein | 80 | 150 | 20 | 10 | 40 |
| Cost (Rs) | 3 | 10 | 1 | 2 | 3 |

Ans: LPP: Minimize $z = 3x_1 + 10x_2 + x_3 + 2x_4 + 3x_5$.

$$\text{s.t. } 2500x_1 + 3000x_2 + 600x_3 + 100x_4 + 600x_5 = 3000$$

$$80x_1 + 150x_2 + 20x_3 + 10x_4 + 40x_5 = 100,$$

$$x_1, x_2, x_3, x_4, x_5 \geq 0; m = 2, n = 5, {}^5c_2 = 10$$

basic solutions: F = Feasible, NF: non-feasible, D: degenerate, ND: non degenerate

$$1. x_1 = \frac{10}{9}, x_2 = \frac{2}{27}, z = \frac{110}{7}, \text{ F, ND}$$

$$2. x_1 = 0, x_3 = 5, z = 5, \text{ F, D}$$

$$3. x_1 = \frac{20}{17}, x_4 = \frac{10}{17}, z = \frac{80}{77}, \text{ F, ND}$$

$$4. x_1 = \frac{15}{13}, x_5 = \frac{5}{26}, z = \frac{105}{26}, \text{ F, ND, optimal,}$$

$$5. x_2 = 0, x_3 = 5, z = 5, \text{ F, ND}$$

$$6. x_2 = \frac{4}{3}, x_4 = -10, z = -\frac{20}{3}, \text{ NF, ND}$$

$$7. x_2 = 2, x_5 = -5, z = 5, \text{ NF, ND}$$

$$8. x_3 = 5, x_4 = 0, z = 5, \text{ F, D}$$

$$9. x_3 = 5, x_5 = 0, z = 5, \text{ F, D}$$

$$10. x_4 = 10, x_5 = -30, z = -30, \text{ NF, ND}$$

All the remaining non basic variables are zero.

2. Find all basic solutions for
 $x_1 + 2x_2 + x_3 = 4, 2x_1 + x_2 + 5x_3 = 5$

Ans: (2, 1, 0) F, ND; (5, 0, -1), NF, ND;
 (0, $\frac{5}{3}$, $\frac{2}{3}$) F, ND.

3. Find the optimal solution by enumeration

$$\text{Max: } z = 5x_1 + 10x_2 + 12x_3$$

$$\text{s.t. } x_1, x_2, x_3 \geq 0,$$

$$15x_1 + 10x_2 + 10x_3 \leq 200, 10x_1 + 25x_2 + 20x_3 = 300$$

Ans: 1. (7.27, 9.1, 0, 0), $z = 127.27$

2. (5, 0, 12.5, 0), $z = 175$

3. (30, 0, 0, -250), NF

4. (0, -20, 40, 0), NF

5. (0, 12, 0, 80), $z = 120$

6. (0, 0, 15, 50), $z = 180$

(1) (2) (5) are F, ND:

(6) is optimal solution;

4. Find the optimal solution by enumeration

$$\text{Max: } z = 2x_1 + 3x_2 \quad \text{s.t. } 2x_1 + x_2 \leq 4, x_1, x_2 \geq 0, x_1 + 2x_2 \leq 5.$$

Ans: 1. (0, 0, 4, 5), $z = 0$, F, ND

2. (0, 4, 0, -3) NF

3. (0, 2.5, 1.5, 0), $z = 7.5$, F, ND

4. (2, 0, 0, 3), $z = 4$, F, ND

5. (5, 0, -6, 0), NF

6. (1, 2, 0, 0), $z = 8$, F, ND, optimal.

Simplex Method

Solve the following LPP by simplex method.

1. A firm can produce 5 different products using 3 different input quantities, as follows.

| Input quantity | Technical coefficients | | | | | Capacity |
|----------------|------------------------|---|---|---|---|----------|
| | 1 | 2 | 3 | 4 | 5 | |
| A | 1 | 2 | 1 | 0 | 1 | 100 |
| B | 0 | 1 | 1 | 1 | 1 | 80 |
| C | 1 | 0 | 1 | 1 | 0 | 50 |
| Profit | 2 | 1 | 3 | 1 | 2 | |

Maximize the profit

Ans: $x_1 = 20, x_3 = 30, x_5 = 50$, profit: Rs = 30

Hint: Max: $z = 2x_1 + x_2 + 3x_3 + x_4 + 2x_5$ s.t.
 $x_1 + 2x_2 + x_3 + x_5 \leq 100; x_2 + x_3 + x_4 + x_5 \leq 80; x_1 + x_3 + x_4 \leq 50$

2. Max: $z = 2x_1 + x_2$ s.t. $x_1, x_2 \geq 0; 3x_1 + 5x_2 \leq 15; 6x_1 + 2x_2 \leq 24$.

Ans: $x_1 = \frac{15}{4}, x_2 = \frac{3}{4}, z = \frac{33}{4}$

3. Max: $z = 3x_1 + 4x_2 + x_3 + 7x_4$ s.t. $8x_1 + 3x_2 + 4x_3 + x_4 \leq 7$,

$$2x_1 + 6x_2 + x_3 + 5x_4 \leq 3,$$

$$x_1 + 4x_2 + 5x_3 + 2x_4 \leq 8$$

$$x_1, x_2, x_3, x_4 \geq 0.$$

Ans: $x_1 = \frac{16}{19}, x_4 = \frac{5}{19}, x_7 = \frac{126}{19}, z = \frac{83}{19}$

4. Minimize $z = x_2 - 3x_3 + 2x_5$

$$\text{s.t. } x_1 + 3x_2 - x_3 + 2x_5 = 7,$$

$$-2x_2 + 4x_3 + x_4 = 12,$$

$$-4x_2 + 3x_3 + 8x_5 + x_6 = 10$$

Ans: $x_2 = 4, x_3 = 5, x_6 = 11, z = -11$

5. Max: $z = 2x_1 + 5x_2 + 4x_3$

$$\text{s.t. } x_1 + 2x_2 + x_3 \leq 4; x_1 + 2x_2 + 2x_3 \leq 6$$

Ans: $x_2 = 1, x_3 = 2, z = 13$

6. Max: $z = 5x_1 + 4x_2$ s.t., $x_1, x_2 \geq 0$;

$$6x_1 + 4x_2 \leq 24; x_1 + 2x_2 \leq 6,$$

$$x_1 - x_2 \geq -1; -x_2 \geq -2$$

Ans: $x_1 = 3, x_2 = \frac{3}{2}, z = 21$

7. Max: $z = x_1 + 2x_2 + x_3$ s.t. $x_1, x_2, x_3 \geq 0$,

$$2x_1 + x_2 - x_3 \leq 2; -2x_1 + x_2 - 5x_3 \geq -6;$$

$$4x_1 + x_2 + x_3 \leq 6.$$

Ans: $x_2 = 4, x_3 = 2, x_6 = 0, z = -10$

(Note: Degenerate solution)

8. Max: $z = -x_1 + 3x_2 - 2x_3$ s.t.

$$3x_1 - x_2 + 2x_3 \leq 7, 2x_1 - 4x_2 \geq -12;$$

$$4x_1 - 3x_2 - 8x_3 \geq -10; x_1, x_2, x_3 \geq 0.$$

Ans: $x_1 = 4, x_2 = 5, z = 11$

9. Max: $z = 6x_1 + 9x_2$ s.t. $x_1, x_2 \geq 0, 2x_1 + 2x_2 \leq 24; x_1 + 5x_2 \leq 44, 6x_1 + 2x_2 \leq 60$

Ans: $x_1 = 4, x_2 = 8, x_6 = 20, z = 96$

Multiple optima:

10. Minimize: $z = -x_1 - x_2$ s.t. $x_1, x_2 \geq 0$

$$x_1 + x_2 \leq 2, x_1 - x_2 \leq 1, x_2 \leq 1$$

Ans: $x_1 = \frac{3}{2}, x_2 = \frac{1}{2}, z = -2$

38.18 — MATHEMATICAL METHODS

Also another optimal solution is $x_1 = 1, x_2 = 1, z = -2$

11. Max: $z = 6x_1 + 4x_2$ s.t. $x_1, x_2 \geq 0, x_1 \leq 4, 2x_2 \leq 12, 3x_1 + 2x_2 \leq 18$

Ans: $x_1 = 4, x_2 = 3, z = 36$

Another optimal solution: $x_1 = 2, x_2 = 6, z = 36$

Unbounded solution

12. Max: $z = 4x_1 + x_2 + 3x_3 + 5x_4$ s.t.
 $3x_1 - 2x_2 + 4x_3 + x_4 \leq 10,$
 $8x_1 - 3x_2 + 3x_3 + 2x_4 \leq 20,$
 $-4x_1 + 6x_2 + 5x_3 - 4x_4 \leq 20$

Ans: Unbounded solution

Note: In the second simplex tableau, since x_2 has most negative coefficient in z -row, normally x_2 should enter the basis. But all the entries in the column under x_2 are negative or zero. So *no* variable can leave the basis. Hence the solution is *not* bounded

13. Min: $z = -3x_1 - 2x_2$ s.t. $x_1, x_2 \geq 0, x_1 - x_2 \leq 1, 3x_1 - 2x_2 \leq 6.$

Ans: Unbounded solution

Note: In the 3rd simplex tableau, x_3 having the most positive value (12) in z -row should normally enter the basis. But *all* the entries under x_3 are negative. So OF can be decreased indefinitely.

M-Method

14. Minimize: $z = 4x_1 + 2x_2$ s.t. $x_1, x_2 \geq 0, 3x_1 + x_2 \geq 27; -x_1 - x_2 \leq -21, x_1 + 2x_2 \geq 30.$

Ans: $x_1 = 3, x_2 = 18, z = 48$

15. Max: $z = x_1 + 2x_2 + 3x_3 - x_4$ s.t.
 $x_1 + 2x_2 + 3x_3 = 15, 2x_1 + x_2 + 5x_3 = 20,$
 $x_1 + 2x_2 + x_3 + x_4 = 10, x_1, x_2, x_3, x_4 \geq 0$

Ans: $x_1 = x_2 = x_3 = \frac{5}{2}, x_4 = 0, z = 15$

16. Min: $z = 2x_1 + x_2$ s.t. $x_1, x_2 \geq 0, 3x_1 + x_2 = 3, 4x_1 + 3x_2 \geq 6, x_1 + 2x_2 \leq 3$

Ans: $x_1 = \frac{3}{5}, x_2 = \frac{6}{5}, z = -\frac{12}{5}$

17. Min: $z = 3x_1 - x_2$ s.t. $x_1, x_2 \geq 0, 2x_1 + x_2 \geq 2; x_1 + 3x_2 \leq 3; x_2 \leq 4$

Ans: $x_1 = 3, x_3 = 4, x_6 = 4, z = 9$

18. Max: $z = x_1 + 5x_2$ s.t. $x_1, x_2 \geq 0, 3x_1 + 4x_2 \leq 6; x_1 + 3x_2 \geq 2$

Ans: $x_2 = \frac{3}{2}, x_4 = \frac{5}{2}, z = -\frac{15}{2}$

19. Min: $z = 2x_1 + 4x_2 + x_3$ s.t. $x_1 + 2x_2 - x_3 \leq 5; 2x_1 - x_2 + 2x_3 = 2; -x_1 + 2x_2 + 2x_3 \geq 1$

Ans: $x_3 = 1, x_4 = 6, x_6 = 1, z = 1$

Two-Phase Method:

20. Max: $z = x_1 + 5x_2 + 3x_3$ s.t. $x_1, x_2, x_3 \geq 0,$ and $x_1 + 2x_2 + x_3 = 3; 2x_1 - x_2 = 4$

Ans: $(2, 0, 1), z = 5$

21. Min: $z = 4x_1 + x_2$ s.t. $x_1, x_2, x_3, x_4 \geq 0,$ and $3x_1 + x_2 = 3; 4x_1 + 3x_2 \geq 6, x_1 + 2x_2 \leq 4.$

Ans: $(\frac{2}{5}, \frac{9}{5}, 1, 0), z = \frac{17}{5}$

22. Minimize $z = 7.5x_1 - 3x_2$ s.t. $x_1, x_2, x_3 \geq 0, 3x_1 - x_2 - x_3 \geq 3; x_1 - x_2 + x_3 \geq 2$

Ans: $x_1 = \frac{5}{4}, x_2 = 0, x_3 = \frac{3}{4}, z = \frac{75}{8}$

23. Minimize $z = 3x_1 + 2x_2$ s.t. $x_1, x_2, \geq 0, x_1 + x_2 \geq 2; x_1 + 3x_2 \leq 3, x_1 - x_2 = 1$

Ans: $x_1 = \frac{3}{2}; x_2 = \frac{1}{2}, z = \frac{11}{2}$

24. Minimize: $z = 5x_1 - 6x_2 - 7x_3$ s.t. $x_1 + 5x_2 - 3x_3 \geq 15; 5x_1 - 6x_2 + 10x_3 \leq 20; x_1 + x_2 + x_3 = 5, x_1, x_2, x_3 \geq 0$

Ans: $x_2 = \frac{15}{4}; x_3 = \frac{5}{4}, x_5 = 30, z = \frac{-125}{4}$

25. Max: $z = 2x_1 + x_2 + x_3$ s.t.
 $4x_1 + 6x_2 + 3x_3 \leq 8;$
 $3x_1 - 6x_2 - 4x_3 \leq 1; 2x_1 + 3x_2 - 5x_3 \geq 4;$
 $x_1, x_2, x_3 \geq 0$

Ans: $x_1 = \frac{9}{7}; x_2 = \frac{10}{21}, z = \frac{64}{21}$

38.7 THE TRANSPORTATION PROBLEM

The transportation problem is a special class of Linear programming problem. It is one of the earliest and most useful application of linear programming problem. It is credited to Hitchcock, Koopmans and Kantorovich. The transportation model consists of transporting (or shipping) a homogeneous product from ' m ' sources (or origins) to ' n ' destinations, with the objective of minimizing the total cost of transportation, while satisfying the supply and demand limits.

Let a_i denote the amount of supply at the i th source, b_j denote the demand at destination j ; c_{ij} denote the cost of transportation per unit from i th source to j th destination; x_{ij} the amount shipped from origin i to destination j . Then the transportation problem is to minimize the total cost of transportation

$$z = \sum_{i=1}^m \sum_{j=1}^n c_{ij} x_{ij} \quad (1)$$

subject to the constraints

$$\begin{aligned} \text{source constraint : } \sum_{j=1}^n x_{ij} &= a_i, \\ a_i &> 0; i = 1, 2, \dots, m \end{aligned} \quad (2)$$

Destination constraint:

$$\sum_{i=1}^m x_{ij} = b_j, \quad b_j > 0; j = 1, 2, \dots, n \quad (3)$$

and

$$x_{ij} \geq 0 \quad (4)$$

In the balanced transportation problem it is assumed that the total quantity required at the destinations is precisely the same as the amount available at the origins i.e.

$$\sum_{i=1}^m a_i = \sum_{j=1}^n b_j. \quad (5)$$

(5) is the necessary and sufficient condition for the existence of a feasible solution to (2) and (3).

Denoting the sources and destinations as nodes and routes as arcs, the transportation problem can be represented as a network shown below:

The system of equations (1) to (4) is a linear programming problem with $m + n$ equations in mn variables. The transportation problem always has a finite minimum feasible solution and an optimal solution contains $m + n - 1$ positive x_{ij} 's when there are m origins and n destinations. It is degenerate if less than $m + n - 1$ of the x_{ij} 's are positive. No transportation problem has ever been known to cycle.

Table for Transportation Problem

| | | Destinations | | | | | | |
|---------|----------|-------------------------|-------------------------|---------|-------------------------|---------|-------------------------|---------------------------|
| | | D_1 | D_2 | $\dots$ | D_j | $\dots$ | D_n | a_i |
| Sources | S_1 | $\frac{c_{11}}{x_{11}}$ | $\frac{c_{12}}{x_{12}}$ | | $\frac{c_{1j}}{x_{1j}}$ | | $\frac{c_{1n}}{x_{1n}}$ | a_1 |
| | S_2 | | | | | | | a_2 |
| | $\vdots$ | | | | | | | |
| | S_i | | | | | | | a_i |
| | $\vdots$ | | | | | | | |
| | S_m | $\frac{c_{m1}}{x_{m1}}$ | $\frac{c_{m2}}{x_{m2}}$ | | $\frac{c_{mj}}{x_{mj}}$ | | $\frac{c_{mn}}{x_{mn}}$ | a_m |
| | b_j | b_1 | b_2 | | b_j | | b_n | $\Sigma a_i = \Sigma b_j$ |

Note: Zero values for nonbasic variables are not filled while zero values for basic variables are shown in the tableau.

Like the simplex method the transport algorithm consists of determining the initial basic feasible solution, identifying the entering variable by the use of optimality condition and finally locating the leaving variable by the use of feasibility condition.

Determination of Initial (starting) Basic Feasible Solution

An initial basic feasible solution containing $m + n - 1$ basic variables can be obtained by any one of the following methods (a) the north west corner rule (b) row minimum (c) column minimum (d) matrix minimum (or least cost method) (e) Vogel approximation method. In general, Vogel's method gives the best starting solution. Although computationally north west corner rule is simple, the basic feasible solution obtained by this method may be far from optimal since the costs are completely ignored.

(a) North-west corner rule (due to Dantzig):

Step I: Allocate as much as possible to the north west corner cell $(1, 1)$. Thus let $x_{11} = \min(a_1, b_1)$. If $a_1 \leq b_1$ then $x_{11} = a_1$ and all $x_{1j} = 0$ for $j = 2, 3, \dots, n$ i.e. except x_{11} all other elements of the first row are zero. The first row is satisfied so cross out the first row and move to x_{21} of second row.

If $a_1 \geq b_1$ then $x_{11} = b_1$ and all $x_{i1} = 0$ for $i = 2, 3, \dots, m$ i.e., except x_{11} all other elements in the first column are zero. The first column is satisfied so cross out the first column and move to x_{12} of the second column.

Note: If both a row and column are satisfied (i.e., say $x_{11} = a_1 = b_1$) simultaneously, then cross out either row or column only but *not both* row and column.

Step II: Allocating as much as possible to the cell $(2, 1)$ or $(1, 2)$ cross out the row or column and move to $(3, 1)$ or $(1, 3)$.

Step III: If *exactly one* row or column is left uncrossed out, stop. Otherwise go to step II wherein move to lower row (below) if a row has just been crossed out or move to right column if a column has just been crossed out.

Note: Cells from "crossed out" row or column can not be chosen for basis cells at a later step in the determination of starting basic solution.

(b) Row-minimum

Identify the minimum cost element c_{1k} in the first row. (Ties are broken arbitrarily). Allocate as much as possible to cell $(1, k)$. If $a_1 \leq b_k$ then $x_{1k} = a_1$ so move to the second row after changing b_k to $b_k - a_1$. Identify the minimum element in second row and allocate as much as possible. Continue this process until all rows are exhausted. If $a_1 > b_k$ then $x_{11} = b_k$, change a_1 to $a_1 - b_k$, and identify the next smallest (minimum) element in the first row allocate, continue the process until the first row is completely satisfied.

(c) Column-minimum

This is exact parallel to the above row-minimum method except that minimum in the columns are identified instead of rows.

(d) Matrix minimum (least-cost method):

Identify the least (minimum) element c_{ij} in the entire matrix. (Ties are broken arbitrarily). Allocate as much as possible to the (i, j) th cell. If $a_i \leq b_j$ then $x_{ij} = a_i$, change b_j to $b_j - a_i$. If $a_i \geq b_j$ then $x_{ij} = b_j$, change a_i to $a_i - b_j$. Identify the next least element and allocate as much as possible. Continue this process until all the elements in the matrix are allocated (satisfied).

(e) Vogel approximation method

Step I. The row penalty for a row is obtained by subtracting the *smallest* cost element in that row from the *next smallest* cost element in the same row. Calculate the row penalties for each row and similarly column penalties for each column.

Step II. Identify the row or column with the largest penalty (ties are broken arbitrarily). In the selected row or column, allocate as much as possible to the cell with the least unit cost. Cross out the satisfied row or column. If a row and column are satisfied simultaneously, cross out either a row or column but *not both*. Assign zero supply (or demand) to the remaining row (or column). Any row or column with zero supply or demand should not be used in computing future penalties.

Step III.

- (a) A starting solution is obtained when exactly one row or one column with zero supply or demand remains uncrossed out. Stop.
- (b) Determine the basic variables in an uncrossed row (column) with positive (non zero) supply (demand) by the least-cost method. Stop.
- (c) Determine the *zero* basic variables in all the uncrossed out rows and columns having zero supply and demand by the least cost method. Stop.
- (d) Otherwise, go to step 1, recalculate the row and column penalties and go to step II.

Note: Vogel's method, which is a generalization of the matrix minimum (least cost method) gives better solution in most cases than all the other methods listed above.

Method of Multipliers

The optimal solution to the transportation problem is obtained by iterative computations using the method of multipliers (also known as *UV*-method or stepping-stone method or MODI (modified distribution) method). First of all, obtain a starting initial basic feasible solution containing $m + n - 1$ basic variables (by any one of the above methods).

Step I: Introduce unknowns u_i with row i and v_j with column j such that for each current basic variable x_{ij} in the tableau,

$$u_i + v_j = c_{ij}$$

is satisfied. This results in $m + n$ equations in $m + n$ unknowns. Assume that $u_1 = 1$ (or $u_1 = 0$). (Instead of u_1 , any other variable u_i or v_j can be chosen as zero or one, resulting in the same optimal solution but with different values in the tableau). Solving the equations in u_i, v_j we get u_i for $i = 1$ to m and v_j for $j = 1$ to n .

Step II. For each non basic variable, compute

$$\bar{c}_{ij} = u_i + v_j - c_{ij}$$

Step III: (a) If $\bar{c}_{ij} \leq 0$ for any i and j (i.e. for all non basic variables), stop. The current tableau gives the optimal solution with *minimum* cost.

(b) If $\bar{c}_{ij} > 0$, then solution is to be revised. The *entering variable* is one which has most positive $\bar{c}_{ij}$ (i.e., $\max \bar{c}_{ij}$ for all i and j).

(c) The *leaving variable* is determined by constructing a closed θ -loop which starts and ends at the entering variable and consists of connected horizontal and vertical lines (without any diagonals). Thus each corner of the loop lies in the basic cell, except the starting cell. The unknown θ is subtracted and added alternatively at the successive corners so as to adjust the supply and demand. From the cells in which θ is subtracted, choose the maximum value of θ such that $x_{ij} - \theta \geq 0$. This feasibility condition determines the leaving variable. Now go to step I.

Maximization A transportation problem in which the objective is to maximize (the profit) can be transferred to a minimization problem by subtracting all the entries of the cost matrix from the largest entry of the matrix.

Unbalanced problem in which the total supply is not equal to the total demand can always be transferred to a balanced transportation problem by augmenting it with a dummy source or dummy destination. A dummy destination is added when supply is greater than the demand. The cost of transportation from any source to this dummy destination is taken as zero. Similarly when demand is greater than supply, a dummy source is added. The cost of shipping from this dummy source to any destination is taken as zero. Now the corresponding balanced problem is solved by the method of multipliers.

Transshipment problem consists of transporting from source to destination via (through) intermediate or transient nodes, known as *transshipment nodes* which act as both sources and destination. The transshipment node should be large enough to allow the entire supply or demand to pass through it. Thus the 'capacity' of the transient node is the 'buffer' amount which equal the total supply or demand. Thus the transshipment model consists of pure supply nodes which tranship the original supply, pure demand nodes which receive the original demand, and transshipment node which can receive original supply plus the buffer or can tranship the original demand plus the buffer. A given transshipment prob-

38.22 — MATHEMATICAL METHODS

lem can be transformed to a regular transportation problem as follows:

- I. Identify the pure supply nodes, pure demand nodes and transshipment nodes from the given network.
- II. Denote the pure supply nodes and transshipment nodes as the sources.
- III. Denote the pure demand nodes and transshipment nodes as the destinations.
- IV. Note down the transportation costs c_{ij} read from the given network. If i th source is not connected to j th destination, put $c_{ij} = M$ where M is a large (penalty) value. Take $c_{ii} = 0$ since it costs zero for transporting from i th source to itself (i th destination).
- V. Identify supply at a pure supply node as the original supply; demand at a pure demand node as the original demand; supply at a transshipment node as the sum of original supply and buffer and finally demand at a transshipment node as the sum of the original demand and buffer.

Now the above transformed regular transportation problem can be solved by using the method of multipliers.

Degeneracy The solution of a transport problem is said to be degenerate when the number of basic variables in the solution is less than $m + n - 1$. In such cases, assign a small value ε to as many non-basic variables as needed to augment to $m + n - 1$ variables. The problem is solved in the usual way treating the ε cells as basic cells. As soon as the optimum solution is obtained, let $\varepsilon \rightarrow 0$.

38.8 Transportation Problem

WORKED OUT EXAMPLES

Starting Solution:

Example 1: Obtain a (non artificial) starting basic solution to the following transportation problem using (a) North west corner rule (b) Row-minimum (c) Column minimum (d) Least cost (Matrix minima)

(e) Vogel's (approximation) method

| | D_1 | D_2 | D_3 | |
|-------|-------|-------|-------|---|
| S_1 | 0 | 4 | 2 | 8 |
| S_2 | 2 | 3 | 4 | 5 |
| S_3 | 1 | 2 | 0 | 6 |
| | 7 | 6 | 6 | |

Solution:

(a) NWCR:

| | D_1 | D_2 | D_3 | |
|-------|---------------|------------------------------|---------------|------------------------------|
| S_1 | ⑦ 0 | ① 4 | 2 | 8 , $\mathcal{X}$ |
| S_2 | 2 | ⑤ 3 | 4 | $\mathcal{X}$ |
| S_3 | 1 | 2 | ⑥ 0 | $\mathcal{X}$ |
| | $\mathcal{X}$ | 6 , $\mathcal{X}$ | $\mathcal{X}$ | |

Supply as much as possible to the north-west corner cell (1, 1).

$$\text{Cost: } 7 \times 0 + 1 \times 4 + 5 \times 3 + 6 \times 0 = 19$$

Note: This is a degenerate solution because it contains only 4 basic variables (instead of $3 + 3 - 1 = 5$ basic variables).

(b) Row Minimum

| | D_1 | D_2 | D_3 | |
|-------|---------------|------------------------------|------------------------------|------------------------------|
| S_1 | ⑦ 0 | 4 | ① 2 | 8 , $\mathcal{X}$ |
| S_2 | 2 | ⑤ 3 | 4 | $\mathcal{X}$ |
| S_3 | 1 | ① 2 | ⑤ 0 | $\mathcal{X}$ |
| | $\mathcal{X}$ | 6 , $\mathcal{X}$ | 6 , $\mathcal{X}$ | |

Allot as much as possible in the first row to the cell with least (minimum) cost i.e. (1, 1). The balance allot to the next least cell in the first row.

$$\text{Cost: } 7 \times 0 + 1 \times 2 + 5 \times 3 + 1 \times 2 + 5 \times 0 = 19$$

Note: This is a non-degenerate solution (since it contains $3 + 3 - 1 = 5$ basic variables).

(c) Column Minimum

| | D_1 | D_2 | D_3 | |
|-------|--------------|-----------------------------|-----------------------------|-----------------------------|
| S_1 | ⑦ 0 | 4 | ① 2 | 8 , 8 |
| S_2 | 2 | 3 | ⑤ 4 | 8 |
| S_3 | 1 | ⑥ 2 | 0 | 8 |
| | 8 | 8 , 8 | 8 , 8 | |

Cost: $7 \times 0 + 1 \times 2 + 5 \times 4 + 6 \times 2 = 34$

This is a degenerate solution containing 4 basic variables.

(d) Least cost method (matrix minima)

| | D_1 | D_2 | D_3 | |
|-------|--------------|-----------------------------|--------------|-----------------------------|
| S_1 | ⑦ 0 | ① 4 | 2 | 8 , 8 |
| S_2 | 2 | ⑤ 3 | 4 | 8 |
| S_3 | 1 | 2 | ⑥ 0 | 8 |
| | 8 | 8 , 8 | 8 | |

Allot as much possible to that cell which has least cost in the entire matrix say (1, 1) (tie broken arbitrarily between (1, 1) and (3, 3)).

Cost: $7 \times 0 + 1 \times 4 + 5 \times 3 + 6 \times 0 = 19$

This is a degenerate solution.

(e) Vogel's (approximation) method

| | D_1 | D_2 | D_3 | |
|-------|--------------|-----------------------------|-----------------------------|-----------------------------|
| S_1 | ⑦ 0 | 4 | ① 2 | 8 , 8 |
| S_2 | 2 | ⑤ 3 | 4 | 8 |
| S_3 | 1 | ① 2 | ⑤ 0 | 8 , 8 |
| | 8 | 8 , 8 | 8 , 8 | |

| | | | |
|---------------|----|----|---|
| Row penalties | 2✓ | 2✓ | |
| | 1 | 1 | 1 |
| | 1 | 2 | 2 |

| | | | |
|------------------|---|---|------|
| Column penalties | 1 | 1 | 2 |
| | | 1 | 2 |
| | | | 1 4✓ |

Cost: $7 \times 0 + 2 \times 1 + 3 \times 5 + 2 \times 1 + 0 \times 5 = 19$

This is a non-degenerate solution.

Method of Multipliers

Example 1: Solve the following transportation problem by *UV*-method obtaining the initial basic solution by (a) Vogel's method (b) NWCR (c) compare the number of iterations in (a) and (b).

| | D_1 | D_2 | D_3 | D_4 | a_i |
|-------|-------|-------|-------|-------|-------|
| S_1 | 3 | 1 | 0 | 2 | 30 |
| S_2 | 0 | 2 | 1 | 4 | 20 |
| S_3 | 2 | 0 | 5 | 0 | 50 |
| b_j | 10 | 25 | 30 | 35 | 100 |

(a) Initial solution by Vogel's method

| | D_1 | D_2 | D_3 | D_4 | a_i | Row penalties |
|-------|-------|-------|-------|-------|-------|---------------|
| S_1 | 3 | 1 | 0 | 2 | 30 | 1 2 2 2 |
| S_2 | 0 | 2 | 1 | 4 | 20 | 1 1 1 3✓ |
| S_3 | 2 | 0 | 5 | 0 | 50 | 2✓ 2✓ |
| b_j | 10 | 25 | 30 | 35 | 100 | |

| | | | | |
|------------------|----|---|---|---|
| Column penalties | 2 | 1 | 1 | 2 |
| | 2 | | 1 | 2 |
| | 3✓ | | 1 | 2 |
| | | | 1 | 2 |

Thus the initial basic feasible solution by Vogel's method is given by

| | D_1 | D_2 | D_3 | D_4 |
|-------|-------|-------|-------|-------|
| S_1 | 3 | 1 | 0 | 2 |
| S_2 | 0 | 2 | 1 | 4 |
| S_3 | 2 | 0 | 5 | 0 |

where the basic variables are circled

Total cost: $(20 \times 0) + (10 \times 2) + (10 \times 0) + (10 \times 1) + (25 \times 0) + (25 \times 0) = 30$

In the *UV*-method (method of multipliers) associate the multipliers u_i and v_j with row i and column

38.24 — MATHEMATICAL METHODS

j such that for each basic variable x_{ij} we have

$$u_i + v_j = x_{ij}$$

Arbitrarily choosing $u_1 = 1$ we solve for the remaining u_i, v_j 's as follows:

| Basic variable | u, v equation | solution |
|----------------|-----------------|------------|
| x_{13} | $u_1 + v_3 = 0$ | $v_3 = -1$ |
| x_{14} | $u_1 + v_4 = 2$ | $v_4 = 1$ |
| x_{34} | $u_3 + v_4 = 0$ | $u_3 = -1$ |
| x_{32} | $u_3 + v_2 = 0$ | $v_2 = 1$ |
| x_{23} | $u_2 + v_3 = 1$ | $u_2 = 2$ |
| x_{21} | $u_2 + v_1 = 0$ | $v_1 = -2$ |

To summarize $u_1 = 1, u_2 = 2, u_3 = -1$

$v_1 = -2, v_2 = 1, v_3 = -1, v_4 = 1$

Now using u_i and v_j the non basic variables are calculated as

$$x_{ij} = u_i + v_j - c_{ij}$$

Thus

| Nonbasic variable x_{ij} | Value
$u_i + v_j - c_{ij}$ |
|----------------------------|--|
| x_{11} | $u_1 + v_1 - c_{11} = 1 - 2 - 3 = -4$ |
| x_{12} | $u_1 + v_2 - c_{12} = 1 + 1 - 1 = 1$ |
| x_{22} | $u_2 + v_2 - c_{22} = 2 + 1 - 2 = 1$ |
| x_{24} | $u_2 + v_4 - c_{24} = 2 + 1 - 4 = -1$ |
| x_{31} | $u_3 + v_1 - c_{31} = -1 - 2 - 2 = -5$ |
| x_{33} | $u_3 + v_3 - c_{33} = -1 - 1 - 5 = -7$ |

Non basic variables are placed in the south east corner of each cell. Then the new table is

| | | | | | | |
|------------|-------|--|---|--|--|-------|
| | | $v_1 = -2$ | $v_2 = 1$ | $v_3 = -1$ | $v_4 = 1$ | |
| | | D_1 | D_2 | D_3 | D_4 | a_i |
| $u_1 = 1$ | S_1 | $\begin{array}{ c } \hline 3 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 1 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | 30 |
| | | $\begin{array}{ c } \hline -4 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 1 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 20 \\ \hline \end{array}$ | $\begin{array}{ c } \hline \theta \\ \hline \end{array}$ | |
| $u_2 = 2$ | S_2 | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 1 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 4 \\ \hline \end{array}$ | 20 |
| | | $\begin{array}{ c } \hline 10 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 1 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 10 \\ \hline \end{array}$ | $\begin{array}{ c } \hline -1 \\ \hline \end{array}$ | |
| $u_3 = -1$ | S_3 | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | $\begin{array}{ c } \hline -\theta \\ \hline \end{array}$ | $\begin{array}{ c } \hline 5 \\ \hline \end{array}$ | $\begin{array}{ c } \hline \theta \\ \hline \end{array}$ | 50 |
| | | $\begin{array}{ c } \hline -5 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 25 \\ \hline \end{array}$ | $\begin{array}{ c } \hline -7 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 25 \\ \hline \end{array}$ | |
| | b_j | 10 | 25 | 30 | 35 | |

During computation, it is not necessary to write u, v equations and solve them explicitly. Instead, choosing $u_1 = 1$, compute v_3, v_4 from the basic variables x_{13}, x_{14} in the first row. Now using v_4, u_3 is obtained from the basic variable x_{34} . Similarly u_2 is obtained using v_3 from the basic variable x_{23} . Now using u_2 we get v_1 and finally using u_3 we get v_2 .

Incoming: Amongst the nonbasic variables, the entering variable is the one with the most positive value (in the south east corner of the cell). Thus x_{21} will be the entering variable.

Outgoing: The leaving (basic) variable is determined by constructing a closed θ -loop which starts and ends at the entering variable x_{21} . In this modified distribution all variables should be nonnegative and supply and demand satisfied. Then

$$x_{14} = 10 - \theta \geq 0$$

$$x_{22} = 25 - \theta \geq 0$$

The maximum value of θ is 10 (which keeps both x_{14}, x_{22} nonnegative i.e., $x_{14} = 0, x_{22} = 15 > 0$). Thus the new table is

| | | | | | | |
|-----------|-------|--|--|--|--|-------|
| | | $v_1 = -2$ | $v_2 = 0$ | $v_3 = -1$ | $v_4 = 0$ | |
| | | D_1 | D_2 | D_3 | D_4 | a_i |
| $u_1 = 1$ | S_1 | $\begin{array}{ c } \hline 3 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 1 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | 30 |
| | | $\begin{array}{ c } \hline -4 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 10 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 20 \\ \hline \end{array}$ | | |
| $u_2 = 2$ | S_2 | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 1 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 4 \\ \hline \end{array}$ | 20 |
| | | $\begin{array}{ c } \hline 10 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 10 \\ \hline \end{array}$ | $\begin{array}{ c } \hline -2 \\ \hline \end{array}$ | |
| $u_3 = 0$ | S_3 | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 5 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | 50 |
| | | $\begin{array}{ c } \hline -4 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 15 \\ \hline \end{array}$ | $\begin{array}{ c } \hline -6 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 35 \\ \hline \end{array}$ | |
| | b_j | 10 | 25 | 30 | 35 | |

Since for all non basic variables $x_{11}, x_{14}, x_{22}, x_{24}, x_{31}, x_{33}$ the values (in the southeast) of $u_i + v_j - c_{ij}$ are all negative, the current table is the optimal. The optimal solution with least cost is $(10 \times 1) + (20 \times 0) + (10 \times 0) + (10 \times 1) + (15 \times 0) + (35 \times 0) = 20$.

(b) Initial solution by NWC rule: Suppressing the working details we get the optimal solution in 3 iterations.

| | | | | | | |
|--|--|--|--|---|----|----|
| | $\begin{array}{ c } \hline 3 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 1 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | 30 | 20 |
| | $\begin{array}{ c } \hline 10 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 20 \\ \hline \end{array}$ | | | | |
| | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 1 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 4 \\ \hline \end{array}$ | 20 | 15 |
| | | $\begin{array}{ c } \hline 5 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 15 \\ \hline \end{array}$ | | | |
| | $\begin{array}{ c } \hline 2 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 5 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 0 \\ \hline \end{array}$ | 30 | 35 |
| | | $\begin{array}{ c } \hline 15 \\ \hline \end{array}$ | $\begin{array}{ c } \hline 35 \\ \hline \end{array}$ | | | |
| | 10 | 25 | 30 | 35 | | |
| | | 5 | 15 | | | |

Associated cost

$$= (10 \times 3) + (20 \times 1) + (5 \times 2) + (15 \times 1) + (15 \times 5) + (35 \times 0) = 150$$

By UV method with $u_1 = 1$ we get

| | | | | |
|-----------|-----------|------------|------------|------------|
| | $v_1 = 2$ | $v_2 = 0$ | $v_3 = -1$ | $v_4 = -6$ |
| $u_1 = 1$ | 3 | 1 | 0 | 2 |
| | (10) | (20) | 0 | -7 |
| $u_2 = 2$ | 0 | 2 | 1 | 4 |
| | 4 | (5) | + | (15) |
| $u_3 = 6$ | 2 | ✓ θ | 0 | -5 |
| | 6 | 6 | (15) | (35) |

with $\theta = 5$, x_{22} is outgoing and x_{12} is the incoming variable.

Then the new table is

| | | | | |
|----|------|------|------|------------|
| | 2 | 0 | 5 | 0 |
| 1 | 3 | - | 1 | ✓ θ |
| | (10) | (20) | 6 | -1 |
| -4 | 0 | 2 | 1 | 4 |
| | -2 | -6 | (20) | -8 |
| 0 | 2 | + | 0 | 5 |
| | 0 | (5) | (10) | (35) |

with cost 120. Now choose $\theta = 10$, x_{13} will be incoming and x_{33} will be outgoing variable resulting in the following table.

| | | | | |
|---|------------|------|------|------|
| | 2 | 0 | -1 | 0 |
| 1 | 3 | 1 | 0 | 2 |
| | (10) | (10) | (10) | + |
| 2 | ✓ θ | 0 | 2 | 1 |
| | 4 | 0 | (20) | - |
| 0 | 2 | 0 | 5 | 0 |
| | 0 | (15) | -6 | (35) |

choose $\theta = 10$. Then x_{11} is outgoing and x_{21} is incoming with new following table which is the optimal solution since all $x_{ij} = u_i + v_j - c_{ij} \leq 0$.

| | | | | |
|---|------|------|------|------|
| | -2 | 0 | -1 | 0 |
| 1 | 3 | 1 | 0 | 2 |
| | (10) | (20) | - | -1 |
| 2 | (10) | 0 | 2 | 1 |
| | 4 | 0 | (10) | -2 |
| 0 | 2 | 0 | 5 | 0 |
| | -4 | (15) | -6 | (35) |

optimal cost is 20. Optimal solution is $x_{12} = 10$, $x_{13} = 20$, $x_{21} = 10$, $x_{23} = 10$, $x_{32} = 15$, $x_{34} = 35$.

(c) **The number of iterations** is less when the initial solution is obtained by Vogel's method.

Unbalanced Transportation Problem

Example 1: Three electric power plants P_1 , P_2 , P_3 with capacities of 25, 40 and 30 kWh supply electricity to three cities C_1 , C_2 , C_3 . The maximum demand at the three cities are estimated at 30, 35 and 25 kWh. The price per kWh at the three cities is given in the following table

| | | City | | |
|-------|-------|-------|-------|-------|
| | | c_1 | c_2 | c_3 |
| Plant | P_1 | 600 | 700 | 400 |
| | P_2 | 320 | 300 | 350 |
| | P_3 | 500 | 480 | 450 |

During the month of August, there is a 20% increase in demand at each of the three cities, which can be met by purchasing electricity from another plant P_4 at a premium rate of Rs 1000/- per kWh. plant 4 is not linked to city 3. Determine the most economical plane for the distribution and purchase of additional energy. Determine the cost of additional power purchased by each of the three cities.

Solution:

| | | City | | |
|-------|------|-------|-------|-------|
| | | c_1 | c_2 | c_3 |
| P_1 | 600 | 700 | 400 | 25 |
| P_2 | 320 | 300 | 350 | 40 |
| P_3 | 500 | 480 | 450 | 70 |
| P_4 | 1000 | 1000 | M | 13 |
| | 30+6 | 35+7 | 25+5 | 148 |

Apply Vogel's method to obtain the initial solution. For all nonbasic variables $u_i + v_j - c_{ij} \leq 0$. The present table is optimal. The optimal solution is $P_1C_3 : 25$, $P_2C_1 = 23$, $P_2C_2 = 17$, $P_3C_2 = 25$, $P_3C_3 = 5$, $P_4C_1 = 13$.

Total cost: Rs 36,710 + Rs 13000 = Rs 49710 only city C_1 purchases an additional 13 kWh power from plant P_4 at an additional cost of Rs 13,000/-.

| | c_1 | c_2 | c_3 | | |

Transshipment Problem

Example 1: The unit shipping costs through the routes from nodes 1 and 2 to nodes 5 and 6 via nodes 3 and 4 are given in the following network. Solve the transshipment model to find how the shipments are made from the sources to destinations.

Solution: The entire supply of 300 units is transshipped from nodes P_1 and P_2 through T_3 and T_4 ultimately to destination nodes D_5 and D_6 . Here P_1 , P_2 are pure supply nodes; T_3 , T_4 , D_5 are transshipment nodes; D_6 is pure demand node. The transshipment model gets converted to a regular transportation problem with 5 sources P_1 , P_2 , T_3 , T_4 , D_5 and 4 destinations T_3 , T_4 , D_5 and D_6 . The buffer amount B = total supply (or demand) = $100 + 200 =$ (or $150 +$

150) = 300 units. A high penalty cost M is associated with cell c_{ij} when there is no route from i th origin to the j th destination. Zero cost is associated with cells (i, i) which do not transfer to itself. The initial solution is obtained by Vogel's method. Taking $u_1 = 0$ and $M = 99$ and applying method of multipliers we have

| | | | | | |
|-------------|-----------|-----------|------------|------------|-----|
| | $v_1 = 1$ | $v_2 = 0$ | $v_3 = 97$ | $v_4 = 98$ | |
| | T_3 | T_4 | D_5 | D_6 | |
| $u_1 = 0$ | P_1 | 1 | 4 | 99 | 99 |
| | | 100 | -4 | -2 | -1 |
| $u_2 = 2$ | P_2 | 3 | 2 | 99 | 99 |
| | | 200 | 0 | 0 | 1 |
| $u_3 = -91$ | T_3 | 0 | 1 | 6 | 99 |
| | | -90 | -92 | 300 | -92 |
| $u_4 = 0$ | T_4 | 3 | 0 | 5 | 8 |
| | | -2 | 300 | 0 | 90 |
| $u_5 = 97$ | D_5 | 99 | 99 | 0 | 1 |
| | | -195 | -196 | 150 | 150 |
| | | 300 | 300 | 450 | 150 |

value of objective function is Rs 2650. Not all $\bar{c}_{ij} \leq 0$. Note that $\bar{c}_{43} = 92$ is most positive so the variable x_{43} will enter into the basis. To determine the variable leaving the basis, construct θ -loop from cells (4, 3) to (2, 3) to (2, 2) to (4, 2). Choose $\theta = 0$ to maintain feasibility. Adjusting $\theta = 0$, the leaving variable is x_{23} . Thus the new tableau is

| | | | | | |
|-----------|-----------|-------|-------|-------|-----|
| | $v_1 = 1$ | 0 | 5 | 6 | |
| | t_3 | t_4 | d_5 | d_6 | |
| $u_1 = 0$ | P_1 | 1 | 4 | 99 | 99 |
| | | 100 | -4 | -94 | -93 |
| 2 | P_2 | 3 | 2 | 99 | 99 |
| | | 200 | 0 | 0 | -91 |
| 1 | t_3 | 0 | 1 | 6 | 99 |
| | | 0 | 2 | 0 | -92 |
| 0 | t_4 | 3 | 0 | 5 | 8 |
| | | -2 | 300 | 0 | -2 |
| -5 | d_5 | 99 | 99 | 0 | 1 |
| | | -103 | -104 | 150 | 150 |
| | | 300 | 300 | 150 | 150 |

value of objective function is Rs 2650. Not all $\bar{c}_{ij} \leq 0$. Note that $\bar{c}_{31} = 2$ is most positive. So x_{31} is the entering variable. To determine the leaving

variable construct a θ -loop from cells (3, 1) to (2, 1) to (2, 2), to (4, 2) to (4, 3) to (3, 3) to (3, 1). Choose maximum value of $\theta = 200$. Then x_{21} will be the leaving variable. Adjusting $\theta = 200$, the new tableau is given below.

| | | 1 | 2 | 7 | 8 | |
|----|-------|-------|-------|-------|-------|-----|
| | | t_3 | t_4 | d_5 | d_6 | |
| 0 | p_1 | (100) | 1 | 4 | 99 | 99 |
| | | | -2 | -92 | -91 | 100 |
| 0 | p_2 | | 3 | 2 | 99 | 99 |
| | | -2 | (200) | -92 | -91 | 200 |
| -1 | t_3 | (200) | 0 | 1 | 6 | 99 |
| | | | 0 | (100) | -92 | 300 |
| -2 | t_4 | | 3 | 0 | 5 | 8 |
| | | -4 | (100) | (200) | -2 | 300 |
| -7 | d_5 | | 99 | 99 | 0 | 1 |
| | | -105 | -104 | (150) | (150) | 300 |
| | | 300 | 300 | 450 | 150 | |

Observe that all $\bar{c}_{ij} \leq 0$. Therefore the current tableau is optimal. The basic feasible optimal solution is $x_{11} = 100$, $x_{22} = 200$, $x_{31} = 200$, $x_{33} = 100$, $x_{42} = 100$, $x_{43} = 200$, $x_{53} = 150$, $x_{54} = 150$. The value of the objective function is $(100 \times 1) + (200 \times 2) + (200 \times 0) + (100 \times 6) + (100 \times 0) + (200 \times 5) + (150 \times 0) + (150 \times 1) = 2250$

Maximization:

Example 1: Solve the following transportation problem to maximize the profit.

| | D_1 | D_2 | D_3 | |
|-------|-------|-------|-------|----|
| S_1 | 5 | 1 | 8 | 12 |
| S_2 | 2 | 4 | 0 | 14 |
| S_3 | 3 | 6 | 7 | 4 |
| | 9 | 10 | 11 | |

Solution: To transform this problem to a minimization problem, subtract all the cost entries in the matrix from the largest cost entry 8. Then the relative loss matrix is

| | | | | |
|---|----|----|----|-----|
| 3 | 7 | 0 | 12 | 3 ✓ |
| 6 | 4 | 8 | 14 | 2 |
| 5 | 2 | 1 | 4 | 1 |
| 9 | 10 | 11 | | |
| 2 | 2 | 1 | | |

Applying vogel's method we get max penalty 3. So allocate to (1, 3).

| | | | | | |
|---|----|----|----|---|-----|
| 3 | 7 | 0 | 12 | 1 | 4 ✓ |
| 6 | 4 | 8 | 14 | 2 | |
| 5 | 2 | 1 | 4 | 3 | |
| 9 | 10 | 11 | | | |
| 2 | 2 | | | | |

Allocate to (1, 1) since 4 is the largest penalty

| | | | | | |
|---|----|----|----|---|-----|
| 3 | 7 | 0 | 12 | 1 | 4 ✓ |
| 6 | 4 | 8 | 14 | 2 | |
| 5 | 2 | 1 | 4 | 3 | |
| 9 | 10 | 11 | | | |
| 2 | 2 | | | | |

Allocate to (3, 2) since 3 is the largest penalty.

| | | | | | |
|-----|----|----|----|-----|-----|
| ① 3 | 7 | 0 | 12 | 1 | 4 ✓ |
| 6 | 4 | 8 | 14 | 2 | |
| 5 | 2 | 1 | 4 | 3 ✓ | |
| 9 | 10 | 11 | | | |
| 8 | 2 | | | | |

| | | | | | |
|-----|----|----|----|-----|-----|
| ① 3 | 7 | 0 | 12 | 1 | 4 ✓ |
| 6 | 4 | 8 | 14 | 2 | |
| 5 | 2 | 1 | 4 | 3 ✓ | |
| 9 | 10 | 11 | | | |
| 8 | 6 | | | | |

Finally

| | | | | | |
|-----|-----|----|----|-----|-----|
| ① 3 | 7 | 0 | 12 | 1 | 4 ✓ |
| ⑧ 6 | ④ 4 | 8 | 14 | 2 | |
| 5 | ④ 2 | 1 | 4 | 3 ✓ | |
| 9 | 10 | 11 | | | |
| 8 | 6 | | | | |

The maximum profit (wrt the original cost matrix) is $(1 \times 5) + (11 \times 8) + (8 \times 2) + (6 \times 4) + (4 \times 6) = 157$

38.28 — MATHEMATICAL METHODS

Degeneracy

Example 1: Solve the following TP using NWCR

| | D_1 | D_2 | D_3 | |
|-------|-------|-------|-------|---|
| S_1 | 0 | 4 | 2 | 8 |
| S_2 | 2 | 3 | 4 | 5 |
| S_3 | 1 | 2 | 0 | 6 |
| | 7 | 6 | 6 | |

Solution: By NWC rule

| | D_1 | D_2 | D_3 | |
|-------|-------|-------|-------|---|
| S_1 | ⑦ | ① | 2 | 8 |
| S_2 | 2 | ⑤ | 4 | 5 |
| S_3 | 1 | 2 | ⑥ | 6 |
| | 7 | 6 | 6 | |

This is a degenerate solution since it contains only 4 basic variables (instead of $3 + 3 - 1 = 5$ basic variables). To get rid of degeneracy, introduce any one non-basic variable say in cell (3, 2) at ' ε ' level where ε is a small quantity. Thus

| | | -1 | 3 | 1 | |
|-----------|-------|-------|-------|-------|----|
| | | D_1 | D_2 | D_3 | |
| $u_1 = 1$ | S_1 | ⑦ | ① | 2 | 0 |
| 0 | S_2 | 2 | ⑤ | 4 | -3 |
| -1 | S_3 | 1 | ⑥ | 0 | -3 |
| | | -3 | ⑥ | 0 | |

since all $\bar{c}_{ij} \leq 0$ current solution is optimal. Now letting $\varepsilon \rightarrow 0$ we get the solution as $x_{11} = 7, x_{12} = 1, x_{22} = 5, x_{32} = 0, x_{33} = 6$ with OF = $19 + 2 \cdot \varepsilon = 19$ as $\varepsilon \rightarrow 0$

38.9 TRANSPORTATION PROBLEM

EXERCISE

- Obtain the starting solution (and the corresponding cost i.e. value of objective function: OF)

of the following transportation problems by (a) North west corner rule (b) Row minimum (c) Column minimum (d) Least cost method (e) Vogel's method.

| | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-------|---|----|---------------|---|---|----|---|----|---|---|----|----|----|------|---|---|---|---|----|---|----|----|----|----|----|----|----------------------------|
| (i) | <table><tr><td>1</td><td>2</td><td>6</td></tr><tr><td>0</td><td>4</td><td>2</td></tr><tr><td>3</td><td>1</td><td>5</td></tr><tr><td>10</td><td>10</td><td>10</td></tr></table> | 1 | 2 | 6 | 0 | 4 | 2 | 3 | 1 | 5 | 10 | 10 | 10 | (ii) | <table><tr><td>5</td><td>1</td><td>8</td></tr><tr><td>2</td><td>4</td><td>0</td></tr><tr><td>3</td><td>6</td><td>7</td></tr><tr><td>9</td><td>10</td><td>11</td></tr></table> | 5 | 1 | 8 | 2 | 4 | 0 | 3 | 6 | 7 | 9 | 10 | 11 |
| 1 | 2 | 6 | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0 | 4 | 2 | | | | | | | | | | | | | | | | | | | | | | | | | |
| 3 | 1 | 5 | | | | | | | | | | | | | | | | | | | | | | | | | |

| 60 | 60 | 20 | 10 | | | | | | | | | | | | | | | | | | | | | | | | |

Ans. (i) (a) $x_{11} = 7, x_{21} = 3, x_{22} = 9, x_{32} = 1, x_{33} = 10$, OF: 94

(i) (b) $x_{11} = 7, x_{21} = 3, x_{23} = 9, x_{32} = 10, x_{31} = 1$, OF: 40

(i) (c) $x_{13} = 7, x_{21} = 10, x_{23} = 2, x_{32} = 10, x_{33} = 1$, OF: 61

(i) (d) $x_{13} = 7, x_{21} = 10, x_{23} = 2, x_{32} = 10, x_{33} = 1$, OF: 61

(i) (e) $x_{11} = 7, x_{21} = 2, x_{23} = 10, x_{31} = 1, x_{32} = 10$, OF: 40

(ii) (a) $x_{11} = 9, x_{12} = 3, x_{22} = 7, x_{23} = 7, x_{33} = 4$, OF: 104

(ii) (b) $x_{11} = 2, x_{12} = 10, x_{21} = 3, x_{23} = 11, x_{31} = 4$, OF: 38

(ii) (c) $x_{12} = 10, x_{13} = 2, x_{21} = 9, x_{23} = 5, x_{33} = 4$, OF: 72

(ii) (d) $x_{11} = 2, x_{12} = 10, x_{21} = 3, x_{23} = 11, x_{33} = 4$, OF: 38

(ii) (e) $x_{11} = 2, x_{12} = 10, x_{21} = 3, x_{23} = 11, x_{33} = 4$, OF: 38

(iii) (a) $x_{11} = 10, x_{21} = 20, x_{31} = 30, x_{42} = 40, x_{52} = 20, x_{53} = 20, x_{54} = 10$, OF: 1290

(iii) (b) $x_{13} = 10, x_{21} = 10, x_{24} = 10, x_{31} = 30, x_{42} = 30, x_{43} = 10, x_{51} = 30, x_{52} = 20$, OF: 890

(iii) (c) $x_{13} = 10, x_{21} = 20, x_{31} = 10, x_{33} = 10, x_{34} = 10, x_{42} = 40, x_{51} = 50$, OF: 860

(iii) (d) $x_{12} = 10, x_{22} = 20, x_{31} = 10, x_{32} = 20, x_{42} = 10, x_{43} = 20, x_{44} = 10, x_{51} = 50$, OF: 960

(iii) (e) $x_{11} = 10, x_{22} = 20, x_{31} = 30, x_{42} = 10, x_{43} = 20, x_{44} = 10, x_{51} = 20, x_{52} = 30$, OF: 910

2. Solve the following TP by method of multipliers method obtaining the starting solution by north west corner rule.

| | | | | | | |
|-----|----|----|----|----|----|----|
| (i) | 3 | 0 | 4 | 1 | 1 | 40 |
| | 2 | 2 | 4 | 0 | 6 | 70 |
| | 0 | 0 | 0 | 1 | 1 | 60 |
| | 3 | 5 | 1 | 3 | 0 | 30 |
| | 30 | 60 | 50 | 40 | 20 | |

Ans. $x_{21} = 40, x_{21} = 10, x_{22} = 20, x_{24} = 40, x_{31} = 20, x_{33} = 40, x_{43} = 10, x_{45} = 20$ OF: 70

| | | | | | | | |
|------|----|----|----|----|----|----|----|
| (ii) | 1 | 2 | 1 | 4 | 5 | 2 | 30 |
| | 3 | 3 | 2 | 1 | 4 | 3 | 50 |
| | 4 | 2 | 5 | 9 | 6 | 2 | 75 |
| | 3 | 1 | 7 | 3 | 4 | 6 | 20 |
| | 20 | 40 | 30 | 10 | 50 | 25 | |

Ans. $x_{11} = 20, x_{13} = 10, x_{23} = 20, x_{24} = 10, x_{25} = 20, x_{32} = 40, x_{35} = 10, x_{36} = 25, x_{45} = 20$ OF: 430

3. Solve the above problem 2 (ii) by obtaining the initial solution by (a) row minimum (b) column minimum (c) matrix minimum (d) Vogel's method (e) compare the number of iterations required in each of these methods including the north west corner rule.

Ans. Optimal solution and value of OF is same as in 2 (ii) above for (a) (b) (c) (d). The number of iterations required are 7 in NWCR, 1 in row minimum 2 in column minimum, 1 in matrix minimum, 1 in Vogel's method.

4. Solve the TP by UV-method obtaining initial solution by (a) NWC rule

Vogel's method (c) compare the two methods.

| | | | | | |
|--|----|----|----|----|----|
| | 10 | 0 | 20 | 11 | 15 |
| | 12 | 7 | 9 | 20 | 25 |
| | 0 | 14 | 16 | 18 | 5 |
| | 5 | 15 | 15 | 10 | |

Ans. (a) $x_{12} = 5, x_{14} = 10, x_{22} = 10, x_{23} = 15, x_{31} = 5$ OF: 315

(b) same (c) Vogel's method give solution closer to optimal. Number of iterations required in Vogel is one while 3 in NWC rule.

5. Solve the following TP by method of multipliers by obtaining the starting solution by (a) NWC rule (b) Least-cost method (c) Vogel approximation method. State the starting solution and the corresponding value of OF.

| | | | | | |
|-------|-------|-------|-------|-------|----|
| | D_1 | D_2 | D_3 | D_4 | |
| S_1 | 10 | 2 | 20 | 11 | 15 |
| S_2 | 12 | 7 | 9 | 20 | 25 |
| S_3 | 4 | 14 | 16 | 18 | 10 |
| | 5 | 15 | 15 | 15 | |

Ans. Starting solution and associated OF (a) $x_{11} = 5, x_{12} = 10, x_{22} = 5, x_{23} = 15, x_{24} = 5, x_{34} = 10$, OF: 520

(b) $x_{12} = 15, x_{14} = 0, x_{23} = 15, x_{24} = 10, x_{31} = 5, x_{34} = 5$, OF: 475

(c) $x_{12} = 15, x_{14} = 0, x_{23} = 15, x_{24} = 10, x_{31} = 5, x_{34} = 5$, OF: 475

(d) Solution by UV method

$x_{12} = 5, x_{14} = 10, x_{22} = 10, x_{23} = 15, x_{31} = 5, x_{34} = 5$, OF: 435

6. Solve the TP (use VAM)

| | | | | | |
|-------|-------|-------|-------|-------|----|
| | D_1 | D_2 | D_3 | D_4 | |
| S_1 | 21 | 16 | 25 | 13 | 11 |
| S_2 | 17 | 18 | 14 | 23 | 13 |
| S_3 | 32 | 27 | 18 | 41 | 19 |
| | 6 | 10 | 12 | 15 | |

38.30 — MATHEMATICAL METHODS

Ans. $x_{14} = 11, x_{21} = 6, x_{22} = 3, x_{24} = 4, x_{32} = 7, x_{33} = 12$ optimal minimum cost: Rs 796
Degeneracy:

7. Solve the following TP.

| | | | | | | |
|---|----|----|----|---|----|---|
| 9 | 12 | 9 | 6 | 9 | 10 | 5 |
| 7 | 3 | 7 | 7 | 5 | 5 | 6 |
| 6 | 5 | 9 | 11 | 3 | 11 | 2 |
| 6 | 8 | 11 | 2 | 2 | 10 | 9 |
| 4 | 4 | 6 | 2 | 4 | 2 | |

Ans. $x_{13} = 5, x_{22} = 4, x_{26} = 2, x_{31} = 1, x_{33} = 1, x_{41} = 3, x_{44} = 2, x_{45} = 4, x_{13} = \infty$
minimum cost = $112 + 76\epsilon = 112$ as $\epsilon \rightarrow 0$

Hint: The starting solution obtained by Vogel's method is a degenerate since it contains only 8 basic variables (instead of $6 + 4 - 1 = 9$ basic variables). Introduce any one of the non basic variable at ϵ level where ϵ is small and let $\epsilon \rightarrow 0$.

Maximization:

8. Solve the following TP to maximize the profit

| | | | | |
|----|----|----|----|----|
| 15 | 51 | 42 | 33 | 23 |
| 80 | 42 | 26 | 81 | 44 |
| 90 | 40 | 66 | 60 | 33 |
| 23 | 31 | 16 | 30 | |

Ans. $x_{12} = 23, x_{21} = 6, x_{22} = 8, x_{24} = 30, x_{31} = 17, x_{33} = 16, \text{OF} = 7005$

Hint: Obtain the relative loss matrix by subtracting all the entries of the cost matrix from the largest entry 90.

Unbalanced TP:

9. Solve the following unbalanced TP.

| | | | | | |
|-------|-------|-------|-------|-------|----|
| | D_1 | D_2 | D_3 | D_4 | |
| S_1 | 11 | 20 | 7 | 8 | 50 |
| S_2 | 21 | 16 | 10 | 12 | 40 |
| S_3 | 8 | 12 | 18 | 9 | 70 |
| | 30 | 25 | 35 | 40 | |

Ans. $x_{13} = 25, x_{14} = 25, x_{23} = 10, x_{25} = 30, x_{31} = 30, x_{32} = 25, x_{34} = 15$
minimum cost = 1150

Hint: Total supply = $50 + 40 + 70 = 160$

Total demand = $30 + 25 + 35 + 40 = 130$

Introduce a dummy destination D_5 with demand (requirement) of 30. Use VAM.

Note: $x_{25} = 30$ means, 30 units are left undispached from S_2 . (Since it can not be send to the dummy destination D_5).

10. Solve the unbalanced TP;

| | | | | |
|-------|-------|-------|-------|----|
| | D_1 | D_2 | D_3 | |
| S_1 | 5 | 1 | 7 | 10 |
| S_2 | 6 | 4 | 6 | 80 |
| S_3 | 3 | 2 | 5 | 15 |
| | 75 | 20 | 50 | |

Ans. $x_{12} = 10, x_{21} = 20, x_{22} = 10, x_{23} = 50, x_{31} = 15$ minimum cost: 515

Hint: Introduce fictitious source S_4 with supply of 40. Demand of 40 units is not met at destination 1.

Transshipment Problem

11. Solve the following transshipment problem

Ans. $P_1 T_2 = 1000, P_2 T_1 = 1200, T_1 D_1 = 800$

$T_1 D_2 = 400, T_2 D_2 = 1000, D_2 D_3 = 500$

minimum cost = $(1000 \times 4) + (1200 \times 2) + (800 \times 8) + (400 \times 6) + (100 \times 4) + (500 \times 3) = 20,700$.

Hint: The corresponding TP is given below:

| | T_1 | T_2 | D_1 | D_2 | D_3 | |
|-------|-------|-------|---------|---------|-------|------|
| P_1 | 3 | 4 | M | M | M | 1000 |
| P_2 | 2 | 5 | M | M | M | 1200 |
| T_1 | 0 | 7 | 8 | 6 | M | B |
| T_2 | M | 0 | M | 4 | 9 | B |
| D_1 | M | M | 0 | 5 | M | B |
| D_2 | M | M | M | 0 | 3 | B |
| | B | B | $800+B$ | $900+B$ | 500 | |

Here $B = \text{buffer} = 1000 + 1200 = 2200 = (800 + 900 + 500)$ and $M = \text{large penalty}$.

38.10 THE ASSIGNMENT PROBLEM

The assignment problem (or model) is a special case of the transportation problem in which to each origin there will correspond one and only one destination. This can be described as a person-job assignment or machine-task assignment model. Suppose there are n persons who can perform any of the n different jobs with varying degree of efficiency measured in terms of c_{ij} representing the cost of assigning the i th person to j th job ($i = 1, 2, 3, \dots, n, j = 1, 2, \dots, n$). Then the objective of the assignment problem is to minimize the total cost of performing all the n jobs by assigning “the best person for the job” on the one to one basis of one person to one job. The assignment problem can be solved as a regular transportation problem in which the persons represent the sources, the jobs represent the destinations, the supply amount at each source and demand amount at each destination being exactly equal to 1.

Let $x_{ij} = \begin{cases} 1 & \text{if } i\text{th person assigned to } j\text{th job} \\ 0 & \text{if } i\text{th person not assigned to } j\text{th job} \end{cases}$

Since the i th person can be assigned to only one job we have $\sum_{j=1}^n x_{ij} = 1$ for $i = 1, 2, \dots, n$.

Since the j th job can be assigned to only one person we have $\sum_{i=1}^n x_{ij} = 1$ for $j = 1, 2, \dots, n$. The assignment problem consists of determining the inte-

gers x_{ij} (either 1 or 0) such that the total cost represented by the objective function $\sum_{i=1}^n \sum_{j=1}^n c_{ij} x_{ij}$ is minimized. Thus the assignment problem is an integer linear programming problem. This combinatorial problem has $n!$ number of possible assignments which can be enumerated for small n . Even for $n = 10$, ($n! = 3,628,800$) the enumeration becomes very time consuming and cumbersome. However the solution to the assignment problem is obtained by a simple method known as the “Hungarian method” or “Floods’ technique”.

Hungarian Method or Flood’s Technique

1. Minimization case:

Step I. Determination of total-opportunity cost (TOC) matrix:

- Subtracting the *lowest* entry of each column of the given payoff (cost) matrix from all the entries of that corresponding column results in the column-opportunity cost matrix.
- Now subtracting the *lowest* entry of each row of the column-opportunity matrix (obtained in step (a) above) from all the entries of the corresponding row results in the total opportunity cost (TOC) matrix.

Step II. Check for optimal assignment: Let n be the *minimum* number of horizontal and vertical lines required which cover ALL the zeros in the current TOC matrix. Let m be the order of the cost (TOC) matrix.

- If $n = m$, an optimal assignment can be made. Goto step V
- If $n < m$, revise the TOC matrix. Goto step III.

Step III. Revision of TOC matrix:

- Subtract the lowest entry (among the uncovered cells) of the current TOC matrix from all the uncovered cells.
- Add this lowest entry to *only* those cells at which the covering lines of step II *cross*. This revises TOC matrix.

38.32 — MATHEMATICAL METHODS

Step IV. Repeat steps II and III initial an optimal assignment is reached:

Step V. Optimal assignment:

- Identify a row or column (in the final TOC matrix) having *only one* zero cell.
- Make assignment to this cell. Cross off *both* the row and column in which this zero cell occurs.
- Repeat (a) for the remaining rows and columns and make an assignment until a complete assignment is achieved.

2. Maximization case:

The maximization problem can be converted to a minimization problem by subtracting *all* the entries of the original cost matrix from the largest entry (of the original cost matrix). The transformed entries give the “relative costs”.

3. Alternative Optima:

The presence of alternative optimal solutions is indicated by the existence of a row *or* column in the final TOC matrix with more than one zero cells.

4. Unbalanced Problem:

When the cost matrix is rectangular, a dummy row or a dummy column added makes the cost matrix a square matrix. All the costs c_{ij} associated with this dummy row (or column) are taken as zeros.

5. Problem with Restrictions:

When the assignment problem includes certain restrictions such that a particular (specified) i th person can *not* be assigned to a particular j th job then the associated cost c_{ij} is taken as a very big value M (generally infinity) so that it is prohibitively expensive to make this undesirable assignment.

WORKED OUT EXAMPLES

Example 1: A national highway project consists of 5 major jobs for which 5 contractors have submitted tenders. The tender amounts (in lakhs of rupees)

quoted is given in the pay-off matrix below. If each contractor is to be assigned one job, find the assignment which minimises the total cost of the project.

| Contractor | Jobs | | | | |
|------------|------|-----|-----|-----|-----|
| | A | B | C | D | E |
| 1 | 120 | 150 | 75 | 90 | 100 |
| 2 | 140 | 80 | 90 | 85 | 170 |
| 3 | 50 | 40 | 40 | 70 | 110 |
| 4 | 75 | 65 | 45 | 70 | 90 |
| 5 | 110 | 90 | 140 | 115 | 100 |

Solution: The column opportunity matrix is obtained by subtracting the lowest entry in each column from all the entries in that column

| Column-opportunity matrix | | | | | |
|---------------------------|----|-----|-----|----|----|
| | A | B | C | D | E |
| 1 | 70 | 110 | 35 | 20 | 10 |
| 2 | 90 | 40 | 50 | 15 | 80 |
| 3 | 0 | 0 | 0 | 0 | 20 |
| 4 | 25 | 25 | 5 | 0 | 0 |
| 5 | 60 | 50 | 100 | 45 | 10 |

The total-opportunity-cost (TOC) matrix is now obtained by subtracting the lowest entry from each row from all the entries in that row.

| ToC Matrix | | | | | |
|------------|----|-----|----|----|----|
| | A | B | C | D | E |
| 1 | 60 | 100 | 25 | 10 | 0 |
| 2 | 75 | 25 | 35 | 0 | 65 |
| 3 | 0 | 0 | 0 | 0 | 20 |
| 4 | 25 | 25 | 5 | 0 | 0 |
| 5 | 50 | 40 | 90 | 35 | 0 |

Since the *minimum* number of vertical and horizontal lines (n) needed to cover *all* the zeros is less than the number of row m (or columns) i.e. $n = 3 < m = 5$, the current TOC matrix is to be revised by subtracting the lowest entry among the uncovered cells from all the uncovered cells and adding it to crossed cells (where the vertical and horizontal lines intersect). Thus the lowest entry 5 will be subtracted from all

the uncovered cells and added at the crossed cells (3, 4), and (3, 5). Then the revised TOC is

| | A | B | C | D | E |
|---|----|----|----|----|----|
| 1 | 55 | 95 | 20 | 10 | 0 |
| 2 | 70 | 20 | 30 | 0 | 65 |
| 3 | 0 | 0 | 0 | 5 | 25 |
| 4 | 20 | 20 | 0 | 0 | 0 |
| 5 | 45 | 35 | 85 | 35 | 0 |

Here the minimum number of lines covering all the zeros is less than the number of rows i.e. $n = 4 < m = 5$. Revise the matrix as above

| | A | B | C | D | E |
|---|----|----|----|----|----|
| 1 | 35 | 75 | 0 | 10 | 0 |
| 2 | 50 | 0 | 10 | 0 | 65 |
| 3 | 0 | 0 | 0 | 25 | 45 |
| 4 | 20 | 20 | 0 | 20 | 20 |
| 5 | 25 | 15 | 65 | 35 | 0 |

Here $n = 4 < m = 5$

Optimal Toc matrix

| | A | B | C | D | E |
|---|----|----|----|----|----|
| 1 | 25 | 65 | 0 | 0 | 0 |
| 2 | 50 | 0 | 20 | 0 | 75 |
| 3 | 0 | 0 | 10 | 25 | 55 |
| 4 | 10 | 10 | 0 | 10 | 20 |
| 5 | 15 | 5 | 65 | 25 | 0 |

$n = 5 = m = 5$

1st optimal assignment: choose a row (or column) containing *only one* zero. Choosing so the first column, make an assignment. Thus

| | A | B | C | D | E |
|---|----|----|----|----|----|
| 1 | 25 | 65 | 0 | 0 | 0 |
| 2 | 50 | 0 | 20 | 0 | 75 |
| 3 | 0 | 0 | 10 | 25 | 55 |
| 4 | 10 | 10 | 0 | 10 | 20 |
| 5 | 15 | 5 | 65 | 25 | 0 |

i.e. assign A to 3. Cross off first column and 3rd row.

Second and Third optimal assignment

| | A | B | C | D | E |
|---|----|----|----|----|----|
| 1 | 25 | 65 | 0 | 0 | 0 |
| 2 | 50 | 0 | 20 | 0 | 75 |
| 3 | 0 | 0 | 10 | 25 | 55 |
| 4 | 10 | 10 | 0 | 10 | 20 |
| 5 | 15 | 5 | 65 | 25 | 0 |

From among the remaining non-crossed out rows and columns, choose a row or column with only one zero. Thus assign B to 2 and D to 1. Cross off the 2 row and 2 column and 4th column and first row.

4th and 5th optimal assignment:

| | A | B | C | D | E |
|---|----|----|----|----|----|
| 1 | 25 | 65 | 0 | 0 | 0 |
| 2 | 50 | 0 | 20 | 0 | 75 |
| 3 | 0 | 0 | 10 | 25 | 55 |
| 4 | 10 | 10 | 0 | 10 | 20 |
| 5 | 15 | 5 | 65 | 25 | 0 |

i.e. assign C to 4 and E to 5

Thus the optimal assignment is

A3, B2, C4, D1, E5

with minimum cost = $50 + 80 + 45 + 90 + 100 = 365$

Example 2: Maximization: The profit of assigning a particular job to a specific machine is given in the following matrix. Maximize the profit to accomplish all the jobs by assigning one machine to one job. Check by enumeration.

| | Machine | | |
|-----|---------|-----|-----|
| Job | A | B | C |
| 1 | 380 | 610 | 330 |
| 2 | 210 | 380 | 415 |
| 3 | 260 | 210 | 300 |

Solution: To convert into a minimization problem, subtract all the entries of the matrix from the largest entry 610. Then

| | A | B | C |
|---|-----|-----|-----|
| 1 | 230 | 0 | 280 |
| 2 | 400 | 230 | 195 |
| 3 | 350 | 400 | 310 |

38.34 — MATHEMATICAL METHODS

Job opportunity column matrix

| | A | B | C |
|---|-----|-----|-----|
| 1 | 0 | 0 | 85 |
| 2 | 170 | 230 | 0 |
| 3 | 120 | 400 | 115 |

TOC matrix

| | A | B | C |
|---|-----|-----|-----|
| 1 | -0 | -0 | -85 |
| 2 | 170 | 230 | 0 |
| 3 | 5 | 285 | 0 |

$$n = 2 < m = 3$$

Revised TOC matrix

| | A | B | C |
|---|-----|-----|-----|
| 1 | -0 | -0 | -90 |
| 2 | 165 | 225 | 0 |
| 3 | 0 | 280 | 0 |

$$n = 3 = m = 3$$

Optimal assignment: A3, B1, C2

| | A | B | C |
|---|-----|-----|----|
| 1 | 0 | 0 | 90 |
| 2 | 165 | 225 | 0 |
| 3 | 0 | 280 | 0 |

Maximum profit: $260 + 610 + 415 = 1285$

Check by enumeration:

$$A1, B2, C3 : 380 + 380 + 300 = 1060$$

$$A1, B3, C2 : 380 + 210 + 415 = 1005$$

$$A2, B3, C1 : 210 + 210 + 330 = 750$$

$$A2, B1, C3 : 210 + 610 + 300 = 1120$$

$$A3, B1, C2 : 260 + 610 + 415 = 1285 \text{ Optimal solution}$$

$$A3, B2, C1 : 260 + 380 + 330 = 970$$

Example 3: *Unbalanced problem:* The amount of time (in hours) to perform a job by different men is given below. Solve the unbalanced problem by assigning four jobs to three men subject to one job

to one man.

| | Jobs | | | |
|-------|-------|-------|-------|-------|
| Men | J_1 | J_2 | J_3 | J_4 |
| M_1 | 7 | 5 | 8 | 4 |
| M_2 | 5 | 6 | 7 | 4 |
| M_3 | 8 | 7 | 9 | 8 |

Solution: Add a fictitious (dummy) fourth man, to convert the unbalanced to balanced assignment problem. The amount of time taken by the fourth man is taken as zero for each job.

| | Jobs | | | |
|-------|-------|-------|-------|-------|
| Men | J_1 | J_2 | J_3 | J_4 |
| M_1 | 7 | 5 | 8 | 4 |
| M_2 | 5 | 6 | 7 | 4 |
| M_3 | 8 | 7 | 9 | 8 |
| M_4 | 0 | 0 | 0 | 0 |

TOC matrix

| | J_1 | J_2 | J_3 | J_4 |
|-------|-------|-------|-------|-------|
| M_1 | 3 | 1 | 4 | 0 |
| M_2 | 1 | 2 | 3 | 0 |
| M_3 | -1 | -0 | -2 | -1 |
| M_4 | -0 | -0 | -0 | -0 |

$$n = 3 < m = 4$$

Revised TOC Matrix

| | J_1 | J_2 | J_3 | J_4 |
|-------|-------|-------|-------|-------|
| M_1 | 2 | 0 | 3 | 0 |
| M_2 | 0 | 1 | 2 | 0 |
| M_3 | 1 | 0 | 2 | 2 |
| M_4 | -0 | -0 | -0 | -1 |

$$n = 4 = m = 4$$

Optimal assignment

| | J_1 | J_2 | J_3 | J_4 |
|-------|-------|-------|-------|-------|
| M_1 | 2 | 0 | 3 | 0 |
| M_2 | 0 | 1 | 2 | 0 |
| M_3 | 1 | 0 | 2 | 2 |
| M_4 | 0 | 0 | 0 | 1 |

$M_1 J_4, M_2 J_1, M_3 J_2, M_4 J_3$

Thus the job J_3 is not assigned. The minimum amount of time taken to accomplish all the three jobs is $4 + 5 + 7 = 16$ hours.

| Persons | Machines | | | |
|---------|----------|-------|-------|-------|
| | M_1 | M_2 | M_3 | M_4 |
| P_1 | 5 | 5 | — | 2 |
| P_2 | 7 | 4 | 2 | 3 |
| P_3 | 9 | 3 | 5 | — |
| P_4 | 7 | 2 | 6 | 7 |

Example 4: *Assignment with restrictions:* The following matrix consists of cost (in thousands of rupees) of assigning each of the four jobs to four different persons. However the first person can not be assigned to machine 3 and third person can not be assigned to machine 4.

- Find the optimal assignment to minimize the cost
- Suppose a 5th machine is available the assignment costs to the four persons as 2, 1, 2, 8, respectively. Find the optimal solution
- Is it economical to replace one of the existing machines by the new (5th) machine
- In such case which machine is to be replaced (unused). (A dash indicates that assignment is *not* possible because of the restrictions imposed)

Solution: (a) Since first person can not be assigned to machine 3 a prohibitive (penalty) cost is imposed, denoted by ∞ . Thus the cost matrix is

| | M_1 | M_2 | M_3 | M_4 |
|-------|-------|-------|----------|----------|
| P_1 | 5 | 5 | ∞ | 2 |
| P_2 | 7 | 4 | 2 | 3 |
| P_3 | 9 | 3 | 5 | ∞ |
| P_4 | 7 | 2 | 6 | 7 |

Row matrix

| | M_1 | M_2 | M_3 | M_4 |
|-------|-------|-------|----------|----------|
| P_1 | 3 | 3 | ∞ | 0 |
| P_2 | 5 | 2 | 0 | 1 |
| P_3 | 6 | 0 | 2 | ∞ |
| P_4 | 5 | 0 | 4 | 5 |

TOC Matrix

| | | | |
|---|---|----------|----------|
| 0 | 3 | ∞ | 0 |
| 2 | 2 | 0 | 1 |
| 3 | 0 | 2 | ∞ |
| 2 | 0 | 4 | 5 |

Revised TOC

| | | | |
|---|---|----------|----------|
| 0 | 4 | ∞ | 0 |
| 1 | 2 | 0 | 0 |
| 2 | 0 | 2 | ∞ |
| 1 | 0 | 4 | 4 |

$$n = 3 < m = 4$$

$$n = 3 < m = 4$$

Optimal assignment

| | M_1 | M_2 | M_3 | M_4 |
|-------|-------|-------|----------|----------|
| P_1 | 0 | 5 | ∞ | 0 |
| P_2 | 1 | 3 | 0 | 0 |
| P_3 | 1 | 0 | 1 | ∞ |
| P_4 | 0 | 0 | 3 | 3 |

P_1 to M_4 , P_2 to M_3 , P_3 to M_2 , P_4 to M_1

minimal cost: $2 + 2 + 3 + 7 = 14$

- Introducing the 5th machine, the new cost matrix is

| | M_1 | M_2 | M_3 | M_4 | M_5 |
|-------|-------|-------|----------|----------|-------|
| P_1 | 3 | 5 | ∞ | 2 | 2 |
| P_2 | 7 | 4 | 2 | 3 | 1 |
| P_3 | 9 | 3 | 5 | ∞ | 2 |
| P_4 | 7 | 2 | 6 | 7 | 8 |
| P_5 | 0 | 0 | 0 | 0 | 0 |

Subtracting the row minimums from each row, we get

| optimal matrix | | | | | |
|----------------|-------|-------|----------|----------|-------|
| | M_1 | M_2 | M_3 | M_4 | M_5 |
| P_1 | 3 | 4 | ∞ | 0 | 0 |
| P_2 | 5 | 3 | 0 | 1 | 0 |
| P_3 | 6 | 1 | 2 | ∞ | 0 |
| P_4 | 4 | 0 | 3 | 4 | 5 |
| P_5 | 0 | 0 | 0 | 0 | 0 |

$$n = 4 < m = 5$$

$$n = 5 \quad m = 5$$

Optimal assignment:

P_1 to M_4 ; P_2 to M_3 , P_3 to M_5 , P_4 to M_2 ; P_5 to M_1 Minimum cost: $2 + 2 + 2 + 2 = 8$

- With the introduction of 5th machine the cost has come down from 14 to 8. So it is economical to introduce 5th machine.

38.36 — MATHEMATICAL METHODS

(d) Since the dummy person P_5 is assigned to machine 1, it means that M_1 is not used and therefore can be replaced (dispensed with).
 Ans: P_1 to J_2 , P_2 to J_1 , P_3 to J_3 , minimum cost: 27

38.11 ASSIGNMENT PROBLEM

EXERCISE

1. Solve the following assignment Problem for minimum total cost. Check by enumeration.

| Job | Machine | | |
|-----|---------|-----|-----|
| | A | B | C |
| 1 | 380 | 610 | 330 |
| 2 | 210 | 380 | 415 |
| 3 | 260 | 210 | 300 |

Ans. A_2, B_3, C_1 : minimal cost: 750

$A_1B_2C_3$ (1060), $A_1B_3C_2$ (1005), $A_2B_1C_3$ (1120),
 $A_2B_3C_1$ (750), $A_3B_1C_2$ (1285), $A_3B_2C_1$ (970).

2. Find the optimal solution with minimum cost in the following assignment problem

| Origins | Destinations | | |
|---------|--------------|-------|-------|
| | D_1 | D_2 | D_3 |
| O_1 | 20 | 27 | 30 |
| O_2 | 10 | 18 | 16 |
| O_3 | 14 | 16 | 12 |

Ans. O_1 to D_2 , O_2 to D_1 ; O_3 to D_3
 Total minimum cost: 49

3. Find the optimal assignment which maximizes the total cost in the above problem 2.

Ans. O_3 to D_1 , O_2 to D_2 , O_1 to D_3 , maximum cost: 62
 Solve the following assignment problem for minimum cost

4.

| Person | Jobs | | |
|--------|-------|-------|-------|
| | J_1 | J_2 | J_3 |
| P_1 | 15 | 10 | 9 |
| P_2 | 9 | 15 | 10 |
| P_3 | 10 | 12 | 8 |

5.

| Persons | Jobs | | | |
|---------|-------|-------|-------|-------|
| | J_1 | J_2 | J_3 | J_4 |
| P_1 | 1 | 4 | 6 | 3 |
| P_2 | 9 | 7 | 10 | 9 |
| P_3 | 4 | 5 | 11 | 7 |
| P_4 | 8 | 7 | 8 | 5 |

Ans. P_1 to J_1 , P_2 to J_3 ; P_3 to J_2 , P_4 to J_4 minimum cost: 21

6. Assign the five jobs to the five machines so as to maximize the total return if the following matrix shows the return in (thousands of) 1 rupees for assigning the i th machine ($i = 1, 2, 3, 4, 5$) to the j th job ($j = 1, 2, 3, 4, 5$).

| Machine | Job | | | | |
|---------|-----|----|----|----|---|
| | 1 | 2 | 3 | 4 | 5 |
| 1 | 5 | 11 | 10 | 12 | 4 |
| 2 | 2 | 4 | 6 | 3 | 5 |
| 3 | 3 | 12 | 5 | 14 | 6 |
| 4 | 6 | 14 | 4 | 11 | 7 |
| 5 | 7 | 9 | 8 | 12 | 5 |

Ans. $M_1 J_3$; $M_2 J_5$; $M_3 J_4$; $M_4 J_2$; $M_5 J_1$, Maximum cost: 50

7. Four men can perform any of the four tasks with different efficiency measured in terms of time required to complete each task which is given in the following table. Assign one task to one man so as to minimize the total time spent on accomplishing the four tasks.

| Task | Men | | | |
|-------|-------|-------|-------|-------|
| | M_1 | M_2 | M_3 | M_4 |
| T_1 | 18 | 26 | 17 | 11 |
| T_2 | 13 | 28 | 14 | 26 |
| T_3 | 38 | 19 | 18 | 15 |
| T_4 | 19 | 26 | 24 | 10 |

Ans. M_1 to T_2 ; M_2 to T_3 ; M_3 to T_1 ; M_4 to T_4 , minimum total time = 59

8. *Multiple Optima*: Solve the following assignment problem for minimum cost.

| Jobs | J_1 | J_2 | J_3 | J_4 |
|-------|-------|-------|-------|-------|
| Men | | | | |
| M_1 | 20 | 13 | 7 | 5 |
| M_2 | 25 | 18 | 13 | 10 |
| M_3 | 31 | 23 | 18 | 15 |
| M_4 | 45 | 40 | 23 | 21 |

Ans. Four optimal assignments all with the same minimum total cost: 76.

- (i) $M_1 J_1; M_2 J_4; M_3 J_2; M_4 J_3$.
(ii) $M_1 J_2; M_2 J_1; M_3 J_4; M_4 J_3$.
(iii) $M_1 J_1; M_2 J_2; M_3 J_4; M_4 J_3$.
(iv) $M_1 J_4; M_2 J_1; M_3 J_2; M_4 J_3$.

9. *Unbalanced assignment problem* Three work centers are required to manufacture, assemble and to package a product. The handling cost at each of the four locations in the factory are given in the following matrix. Determine the location of work centres that minimizes total handling cost.

| | Locations | | | |
|------------------------|-----------|-------|-------|-------|
| Job | L_1 | L_2 | L_3 | L_4 |
| Manufacturing
M_1 | 18 | 15 | 16 | 13 |
| Assembly
M_2 | 16 | 11 | — | 15 |
| Packaging
M_3 | 9 | 10 | 12 | 8 |

Ans: M_1 to L_4 ; M_2 to L_2 ; M_3 to L_1 . Location 3 is kept idle (assigned to dummy job and no job is done).

10.

| | | Jobs | | | | |
|-----|-------|------|----|-----|-----|----|
| | | A | B | C | D | E |
| Men | M_1 | 62 | 78 | 50 | 101 | 82 |
| | M_2 | 71 | 84 | 61 | 73 | 59 |
| | M_3 | 87 | 92 | 111 | 71 | 81 |
| | M_4 | 48 | 64 | 87 | 77 | 80 |

Maximize the profit. Which job should be declined?

Ans. $M_1 D; M_2 B; M_3 C; M_4 E, M_5 A$. Since (dummy man) M_5 is assigned to job A, the job A should be declined. Maximum profit: $101 + 84 + 111 + 80 = 376$

11. *With Restrictions* Suppose five men are to be assigned to five jobs with assignment costs given in the following matrix. Find the optimal assignment schedule subject to the restriction that first person M_1 can not be assigned job 3 and third person M_3 can not be assigned to job 4.

| | Jobs | | | | |
|-------|-------|-------|-------|-------|-------|
| Men | J_1 | J_2 | J_3 | J_4 | J_5 |
| M_1 | 5 | 5 | — | 2 | 6 |
| M_2 | 7 | 4 | 2 | 3 | 4 |
| M_3 | 9 | 3 | 5 | — | 3 |
| M_4 | 7 | 2 | 6 | 7 | 2 |
| M_5 | 6 | 5 | 7 | 9 | 1 |

Ans. Minimal cost is 15 with three alternative optimum solutions.

- (i) $M_1 J_4, M_2 J_3, M_3 J_2, M_4 J_1, M_5 J_5$
(ii) $M_1 J_4, M_2 J_3, M_3 J_5, M_4 J_2, M_5 J_1$
(iii) $M_1 J_4, M_2 J_3, M_3 J_2, M_4 J_5, M_5 J_1$

12. Determine optimal location of three machines at four different locations in a shop floor given the cost estimate per unit of time of material handling is given in the following matrix. Note that machine 2 can not be placed in location 2.

| | Locations | | | |
|----------|-----------|-------|-------|-------|
| Machines | L_1 | L_2 | L_3 | L_4 |
| M1 | 12 | 9 | 12 | 9 |
| M2 | 15 | — | 0 | 20 |
| M3 | 4 | 8 | 115 | 6 |

Ans. M_1 to L_2 or L_4 ; M_2 to L_3 , M_3 to L_1
Dummy (fictitious) machine M_4 is assigned to location L_4 or L_2 .

Minimum cost: $9 + 13 + 4 = 26$

Appendix B

Basic Results

1. Exponential function e^x :

$$e = 2.71828\ 18284$$

$$e^x y^y = e^{x+y}, \quad e^x / e^y = e^{x-y}, \quad (e^x)^y = e^{xy}$$

2(a) Natural logarithm:

$\ln x$ is the inverse of e^x and has base e and $e^{\ln x} = x$, $e^{-\ln x} = e^{\ln(1/x)} = 1/x$.

$$\ln(xy) = \ln x + \ln y,$$

$$\ln(x/y) = \ln x - \ln y,$$

$$\ln(x^a) = a \ln x$$

(b) Logarithm of base ten $\log_{10} x$ or simply $\log x$ (known as common logarithm)

$\log x$ is the inverse of 10^x , and

$$10^{\log x} = x, \quad 10^{-\log x} = 1/x.$$

$$\log x = M \ln x, \quad M = \log e = 0.43429$$

$$\ln x = \frac{1}{M} \log x, \quad \frac{1}{M} = 2.30258$$

3(a) Sine and cosine functions:

$\sin x$ is odd, $\sin(-x) = -\sin x$

$\cos x$ is even, $\cos(-x) = \cos x$

Note: Angles are measured in radians in calculus, so that $\sin x$ and $\cos x$ have period 2π .

$$\sin^2 x + \cos^2 x = 1$$

$$\sin(x \pm y) = \sin x \cos y \pm \cos x \sin y$$

$$\cos(x \pm y) = \cos x \cos y \mp \sin x \sin y$$

$$\sin 2x = 2 \sin x \cos x = 2 \tan x / (1 + \tan^2 x),$$

$$\cos 2x = \cos^2 x - \sin^2 x = 1 - 2 \sin^2 x =$$

$$= 2 \cos^2 x - 1 = \frac{1 - \tan^2 x}{1 + \tan^2 x}$$

Exponential function e^x

Natural logarithm $\ln x$

$\sin x$

$\cos x$

B.2 — BASIC RESULTS

$$\sin x = \cos\left(x - \frac{\pi}{2}\right) = \cos\left(\frac{\pi}{2} - x\right)$$

$$\cos x = \sin\left(x + \frac{\pi}{2}\right) = \sin\left(\frac{\pi}{2} - x\right)$$

$$\sin(\pi - x) = \sin x, \quad \cos(\pi - x) = -\cos x$$

$$\cos^2 x = \frac{1}{2}(1 + \cos 2x), \quad \sin^2 x = \frac{1}{2}(1 - \cos 2x)$$

$$\sin x \sin y = \frac{1}{2}[-\cos(x + y) + \cos(x - y)]$$

$$\cos x \cos y = \frac{1}{2}[\cos(x + y) + \cos(x - y)]$$

$$\sin x \cos y = \frac{1}{2}[\sin(x + y) + \sin(x - y)]$$

$$\cos x \sin y = \frac{1}{2}[\sin(x + y) - \sin(x - y)]$$

$$\sin u + \sin v = 2 \sin \frac{u + v}{2} \cos \frac{u - v}{2}$$

$$\sin u - \sin v = 2 \cos \frac{u + v}{2} \sin \frac{u - v}{2}$$

$$\cos u + \cos v = 2 \cos \frac{u + v}{2} \cos \frac{u - v}{2}$$

$$\cos v - \cos u = 2 \sin \frac{u + v}{2} \sin \frac{u - v}{2}$$

$$A \cos x + B \sin x = \sqrt{A^2 + B^2} \cos(x \pm \delta),$$

$$\tan \delta = \frac{\sin \delta}{\cos \delta} = \mp \frac{B}{A}$$

$$A \cos x + B \sin x = \sqrt{A^2 + B^2} \sin(x \pm \delta),$$

$$\tan \delta = \frac{\sin \delta}{\cos \delta} = \mp \frac{A}{B}$$

(b) Tangent, cotangent, secant, cosecant:

$$\tan x = \frac{\sin x}{\cos x}, \quad \cot x = \frac{\cos x}{\sin x},$$

$$\sec x = \frac{1}{\cos x}, \quad \csc x = \frac{1}{\sin x}$$

$$\tan(x \pm y) = \frac{\tan x \pm \tan y}{1 \mp \tan x \tan y},$$

$$\tan 2x = \frac{2 \tan x}{1 - \tan^2 x}$$

Any t -ratio of $(n \cdot 90^\circ \pm \theta)$

$= \pm$ same ratio of θ when n is even.

$= \pm$ co-ratio of θ , when n is odd.

The sign $+$ or $-$ is to be decided from the quadrant in which $(n \cdot 90^\circ \pm \theta)$ lies.

Examples:

$$\sin 570^\circ = \sin(6 \times 90^\circ + 30^\circ) = -\sin 30^\circ = -\frac{1}{2};$$

$$\tan 315^\circ = \tan(3 \times 90^\circ + 45^\circ) = -\cot 45^\circ = -1$$

In any $\triangle ABC$, $a/\sin A = b/\sin B = c/\sin C$ and $\cos C = \frac{a^2 + b^2 - c^2}{2ab}$.

4. Hyperbolic functions:

$$\sinh x = \frac{1}{2}(e^x - e^{-x}), \quad \cosh x = \frac{1}{2}(e^x + e^{-x})$$

$$\tanh x = \frac{\sinh x}{\cosh x}, \quad \coth x = \frac{\cosh x}{\sinh x}$$

$$\cosh x + \sinh x = e^x, \quad \cosh x - \sinh x = e^{-x}$$

$$\cosh^2 x - \sinh^2 x = 1$$

$$\sinh^2 x = \frac{1}{2}(\cosh 2x - 1), \quad \cosh^2 x = \frac{1}{2}(\cosh 2x + 1)$$

$$\begin{cases} \sinh(x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y \\ \cosh(x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y \end{cases}$$

$$\tanh(x \pm y) = \frac{\tanh x \pm \tanh y}{1 \pm \tanh x \tanh y}$$

 sinh x (dashed) and cosh x (solid)

 tanh x (dashed) and coth x (solid)

5. Differentiation:

$$\begin{aligned} \frac{d}{dx}(uv) &= u \frac{dv}{dx} + v \frac{du}{dx} & \frac{d}{dx} \left(\frac{u}{v} \right) &= \frac{v \frac{du}{dx} - u \frac{dv}{dx}}{v^2} \\ \frac{du}{dx} &= \frac{du}{dy} \cdot \frac{dy}{dx} \text{ (Chain Rule)} & \frac{d}{dx}(ax + b)^n &= n(ax + b)^{n-1} \cdot a \\ \frac{d}{dx}(e^x) &= e^x & \frac{d}{dx}(a^x) &= a^x \log_e a \\ \frac{d}{dx}(\log_e x) &= 1/x & \frac{d}{dx}(\log_a x) &= \frac{1}{x \log a} \\ \frac{d}{dx}(\sin x) &= \cos x & \frac{d}{dx}(\cos x) &= -\sin x \\ \frac{d}{dx}(\tan x) &= \sec^2 x & \frac{d}{dx}(\cot x) &= -\operatorname{cosec}^2 x \\ \frac{d}{dx}(\sec x) &= \sec x \tan x & \frac{d}{dx}(\operatorname{cosec} x) &= -\operatorname{cosec} x \cot x \\ \frac{d}{dx}(\sin^{-1} x) &= \frac{1}{\sqrt{1-x^2}} & \frac{d}{dx}(\cos^{-1} x) &= -\frac{1}{\sqrt{1-x^2}} \\ \frac{d}{dx}(\tan^{-1} x) &= \frac{1}{1+x^2} & \frac{d}{dx}(\cot^{-1} x) &= \frac{-1}{1+x^2} \\ \frac{d}{dx}(\sec^{-1} x) &= \frac{1}{x\sqrt{x^2-1}} & \frac{d}{dx}(\operatorname{cosec}^{-1} x) &= \frac{-1}{x\sqrt{x^2-1}} \\ \frac{d}{dx}(\sinh x) &= \cosh x & \frac{d}{dx}(\cosh x) &= \sinh x \\ D^n(e^{mx}) &= m^n e^{mx} & D^n(a^{mx}) &= m^n (\log a)^n \cdot a^{mx} \end{aligned}$$

$$D^n(ax+b)^n = m(m-1)(m-2)\dots(m-n+1)(ax+b)^{m-n}$$

$$D^n \log(ax+b) = (-1)^{n-1} (n-1)! a^n / (ax+b)^n$$

$$D^n \sin(ax+b) = a^n \sin(ax+b+n\pi/2)$$

$$D^n \cos(ax+b) = a^n \cos(ax+b+n\pi/2)$$

$$D^n \{e^{ax} \sin(bx+c)\} = (a^2+b^2)^{n/2} e^{ax}$$

$$\sin(bx+c+n \tan^{-1} b/a)$$

$$D^n \{e^{ax} \cos(bx+c)\} = (a^2+b^2)^{n/2} e^{ax}$$

$$\cos(bx+c+n \tan^{-1} b/a)$$

$$D^n(uv) = u_n + {}^nC_1 u_{n-1} v + {}^nC_2 u_{n-2} v_2 + \dots + {}^nC_r u_{n-r} v_r + \dots + {}^nC_n v_n$$

6. Integration:

$$\begin{aligned} \int x^n dx &= \frac{x^{n+1}}{n+1} \quad (n \neq -1) & \int \frac{1}{x} dx &= \log_e x \\ \int e^x dx &= e^x & \int a^x dx &= a^x / \log_e a \\ \int \sin x dx &= -\cos x & \int \cos x dx &= \sin x \\ \int \tan x dx &= -\log \cos x & \int \cot x dx &= \log \sin x \\ \int \sec x dx &= \log(\sec x + \tan x) & \int \operatorname{cosec} x dx &= \log(\operatorname{cosec} x - \cot x) \\ \int \sec^2 x dx &= \tan x & \int \operatorname{cosec}^2 x dx &= -\cot x \\ \int \sinh x dx &= \cosh x & \int \cosh x dx &= \sinh x \\ \int \frac{dx}{a^2+x^2} &= \frac{1}{a} \tan^{-1} \frac{x}{a} & \int \frac{dx}{\sqrt{a^2-x^2}} &= \sin^{-1} \frac{x}{a} \\ \int \frac{dx}{a^2-x^2} &= \frac{1}{2a} \log \frac{a+x}{a-x} & \int \frac{dx}{\sqrt{a^2+x^2}} &= \sinh^{-1} \frac{x}{a} \\ \int \frac{dx}{x^2-a^2} &= \frac{1}{2a} \log \frac{x-a}{x+a} & \int \frac{dx}{\sqrt{x^2-a^2}} &= \cosh^{-1} \frac{x}{a} \end{aligned}$$

$$\int \sqrt{a^2-x^2} dx = \frac{x\sqrt{a^2-x^2}}{2} + \frac{a^2}{2} \sin^{-1} \frac{x}{a}$$

$$\int \sqrt{a^2+x^2} dx = \frac{x\sqrt{a^2+x^2}}{2} + \frac{a^2}{2} \sinh^{-1} \frac{x}{a}$$

$$\int \sqrt{x^2-a^2} dx = \frac{x\sqrt{x^2-a^2}}{2} - \frac{a^2}{2} \cosh^{-1} \frac{x}{a}$$

$$\int e^{ax} \sin bx dx = \frac{e^{ax}}{a^2+b^2} (a \sin bx - b \cos bx)$$

$$\int_0^\infty e^{-ax} \sin bxdx = \frac{b}{a^2+b^2}$$

$$\int e^{ax} \cos bx dx = \frac{e^{ax}}{a^2+b^2} (a \cos bx + b \sin bx)$$

$$\int_0^\infty e^{-ax} \cos bxdx = \frac{a}{a^2+b^2}$$

$$\int_{-\infty}^\infty e^{-x^2} dx = \sqrt{\pi}$$

$$\int_0^\infty \frac{e^{-ax}}{x} \sin bxdx = \tan^{-1} \frac{b}{c}, \quad c > 0, \quad b > 0$$

$$\int_0^\infty \frac{\sin ax}{x} dx = \frac{\pi}{2} \quad \text{if } a > 0$$

B.4 — BASIC RESULTS

$$\int_0^{\infty} \frac{e^{ax} - e^{-ax}}{e^{-\pi x} - e^{-\pi x}} dx = \frac{1}{2} \tan \frac{a}{2}$$

$$\int_0^{\infty} \frac{e^{ax} + e^{-ax}}{e^{-\pi x} - e^{-\pi x}} dx = \frac{1}{2} \sec \frac{a}{2}$$

$$\begin{aligned} \int_0^{\pi/2} \sin^n x \, dx &= \int_0^{\pi/2} \cos^n x \, dx \\ &= \frac{(n-1)(n-3)(n-5)\dots}{n(n-2)(n-4)\dots} \end{aligned}$$

Note: R.H.S. is multiplied by $\pi/2$ when n is even

$$\begin{aligned} \int_0^{\pi/2} \sin^m x \cos^n x \, dx \\ = \frac{(m-1)(m-3)\dots \times (n-1)(n-3)\dots}{(m+n)(m+n-2)(m+n-4)\dots} \end{aligned}$$

Note: R.H.S. is multiplied by $\pi/2$ when both m and n are even

$$\begin{aligned} \int_{-a}^a f(x) \, dx &= \begin{cases} 2 \int_0^a f(x) \, dx, & \text{if } f(x) \text{ is an even function.} \\ 0 & \text{if } f(x) \text{ is an odd function.} \end{cases} \\ \int_0^{2a} f(x) \, dx &= \begin{cases} 2 \int_0^a f(x) \, dx, & \text{if } f(2a-x) = f(x) \\ \int_0^a f(x) \, dx - \int_0^a f(2a-x) \, dx, & \text{if } f(2a-x) = -f(x). \end{cases} \end{aligned}$$

$$\int u \, dv = uv - \int v \, du \quad (\text{Integration by parts})$$

$$\int u(x)v(x) \, dx = uv_1 - u'v_2 + u''v_3 - u'''v_4 + \dots$$

(Leibnitz General rule of integration by parts)

Note: Superscript ' denotes differentiation, i.e., u'' denotes differentiation of u twice. Subscript number denotes number of times integration of v , i.e., v_3 denotes integration of v thrice.

7. Series:

Exponential series: $e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots$

sin, cos, sinh, cosh series:

$$\begin{aligned} \sin x &= x - \frac{x^3}{3!} + \frac{x^5}{5!} - \dots, \quad \cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \dots \\ \sinh x &= x + \frac{x^3}{3!} + \frac{x^5}{5!} + \dots, \quad \cosh x = 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \dots \end{aligned}$$

Log series:

$$\log(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \dots,$$

$$\log(1-x) = -\left(x + \frac{x^2}{2} + \frac{x^3}{3} + \dots\right)$$

Gregory series:

$$\tan^{-1} x = x - \frac{x^3}{3} + \frac{x^5}{5} - \dots,$$

$$\tanh^{-1} x = \frac{1}{2} \log \frac{1+x}{1-x} = x + \frac{x^3}{3} + \frac{x^5}{5} + \dots$$

Binomial series:

$$(1+x)^n = 1 + nx + \frac{n(n-1)}{1 \cdot 2} x^2 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} x^3 + \dots$$

$$(1+x)^{-1} = 1 - nx + \frac{n(n+1)}{1 \cdot 2} x^2 - \frac{n(n+1)(n+2)}{1 \cdot 2 \cdot 3} x^3 + \dots$$

$$(1-x)^{-n} = 1 + nx + \frac{n(n+1)}{1 \cdot 2} x^2 + \frac{n(n+1)(n+2)}{1 \cdot 2 \cdot 3} x^3 + \dots$$

8(a) Progressions:

i. Numbers $a, a+d, a+2d, \dots$ are said to be in *Arithmetic progression (A.P.)*

Its n th term $T_n = a + (n-1)d$ and sum $S_n = \frac{n}{2}(2a + (n-1)d)$

ii. Numbers $a, ar, ar^2, \dots$ are said to be in *Geometric progression (G.P.)*

Its n th term $T_n = ar^{n-1}$ and sum $S_n = \frac{a(1-r^n)}{1-r}$, $\lim_{n \rightarrow \infty} S_n = \frac{a}{1-r}$ when $|r| < 1$.

iii. Numbers $a_1, a_2, a_3, \dots$ are said to be in *Harmonic progression (H.P.)* if $1/a_1, 1/a_2, 1/a_3, \dots$ are in A.P.

iv. For any two numbers a and b , their

Arithmetic mean $= \frac{1}{2}(a+b)$,

Geometric mean $= \sqrt{ab}$,

Harmonic mean $= \frac{2ab}{(a+b)}$.

v. For the first n natural numbers $1, 2, 3, \dots, n$,

$$\sum n = \frac{n(n+1)}{2},$$

$$\sum n^2 = \frac{n(n+1)(2n+1)}{6},$$

$$\sum n^3 = \left\{ \frac{n(n+1)}{2} \right\}^2$$

vi. **Stirling's approximation.** When n is large $n! \sim \sqrt{2\pi n} \cdot n^n e^{-n}$.

(b) Permutations and combinations:

$${}^n P_r = \frac{n!}{(n-r)!};$$

$${}^n C_r = \frac{n!}{r!(n-r)!} = \frac{{}^n P_r}{r!};$$

$$n_{C_{n-r}} = n_{C_r}, n_{C_0} = 1 = n_{C_n}$$

9. Matrices:

$$A^{-1} = \frac{1}{|A|} \text{adj} A, \quad (AB)^{-1} = B^{-1} A^{-1},$$

$$(AB)^T = B^T A^T, \quad (A^T)^{-1} = (A^{-1})^T$$

10. Ordinary differential equations:

First order linear:

$$y' + p(x)y = q(x), \text{ I.F.} = e^{\int p(x)dx}$$

$$\text{G.S: } y \cdot (\text{I.F.}) = \int (\text{I.F.})(Q|x)dx$$

Bessel equation: $x^2 y'' + xy' + (x^2 - v^2)y = 0$

Legendre equation: $(1-x^2)y'' - 2xy' + \lambda y = 0$

| | | | | | | | | |
|-----------------------|---|----------------------|----------------------|----------------------|-----------------|-------|------------------|--------|
| θ
(degrees) | 0 | 30 | 45 | 60 | 90 | 180 | 270 | 360 |
| θ
(radians) | 0 | $\frac{\pi}{6}$ | $\frac{\pi}{4}$ | $\frac{\pi}{3}$ | $\frac{\pi}{2}$ | π | $\frac{3\pi}{2}$ | 3π |
| $\sin \theta$ | 0 | $\frac{1}{2}$ | $\frac{1}{\sqrt{2}}$ | $\frac{\sqrt{3}}{2}$ | 1 | 0 | -1 | 0 |
| $\cos \theta$ | 1 | $\frac{\sqrt{3}}{2}$ | $\frac{1}{\sqrt{2}}$ | $\frac{1}{2}$ | 0 | -1 | 0 | 1 |
| $\tan \theta$ | 0 | $\frac{1}{\sqrt{3}}$ | 1 | $\sqrt{3}$ | ∞ | 0 | $-\infty$ | 0 |

11. (a) Law of exponents

$$a^m \cdot a^n = a^{m+n}; (ab)^m = a^m b^m, (a^m)^n = a^{mn}, a^{\frac{m}{n}} = \sqrt[n]{a^m}$$

$$\text{If } a \neq 0, \frac{a^m}{a^n} = a^{m-n}, a^0 = 1, a^{-m} = \frac{1}{a^m}$$

(b) Difference of like integer power, $n > 1$:

$$a^n - b^n = (a-b)(a^{n-1} + a^{n-2}b + a^{n-3}b^2 + \dots + ab^{n-2} + b^{n-1})$$

For example

$$a^3 - b^3 = (a-b)(a^2 + ab + b^2)$$

$$a^4 - b^4 = (a-b)(a^3 + a^2b + ab^2 + b^3)$$

12. (a) Hyperbolic functions:

$$\sinh x = \frac{e^x - e^{-x}}{2}, \quad \cosh x = \frac{e^x + e^{-x}}{2},$$

$$\tanh x = \frac{\sinh x}{\cosh x}$$

(b) Complex number: $z = x + iy = r(\cos \theta + i \sin \theta)$

Euler's Theorem: $\cos \theta + i \sin \theta = \text{cis } \theta = e^{i\theta}$

$$\text{So } z = r \text{cis } \theta = r e^{i\theta}$$

De Moivre's Theorem:

$$(\cos \theta + i \sin \theta)^n = \cos n\theta + i \sin n\theta$$

$$\sin x = \frac{e^{ix} - e^{-ix}}{2i}, \quad \cos x = \frac{e^{ix} + e^{-ix}}{2}$$

(c) Relations between hyperbolic and trigonometric functions:

$$\sin ix = i \sinh x, \quad \cos ix = \cosh x,$$

$$\tan ix = i \tanh x,$$

$$\sinh iz = i \sin z, \quad \cosh iz = \cos z,$$

$$\tanh iz = i \tan z$$

13. Frequently used limits

$$1. \lim_{x \rightarrow 0} \frac{\sin x}{x} = 1, \quad 2. \lim_{x \rightarrow 0} \frac{a^x - 1}{x} = \log_e a$$

$$3. \lim_{x \rightarrow a} \frac{x^n - a^n}{x - a} = na^{n-1}, \quad n \text{ any rational number}$$

$$4. (a) \lim_{n \rightarrow \infty} \frac{1}{n} = 0 \quad (b) \lim_{n \rightarrow \infty} \frac{1}{n^2} = 0,$$

$$(c) \lim_{n \rightarrow \infty} \frac{1}{\sqrt{n}} = 0$$

$$5. \lim_{n \rightarrow \infty} n^{\frac{1}{n}} = 1, \quad 6. \lim_{n \rightarrow \infty} \frac{\log n}{n} = 0$$

$$7. \lim_{n \rightarrow \infty} \left(1 + \frac{x}{n}\right)^n = e^x \text{ for any } x$$

$$8. \lim_{n \rightarrow \infty} x^{1/n} = 1 \quad \text{for } x > 0 \quad \left. \begin{array}{l} x \text{ remains} \\ \text{fixed as} \\ n \rightarrow \infty \end{array} \right\}$$

$$9. (a) \lim_{n \rightarrow \infty} \frac{x^n}{n!} = 0 \text{ for any } x > 0$$

$$(b) \lim_{n \rightarrow \infty} x^n = 0 \text{ for } |x| < 1 \text{ i.e., } -1 < x < 1.$$
